This collection of documents provides the API reference for the Core Services framework, which encompasses many fundamental operating system services used by Carbon applications.

Opaque Types

CFFTPStream Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFFTPStream.h
Companion guide	CFNetwork Programming Guide

Overview

This document describes the CFStream functions for working with FTP connections. It is part of the CFFTP API.

Functions

CFFTPCreateParsedResourceListing

Parses an FTP listing to a dictionary.

```
CFIndex CFFTPCreateParsedResourceListing (
   CFAllocatorRef alloc,
   const UInt8 *buffer,
   CFIndex bufferLength,
   CFDictionaryRef *parsed
);
```

Parameters

alloc

The allocator to use to allocate memory for the dictionary. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

buffer

A pointer to a buffer holding zero or more lines of resource listing.

bufferLength

The length in bytes of the buffer pointed to by `buffer`.

parsed

Upon return, contains a dictionary containing the parsed resource information. If parsing fails, a `NULL` pointer is returned.

Return Value

The number of bytes parsed, `0` if no bytes were available for parsing, or `-1` if parsing failed.

Discussion
This function examines the contents of buffer as an FTP directory listing and parses into a CFDictionary the information for a single file or folder. The CFDictionary is returned in the `parsed` parameter, and the number of bytes used from buffer is returned.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFFTPStream.h`

CFReadStreamCreateWithFTPURL

Creates an FTP read stream.

```
CFReadStreamRef CFReadStreamCreateWithFTPURL (
   CFAllocatorRef alloc,
   CFURLRef ftpURL
);
```

Parameters

`alloc`

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

`ftpURL`

A pointer to a CFURL structure for the URL to be downloaded that can be created by calling any of the `CFURLCreate` functions, such as `CFURLCreateWithString`.

Return Value
A new read stream, or `NULL` if the call failed. Ownership follows the Create Rule.

Discussion
This function creates an FTP read stream for downloading data from an FTP URL. If the `ftpURL` parameter is created with the user name and password as part of the URL (such as `ftp://username:password@ftp.example.com`) then the user name and password will automatically be set in the `CFReadStream`. Otherwise, call `CFReadStreamSetProperty` to set the steam's properties, such as `kCFStreamPropertyFTPUserName` and `kCFStreamPropertyFTPPassword` to associate a user name and password with the stream that are used to log in when the stream is opened. See "Constants" (page 21) for a description of all FTP stream properties.

To initiate a connection with the FTP server, call `CFReadStreamOpen`. To read the FTP stream, call `CFReadStreamRead`. If the URL refers to a directory, the stream provides the listing results sent by the server. If the URL refers to a file, the stream provides the data in that file.

To close a connection with the FTP server, call `CFReadStreamClose`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFFTPStream.h`

CFWriteStreamCreateWithFTPURL

Creates an FTP write stream.

```
CFWriteStreamRef CFWriteStreamCreateWithFTPURL (
   CFAllocatorRef alloc,
   CFURLRef ftpURL
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

ftpURL

A pointer to a CFURL structure for the URL to be uploaded created by calling any of the `CFURLCreate` functions, such as `CFURLCreateWithString`.

Return Value
A new write stream, or `NULL` if the call failed. Ownership follows the Create Rule.

Discussion
This function creates an FTP write stream for uploading data to an FTP URL. If the `ftpURL` parameter is created with the user name and password as part of the URL (such as `ftp://username:password@ftp.example.com`) then the user name and password will automatically be set in the `CFWriteStream`. Call `CFWriteStreamSetProperty` to set the steam's properties, such as `kCFStreamPropertyFTPUserName` and `kCFStreamPropertyFTPPassword` to associate a user name and password with the stream that are used to log in when the stream is opened. See "Constants" (page 21) for a description of all FTP stream properties.

After creating the write stream, you can call `CFWriteStreamGetStatus` at any time to check the status of the stream.

To initiate a connection with the FTP server, call `CFWriteStreamOpen`. If the URL specifies a directory, the open is immediately followed by the event `kCFStreamEventEndEncountered` (and the stream passes to the state `kCFStreamStatusAtEnd`). Once the stream reaches this state, the directory has been created. Intermediary directories are not created.

To write to the FTP stream, call `CFWriteStreamWrite`.

To close a connection with the FTP server, call `CFWriteStreamClose`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFFTPStream.h`

Constants

CFStream FTP Property Constants

Constants for setting and copying CFStream FTP properties.

```
const CFStringRef kCFStreamPropertyFTPUserName;
const CFStringRef kCFStreamPropertyFTPPassword;
const CFStringRef kCFStreamPropertyFTPUsePassiveMode;
const CFStringRef kCFStreamPropertyFTPResourceSize;
const CFStringRef kCFStreamPropertyFTPFetchResourceInfo;
const CFStringRef kCFStreamPropertyFTPFileTransferOffset;
const CFStringRef kCFStreamPropertyFTPAttemptPersistentConnection;
const CFStringRef kCFStreamPropertyFTPProxy;
const CFStringRef kCFStreamPropertyFTPProxyHost;
extern const CFStringRef kCFStreamPropertyFTPProxyPort;
extern const CFStringRef kCFStreamPropertyFTPProxyUser;
extern const CFStringRef kCFStreamPropertyFTPProxyPassword;
```

Constants

`kCFStreamPropertyFTPUserName`

FTP User Name stream property key for set and copy operations. A value of type CFString for storing the login user name. Don't set this property when anonymous FTP is desired.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPPassword`

FTP Password stream property key for set and copy operations. A value of type CFString for storing the login password. Don't set this property when anonymous FTP is desired.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPUsePassiveMode`

FTP Passive Mode stream property key for set and copy operations. Set this property to `kCFBooleanTrue` to enable passive mode; set this property to `kCFBooleanFalse` to disable passive mode.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPResourceSize`

FTP Resource Size read stream property key copy operations. This property stores a CFNumber of type `kCFNumberLongLongType` representing the size of a resource in bytes.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPFetchResourceInfo`

FTP Fetch Resource Information stream property key for set and copy operations. Set this property to `kCFBooleanTrue` to require that resource information, such as size, must be provided before download starts; set this property to `kCFBooleanFalse` to allow downloads to start without resource information. For this version, size is the only resource information.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPFileTransferOffset`

FTP File Transfer Offset stream property key for set and copy operations. The value of this property is a CFNumber of type `kCFNumberLongLongType` representing the file offset at which to start the transfer.

Available in Mac OS X v10.3 and later.

Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPAttemptPersistentConnection`
: FTP Attempt Persistent Connection stream property key for set and copy operations. Set this property to `kCFBooleanTrue` to enable the reuse of existing server connections; set this property to `kCFBooleanFalse` to not reuse existing server connections. By default, this property is set to `kCFBooleanTrue`.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPProxy`
: FTP Proxy stream property key for set and copy operations. The property is a value of type CFDictionary that holds proxy dictionary key-value pairs. The dictionary returned by SystemConfiguration can also be set as the value of this property.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPProxyHost`
: FTP Proxy Host stream property key or an FTP Proxy dictionary key for set and copy operations. The value of this property is a CFString containing the host name of a proxy server. This property can be set and copied individually or via a CFDictionary. This property is the same as the `kSCPropNetProxiesFTPProxy` property defined in `SCSchemaDefinitions.h`.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPProxyPort`
: FTP Proxy Port stream property key or an FTP Proxy dictionary key for set and copy operations. The value of this property is a CFNumber of type `kCFNumberIntType` containing the port number of a proxy server. This property can be set and copied individually or via a CFDictionary. This property is the same as the `kSCPropNetProxiesFTPPort` property defined in `SCSchemaDefinitions.h`.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPProxyUser`
: FTP Proxy Host stream property key or FTP Proxy dictionary key for set and copy operations. The value of this property is a CFString containing the username to be used when connecting to the proxy server.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFStreamPropertyFTPProxyPassword`
: FTP Proxy Port stream property key or FTP Proxy dictionary key for set and copy operations. The value of this property is a CFString containing the password to be used when connecting to the proxy server.

  Available in Mac OS X v10.3 and later.

  Declared in `CFFTPStream.h`.

Discussion
The CFStream property constants are used to specify the property to set when calling `CFReadStreamSetProperty` or `CFWriteStreamSetProperty` and to copy when calling `CFReadStreamCopyProperty` or `CFWriteStreamCopyProperty`. They can also be passed to a CFDictionary creator or to an item accessor or mutator.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFNetwork/CFFTPStream.h`

CFStream FTP Resource Constants

FTP resource constants.

```
const CFStringRef kCFFTPResourceMode;
const CFStringRef kCFFTPResourceName;
const CFStringRef kCFFTPResourceOwner;
const CFStringRef kCFFTPResourceGroup;
const CFStringRef kCFFTPResourceLink;
const CFStringRef kCFFTPResourceSize;
const CFStringRef kCFFTPResourceType;
const CFStringRef kCFFTPResourceModDate;
```

Constants

`kCFFTPResourceMode`
: CFDictionary key for getting the CFNumber containing the access permissions, defined in `sys/types.h`, of the FTP resource.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceName`
: CFDictionary key for getting the CFString containing the name of the FTP resource.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceOwner`
: CFDictionary key for getting the CFString containing the name of the owner of the FTP resource.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceGroup`
: CFDictionary key for getting the CFString containing the name of a group that shares the FTP resource.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceLink`
: CFDictionary key for getting the CFString containing the symbolic link information. If the item is a symbolic link, the CFString contains the path to the item that the link references.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceSize`
: CFDictionary key for getting the CFNumber containing the size in bytes of the FTP resource.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceType`
: CFDictionary key for getting the CFNumber containing the type of the FTP resource as defined in `sys/dirent.h`.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

`kCFFTPResourceModDate`
: CFDictionary key for getting the CFDate containing the last date and time the FTP resource was modified.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

Discussion
The values of FTP resource keys are extracted from a line of the directory list by the `CFFTPCreateParsedResourceListing` (page 19) function.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFNetwork/CFFTPStream.h`

Error Domains

Error domains specific to `CFFTPStream` calls.

```
extern const SInt32 kCFStreamErrorDomainFTP;
```

Constants
`kCFStreamErrorDomainFTP`
: Error domain that returns the last result code returned by the FTP server.

  Available in Mac OS X version 10.3 and later.

  Declared in `CFFTPStream.h`.

Discussion
To determine the source of an error, examine the `userInfo` dictionary included in the `CFError` object returned by a function call or call `CFErrorGetDomain` and pass in the `CFError` object and the domain whose value you want to read.

CFHost Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFHost.h
Companion guide	CFNetwork Programming Guide

Overview

The CFHost API allows you to create instances of the CFHost object that you can use to acquire host information, including names, addresses, and reachability information.

The process of acquiring information about a host is known as resolution. Begin by calling `CFHostCreateWithAddress` or `CFHostCreateWithName` to create an instance of a CFHost using an address or a name, respectively. If you want to resolve the host asynchronously. call `CFHostSetClient` to associate your client context and user-defined callback function with the host. Then call `CFHostScheduleWithRunLoop` to schedule the host on a run loop.

To start resolution, call `CFHostStartInfoResolution`. If you set up for asynchronous resolution, `CFHostStartInfoResolution` returns immediately. Your callback function will be called when resolution is complete. If you didn't set up for asynchronous resolution, `CFHostStartInfoResolution` blocks until resolution is complete, an error occurs, or the resolution is cancelled.

When resolution is complete, call `CFHostGetAddressing` or `CFHostGetNames` to get an array of known addresses or known names, respectively, for the host. Call `CFHostGetReachability` to get flags, declared in `SystemConfiguration/SCNetwork.h`, that describe the reachability of the host.

When you no longer need a CFHost object, call `CFHostUnscheduleFromRunLoop` and `CFHostSetClient` to disassociate the host from your user-defined client context and callback function (if it was set up for asynchronous resolution). Then dispose of it.

Functions by Task

Creating a host

`CFHostCreateCopy` (page 29)
Creates a new host object by copying.

`CFHostCreateWithAddress` (page 29)
Uses an address to create an instance of a host object.

`CFHostCreateWithName` (page 30)
Uses a name to create an instance of a host object.

CFHost Functions

`CFHostCancelInfoResolution` (page 28)
Cancels the resolution of a host.

`CFHostGetAddressing` (page 31)
Gets the addresses from a host.

`CFHostGetNames` (page 31)
Gets the names from a CFHost.

`CFHostGetReachability` (page 32)
Gets reachability information from a host.

`CFHostStartInfoResolution` (page 34)
Starts resolution for a host object.

`CFHostSetClient` (page 34)
Associates a client context and a callback function with a CFHost object or disassociates a client context and callback function that were previously set.

`CFHostScheduleWithRunLoop` (page 33)
Schedules a CFHost on a run loop.

`CFHostUnscheduleFromRunLoop` (page 35)
Unschedules a CFHost from a run loop.

Getting the CFHost Type ID

`CFHostGetTypeID` (page 33)
Gets the Core Foundation type identifier for the CFHost opaque type.

Functions

CFHostCancelInfoResolution

Cancels the resolution of a host.

```
void CFHostCancelInfoResolution (
   CFHostRef theHost,
   CFHostInfoType info
);
```

Parameters

theHost
The host for which a resolution is to be cancelled. This value must not be `NULL`.

info

A value of type `CFHostInfoType` specifying the type of resolution that is to be cancelled. See CFHostInfoType Constants (page 38) for possible values.

Discussion
This function cancels the asynchronous or synchronous resolution specified by `info` for the host specified by `theHost`.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostCreateCopy

Creates a new host object by copying.

```
CFHostRef CFHostCreateCopy (
   CFAllocatorRef alloc,
   CFHostRef host
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

addr

The host to copy. This value must not be `NULL`.

Return Value
A valid CFHost object or `NULL` if the copy could not be created. The new host contains a copy of all previously resolved data from the original host. Ownership follows the Create Rule.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostCreateWithAddress

Uses an address to create an instance of a host object.

```
CFHostRef CFHostCreateWithAddress (
   CFAllocatorRef allocator,
   CFDataRef addr
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

addr

A CFDataRef object containing a `sockaddr` structure for the address of the host. This value must not be `NULL`.

Return Value

A valid CFHostRef object that can be resolved, or `NULL` if the host could not be created. Ownership follows the Create Rule.

Discussion

Call `CFHostStartInfoResolution` (page 34) to resolve the return object's name and reachability information.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFHost.h`

CFHostCreateWithName

Uses a name to create an instance of a host object.

```
CFHostRef CFHostCreateWithName (
   CFAllocatorRef allocator,
   CFStringRef hostname
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

hostname

A string representing the name of the host. This value must not be `NULL`.

Return Value

A valid CFHostRef object that can be resolved, or `NULL` if the host could not be created. Ownership follows the Create Rule.

Discussion

Call `CFHostStartInfoResolution` (page 34) to resolve the object's addresses and reachability information.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFHost.h`

CFHostGetAddressing

Gets the addresses from a host.

```
CFArrayRef CFHostGetAddressing (
   CFHostRef theHost,
   Boolean *hasBeenResolved
);
```

Parameters

`theHost`

The CFHost whose addresses are to be obtained. This value must not be `NULL`.

`hasBeenResolved`

On return, a pointer to a Boolean that is `TRUE` if addresses were available and `FALSE` if addresses were not available. This parameter can be null.

`function result`

A CFArray of addresses where address is a `sockaddr` structure wrapped by a CFDataRef, or null if no addresses were available.

Discussion

This function gets the addresses from a CFHost. The CFHost must have been previously resolved. To resolve a CFHost, call `CFHostStartInfoResolution` (page 34).

Special Considerations

This function gets the addresses in a thread-safe way, but the resulting data is not thread-safe. The data is returned as a "get" as opposed to a copy, so the data is not safe if the CFHost is altered from another thread.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFHost.h`

CFHostGetNames

Gets the names from a CFHost.

```
CFArrayRef CFHostGetNames (
   CFHostRef theHost,
   Boolean *hasBeenResolved
);
```

Parameters

theHost

The host to examine. The host must have been previously resolved. (To resolve a host, call `CFHostStartInfoResolution` (page 34).) This value must not be `NULL`.

hasBeenResolved

On return, contains `TRUE` if names were available, otherwise `FALSE`. This value may be `NULL`.

Return Value

An array containing the of names of *theHost*, or `NULL` if no names were available.

Special Considerations

This function gets the names in a thread-safe way, but the resulting data is not thread-safe. The data is returned as a "get" as opposed to a copy, so the data is not safe if the CFHost is altered from another thread.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFHost.h`

CFHostGetReachability

Gets reachability information from a host.

```
CFDataRef CFHostGetReachability (
   CFHostRef theHost,
   Boolean *hasBeenResolved
);
```

Parameters

theHost

The host whose reachability is to be obtained. The host must have been previously resolved. (To resolve a host, call `CFHostStartInfoResolution` (page 34).) This value must not be `NULL`.

hasBeenResolved

On return, contains `TRUE` if the reachability was available, otherwise `FALSE`. This value may be `NULL`.

Return Value

A CFData object that wraps the reachability flags (`SCNetworkConnectionFlags`) defined in `SystemConfiguration/SCNetwork.h`, or `NULL` if reachability information was not available.

Special Considerations

This function gets reachability information in a thread-safe way, but the resulting data is not thread-safe. The data is returned as a "get" as opposed to a copy, so the data is not safe if the CFHost is altered from another thread.

Availability

Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostGetTypeID

Gets the Core Foundation type identifier for the CFHost opaque type.

```
CFTypeID CFHostGetTypeID ();
```

Return Value
The Core Foundation type identifier for the CFHost opaque type.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostScheduleWithRunLoop

Schedules a CFHost on a run loop.

```
void CFHostScheduleWithRunLoop (
   CFHostRef theHost,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

theHost
The host to be schedule on a run loop. This value must not be `NULL`.

runLoop
The run loop on which to schedule *theHost*. This value must not be `NULL`.

runLoopMode
The mode on which to schedule *theHost*. This value must not be `NULL`.

Discussion
Schedules *theHost* on a run loop, which causes resolutions of the host to be performed asynchronously. The caller is responsible for ensuring that at least one of the run loops on which the host is scheduled is being run.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostSetClient

Associates a client context and a callback function with a CFHost object or disassociates a client context and callback function that were previously set.

```
Boolean CFHostSetClient (
   CFHostRef theHost,
   CFHostClientCallBack clientCB,
   CFHostClientContext *clientContext
);
```

Parameters

theHost

The host to modify. The value must not be `NULL`.

clientCB

The callback function to associate with *theHost*. The callback function will be called when a resolution completes or is cancelled. If you are calling this function to disassociate a client context and callback from `theHost`, p`clientCB`ass `NULL`.

clientContext

A `CFHostClientContext` (page 37) structure whose `info` field will be passed to the callback function specified by `clientCB` when `clientCB` is called. This value must not be `NULL` when setting an association.

Pass `NULL` when disassociating a client context and a callback from a host.

Return Value

`TRUE` if the association could be set or unset, otherwise `FALSE`.

Discussion

The callback function specified by `clientCB` will be called when a resolution completes or is cancelled.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFHost.h`

CFHostStartInfoResolution

Starts resolution for a host object.

```
Boolean CFHostStartInfoResolution (
   CFHostRef theHost,
   CFHostInfoType info,
   CFStreamError *error
);
```

Parameters

theHost

The host, obtained by previously calling `CFHostCreateCopy` (page 29), `CFHostCreateWithAddress` (page 29), or `CFHostCreateWithName` (page 30), that is to be resolved. This value must not be `NULL`.

info
: A value of type `CFHostInfoType` specifying the type of information that is to be retrieved. See CFHostInfoType Constants (page 38) for possible values.

error
: A pointer to a `CFStreamError` structure, that, if an error occurs, is set to the error and the error's domain. In synchronous mode, the error indicates why resolution failed, and in asynchronous mode, the error indicates why resolution failed to start.

Return Value
`TRUE` if the resolution was started (asynchronous mode); `FALSE` if another resolution is already in progress for *theHost* or if an error occurred.

Discussion
This function retrieves the information specified by `info` and stores it in the host.

In synchronous mode, this function blocks until the resolution has completed, in which case this function returns `TRUE`, until the resolution is stopped by calling `CFHostCancelInfoResolution` (page 28) from another thread, in which case this function returns `FALSE`, or until an error occurs.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostUnscheduleFromRunLoop

Unschedules a CFHost from a run loop.

```
void CFHostUnscheduleFromRunLoop (
   CFHostRef theHost,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

theService
: The host to unschedule. This value must not be `NULL`.

runLoop
: The run loop. This value must not be `NULL`.

runLoopMode
: The mode from which the service is to be unscheduled. This value must not be `NULL`.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

Callbacks

CFHostClientCallBack

Defines a pointer to the callback function that is called when an asynchronous resolution of a CFHost completes or an error occurs for an asynchronous CFHost resolution.

```
typedef void (CFHostClientCallBack) (
   CFHostRef theHost,
   CFHostInfoType typeInfo,
   const CFStreamError *error,
   void *info);
```

If you name your callback `MyHostClientCallBack`, you would declare it like this:

```
void MyHostClientCallBack (
   CFHostRef theHost,
   CFHostInfoType typeInfo,
   const CFStreamError *error,
   void *info
);
```

Parameters

`theHost`
The host for which an asynchronous resolution has been completed.

`typeInfo`
Value of type `CFHostInfoType` representing the type of information (addresses, names, or reachability information) obtained by the completed resolution. See CFHostInfoType Constants (page 38) for possible values.

`error`
If the resolution failed, contains a `CFStreamError` structure whose `error` field contains an error code.

`info`
User-defined context information. The value pointed to by `info` is the same as the value pointed to by the `info` field of the `CFHostClientContext` (page 37) structure that was provided when the host was associated with this callback function.

Discussion
The callback function for a CFHost object is called one or more times when an asynchronous resolution completes for the specified host, when an asynchronous resolution is cancelled, or when an error occurs during an asynchronous resolution.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

Data Types

CFHostRef

An opaque reference representing an CFHost object.

```
typedef struct __CFHost* CFHostRef;
```

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

CFHostClientContext

A structure containing user-defined data and callbacks for CFHost objects.

```
struct CFHostClientContext {
    CFIndex version;
    void *info;
    CFAllocatorRetainCallBack retain;
    CFAllocatorReleaseCallBack release;
    CFAllocatorCopyDescriptionCallBack copyDescription;
} CFHostClientContext;
typedef struct CFHostClientContext CFHostClientContext;
```

Fields

`version`
: The version number of the structure type passed as a parameter to the host client function. The only valid version number is `0`.

`info`
: An arbitrary pointer to allocated memory containing user-defined data that can be associated with the host and that is passed to the callbacks.

`retain`
: The callback used to add a retain for the host on the info pointer for the life of the host, and may be used for temporary references the host needs to take. This callback returns the actual info pointer to store in the host, almost always just the pointer passed as the parameter.

`release`
: The callback used to remove a retain previously added for the host on the info pointer.

`copyDescription`
: The callback used to create a descriptive string representation of the info pointer (or the data pointed to by the info pointer) for debugging purposes. This callback is called by the `CFCopyDescription` function.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CFHost.h`

Constants

CFHostInfoType Constants

Values indicating the type of data that is to be resolved or the type of data that was resolved.

```
enum CFHostInfoType {
    kCFHostAddresses = 0,
    kCFHostNames = 1,
    kCFHostReachability = 2
};
typedef enum CFHostInfoType CFHostInfoType;
```

Constants

`kCFHostAddresses`

Specifies that addresses are to be resolved or that addresses were resolved.

Available in Mac OS X v10.3 and later.

Declared in `CFHost.h`.

`kCFHostNames`

Specifies that names are to be resolved or that names were resolved.

Available in Mac OS X v10.3 and later.

Declared in `CFHost.h`.

`kCFHostReachability`

Specifies that reachability information is to be resolved or that reachability information was resolved.

Available in Mac OS X v10.3 and later.

Declared in `CFHost.h`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CFNetwork/CFHost.h`

Error Domains

Error domains specific to `CFHost` calls.

```
extern const SInt32 kCFStreamErrorDomainNetDB;
extern const SInt32 kCFStreamErrorDomainSystemConfiguration;
```

Constants

`kCFStreamErrorDomainNetDB`

The error domain that returns errors from the network database (DNS resolver) layer (described in `/usr/include/netdb.h`).

Available in Mac OS X version 10.5 and later.

Declared in `CFHost.h`.

`kCFStreamErrorDomainSystemConfiguration`

The error domain that returns errors from the system configuration layer (described in *System Configuration Framework Reference*).

Available in Mac OS X version 10.5 and later.

Declared in `CFHost.h`.

Discussion

To determine the source of an error, examine the `userInfo` dictionary included in the `CFError` object returned by a function call or call `CFErrorGetDomain` and pass in the `CFError` object and the domain whose value you want to read.

CFHTTPAuthentication Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFHTTPAuthentication.h
Companion guide	CFNetwork Programming Guide

Overview

The CFHTTPAuthentication opaque type provides an abstraction of HTTP authentication information.

Functions by Task

Creating an HTTP authentication

`CFHTTPAuthenticationCreateFromResponse` (page 44)
Uses an authentication failure response to create a CFHTTPAuthentication object.

CFHTTP Authentication Functions

This section describes the CFNetwork authentication functions that are used to manage authentication information associated with a request. The functions work with a CFHTTPAuthentication object, which is created from an HTTP response that failed with a 401 or 407 error code.

When you have analyzed the CFHTTPAuthentication object and acquired the necessary credentials to perform the authentication, call `CFHTTPMessageApplyCredentials` (page 55) or `CFHTTPMessageApplyCredentialDictionary` (page 54) to perform the authentication.

`CFHTTPAuthenticationAppliesToRequest` (page 42)
Returns a Boolean value that indicates whether a CFHTTPAuthentication object is associated with a CFHTTPMessage object.

`CFHTTPAuthenticationCopyDomains` (page 43)
Returns an array of domain URLs to which a given CFHTTPAuthentication object can be applied.

`CFHTTPAuthenticationCopyMethod` (page 43)
Gets the strongest authentication method that will be used when a CFHTTPAuthentication object is applied to a request.

`CFHTTPAuthenticationCopyRealm` (page 43)
Gets an authentication information's namespace.

`CFHTTPAuthenticationIsValid` (page 45)
Returns a Boolean value that indicates whether a CFHTTPAuthentication object is valid.

`CFHTTPAuthenticationRequiresAccountDomain` (page 46)
Returns a Boolean value that indicates whether a CFHTTPAuthentication object uses an authentication method that requires an account domain.

`CFHTTPAuthenticationRequiresOrderedRequests` (page 46)
Returns a Boolean value that indicates whether authentication requests should be made one at a time.

`CFHTTPAuthenticationRequiresUserNameAndPassword` (page 47)
Returns a Boolean value that indicates whether a CFHTTPAuthentication object uses an authentication method that requires a username and a password.

Getting the CFHTTPAuthentication type ID

`CFHTTPAuthenticationGetTypeID` (page 45)
Gets the Core Foundation type identifier for the CFHTTPAuthentication opaque type.

Functions

CFHTTPAuthenticationAppliesToRequest

Returns a Boolean value that indicates whether a CFHTTPAuthentication object is associated with a CFHTTPMessage object.

```
Boolean CFHTTPAuthenticationAppliesToRequest (
   CFHTTPAuthenticationRef auth,
   CFHTTPMessageRef request
);
```

Parameters

auth
The CFHTTPAuthentication object to examine.

request
Request that `auth` is to be tested against.

Return Value
`TRUE` if `auth` is associated with `request`, otherwise `FALSE`.

Discussion
If this function returns `TRUE`, you can use *auth* to provide authentication information when using *request*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CFHTTPAuthentication.h`

CFHTTPAuthenticationCopyDomains

Returns an array of domain URLs to which a given CFHTTPAuthentication object can be applied.

```
CFArrayRef CFHTTPAuthenticationCopyDomains (
   CFHTTPAuthenticationRef auth
);
```

Parameters

auth

The CFHTTPAuthentication object to examine.

Return Value

A CFArray object that contains the domain URL's to which `auth` should be applied. Ownership follows the Create Rule.

Discussion

This function is provided for informational purposes only.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFHTTPAuthentication.h`

CFHTTPAuthenticationCopyMethod

Gets the strongest authentication method that will be used when a CFHTTPAuthentication object is applied to a request.

```
CFStringRef CFHTTPAuthenticationCopyMethod (
   CFHTTPAuthenticationRef auth
);
```

Parameters

auth

The CFHTTPAuthentication object to examine.

Return Value

A string containing the authentication method that will be used *auth* is applied to a request. If more than one authentication method is available, the strongest authentication method is returned. Ownership follows the Create Rule.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFHTTPAuthentication.h`

CFHTTPAuthenticationCopyRealm

Gets an authentication information's namespace.

```
CFStringRef CFHTTPAuthenticationCopyRealm (
   CFHTTPAuthenticationRef auth
);
```

Parameters

auth

The CFHTTPAuthentication object to examine.

Return Value
The namespace, if there is one; otherwise `NULL`. Ownership follows the Create Rule.

Discussion
Some authentication methods provide a namespace, and it is usually used to prompt the user for a name and password.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

CFHTTPAuthenticationCreateFromResponse

Uses an authentication failure response to create a CFHTTPAuthentication object.

```
CFHTTPAuthenticationRef CFHTTPAuthenticationCreateFromResponse (
   CFAllocatorRef alloc,
   CFHTTPMessageRef response
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

response

Response indicating an authentication failure; usually a 401 or a 407 response.

Return Value
CFHTTPAuthentication object that can be used for adding credentials to future requests. Ownership follows the Create Rule.

Discussion
This function uses a response containing authentication failure information to create a reference to a CFHTTPAuthentication object. You can use the object to add credentials to future requests. You can query the object to get the following information:

- whether it can be used and re-used to authenticate with its corresponding server [`CFHTTPAuthenticationIsValid` (page 45)]
- the authentication method that will be used when it is used to perform an authentication [`CFHTTPAuthenticationCopyMethod` (page 43)]
- whether it is associated with a particular CFHTTPMessageRef [`CFHTTPAuthenticationAppliesToRequest` (page 42)

- whether a user name and a password will be required when it is used to perform an authentication [CFHTTPAuthenticationRequiresUserNameAndPassword (page 47)]
- whether an account domain will be required when it is used to perform an authentication [CFHTTPAuthenticationRequiresAccountDomain (page 46)]
- whether authentication requests should be sent one at a time to the corresponding server [CFHTTPAuthenticationRequiresOrderedRequests (page 46)]
- the namespace (if any) that the domain uses to prompt for a name and password [CFHTTPAuthenticationCopyRealm (page 43)]
- the domain URLs the instance applies to [CFHTTPAuthenticationCopyDomains (page 43)]

When you have determined what information will be needed to perform the authentication and accumulated that information, call CFHTTPMessageApplyCredentials (page 55) or CFHTTPMessageApplyCredentialDictionary (page 54) to perform the authentication.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CFHTTPAuthentication.h

CFHTTPAuthenticationGetTypeID

Gets the Core Foundation type identifier for the CFHTTPAuthentication opaque type.

```
CFTypeID CFHTTPAuthenticationGetTypeID ();
```

Return Value
The Core Foundation type identifier for the CFHTTPAuthentication opaque type.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CFHTTPAuthentication.h

CFHTTPAuthenticationIsValid

Returns a Boolean value that indicates whether a CFHTTPAuthentication object is valid.

```
Boolean CFHTTPAuthenticationIsValid (
   CFHTTPAuthenticationRef auth,
   CFStreamError *error
);
```

Parameters

auth
The CFHTTPAuthentication object to examine.

error
Pointer to a CFStreamError structure, whose fields, if an error has occurred, are set to the error and the error's domain.

Return Value
`TRUE` if `auth` contains enough information to be applied to a request.

If this function returns `FALSE`, the CFHTTPAuthentication object may still contain useful information, such as the name of an unsupported authentication method.

Discussion
If this function returns `TRUE` for *`auth`*, the object is good for use with functions such as `CFHTTPMessageApplyCredentials` (page 55) and `CFHTTPMessageApplyCredentialDictionary` (page 54). If this function returns `FALSE`, *`auth`* is invalid, and authentications using it will not succeed.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

CFHTTPAuthenticationRequiresAccountDomain

Returns a Boolean value that indicates whether a CFHTTPAuthentication object uses an authentication method that requires an account domain.

```
Boolean CFHTTPAuthenticationRequiresAccountDomain (
   CFHTTPAuthenticationRef auth
);
```

Parameters
`auth`
The CFHTTPAuthentication object to examine.

Return Value
`TRUE` if `auth` uses an authentication method that requires an account domain, otherwise `FALSE`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

CFHTTPAuthenticationRequiresOrderedRequests

Returns a Boolean value that indicates whether authentication requests should be made one at a time.

```
Boolean CFHTTPAuthenticationRequiresOrderedRequests (
   CFHTTPAuthenticationRef auth
);
```

Parameters
`auth`
The CFHTTPAuthentication object to examine.

Return Value
`TRUE` if `auth` requires ordered requests, otherwise `FALSE`.

Discussion
Some authentication methods require that future requests must be performed in an ordered manner. If this function returns `TRUE`, clients can improve their chances of authenticating successfully by issuing requests one at a time as responses come back from the server.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

CFHTTPAuthenticationRequiresUserNameAndPassword

Returns a Boolean value that indicates whether a CFHTTPAuthentication object uses an authentication method that requires a username and a password.

```
Boolean CFHTTPAuthenticationRequiresUserNameAndPassword (
   CFHTTPAuthenticationRef auth
);
```

Parameters

auth

The CFHTTPAuthentication object to examine.

Return Value
`TRUE` if `auth` requires a username and password when it is applied to a request; otherwise, `FALSE`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

Data Types

CFHTTPAuthenticationRef

An opaque reference representing HTTP authentication information.

```
typedef struct __CFHTTPAuthentication *CFHTTPAuthenticationRef;
```

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFHTTPAuthentication.h`

Constants

CFHTTP Authentication Scheme Constants

Specifies the authentication scheme when adding authentication information to a CFHTTP request message object.

```
const CFStringRef kCFHTTPAuthenticationSchemeBasic;
const CFStringRef kCFHTTPAuthenticationSchemeDigest;
const CFStringRef kCFHTTPAuthenticationSchemeNegotiate;
const CFStringRef kCFHTTPAuthenticationSchemeNTLM;
```

Constants

`kCFHTTPAuthenticationSchemeBasic`

Specifies basic authentication consisting of a user name and a password.

Available in Mac OS X v10.1 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeDigest`

Reserved.

Available in Mac OS X v10.1 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeNegotiate`

Specifies the Negotiate authentication scheme.

Available in Mac OS X v10.5 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeNTLM`

Specifies the NTLM authentication scheme.

Available in Mac OS X v10.5 and later.

Declared in `CFHTTPMessage.h`.

Discussion

The authentication scheme constants are used to specify the authentication scheme when calling `CFHTTPMessageAddAuthentication` (page 53).

CFStream HTTP Authentication Error Constants

Authentication error codes that may be returned when trying to apply authentication to a request.

```
enum CFStreamErrorHTTPAuthentication{
    kCFStreamErrorHTTPAuthenticationTypeUnsupported = -1000,
    kCFStreamErrorHTTPAuthenticationBadUserName = -1001,
    kCFStreamErrorHTTPAuthenticationBadPassword = -1002
};
typedef enum CFStreamErrorHTTPAuthentication CFStreamErrorHTTPAuthentication;
```

Constants

`kCFStreamErrorHTTPAuthenticationTypeUnsupported`
Specified authentication type is not supported.

Available in Mac OS X v10.4 and later.

Declared in `CFHTTPAuthentication.h`.

`kCFStreamErrorHTTPAuthenticationBadUserName`
User name is in a format that is not suitable for the request. Currently, user names are decoded using `kCFStringEncodingISOLatin1`.

Available in Mac OS X v10.4 and later.

Declared in `CFHTTPAuthentication.h`.

`kCFStreamErrorHTTPAuthenticationBadPassword`
Password is in a format that is not suitable for the request. Currently, passwords are decoded using `kCFStringEncodingISOLatin1`.

Available in Mac OS X v10.4 and later.

Declared in `CFHTTPAuthentication.h`.

CFHTTPMessageApplyCredentialDictionary Keys

Constants for keys in the dictionary passed to `CFHTTPMessageApplyCredentialDictionary` (page 54).

```
const CFStringRef kCFHTTPAuthenticationUserName;
const CFStringRef kCFHTTPAuthenticationPassword;
const CFStringRef kCFHTTPAuthenticationAccountDomain;
```

Constants

`kCFHTTPAuthenticationUserName`
Username to use for authentication.

`kCFHTTPAuthenticationPassword`
Password to use for authentication.

Available in Mac OS X v10.4 and later.

Declared in `CFHTTPAuthentication.h`.

`kCFHTTPAuthenticationAccountDomain`
Account domain to use for authentication.

Available in Mac OS X v10.4 and later.

Declared in `CFHTTPAuthentication.h`.

CFHTTPMessage Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFHTTPMessage.h
Companion guides	Getting Started with Networking CFNetwork Programming Guide

Overview

The `CFHTTPMessage` opaque type represents an HTTP message.

Functions by Task

Creating a Message

`CFHTTPMessageCreateCopy` (page 60)
Gets a copy of a CFHTTPMessage object.

`CFHTTPMessageCreateEmpty` (page 60)
Creates and returns a new, empty `CFHTTPMessage` object.

`CFHTTPMessageCreateRequest` (page 61)
Creates and returns a `CFHTTPMessage` object for an HTTP request.

`CFHTTPMessageCreateResponse` (page 62)
Creates and returns a `CFHTTPMessage` object for an HTTP response.

Modifying a message

`CFHTTPMessageAppendBytes` (page 54)
Appends data to a `CFHTTPMessage` object.

`CFHTTPMessageSetBody` (page 64)
Sets the body of a `CFHTTPMessage` object.

`CFHTTPMessageSetHeaderFieldValue` (page 64)
Sets the value of a header field in an HTTP message.

Getting information from a message

`CFHTTPMessageCopyBody` (page 57)
Gets the body from a `CFHTTPMessage` object.

`CFHTTPMessageCopyAllHeaderFields` (page 56)
Gets all header fields from a `CFHTTPMessage` object.

`CFHTTPMessageCopyHeaderFieldValue` (page 57)
Gets the value of a header field from a `CFHTTPMessage` object.

`CFHTTPMessageCopyRequestMethod` (page 58)
Gets the request method from a `CFHTTPMessage` object.

`CFHTTPMessageCopyRequestURL` (page 58)
Gets the URL from a `CFHTTPMessage` object.

`CFHTTPMessageCopySerializedMessage` (page 59)
Serializes a CFHTTPMessage object.

`CFHTTPMessageCopyVersion` (page 59)
Gets the HTTP version from a `CFHTTPMessage` object.

`CFHTTPMessageIsRequest` (page 64)
Returns a boolean indicating whether the CFHTTPMessage is a request or a response.

`CFHTTPMessageIsHeaderComplete` (page 63)
Determines whether a message header is complete.

`CFHTTPMessageGetResponseStatusCode` (page 63)
Gets the status code from a `CFHTTPMessage` object representing an HTTP response.

`CFHTTPMessageCopyResponseStatusLine` (page 59)
Gets the status line from a `CFHTTPMessage` object.

Message authentication

`CFHTTPMessageApplyCredentials` (page 55)
Performs the authentication method specified by a `CFHTTPAuthentication` object.

`CFHTTPMessageApplyCredentialDictionary` (page 54)
Use a dictionary containing authentication credentials to perform the authentication method specified by a `CFHTTPAuthentication` object.

`CFHTTPMessageAddAuthentication` (page 53)
Adds authentication information to a request.

Getting the CFHTTPMessage type identifier

`CFHTTPMessageGetTypeID` (page 63)
Returns the Core Foundation type identifier for the `CFHTTPMessage` opaque type.

Functions

CFHTTPMessageAddAuthentication

Adds authentication information to a request.

```
Boolean CFHTTPMessageAddAuthentication (
   CFHTTPMessageRef request,
   CFHTTPMessageRef authenticationFailureResponse,
   CFStringRef username,
   CFStringRef password,
   CFStringRef authenticationScheme,
   Boolean forProxy
);
```

Parameters

request
The message to which to add authentication information.

authenticationFailureResponse
The response message that contains authentication failure information.

username
The username to add to the request.

password
The password to add to the request.

authenticationScheme
The authentication scheme to use (`kCFHTTPAuthenticationSchemeBasic`, `kCFHTTPAuthenticationSchemeNegotiate`, `kCFHTTPAuthenticationSchemeNTLM`, or `kCFHTTPAuthenticationSchemeDigest`), or pass `NULL` to use the strongest supported authentication scheme provided in the `authenticationFailureResponse` parameter.

forProxy
A flag indicating whether the authentication data that is being added is for a proxy's use (`TRUE`) or for a remote server's use (`FALSE`). If the error code provided by the `authenticationFailureResponse` parameter is 407, set `forProxy` to `TRUE`. If the error code is 401, set `forProxy` to `FALSE`.

Return Value

`TRUE` if the authentication information was successfully added, otherwise `FALSE`.

Discussion

This function adds the authentication information specified by the `username`, `password`, `authenticationScheme`, and `forProxy` parameters to the specified request message. The message referred to by the `authenticationFailureResponse` parameter typically contains a 401 or a 407 error code.

This function is best suited for sending a single request to the server. If you need to send multiple requests, use `CFHTTPMessageApplyCredentials` (page 55).

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageAppendBytes

Appends data to a `CFHTTPMessage` object.

```
Boolean CFHTTPMessageAppendBytes (
   CFHTTPMessageRef message,
   const UInt8 *newBytes,
   CFIndex numBytes
);
```

Parameters

message
The message to modify.

newBytes
A reference to the data to append.

numBytes
The length of the data pointed to by `newBytes`.

Return Value

`TRUE` if the data was successfully appended, otherwise `FALSE`.

Discussion

This function appends the data specified by `newBytes` to the specified message object which was created by calling `CFHTTPMessageCreateEmpty` (page 60). The data is an incoming serialized HTTP request or response received from a client or a server. While appending the data, this function deserializes it, removes any HTTP-based formatting that the message may contain, and stores the message in the message object. You can then call `CFHTTPMessageCopyVersion` (page 59), `CFHTTPMessageCopyBody` (page 57), `CFHTTPMessageCopyHeaderFieldValue` (page 57), and `CFHTTPMessageCopyAllHeaderFields` (page 56) to get the message's HTTP version, the message's body, a specific header field, and all of the message's headers, respectively.

If the message is a request, you can also call `CFHTTPMessageCopyRequestURL` (page 58) and `CFHTTPMessageCopyRequestMethod` (page 58) to get the message's request URL and request method, respectively.

If the message is a response, you can also call `CFHTTPMessageGetResponseStatusCode` (page 63) and `CFHTTPMessageCopyResponseStatusLine` (page 59) to get the message's status code and status line, respectively.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageApplyCredentialDictionary

Use a dictionary containing authentication credentials to perform the authentication method specified by a `CFHTTPAuthentication` object.

```
Boolean CFHTTPMessageApplyCredentialDictionary (
   CFHTTPMessageRef request,
   CFHTTPAuthenticationRef auth,
   CFDictionaryRef dict,
   CFStreamError *error
);
```

Parameters

request

The request for which the authentication method is to be performed.

auth

A `CFHTTPAuthentication` object specifying the authentication method to perform.

dict

A dictionary containing authentication credentials to be applied to the request. For information on the keys in this dictionary, see `CFHTTPAuthenticationRef` (page 47).

error

If an error occurs, upon return contains a `CFStreamError` object that describes the error and the error's domain. Pass `NULL` if you don't want to receive error information.

Return Value

`TRUE` if the authentication was successful, otherwise, `FALSE`.

Discussion

This function performs the authentication method specified by `auth` on behalf of the request specified by `request` using the credentials contained in the dictionary specified by `dict`. The dictionary must contain values for the `kCFHTTPAuthenticationUsername` and `kCFHTTPAuthenticationPassword` keys. If `CFHTTPAuthenticationRequiresAccountDomain` (page 46) returns `TRUE` for *auth*, the dictionary must also contain a value for the `kCFHTTPAuthenticationAccountDomain` key.

Special Considerations

This function is thread safe as long as another thread does not alter the same `CFHTTPAuthentication` object at the same time.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFHTTPAuthentication.h`

CFHTTPMessageApplyCredentials

Performs the authentication method specified by a `CFHTTPAuthentication` object.

```
Boolean CFHTTPMessageApplyCredentials (
   CFHTTPMessageRef request,
   CFHTTPAuthenticationRef auth,
   CFStringRef username,
   CFStringRef password,
   CFStreamError *error
);
```

Parameters

request

Request for which the authentication method is to be performed.

auth

A `CFHTTPAuthentication` object specifying the authentication method to perform.

username

Username for performing the authentication.

password

Password for performing the authentication.

error

If an error occurs, upon return contains a `CFStreamError` object that describes the error and the error's domain. Pass `NULL` if you don't want to receive error information.

Return Value

`TRUE` if the authentication was successful, otherwise, `FALSE`.

Discussion

This function performs the authentication method specified by `auth` on behalf of the request specified by `request` using the credentials specified by `username` and `password`. If, in addition to a username and password, you also need to specify an account domain, call `CFHTTPMessageApplyCredentialDictionary` (page 54) instead of this function.

This function is appropriate for performing several authentication requests. If you only need to make a single authentication request, consider using `CFHTTPMessageAddAuthentication` (page 53) instead.

Special Considerations

This function is thread safe as long as another thread does not alter the same `CFHTTPMessage` object at the same time.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFHTTPAuthentication.h`

CFHTTPMessageCopyAllHeaderFields

Gets all header fields from a `CFHTTPMessage` object.

```
CFDictionaryRef CFHTTPMessageCopyAllHeaderFields (
   CFHTTPMessageRef message
);
```

Parameters

message

The message to examine.

Return Value

A `CFDictionary` object containing keys and values that are `CFString` objects, where the key is the header fieldname and the dictionary value is the header field's value. Returns `NULL` if the header fields could not be copied. Ownership follows the Create Rule.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageCopyBody

Gets the body from a `CFHTTPMessage` object.

```
CFDataRef CFHTTPMessageCopyBody (
   CFHTTPMessageRef message
);
```

Parameters

message

The message to examine.

Return Value

A `CFData` object or `NULL` if there was a problem creating the object or if the there is no message body. Ownership follows the Create Rule.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageCopyHeaderFieldValue

Gets the value of a header field from a `CFHTTPMessage` object.

```
CFStringRef CFHTTPMessageCopyHeaderFieldValue (
   CFHTTPMessageRef message,
   CFStringRef headerField
);
```

Parameters

message

The message to examine.

headerField
The header field to copy.

Return Value
A `CFString` object containing a copy of the field specified by *headerField*, or `NULL` if there was a problem creating the object of if the specified header does not exist. Ownership follows the Create Rule.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageCopyRequestMethod

Gets the request method from a `CFHTTPMessage` object.

```
CFStringRef CFHTTPMessageCopyRequestMethod (
   CFHTTPMessageRef request
);
```

Parameters
request
The message to examine. This must be a request message.

Return Value
A `CFString` object containing a copy of the message's request method, or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageCopyRequestURL

Gets the URL from a `CFHTTPMessage` object.

```
CFURLRef CFHTTPMessageCopyRequestURL (
   CFHTTPMessageRef request
);
```

Parameters
request
The message to examine. This must be a request message.

Return Value
A `CFURLRef` object containing the URL or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageCopyResponseStatusLine

Gets the status line from a CFHTTPMessage object.

```
CFStringRef CFHTTPMessageCopyResponseStatusLine (
   CFHTTPMessageRef response
);
```

Parameters

response

The message to examine. This must be a response message.

Return Value
A string containing the message's status line, or NULL if there was a problem creating the object. The status line includes the message's protocol version and a success or error code. Ownership follows the Create Rule.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageCopySerializedMessage

Serializes a CFHTTPMessage object.

```
CFDataRef CFHTTPMessageCopySerializedMessage (
   CFHTTPMessageRef request
);
```

Parameters

request

The message to serialize.

Return Value
A CFData object containing the serialized message, or NULL if there was a problem creating the object. Ownership follows the Create Rule.

Discussion
This function returns a copy of a CFHTTPMessage object in serialized format that is ready for transmission.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageCopyVersion

Gets the HTTP version from a CFHTTPMessage object.

```
CFStringRef CFHTTPMessageCopyVersion (
   CFHTTPMessageRef message
);
```

Parameters

message

The message to examine.

Return Value

A `CFString` object or `NULL`, if there was a problem creating the object. Ownership follows the Create Rule.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageCreateCopy

Gets a copy of a CFHTTPMessage object.

```
CFHTTPMessageRef CFHTTPMessageCreateCopy (
   CFAllocatorRef alloc,
   CFHTTPMessageRef message
);
```

Parameters

allocator

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

message

The message to copy.

Return Value

A `CFHTTPMessage` object, or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Discussion

This function returns a copy of a `CFHTTPMessage` object that you can modify, for example, by calling `CFHTTPMessageCopyHeaderFieldValue` (page 57) or by calling`CFHTTPMessageSetBody` (page 64). Then serialize the message by calling`CFHTTPMessageCopySerializedMessage` (page 59) and send the serialized message to a client or a server.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageCreateEmpty

Creates and returns a new, empty `CFHTTPMessage` object.

```
CFHTTPMessageRef CFHTTPMessageCreateEmpty (
   CFAllocatorRef alloc,
   Boolean isRequest
);
```

Parameters

allocator

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

isRequest

A flag that determines whether to create an empty message request or an empty message response. Pass `TRUE` to create an empty request message; pass `FALSE` to create an empty response message.

Return Value

A new `CFHTTPMessage` object or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Discussion

Call `CFHTTPMessageAppendBytes` (page 54) to store an incoming, serialized HTTP request or response message in the empty message object.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CFHTTPMessage.h`

CFHTTPMessageCreateRequest

Creates and returns a `CFHTTPMessage` object for an HTTP request.

```
CFHTTPMessageRef CFHTTPMessageCreateRequest (
   CFAllocatorRef alloc,
   CFStringRef requestMethod,
   CFURLRef url,
   CFStringRef httpVersion
);
```

Parameters

allocator

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

requestMethod

The request method for the request. Use any of the request methods allowed by the HTTP version specified by *httpVersion*.

url

The URL to which the request will be sent.

httpVersion

The HTTP version for this message. Pass `kCFHTTPVersion1_0` or `kCFHTTPVersion1_1`.

Return Value

A new `CFHTTPMessage` object, or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Discussion
This function returns a `CFHTTPMessage` object that you can use to build an HTTP request. Continue building the request by calling`CFHTTPMessageSetBody` (page 64) to set the message's body. Call `CFHTTPMessageCopyHeaderFieldValue` (page 57) to set the message's headers.

If you are using a `CFReadStream` object to send the message, call `CFReadStreamCreateForHTTPRequest` to create a read stream for the request. If you are not using `CFReadStream`, call `CFHTTPMessageCopySerializedMessage` (page 59) to make the message ready for transmission by serializing it.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageCreateResponse

Creates and returns a `CFHTTPMessage` object for an HTTP response.

```
CFHTTPMessageRef CFHTTPMessageCreateResponse (
   CFAllocatorRef alloc,
   CFIndex statusCode,
   CFStringRef statusDescription,
   CFStringRef httpVersion
);
```

Parameters

allocator
The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

statusCode
The status code for this message response. The status code can be any of the status codes defined in section 6.1.1 of RFC 2616.

statusDescription
The description that corresponds to the status code. Pass NULL to use the standard description for the given status code, as found in RFC 2616.

httpVersion
The HTTP version for this message response. Pass `kCFHTTPVersion1_0` or `kCFHTTPVersion1_1`.

Return Value
A new `CFHTTPMessage` object, or `NULL` if there was a problem creating the object. Ownership follows the Create Rule.

Discussion
This function returns a `CFHTTPMessage` object that you can use to build an HTTP response. Continue building the response by calling`CFHTTPMessageSetBody` (page 64) to set the message's body. Call `CFHTTPMessageSetHeaderFieldValue` (page 64) to set the message's headers. Then call `CFHTTPMessageCopySerializedMessage` (page 59) to make the message ready for transmission by serializing it.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageGetResponseStatusCode

Gets the status code from a CFHTTPMessage object representing an HTTP response.

```
CFIndex CFHTTPMessageGetResponseStatusCode (
   CFHTTPMessageRef response
);
```

Parameters

response
The message to examine. This must be a response message.

function result
The status code as defined by RFC 2616, section 6.1.1.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageGetTypeID

Returns the Core Foundation type identifier for the CFHTTPMessage opaque type.

```
CFTypeID CFHTTPMessageGetTypeID ();
```

Return Value
The Core Foundation type identifier for the CFHTTPMessage opaque type.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
CFHTTPMessage.h

CFHTTPMessageIsHeaderComplete

Determines whether a message header is complete.

```
Boolean CFHTTPMessageIsHeaderComplete (
   CFHTTPMessageRef message
);
```

Parameters

message
The message to verify.

function result
TRUE if the message header is complete, otherwise FALSE.

Discussion
After calling `CFHTTPMessageAppendBytes` (page 54), call this function to see if the message header is complete.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageIsRequest

Returns a boolean indicating whether the CFHTTPMessage is a request or a response.

```
extern Boolean CFHTTPMessageIsRequest(CFHTTPMessageRef message);
```

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageSetBody

Sets the body of a `CFHTTPMessage` object.

```
void CFHTTPMessageSetBody (
   CFHTTPMessageRef message,
   CFDataRef bodyData
);
```

Parameters

message
The message to modify.

bodyData
The data that is to be set as the body of the message.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

CFHTTPMessageSetHeaderFieldValue

Sets the value of a header field in an HTTP message.

```
void CFHTTPMessageSetHeaderFieldValue (
   CFHTTPMessageRef message,
   CFStringRef headerField,
   CFStringRef value
);
```

Parameters

message
The message to modify.

headerField
The header field to set.

value
The value to set.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

Data Types

CFHTTPMessageRef

An opaque reference representing an HTTP message.

```
typedef struct __CFHTTPMessage *CFHTTPMessageRef;
```

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CFHTTPMessage.h`

Constants

CFHTTP Version Constants

Sets the HTTP version in a `CFHTTPMessage` request or response object.

```
const CFStringRef kCFHTTPVersion1_0;
const CFStringRef kCFHTTPVersion1_1;
```

Constants
`kCFHTTPVersion1_0`
Specifies HTTP version 1.0.

Available in Mac OS X version 10.1 and later.

`kCFHTTPVersion1_1`
Specifies HTTP version 1.1.

Available in Mac OS X version 10.1 and later.

Discussion
The HTTP version constants are used when you call `CFHTTPMessageCreateRequest` (page 61) and `CFHTTPMessageCreateResponse` (page 62) to create a request or response message.

Declared In
`CFNetwork/CFHTTPMessage.h`

Authentication Schemes

Constants used to specify the desired authentication scheme for a request.

```
extern const CFStringRef kCFHTTPAuthenticationSchemeBasic;
extern const CFStringRef kCFHTTPAuthenticationSchemeDigest;
extern const CFStringRef kCFHTTPAuthenticationSchemeNTLM;
extern const CFStringRef kCFHTTPAuthenticationSchemeNegotiate;
```

Constants
`kCFHTTPAuthenticationSchemeBasic`
Request the HTTP basic authentication scheme.

Available in Mac OS X version 10.2 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeDigest`
Request the HTTP digest authentication scheme.

Available in Mac OS X version 10.2 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeNTLM`
Request the HTTP NTLM authentication scheme.

Available in Mac OS X version 10.5 and later.

Declared in `CFHTTPMessage.h`.

`kCFHTTPAuthenticationSchemeNegotiate`
Request an automatically negotiated authentication scheme.

Available in Mac OS X version 10.5 and later.

Declared in `CFHTTPMessage.h`.

CFNetDiagnostics Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFNetDiagnostics.h
Companion guide	CFNetwork Programming Guide

Overview

The CFNetDiagnostics opaque type allows you to diagnose network-related problems.

Functions by Task

Creating a net diagnostics object

`CFNetDiagnosticCreateWithStreams` (page 68)
Creates a network diagnostic object from a pair of CFStreams.

`CFNetDiagnosticCreateWithURL` (page 69)
Creates a CFNetDiagnosticRef from a CFURLRef.

CFNetDiagnostics Functions

`CFNetDiagnosticSetName` (page 71)
Overrides the displayed application name.

`CFNetDiagnosticDiagnoseProblemInteractively` (page 70)
Opens a Network Diagnostics window.

`CFNetDiagnosticCopyNetworkStatusPassively` (page 68)
Gets a network status value.

Functions

CFNetDiagnosticCopyNetworkStatusPassively

Gets a network status value.

```
CFNetDiagnosticStatus CFNetDiagnosticCopyNetworkStatusPassively (
   CFNetDiagnosticRef details,
   CFStringRef *description
);
```

Parameters

details

CFNetDiagnosticRef, created by `CFNetDiagnosticCreateWithStreams` (page 68) or `CFNetDiagnosticCreateWithURL` (page 69), for which the Network Diagnostics status is to be obtained.

description

If not `NULL`, upon return contains a localized string containing a description of the current network status. Ownership follows the Create Rule.

Return Value

A network status value.

Discussion

This function returns a status value that can be used to display basic information about the connection, and optionally gets a localized string containing a description of the current network status.

This function is guaranteed not to generate network activity.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetDiagnosticRef at the same time.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetDiagnostics.h`

CFNetDiagnosticCreateWithStreams

Creates a network diagnostic object from a pair of CFStreams.

```
CFNetDiagnosticRef CFNetDiagnosticCreateWithStreams (
   CFAllocatorRef alloc,
   CFReadStreamRef readStream,
   CFWriteStreamRef writeStream
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

readStream

Reference to a read stream whose connection has failed, or `NULL` if you do not want the CFNetDiagnosticRef to have a read stream.

writeStream

Reference to a write stream whose connection has failed, or `NULL` if you do not want the CFNetDiagnosticRef to have a write stream.

function result

CFNetDiagnosticRef that you can pass to `CFNetDiagnosticDiagnoseProblemInteractively` (page 70) or `CFNetDiagnosticCopyNetworkStatusPassively` (page 68). Ownership follows the Create Rule.

Discussion

This function uses references to a read steam and a write stream (or just a read stream or just a write stream) to create a reference to an instance of a CFNetDiagnostic object. You can pass the reference to `CFNetDiagnosticDiagnoseProblemInteractively` (page 70) to open a Network Diagnostics window or to `CFNetDiagnosticCopyNetworkStatusPassively` (page 68) to get a description of the connection referenced by `readStream` and `writeStream`.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetDiagnosticRef at the same time.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetDiagnostics.h`

CFNetDiagnosticCreateWithURL

Creates a CFNetDiagnosticRef from a CFURLRef.

```
CFNetDiagnosticRef CFNetDiagnosticCreateWithURL (
   CFAllocatorRef alloc,
   CFURLRef url
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

url

CFURLRef that refers to the failed connection.

Return Value
CFNetDiagnosticRef that you can pass to `CFNetDiagnosticDiagnoseProblemInteractively` (page 70) or `CFNetDiagnosticCopyNetworkStatusPassively` (page 68). Ownership follows the Create Rule.

Discussion
This function uses a URL to create a reference to an instance of a CFNetDiagnostic object. You can pass the reference to `CFNetDiagnosticDiagnoseProblemInteractively` (page 70) to open a Network Diagnostics window or to `CFNetDiagnosticCopyNetworkStatusPassively` (page 68) to get a description of the connection referenced by `readStream` and `writeStream`.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetDiagnosticRef at the same time.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetDiagnostics.h`

CFNetDiagnosticDiagnoseProblemInteractively

Opens a Network Diagnostics window.

```
CFNetDiagnosticStatus CFNetDiagnosticDiagnoseProblemInteractively (
   CFNetDiagnosticRef details
);
```

Parameters

details

A network diagnostics object, created by `CFNetDiagnosticCreateWithStreams` (page 68) or `CFNetDiagnosticCreateWithURL` (page 69), for which the window is to be opened.

Return Value
`CFNetDiagnosticNoErr` if no error occurred, or `CFNetDiagnosticErr` if an error occurred that prevented this call from completing successfully.

Discussion
This function opens the Network Diagnostics window and returns immediately once the window is open.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetDiagnosticRef at the same time.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetDiagnostics.h`

CFNetDiagnosticSetName

Overrides the displayed application name.

```
void CFNetDiagnosticSetName (
   CFNetDiagnosticRef details,
   CFStringRef name
);
```

Parameters

details

The network diagnostics object for which the application name is to be set.

name

Name that is to be set.

Discussion

Frameworks requiring that an application name be displayed to the user derive the application name from the bundle identifier of the currently running application, in that application's localization. If you want to override the derived application name, use this function to set the name that is displayed.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetDiagnosticRef at the same time.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetDiagnostics.h`

Data Types

CFNetDiagnosticRef

An opaque reference representing a CFNetDiagnostic.

```
typedef struct __CFNetDiagnostic* CFNetDiagnosticRef;
```

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetDiagnostics.h`

CFNetDiagnosticStatus

A CFIndex type that is used to return status values from `CFNetDiagnostic` status and diagnostic functions. For a list of possible values, see "CFNetDiagnosticStatusValues Constants" (page 72).

```
typedef CFIndex                         CFNetDiagnosticStatus;
```

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetDiagnostics.h`

Constants

CFNetDiagnosticStatusValues Constants

Constants for diagnostic status values.

```
enum CFNetDiagnosticStatusValues {
    kCFNetDiagnosticNoErr = 0,
    kCFNetDiagnosticErr = -66560L,
    kCFNetDiagnosticConnectionUp = -66559L,
    kCFNetDiagnosticConnectionIndeterminate = -66558L,
    kCFNetDiagnosticConnectionDown = -66557L
};
typedef enum CFNetDiagnosticStatusValues CFNetDiagnosticStatusValues;
```

Constants

`kCFNetDiagnosticNoErr`
No error occurred but there is no status.
Available in Mac OS X v10.4 and later.
Declared in `CFNetDiagnostics.h`.

`kCFNetDiagnosticErr`
An error occurred that prevented the call from completing.
Available in Mac OS X v10.4 and later.
Declared in `CFNetDiagnostics.h`.

`kCFNetDiagnosticConnectionUp`
The connection appears to be working.
Available in Mac OS X v10.4 and later.
Declared in `CFNetDiagnostics.h`.

`kCFNetDiagnosticConnectionIndeterminate`
The status of the connection is not known.
Available in Mac OS X v10.4 and later.
Declared in `CFNetDiagnostics.h`.

`kCFNetDiagnosticConnectionDown`
The connection does not appear to be working.
Available in Mac OS X v10.4 and later.
Declared in `CFNetDiagnostics.h`.

Discussion
Diagnostic status values are returned by `CFNetDiagnosticDiagnoseProblemInteractively` (page 70) and `CFNetDiagnosticCopyNetworkStatusPassively` (page 68).

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetwork/CFNetDiagnostics.h`

CFNetServices Reference

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFNetServices.h
Companion guides	Bonjour Overview CFNetwork Programming Guide NSNetServices and CFNetServices Programming Guide

Overview

The CFNetServices API is part of Bonjour, Apple's implementation of zero-configuration networking (ZEROCONF). The CFNetServices API allows you to register a network service, such as a printer or file server, so that it can be found by name or browsed for by service type and domain. Applications can use the CFNetServices API to discover the services that are available on the network and to find all access information — such as name, IP address, and port number — needed to use each service.

In effect, Bonjour registration and discovery combine the functions of a local DNS server and AppleTalk, allowing applications to provide the kind of user-friendly browsing available in the AppleTalk Chooser using open protocols, such as Multicast DNS (mDNS). Bonjour gives applications easy access to services over local IP networks without requiring the service to support an AppleTalk stack, and without requiring a DNS server on the local network.

For a full description of Bonjour, see *Bonjour Overview*.

Functions by Task

Creating net service objects

`CFNetServiceCreate` (page 84)
Creates an instance of a Network Service object.

`CFNetServiceCreateCopy` (page 86)
Creates a copy of a CFNetService object.

`CFNetServiceMonitorCreate` (page 92)
Creates an instance of a NetServiceMonitor object that watches for record changes.

`CFNetServiceBrowserCreate` (page 78)
Creates an instance of a Network Service browser object.

CFNetServices Functions

`CFNetServiceBrowserInvalidate` (page 79)
Invalidates an instance of a Network Service browser object.

`CFNetServiceBrowserScheduleWithRunLoop` (page 80)
Schedules a CFNetServiceBrowser on a run loop.

`CFNetServiceBrowserSearchForDomains` (page 80)
Searches for domains.

`CFNetServiceBrowserSearchForServices` (page 81)
Searches a domain for services of a specified type.

`CFNetServiceBrowserStopSearch` (page 82)
Stops a search for domains or services.

`CFNetServiceBrowserUnscheduleFromRunLoop` (page 83)
Unschedules a CFNetServiceBrowser from a run loop and mode.

`CFNetServiceCancel` (page 84)
Cancels a service registration or a service resolution.

`CFNetServiceCreateDictionaryWithTXTData` (page 86)
Uses TXT record data to create a dictionary.

`CFNetServiceCreateTXTDataWithDictionary` (page 87)
Flattens a set of key/value pairs into a CFDataRef suitable for passing to `CFNetServiceSetTXTData` (page 103).

`CFNetServiceGetAddressing` (page 88)
Gets the IP addressing from a CFNetService.

`CFNetServiceGetTargetHost` (page 90)
Queries a CFNetService for its target hosts.

`CFNetServiceGetDomain` (page 88)
Gets the domain from a CFNetService.

`CFNetServiceGetName` (page 89)
Gets the name from a CFNetService.

`CFNetServiceGetPortNumber` (page 89)
This function gets the port number from a CFNetService.

`CFNetServiceGetTXTData` (page 91)
Queries a network service for the contents of its TXT records.

`CFNetServiceGetType` (page 91)
Gets the type from a CFNetService.

`CFNetServiceMonitorInvalidate` (page 94)
Invalidates an instance of a Network Service monitor object.

`CFNetServiceMonitorScheduleWithRunLoop` (page 94)
Schedules a CFNetServiceMonitor on a run loop.

`CFNetServiceMonitorStart` (page 95)
Starts monitoring.

`CFNetServiceMonitorStop` (page 96)
Stops a CFNetServiceMonitor.

`CFNetServiceMonitorUnscheduleFromRunLoop` (page 97)
Unschedules a CFNetServiceMonitor from a run loop.

`CFNetServiceRegisterWithOptions` (page 98)
Makes a CFNetService available on the network.

`CFNetServiceResolveWithTimeout` (page 100)
Gets the IP address or addresses for a CFNetService.

`CFNetServiceScheduleWithRunLoop` (page 101)
Schedules a CFNetService on a run loop.

`CFNetServiceSetClient` (page 102)
Associates a callback function with a CFNetService or disassociates a callback function from a CFNetService.

`CFNetServiceSetTXTData` (page 103)
Sets the TXT record for a CFNetService.

`CFNetServiceUnscheduleFromRunLoop` (page 104)
Unschedules a CFNetService from a run loop.

`CFNetServiceGetProtocolSpecificInformation` (page 90) Deprecated in Mac OS X version 10.4
This function gets protocol-specific information from a CFNetService. (Deprecated. Use `CFNetServiceGetTXTData` (page 91) instead.)

`CFNetServiceRegister` (page 97) Deprecated in Mac OS X version 10.4
Makes a CFNetService available on the network. (Deprecated. Use `CFNetServiceRegisterWithOptions` (page 98) instead.)

`CFNetServiceResolve` (page 99) Deprecated in Mac OS X version 10.4
This function updates the specified CFNetService with the IP address or addresses associated with the service. Call `CFNetServiceGetAddressing` (page 88) to get the addresses. (Deprecated. Use `CFNetServiceResolveWithTimeout` (page 100) instead.)

Modifying a net service

`CFNetServiceSetProtocolSpecificInformation` (page 103) Deprecated in Mac OS X version 10.4
Sets protocol-specific information for a CFNetService. (Deprecated. Use `CFNetServiceSetTXTData` instead.)

Getting the net service type IDs

`CFNetServiceGetTypeID` (page 92)
Gets the Core Foundation type identifier for the Network Service object.

`CFNetServiceMonitorGetTypeID` (page 94)
Gets the Core Foundation type identifier for all CFNetServiceMonitor instances.

`CFNetServiceBrowserGetTypeID` (page 79)
Gets the Core Foundation type identifier for the Network Service browser object.

Functions

CFNetServiceBrowserCreate

Creates an instance of a Network Service browser object.

```
CFNetServiceBrowserRef CFNetServiceBrowserCreate (
   CFAllocatorRef alloc,
   CFNetServiceBrowserClientCallBack clientCB,
   CFNetServiceClientContext *clientContext
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

clientCB

Callback function that is to be called when domains and services are found; cannot be `NULL`. For details, see `CFNetServiceBrowserClientCallBack` (page 104).

clientContext

Context information to be used when `clientCB` is called; cannot be `NULL`. For details, see `CFNetServiceClientContext` (page 107).

Return Value

A new browser object, or `NULL` if the instance could not be created. Ownership follows the Create Rule.

Discussion

This function creates an instance of a Network Service browser object, called a CFNetServiceBrowser, that can be used to search for domains and for services.

To use the resulting CFNetServiceBrowser in asynchronous mode, call `CFNetServiceBrowserScheduleWithRunLoop` (page 80). Then call `CFNetServiceBrowserSearchForDomains` (page 80) and `CFNetServiceBrowserSearchForServices` (page 81) to use the CFNetServiceBrowser to search for services and domains, respectively. The callback function specified by `clientCB` is called from a run loop to pass search results to your application. The search continues until you stop the search by calling `CFNetServiceBrowserStopSearch` (page 82).

If you do not call `CFNetServiceBrowserScheduleWithRunLoop` (page 80), searches with the resulting CFNetServiceBrowser are made in synchronous mode. Calls made to `CFNetServiceBrowserSearchForDomains` (page 80) and `CFNetServiceBrowserSearchForServices` (page 81) block until there are search results, in which case the callback function specified by `clientCB` is called, until the search is are stopped by calling `CFNetServiceBrowserStopSearch` (page 82) from another thread, or an error occurs.

To shut down a CFNetServiceBrowser that is running in asynchronous mode, call `CFNetServiceBrowserUnscheduleFromRunLoop` (page 83), followed by `CFNetServiceBrowserInvalidate` (page 79), and then `CFNetServiceBrowserStopSearch` (page 82).

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceBrowserGetTypeID

Gets the Core Foundation type identifier for the Network Service browser object.

```
CFTypeID CFNetServiceBrowserGetTypeID ();
```

Return Value
The type ID.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceBrowserInvalidate

Invalidates an instance of a Network Service browser object.

```
void CFNetServiceBrowserInvalidate (
   CFNetServiceBrowserRef browser
);
```

Parameters

browser

The CFNetServiceBrowser to invalidate, obtained by a previous call to `CFNetServiceBrowserCreate` (page 78).

Discussion
This function invalidates the specified instance of a Network Service browser object. Any searches using the specified instance that are in progress when this function is called are stopped. An invalidated browser cannot be scheduled on a run loop and its callback function is never called.

Special Considerations

This function is thread safe as long as another thread does not alter the same CFNetServiceBrowserRef at the same time.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceBrowserScheduleWithRunLoop

Schedules a CFNetServiceBrowser on a run loop.

```
void CFNetServiceBrowserScheduleWithRunLoop (
   CFNetServiceBrowserRef browser,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

browser

The CFNetServiceBrowser that is to be scheduled on a run loop; cannot be `NULL`.

runLoop

The run loop on which the browser is to be scheduled; cannot be `NULL`.

runLoopMode

The mode on which to schedule the browser; cannot be `NULL`.

Discussion

This function schedules the specified CFNetServiceBrowser on the run loop, thereby placing the browser in asynchronous mode. The run loop will call the browser's callback function to deliver the results of domain and service searches. The caller is responsible for ensuring that at least one of the run loops on which the browser is scheduled is being run.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceBrowserSearchForDomains

Searches for domains.

```
Boolean CFNetServiceBrowserSearchForDomains (
   CFNetServiceBrowserRef browser,
   Boolean registrationDomains,
   CFStreamError *error
);
```

Parameters

browser

The CFNetServiceBrowser, obtained by previously calling `CFNetServiceBrowserCreate` (page 78), that is to perform the search; cannot be `NULL`.

registrationDomains

`TRUE` to search for only registration domains; `FALSE` to search for domains that can be browsed for services. For this version of the CFNetServices API, the registration domain is the local domain maintained by the mDNS responder running on the same machine as the calling application.

error

A pointer to a `CFStreamError` structure, that, if an error occurs, will be set to the error and the error's domain and passed to your callback function. Pass `NULL` if you don't want to receive the error that may occur as a result of this particular call.

Return Value

`TRUE` if the search was started (asynchronous mode); `FALSE` if another search is already in progress for this CFNetServiceBrowser or if an error occurred.

Discussion

This function uses a CFNetServiceBrowser to search for domains. The search continues until the search is canceled by calling `CFNetServiceBrowserStopSearch` (page 82). If `registrationDomains` is `TRUE`, this function searches only for domains in which services can be registered. If `registrationDomains` is `FALSE`, this function searches for domains that can be browsed for services. When a domain is found, the callback function specified when the CFNetServiceBrowser was created is called and passed an instance of a CFStringRef containing the domain that was found.

In asynchronous mode, this function returns `TRUE` if the search was started. Otherwise, it returns `FALSE`.

In synchronous mode, this function blocks until the search is stopped by calling `CFNetServiceBrowserStopSearch` (page 82) from another thread, in which case it returns `FALSE`, or until an error occurs.

Special Considerations

This function is thread safe.

For any one CFNetServiceBrowser, only one domain search or one service search can be in progress at the same time.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceBrowserSearchForServices

Searches a domain for services of a specified type.

```
Boolean CFNetServiceBrowserSearchForServices (
   CFNetServiceBrowserRef browser,
   CFStringRef domain,
   CFStringRef serviceType,
   CFStreamError *error
);
```

Parameters

browser

The CFNetServiceBrowser, obtained by previously calling `CFNetServiceBrowserCreate` (page 78), that is to perform the search; cannot be `NULL`.

domain

The domain to search for the service type; cannot be `NULL`. To get the domains that are available for searching, call `CFNetServiceBrowserSearchForDomains` (page 80).

type

The service type to search for; cannot be `NULL`. For a list of valid service types, see http://www.iana.org/assignments/port-numbers.

error

A pointer to a `CFStreamError` structure, that, if an error occurs, will be set to the error and the error's domain and passed to your callback function. Pass `NULL` if you don't want to receive the error that may occur as a result of this particular call.

Return Value

`TRUE` if the search was started (asynchronous mode); `FALSE` if another search is already in progress for this CFNetServiceBrowser or if an error occurred.

Discussion

This function searches the specified domain for services that match the specified service type. The search continues until the search is canceled by calling `CFNetServiceBrowserStopSearch` (page 82). When a match is found, the callback function specified when the CFNetServiceBrowser was created is called and passed an instance of a CFNetService representing the service that was found.

In asynchronous mode, this function returns `TRUE` if the search was started. Otherwise, it returns `FALSE`.

In synchronous mode, this function blocks until the search is stopped by calling `CFNetServiceBrowserStopSearch` (page 82) from another thread, in which case this function returns `FALSE`, or until an error occurs.

Special Considerations

This function is thread safe.

For any one CFNetServiceBrowser, only one domain search or one service search can be in progress at the same time.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceBrowserStopSearch

Stops a search for domains or services.

```
void CFNetServiceBrowserStopSearch (
   CFNetServiceBrowserRef browser,
   CFStreamError *error
);
```

Parameters

browser

The CFNetServiceBrowser that was used to start the search; cannot be `NULL`.

error

A pointer to a `CFStreamError` structure that will be passed to the callback function associated with this CFNetServiceBrowser (if the search is being conducted in asynchronous mode) or that is pointed to by the `error` parameter when `CFNetServiceBrowserSearchForDomains` (page 80) or `CFNetServiceBrowserSearchForServices` (page 81) returns (if the search is being conducted in synchronous mode). Set the `domain` field to `kCFStreamErrorDomainCustom` and the `error` field to an appropriate value.

Discussion

This functions stops a search started by a previous call to `CFNetServiceBrowserSearchForDomains` (page 80) or `CFNetServiceBrowserSearchForServices` (page 81). For asynchronous and synchronous searches, calling this function causes the callback function associated with the CFNetServiceBrowser to be called once for each domain or service found. If the search is asynchronous, `error` is passed to the callback function. If the search is synchronous, calling this function causes `CFNetServiceBrowserSearchForDomains` or `CFNetServiceBrowserSearchForServices` to return `FALSE`. If the `error` parameter for either call pointed to a `CFStreamError` structure, the `CFStreamError` structure contains the error code and the error code's domain as set when this function was called.

Special Considerations

This function is thread safe.

If you are stopping an asynchronous search, before calling this function, call `CFNetServiceBrowserUnscheduleFromRunLoop` (page 83), followed by `CFNetServiceBrowserInvalidate` (page 79).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceBrowserUnscheduleFromRunLoop

Unschedules a CFNetServiceBrowser from a run loop and mode.

```
void CFNetServiceBrowserUnscheduleFromRunLoop (
   CFNetServiceBrowserRef browser,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

browser

The CFNetServiceBrowser that is to be unscheduled; cannot be `NULL`.

runLoop

The run loop; cannot be `NULL`.

runLoopMode

The mode from which the browser is to be unscheduled; cannot be `NULL`.

Discussion

Call this function to shut down a browser that is running asynchronously. To complete the shutdown, call `CFNetServiceBrowserInvalidate` (page 79) followed by `CFNetServiceBrowserStopSearch` (page 82).

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceCancel

Cancels a service registration or a service resolution.

```
void CFNetServiceCancel (
   CFNetServiceRef theService
);
```

Parameters

theService

The CFNetService, obtained by previously calling `CFNetServiceCreate` (page 84), for which a registration or a resolution is to be canceled.

Discussion

This function cancels service registrations, started by `CFNetServiceRegister` (page 97), thereby making the service unavailable. It also cancels service resolutions, started by `CFNetServiceResolve` (page 99).

If you are shutting down an asynchronous service, you should first call `CFNetServiceUnscheduleFromRunLoop` (page 104) and `CFNetServiceSetClient` (page 102) with `clientCB` set to `NULL`. Then call this function.

If you are shutting down a synchronous service, call this function from another thread.

This function also cancels service resolutions. You would want to cancel a service resolution if your callback function has received an IP address that you've successfully used to connect to the service. In addition, you might want to cancel a service resolution if the resolution is taking longer than a user would want to wait or if the user canceled the operation.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceCreate

Creates an instance of a Network Service object.

```
CFNetServiceRef CFNetServiceCreate (
   CFAllocatorRef alloc,
   CFStringRef domain,
   CFStringRef serviceType,
   CFStringRef name,
   SInt32 port
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

domain

The domain in which the CFNetService is to be registered; cannot be `NULL`. Call `CFNetServiceBrowserCreate` (page 78) and `CFNetServiceBrowserSearchForDomains` (page 80) to get the registration domain.

type

The type of service being registered; cannot be `NULL`. For a list of valid service types, see http://www.iana.org/assignments/port-numbers.

name

A unique name if the instance will be used to register a service. The name will become part of the instance name in the DNS records that will be created when the service is registered. If the instance will be used to resolve a service, the name should be the name of the machine or service that will be resolved.

port

Local IP port, in host byte order, on which this service accepts connections. Pass zero to get placeholder service. With a placeholder service, the service will not be discovered by browsing, but a name conflict will occur if another client tries to register the same name. Most applications do not need to use placeholder service.

Return Value

A new net service object, or `NULL` if the instance could not be created. Ownership follows the Create Rule.

Discussion

If the service depends on information in DNS TXT records, call `CFNetServiceSetProtocolSpecificInformation` (page 103).

If the CFNetService is to run in asynchronous mode, call `CFNetServiceSetClient` (page 102) to prepare the service for running in asynchronous mode. Then call `CFNetServiceScheduleWithRunLoop` (page 101) to schedule the service on a run loop. Then call `CFNetServiceRegister` (page 97) to make the service available.

If the CFNetService is to run in synchronous mode, call `CFNetServiceRegister` (page 97).

To terminate a service that is running in asynchronous mode, call `CFNetServiceCancel` (page 84) and `CFNetServiceUnscheduleFromRunLoop` (page 104).

To terminate a service that is running in synchronous mode, call `CFNetServiceCancel` (page 84).

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Declared In
CFNetServices.h

CFNetServiceCreateCopy

Creates a copy of a CFNetService object.

```
CFNetServiceRef CFNetServiceCreateCopy (
   CFAllocatorRef alloc,
   CFNetServiceRef service
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass NULL or kCFAllocatorDefault to use the current default allocator.

service

CFNetServiceRef to be copied; cannot be NULL. If service is not a valid CFNetServiceRef, the behavior of this function is undefined.

Return Value
Copy of service, including all previously resolved data, or NULL if service could not be copied. Ownership follows the Create Rule.

Discussion
This function creates a copy of the CFNetService specified by service.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CFNetServices.h

CFNetServiceCreateDictionaryWithTXTData

Uses TXT record data to create a dictionary.

```
CFDictionaryRef CFNetServiceCreateDictionaryWithTXTData (
   CFAllocatorRef alloc,
   CFDataRef txtRecord
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass NULL or kCFAllocatorDefault to use the current default allocator.

txtRecord

TXT record data as returned by CFNetServiceGetTXTData (page 91).

Return Value
A dictionary containing the key/value pairs parsed from `txtRecord`, or `NULL` if `txtRecord` cannot be parsed. Each key in the dictionary is a CFString object, and each value is a CFData object. Ownership follows the Create Rule.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceCreateTXTDataWithDictionary

Flattens a set of key/value pairs into a CFDataRef suitable for passing to `CFNetServiceSetTXTData` (page 103).

```
CFDataRef CFNetServiceCreateTXTDataWithDictionary (
   CFAllocatorRef alloc,
   CFDictionaryRef keyValuePairs
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

keyValuePairs

CFDictionaryRef containing the key/value pairs that are to be placed in a TXT record. Each key must be a CFStringRef and each value should be a CFDataRef or a CFStringRef. (See the discussion below for additional information about values that are CFStringRefs.) This function fails if any other data types are provided. The length of a key and its value should not exceed 255 bytes.

Return Value
A CFData object containing the flattened form of *keyValuePairs*, or `NULL` if the dictionary could not be flattened. Ownership follows the Create Rule.

Discussion
This function flattens the key/value pairs in the dictionary specified by `keyValuePairs` into a CFDataRef suitable for passing to `CFNetServiceSetTXTData` (page 103). Note that this function is not a general purpose function for flattening CFDictionaryRefs.

The keys in the dictionary referenced by `keyValuePairs` must be CFStringRefs and the values must be CFDataRefs. Any values that are CFStringRefs are converted to CFDataRefs representing the flattened UTF-8 bytes of the string. The types of the values are not encoded in the CFDataRefs, so any CFStringRefs that are converted to CFDataRefs remain CFDataRefs when the CFDataRef produced by this function is processed by `CFNetServiceCreateDictionaryWithTXTData` (page 86).

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CFNetServices.h

CFNetServiceGetAddressing

Gets the IP addressing from a CFNetService.

```
CFArrayRef CFNetServiceGetAddressing (
   CFNetServiceRef theService
);
```

Parameters

theService
The CFNetService whose IP addressing is to be obtained; cannot be NULL.

Return Value
A CFArray containing a CFDataRef for each IP address returned, or NULL. Each CFDataRef consists of a sockaddr structure containing the IP address of the service. This function returns NULL if the service's addressing is unknown because CFNetServiceResolve (page 99) has not been called for theService.

Discussion
This function gets the IP addressing from a CFNetService. Typically, the CFNetService was obtained by calling CFNetServiceBrowserSearchForServices (page 81). Before calling this function, call CFNetServiceResolve (page 99) to update the CFNetService with its IP addressing.

Special Considerations

This function gets the data in a thread-safe way, but the data itself is not safe if the service is altered from another thread.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CFNetServices.h

CFNetServiceGetDomain

Gets the domain from a CFNetService.

```
CFStringRef CFNetServiceGetDomain (
   CFNetServiceRef theService
);
```

Parameters

theService
The CFNetService whose domain is to be obtained; cannot be NULL.

Return Value
A CFString object containing the domain of the CFNetService.

Discussion
This function gets the domain from a CFNetService.

Special Considerations

This function is thread safe. The function gets the data in a thread-safe way, but the data is not safe if the service is altered from another thread.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceGetName

Gets the name from a CFNetService.

```
CFStringRef CFNetServiceGetName (
   CFNetServiceRef theService
);
```

Parameters

`theService`

The CFNetService whose name is to be obtained; cannot be `NULL`.

Return Value

A CFString object containing the name of the service represented by the CFNetService.

Discussion

This function gets the name from a CFNetService.

Special Considerations

This function is thread safe. The function gets the data in a thread-safe way, but the data is not safe if the service is altered from another thread.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceGetPortNumber

This function gets the port number from a CFNetService. (Deprecated in Mac OS X version 10.4.)

```
extern SInt32 CFNetServiceGetPortNumber(
    CFNetServiceRef theService);
```

Parameters

`theService`

The CFNetService whose protocol-specific information is to be obtained; cannot be `NULL`. Note that in order to get protocol-specific information, you must resolve `theService` by calling `CFNetServiceResolve` (page 99) or `CFNetServiceResolveWithTimeout` (page 100) before calling this function.

Return Value

A CFString object containing the protocol-specific information, or `NULL` if there is no information.

Special Considerations

This function gets the data in a thread-safe way, but the data itself is not safe if the service is altered from another thread.

Availability

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X version 10.4.

Declared In

`CFNetServices.h`

CFNetServiceGetProtocolSpecificInformation

This function gets protocol-specific information from a CFNetService. (Deprecated in Mac OS X version 10.4. Use `CFNetServiceGetTXTData` (page 91) instead.)

```
CFStringRef CFNetServiceGetProtocolSpecificInformation (
   CFNetServiceRef theService
);
```

Parameters

`theService`

The CFNetService whose protocol-specific information is to be obtained; cannot be `NULL`. Note that in order to get protocol-specific information, you must resolve `theService` by calling `CFNetServiceResolve` (page 99) or `CFNetServiceResolveWithTimeout` (page 100) before calling this function.

Return Value

A CFString object containing the protocol-specific information, or `NULL` if there is no information.

Special Considerations

This function gets the data in a thread-safe way, but the data itself is not safe if the service is altered from another thread.

Availability

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X version 10.4.

Declared In

`CFNetServices.h`

CFNetServiceGetTargetHost

Queries a CFNetService for its target hosts.

```
CFStringRef CFNetServiceGetTargetHost (
   CFNetServiceRef theService
);
```

Parameters

`theService`

Network service to be queried.

Return Value
The target host name of the machine providing the service or `NULL` is of the service's target host is not known. (The target host will not be known if it has not been resolved.)

Special Considerations

This function is thread safe, but the target host name is not safe if the service is altered from another thread.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceGetTXTData

Queries a network service for the contents of its TXT records.

```
CFDataRef CFNetServiceGetTXTData (
   CFNetServiceRef theService
);
```

Parameters

`theService`

Reference for the network service whose TXT record data is to be obtained; cannot be `NULL`. Note that in order to get TXT record data, you must resolve `theService` by calling `CFNetServiceResolve` (page 99) or `CFNetServiceResolveWithTimeout` (page 100) before calling this function.

Return Value
CFDataRef object containing the requested TXT data and suitable for passing to `CFNetServiceCreateDictionaryWithTXTData` (page 86), or `NULL` if the service's TXT data has not been resolved.

Discussion
This function gets the data from the service's TXT records.

Special Considerations

This function gets the data in a thread-safe way, but the data itself is not safe if the service is altered from another thread.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceGetType

Gets the type from a CFNetService.

```
CFStringRef CFNetServiceGetType (
   CFNetServiceRef theService
);
```

Parameters

theService

The CFNetService whose type is to be obtained; cannot be `NULL`.

Return Value
A CFString object containing the type from a CFNetService.

Discussion
This function gets the type of a CFNetService.

Special Considerations

This function is thread safe. The function gets the data in a thread-safe way, but the data is not safe if the service is altered from another thread.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceGetTypeID

Gets the Core Foundation type identifier for the Network Service object.

```
CFTypeID CFNetServiceGetTypeID ();
```

Return Value
The type ID.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceMonitorCreate

Creates an instance of a NetServiceMonitor object that watches for record changes.

```
CFNetServiceMonitorRef CFNetServiceMonitorCreate (
   CFAllocatorRef alloc,
   CFNetServiceRef theService,
   CFNetServiceMonitorClientCallBack clientCB,
   CFNetServiceClientContext *clientContext
);
```

Parameters

alloc

The allocator to use to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

theService

CFNetService to be monitored.

clientCB

Pointer to callback function that is to be called when a record associated with `theService` changes; cannot be `NULL`.

clientContext

Pointer to user-defined contextual information that is to be passed to the callback specified by `clientCB` when the callback is called; cannot be `NULL`. For details, see CFNetServiceClientContext (page 107).

Return Value

A new instance of a CFNetServiceMonitor, or `NULL` if the monitor could not be created. Ownership follows the Create Rule.

Discussion

This function creates a CFNetServiceMonitor that watches for changes in records associated with `theService`.

If the CFNetServiceMonitor is to run in asynchronous mode, call `CFNetServiceMonitorScheduleWithRunLoop` (page 94) to schedule the monitor on a run loop. Then call `CFNetServiceMonitorStart` (page 95) to start monitoring. When a change occurs, the callback function specified by `clientCB` will be called. For details, see CFNetServiceMonitorClientCallBack (page 106).

If the CFNetServiceMonitor is to run in synchronous mode, call `CFNetServiceMonitorStart` (page 95).

To stop a monitor that is running in asynchronous mode, call `CFNetServiceMonitorStop` (page 96) and `CFNetServiceMonitorUnscheduleFromRunLoop` (page 97).

To stop a monitor that is running in synchronous mode, call `CFNetServiceMonitorStop` (page 96).

If you no longer need to monitor record changes, call `CFNetServiceMonitorStop` (page 96) to stop the monitor and then call `CFNetServiceMonitorInvalidate` (page 94)to invalidate the monitor so it cannot be used again. Then call `CFRelease` to release the memory associated with CFNetServiceMonitorRef.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetServices.h`

CFNetServiceMonitorGetTypeID

Gets the Core Foundation type identifier for all CFNetServiceMonitor instances.

```
CFTypeID CFNetServiceMonitorGetTypeID ();
```

Return Value
The type ID.

Special Considerations

This function is thread safe.

Version Notes
Introduced in Mac OS X v10.4.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceMonitorInvalidate

Invalidates an instance of a Network Service monitor object.

```
void CFNetServiceMonitorInvalidate (
   CFNetServiceMonitorRef monitor
);
```

Parameters

monitor
CFNetServiceMonitor to invalidate; cannot be `NULL`.

Discussion
This function invalidates the specified Network Service monitor so that it cannot be used again. Before you call this function, you should call `CFNetServiceMonitorStop` (page 96). If the monitor has not already been stopped, this function stops the monitor for you.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceMonitorScheduleWithRunLoop

Schedules a CFNetServiceMonitor on a run loop.

```
void CFNetServiceMonitorScheduleWithRunLoop (
   CFNetServiceMonitorRef monitor,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

theService

The CFNetServiceMonitor that is to be scheduled on a run loop; cannot be `NULL`.

runLoop

The run loop on which the monitor is to be scheduled; cannot be `NULL`.

runLoopMode

The mode on which to schedule the monitor; cannot be `NULL`.

Discussion

Schedules the specified monitor on a run loop, which places the monitor in asynchronous mode. The caller is responsible for ensuring that at least one of the run loops on which the monitor is scheduled is being run.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetServices.h`

CFNetServiceMonitorStart

Starts monitoring.

```
Boolean CFNetServiceMonitorStart (
   CFNetServiceMonitorRef monitor,
   CFNetServiceMonitorType recordType,
   CFStreamError *error
);
```

Parameters

monitor

CFNetServiceMonitor, created by calling `CFNetServiceMonitorCreate` (page 92), that is to be started.

recordType

CFNetServiceMonitorType that specified the type of record to monitor. For possible values, see CFNetServiceMonitorType Constants (page 110).

error

Pointer to a `CFStreamError` structure. If an error occurs, on output, the structure's `domain` field will be set to the error code's domain and the `error` field will be set to an appropriate error code. Set this parameter to `NULL` if you don't want to receive the error code and its domain.

Return Value

`TRUE` if an asynchronous monitor was started successfully. `FALSE` if an error occurred when starting an asynchronous or synchronous monitor, or if `CFNetServiceMonitorStop` (page 96) was called for an synchronous monitor.

Discussion
This function starts monitoring for changes to records of the type specified by `recordType`. If a monitor is already running for the service associated with the specified CFNetServiceMonitorRef, this function returns `FALSE`.

For synchronous monitors, this function blocks until the monitor is stopped by calling `CFNetServiceMonitorStop` (page 96), in which case, this function returns `FALSE`.

For asynchronous monitors, this function returns `TRUE` or `FALSE`, depending on whether monitoring starts successfully.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceMonitorStop

Stops a CFNetServiceMonitor.

```
void CFNetServiceMonitorStop (
   CFNetServiceMonitorRef monitor,
   CFStreamError *error
);
```

Parameters

monitor

CFNetServiceMonitor, started by calling `CFNetServiceMonitorStart` (page 95), that is to be stopped.

error

Pointer to a `CFStreamError` structure or `NULL`. For synchronous monitors, set the `error` field of this structure to the non-zero value you want to be set in the `CFStreamError` structure when `CFNetServiceMonitorStart` (page 95) returns. Note that when it returns, `CFNetServiceMonitorStart` returns `FALSE`. If the monitor was started asynchronously, set the `error` field to the non-zero value you want the monitor's callback to receive when it is called. If this parameter is `NULL`, default values for the `CFStreamError` structure are used: the domain is set to `kCFStreamErrorDomainNetServices` and the error code is set to `kCFNetServicesErrorCancel`.

Discussion
This function stops the specified monitor. Call `CFNetServiceMonitorStart` (page 95) if you want to start monitoring again.

If you want to stop monitoring and no longer need to monitor record changes, call `CFNetServiceMonitorInvalidate` (page 94) instead of this function.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CFNetServices.h

CFNetServiceMonitorUnscheduleFromRunLoop

Unschedules a CFNetServiceMonitor from a run loop.

```
void CFNetServiceMonitorUnscheduleFromRunLoop (
   CFNetServiceMonitorRef monitor,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

monitor
The CFNetServiceMonitor that is to be unscheduled; cannot be NULL.

runLoop
The run loop; cannot be NULL.

runLoopMode
The mode from which the monitor is to be unscheduled; cannot be NULL.

Discussion
Unschedules the specified monitor from the specified run loop and mode. Call this function to shut down a monitor that is running asynchronously.

To change a monitor so that it cannot be scheduled and so that its callback will never be called, call CFNetServiceMonitorInvalidate (page 94).

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CFNetServices.h

CFNetServiceRegister

Makes a CFNetService available on the network. (Deprecated in Mac OS X version 10.4. Use CFNetServiceRegisterWithOptions (page 98) instead.)

```
Boolean CFNetServiceRegister (
   CFNetServiceRef theService,
   CFStreamError *error
);
```

Parameters

theService
The CFNetService to register; cannot be NULL. The registration will fail if the service doesn't have a domain, a type, a name, and an IP address.

error

A pointer to a `CFStreamError` structure that will be set to an error code and the error code's domain if an error occurs; or `NULL` if you don't want to receive the error code and its domain.

Return Value

`TRUE` if an asynchronous service registration was started; `FALSE` if an asynchronous or synchronous registration failed or if a synchronous registration was canceled.

Discussion

If the service is to run in asynchronous mode, you must call `CFNetServiceSetClient` (page 102) to associate a callback function with this CFNetService before calling this function.

When registering a service that runs in asynchronous mode, this function returns `TRUE` if the service contains all of the required attributes and the registration process can start. If the registration process completes successfully, the service is available on the network until you shut down the service by calling `CFNetServiceUnscheduleFromRunLoop` (page 104), `CFNetServiceSetClient` (page 102), and `CFNetServiceCancel` (page 84). If the service does not contain all of the required attributes or if the registration process does not complete successfully, this function returns `FALSE`.

When registering a service that runs in synchronous mode, this function blocks until an error occurs, in which case this function returns `FALSE`. Until this function returns `FALSE`, the service is available on the network. To force this function to return `FALSE`, thereby shutting down the service, call `CFNetServiceCancel` (page 84) from another thread.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X version 10.4.

Declared In

`CFNetServices.h`

CFNetServiceRegisterWithOptions

Makes a CFNetService available on the network.

```
Boolean CFNetServiceRegisterWithOptions (
   CFNetServiceRef theService,
   CFOptionFlags options,
   CFStreamError *error
);
```

Parameters

theService

Network service to register; cannot be `NULL`. The registration will fail if the service doesn't have a domain, a type, a name, and an IP address.

options

Bit flags for specifying registration options. Currently, the only registration option is `kCFNetServiceFlagNoAutoRename`. For details, see CFNetService Registration Options (page 109).

error

Pointer to a `CFStreamError` structure that will be set to an error code and the error code's domain if an error occurs; or `NULL` if you don't want to receive the error code and its domain.

Return Value

`TRUE` if an asynchronous service registration was started; `FALSE` if an asynchronous or synchronous registration failed or if a synchronous registration was canceled.

Discussion

If the service is to run in asynchronous mode, you must call `CFNetServiceSetClient` (page 102) to associate a callback function with this CFNetService before calling this function.

When registering a service that runs in asynchronous mode, this function returns `TRUE` if the service contains all of the required attributes and the registration process can start. If the registration process completes successfully, the service is available on the network until you shut down the service by calling `CFNetServiceUnscheduleFromRunLoop` (page 104), `CFNetServiceSetClient` (page 102), and `CFNetServiceCancel` (page 84). If the service does not contain all of the required attributes or if the registration process does not complete successfully, this function returns `FALSE`.

When registering a service that runs in synchronous mode, this function blocks until an error occurs, in which case this function returns `FALSE`. Until this function returns `FALSE`, the service is available on the network. To force this function to return `FALSE`, thereby shutting down the service, call `CFNetServiceCancel` (page 84) from another thread.

The `options` parameter is a bit flag for specifying service registration options. Currently, `kCFNetServiceFlagNoAutoRename` is the only supported registration option. If this bit is set and a service of the same name is running, the registration will fail. If this bit is not set and a service of the same name is running, the service that is being registered will be renamed automatically by appending `(n)` to the service name, where *n* is a number that is incremented until the service can be registered with a unique name.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CFNetServices.h`

CFNetServiceResolve

This function updates the specified CFNetService with the IP address or addresses associated with the service. Call `CFNetServiceGetAddressing` (page 88) to get the addresses. (Deprecated in Mac OS X version 10.4. Use `CFNetServiceResolveWithTimeout` (page 100) instead.)

```
Boolean CFNetServiceResolve (
   CFNetServiceRef theService,
   CFStreamError *error
);
```

Parameters

theService

The CFNetService to resolve; cannot be `NULL`. The resolution will fail if the service doesn't have a domain, a type, and a name.

error

A pointer to a `CFStreamError` structure that will be set to an error code and the error code's domain if an error occurs; or `NULL` if you don't want to receive the error code and its domain.

Return Value

`TRUE` if an asynchronous service resolution was started or if a synchronous service resolution updated the CFNetService; `FALSE` if an asynchronous or synchronous resolution failed or if a synchronous resolution was canceled.

Discussion

When resolving a service that runs in asynchronous mode, this function returns `TRUE` if the CFNetService has a domain, type, and name, and the underlying resolution process was started. Otherwise, this function returns `FALSE`. Once started, the resolution continues until it is canceled by calling `CFNetServiceCancel` (page 84).

When resolving a service that runs in synchronous mode, this function blocks until the CFNetService is updated with at least one IP address, until an error occurs, or until `CFNetServiceCancel` (page 84) is called.

Special Considerations

This function is thread safe.

If the service will be used in asynchronous mode, you must call `CFNetServiceSetClient` (page 102) before calling this function.

Availability

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X version 10.4.

Declared In

`CFNetServices.h`

CFNetServiceResolveWithTimeout

Gets the IP address or addresses for a CFNetService.

```
Boolean CFNetServiceResolveWithTimeout (
   CFNetServiceRef theService,
   CFTimeInterval timeout,
   CFStreamError *error
);
```

Parameters

theService

The CFNetService to resolve; cannot be `NULL`. The resolution will fail if the service doesn't have a domain, a type, and a name.

timeout

Value of type `CFTimeInterval` specifying the maximum amount of time allowed to perform the resolution. If the resolution is not performed within the specified amount of time, a timeout error will be returned. If `timeout` is less than or equal to zero, an infinite amount of time is allowed.

error

Pointer to a `CFStreamError` structure that will be set to an error code and the error code's domain if an error occurs; or `NULL` if you don't want to receive the error code and its domain.

Return Value
`TRUE` if an asynchronous service resolution was started or if a synchronous service resolution updated the CFNetService; `FALSE` if an asynchronous or synchronous resolution failed or timed out, or if a synchronous resolution was canceled.

Discussion
This function updates the specified CFNetService with the IP address or addresses associated with the service. Call `CFNetServiceGetAddressing` (page 88) to get the addresses.

When resolving a service that runs in asynchronous mode, this function returns `TRUE` if the CFNetService has a domain, type, and name, and the underlying resolution process was started. Otherwise, this function returns `FALSE`. Once started, the resolution continues until it is canceled by calling `CFNetServiceCancel` (page 84).

When resolving a service that runs in synchronous mode, this function blocks until the CFNetService is updated with at least one IP address, until an error occurs, or until `CFNetServiceCancel` (page 84) is called.

Special Considerations

This function is thread safe.

If the service will be used in asynchronous mode, you must call `CFNetServiceSetClient` (page 102) before calling this function.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceScheduleWithRunLoop

Schedules a CFNetService on a run loop.

```
void CFNetServiceScheduleWithRunLoop (
   CFNetServiceRef theService,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

theService
The CFNetService that is to be scheduled on a run loop; cannot be `NULL`.

runLoop
The run loop on which the service is to be scheduled; cannot be `NULL`.

runLoopMode
The mode on which to schedule the service; cannot be `NULL`.

Discussion
Schedules the specified service on a run loop, which places the service in asynchronous mode. The caller is responsible for ensuring that at least one of the run loops on which the service is scheduled is being run.

Special Considerations

This function is thread safe.

Before calling this function, call `CFNetServiceSetClient` (page 102) to prepare a CFNetService for use in asynchronous mode.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceSetClient

Associates a callback function with a CFNetService or disassociates a callback function from a CFNetService.

```
Boolean CFNetServiceSetClient (
   CFNetServiceRef theService,
   CFNetServiceClientCallBack clientCB,
   CFNetServiceClientContext *clientContext
);
```

Parameters

theService
The CFNetService; cannot be `NULL`.

clientCB
The callback function that is to be associated with this CFNetService. If you are shutting down the service, set `clientCB` to `NULL` to disassociate from this CFNetService the callback function that was previously associated.

clientContext
Context information to be used when `clientCB` is called; cannot be `NULL`.

Return Value
`TRUE` if the client was set; otherwise, `FALSE`.

Discussion
The callback function specified by `clientCB` will be called to report IP addresses (in the case of `CFNetServiceResolve`) or to report registration errors (in the case of `CFNetServiceRegister`).

Special Considerations

This function is thread safe.

For a CFNetService that will operate asynchronously, call this function and then call `CFNetServiceScheduleWithRunLoop` (page 101) to schedule the service on a run loop. Then call `CFNetServiceRegister` (page 97) or `CFNetServiceResolve` (page 99).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceSetProtocolSpecificInformation

Sets protocol-specific information for a CFNetService. (Deprecated in Mac OS X version 10.4. Use `CFNetServiceSetTXTData` instead.)

```
void CFNetServiceSetProtocolSpecificInformation (
   CFNetServiceRef theService,
   CFStringRef theInfo
);
```

Parameters

theService

The CFNetService whose protocol-specific information is to be set; cannot be `NULL`.

theInfo

The protocol-specific information to be set. Pass `NULL` to remove protocol-specific information from the service.

Discussion

The protocol-specific information appears in DNS TXT records for the service. Each TXT record consists of zero or more strings, packed together without any intervening gaps or padding bytes for word alignment. The format of each constituent string is a single length byte, followed by zero to 255 bytes of text data.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X version 10.4.

Declared In

`CFNetServices.h`

CFNetServiceSetTXTData

Sets the TXT record for a CFNetService.

```
Boolean CFNetServiceSetTXTData (
   CFNetServiceRef theService,
   CFDataRef txtRecord
);
```

Parameters

theService

CFNetServiceRef for which a TXT record is to be set; cannot be `NULL`.

txtRecord

Contents of the TXT record that is to be set. The contents must not exceed 1450 bytes.

Return Value

`TRUE` if the TXT record was set; otherwise, `FALSE`.

Discussion

This function sets a TXT record for the specified service. If the service is currently registered on the network, the record is broadcast. Setting a TXT record on a service that is still being resolved is not allowed.

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceUnscheduleFromRunLoop

Unschedules a CFNetService from a run loop.

```
void CFNetServiceUnscheduleFromRunLoop (
   CFNetServiceRef theService,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

`theService`
The CFNetService that is to be unscheduled; cannot be `NULL`.

`runLoop`
The run loop; cannot be `NULL`.

`runLoopMode`
The mode from which the service is to be unscheduled; cannot be `NULL`.

Discussion
Unschedules the specified service from the specified run loop and mode. Call this function to shut down a service that is running asynchronously. To complete the shutdown, call `CFNetServiceSetClient` (page 102) and set `clientCB` to `NULL`. Then call `CFNetServiceCancel` (page 84).

Special Considerations

This function is thread safe.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

Callbacks

CFNetServiceBrowserClientCallBack

Defines a pointer to the callback function for a CFNetServiceBrowser.

```
typedef void (*CFNetServiceBrowserClientCallBack) (
   CFNetServiceBrowserRef browser,
   CFOptionFlags flags,
   CFTypeRef domainOrService,
   CFStreamError* error,
   void* info);
```

If you name your callback `MyNetServiceBrowserClientCallBack`, you would declare it like this:

```
void MyNetServiceBrowserClientCallBack (
   CFNetServiceBrowserRef browser,
   CFOptionFlags flags,
   CFTypeRef domainOrService,
   CFStreamError* error,
   void* info);
```

Parameters

browser

The CFNetServiceBrowser associated with this callback function.

flags

Flags conveying additional information. The `kCFNetServiceFlagIsDomain` bit is set if `domainOrService` contains a domain; if this bit is not set, `domainOrService` contains a CFNetService instance. For additional bit values, see CFNetServiceBrowserClientCallBack Bit Flags (page 109).

domainOrService

A string containing a domain name if this callback function is being called as a result of calling `CFNetServiceBrowserSearchForDomains` (page 80), or a CFNetService instance if this callback function is being called as a result calling `CFNetServiceBrowserSearchForServices` (page 81).

error

A pointer to a `CFStreamError` structure whose `error` field may contain an error code.

info

User-defined context information. The value of `info` is the same as the value of the `info` field of the `CFNetServiceClientContext` (page 107) structure that was provided when `CFNetServiceBrowserCreate` (page 78) was called to create the CFNetServiceBrowser associated with this callback function.

Discussion

The callback function for a CFNetServiceBrowser is called one or more times when domains or services are found as the result of calling `CFNetServiceBrowserSearchForDomains` (page 80) and `CFNetServiceBrowserSearchForServices` (page 81).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceClientCallBack

Defines a pointer to the callback function for a CFNetService.

```
typedef void (*CFNetServiceClientCallBack) (
   CFNetServiceRef theService,
   CFStreamError* error,
   void* info);
```

If you name your callback `MyNetServiceClientCallBack`, you would declare it like this:

```
void MyNetServiceClientCallBack (
   CFNetServiceRef theService,
   CFStreamError* error,
   void* info);
```

Parameters

theService

CFNetService associated with this callback function.

error

Pointer to a `CFStreamError` structure whose `error` field contain may contain an error code.

info

User-defined context information. The value of `info` is the same as the value of the `info` field of the `CFNetServiceClientContext` (page 107) structure that was provided when `CFNetServiceSetClient` (page 102) was called for the CFNetService associated with this callback function.

Discussion

Your callback function will be called when there are results of resolving a CFNetService to report or when there are registration errors to report. In the case of resolution, if the service has more than one IP address, your callback will be called once for each address.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetServices.h`

CFNetServiceMonitorClientCallBack

Defines a pointer to the callback function that is to be called when a monitored record type changes.

```
typedef void (*CFNetServiceMonitorClientCallBack) (
   CFNetServiceMonitorRef theMonitor,
   CFNetServiceRef theService,
   CFNetServiceMonitorType typeInfo,
   CFDataRef rdata,
   CFStreamError* error,
   void* info);
```

If you name your callback `MyNetServiceMonitorClientCallBack`, you would declare it like this:

```
void MyNetServiceMonitorClientCallBack (
   CFNetServiceMonitorRef theMonitor,
   CFNetServiceRef theService,
   CFNetserviceMonitorType typeInfo,
   CFDataRef rdata,
   CFStreamError *error,
```

```
    void *info);
```

Parameters

theMonitor
CFNetServiceMonitor for which the callback is being called.

theService
CFNetService for which the callback is being called.

typeInfo
Type of record that changed. For possible values, see CFNetServiceMonitorType Constants (page 110).

rdata
Contents of the record that changed.

error
Pointer to `CFStreamError` structure whose `error` field contains an error code if an error occurred.

info
Arbitrary pointer to the user-defined data that was specified in the `info` field of the `CFNetServiceClientContext` structure when the monitor was created by `CFNetServiceMonitorCreate` (page 92).

Discussion
The callback function will be called when the monitored record type changes or when the monitor is stopped by calling `CFNetServiceMonitorStop` (page 96).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

Data Types

CFNetServiceBrowserRef

An opaque reference representing a CFNetServiceBrowser.

```
typedef struct __CFNetServiceBrowser* CFNetServiceBrowserRef;
```

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceClientContext

A structure provided when a CFNetService is associated with a callback function or when a CFNetServiceBrowser is created.

```
struct CFNetServiceClientContext {
    CFIndex version;
    void *info;
    CFAllocatorRetainCallBack retain;
    CFAllocatorReleaseCallBack release;
    CFAllocatorCopyDescriptionCallBack copyDescription;
};
typedef struct CFNetServiceClientContext CFNetServiceClientContext;
```

Fields

`version`

Version number for this structure. Currently the only valid value is zero.

`info`

Arbitrary pointer to user-allocated memory containing user-defined data that is associated with the service, browser, or monitor and is passed to their respective callback functions. The data must be valid for as long as the CFNetService, CFNetServiceBrowser, or CFNetServiceMonitor is valid. Set this field to `NULL` if your callback function doesn't want to receive user-defined data.

`retain`

The callback used to add a retain for the service or browser using `info` for the life of the service or browser. This callback may be used for temporary references the service or browser needs to take. This callback returns the actual `info` pointer so it can be stored in the service or browser. This field can be `NULL`.

`release`

Callback that removes a retain previously added for the service or browser on the `info` pointer. This field can be `NULL`, but setting this field to `NULL` may result in memory leaks.

`copyDescription`

Callback used to create a descriptive string representation of the data pointed to by `info`. In implementing this function, return a reference to a CFString object that describes your allocator and some characteristics of your user-defined data, which is used by `CFCopyDescription()`. You can set this field to `NULL`, in which case Core Foundation will provide a rudimentary description.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

CFNetServiceMonitorRef

An opaque reference for a service monitor.

```
typedef struct __CFNetServiceMonitor* CFNetServiceMonitorRef;
```

Discussion
Service monitor references are used to monitor record changes on a CFNetServiceRef.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CFNetServices.h`

CFNetServiceRef

An opaque reference representing a CFNetService.

```
typedef struct __CFNetService* CFNetServiceRef;
```

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetServices.h`

Constants

CFNetService Registration Options

Bit flags used when registering a service.

```
enum {
    kCFNetServiceFlagNoAutoRename = 1
};
```

Constants
`kCFNetServiceFlagNoAutoRename`
Causes registrations to fail if a name conflict occurs.
Available in Mac OS X v10.4 and later.
Declared in `CFNetServices.h`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetwork/CFNetServices.h`

CFNetServiceBrowserClientCallBack Bit Flags

Bit flags providing additional information about the result returned when a client's `CFNetServiceBrowserClientCallBack` function is called.

```
enum {
kCFNetServiceFlagMoreComing = 1,
kCFNetServiceFlagIsDomain = 2,
kCFNetServiceFlagIsDefault = 4,
kCFNetServiceFlagIsRegistrationDomain = 4, /* For compatibility  */
kCFNetServiceFlagRemove = 8
};
```

Constants

`kCFNetServiceFlagMoreComing`

If set, a hint that the client's callback function will be called again soon; therefore, the client should not do anything time-consuming, such as updating the screen.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServiceFlagIsDomain`

If set, the results pertain to a search for domains. If not set, the results pertain to a search for services.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServiceFlagIsDefault`

If set, the resulting domain is the default registration or browse domain, depending on the context. For this version of the CFNetServices API, the default registration domain is the local domain. In previous versions of this API, this constant was `kCFNetServiceFlagIsRegistrationDomain`, which is retained for backward compatibility.

Available in Mac OS X v10.4 and later.

Declared in `CFNetServices.h`.

`kCFNetServiceFlagRemove`

If set, the client should remove the result item instead of adding it.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

Discussion

See `CFNetServiceBrowserClientCallBack` for additional information.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetwork/CFNetServices.h`

CFNetServiceMonitorType Constants

Record type specifier used to tell a service monitor the type of record changes to watch for.

```
enum {
kCFNetServiceMonitorTXT = 1
} typedef enum CFNetServiceMonitorType CFNetServiceMonitorType;
```

Constants

`kCFNetServiceMonitorTXT`

Watch for TXT record changes.

Available in Mac OS X v10.4 and later.

Declared in `CFNetServices.h`.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CFNetwork/CFNetServices.h`

CFNetService Error Constants

Error codes that may be returned by CFNetServices functions or passed to CFNetServices callback functions.

```
typedef enum {
    kCFNetServicesErrorUnknown = -72000,
    kCFNetServicesErrorCollision = -72001,
    kCFNetServicesErrorNotFound = -72002,
    kCFNetServicesErrorInProgress = -72003,
    kCFNetServicesErrorBadArgument = -72004,
    kCFNetServicesErrorCancel = -72005,
    kCFNetServicesErrorInvalid = -72006,
    kCFNetServicesErrorTimeout = -72007
} CFNetServicesError;
```

Constants

`kCFNetServicesErrorUnknown`

An unknown CFNetService error occurred.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorCollision`

An attempt was made to use a name that is already in use.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorNotFound`

Not used.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorInProgress`

A search is already in progress.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorBadArgument`
A required argument was not provided.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorCancel`
The search or service was canceled.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorInvalid`
Invalid data was passed to a CFNetServices function.

Available in Mac OS X v10.2 and later.

Declared in `CFNetServices.h`.

`kCFNetServicesErrorTimeout`
Resolution failed because the timeout was reached.

Available in Mac OS X v10.4 and later.

Declared in `CFNetServices.h`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CFNetwork/CFNetServices.h`

Error Domains

Error domains.

```
extern const SInt32 kCFStreamErrorDomainMach;
extern const SInt32 kCFStreamErrorDomainNetServices;
```

Constants
`kCFStreamErrorDomainMach`
Error domain returning errors reported by Mach. For more information, see the header file `/usr/include/mach/error.h`.

Available in Mac OS X version 10.5 and later.

Declared in `CFNetServices.h`.

`kCFStreamErrorDomainNetServices`
Error domain returning errors reported by the service discovery APIs. These errors are only returned if you use the `CFNetServiceBrowser` API or any APIs introduced in Mac OS X v10.4 or later.

Available in Mac OS X version 10.5 and later.

Declared in `CFNetServices.h`.

CFStream Socket Additions

Derived From:	CFType
Framework:	CoreServices
Declared in	CFNetwork/CFSocketStream.h
Companion guide	CFNetwork Programming Guide

Overview

This document describes the `CFStream` functions for working with sockets. It is part of the CFSocketStream API.

Functions by Task

Creating Socket Pairs

`CFStreamCreatePairWithSocketToCFHost` (page 116)
Creates readable and writable streams connected to a given `CFHost` object.

`CFStreamCreatePairWithSocketToNetService` (page 116)
Creates a pair of streams for a CFNetService.

Setting the Security Protocol

`CFSocketStreamPairSetSecurityProtocol` (page 114)
This function sets the security protocol for the specified pair of socket streams. (Deprecated. Use `CFReadStreamSetProperty` and `CFWriteStreamSetProperty` in conjunction with the security constants defined in `CFSocketStream`.)

Obtaining Errors

`CFSocketStreamSOCKSGetError` (page 114)
This function gets error codes in the `kCFStreamErrorDomainSOCKS` domain from the `CFStreamError` returned by a stream operation.

`CFSocketStreamSOCKSGetErrorSubdomain` (page 115)
Gets the error subdomain associated with errors in the `kCFStreamErrorDomainSOCKS` domain from the `CFStreamError` returned by a stream operation.

Functions

CFSocketStreamPairSetSecurityProtocol

This function sets the security protocol for the specified pair of socket streams. (Deprecated in Mac OS X v10.2. Use `CFReadStreamSetProperty` and `CFWriteStreamSetProperty` in conjunction with the security constants defined in `CFSocketStream`.)

```
Boolean CFSocketStreamPairSetSecurityProtocol (
    CFReadStreamRef socketReadStream,
    CFWriteStreamRef socketWriteStream,
    CFStreamSocketSecurityProtocol securityProtocol
);
```

Parameters

socketReadStream
The read stream.

socketWriteStream
The write stream.

securityProtocol
The security protocol to be set. See CFStream Socket Security Protocol Constants (page 121) for possible values.

function result
`TRUE` if specified security protocol was set; otherwise, `FALSE`.

Discussion

Call this function before you call `CFReadStreamOpen` to open the read stream or `CFWriteStreamOpen` to open the write stream.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.2.

Declared In

`CFSocketStream.h`

CFSocketStreamSOCKSGetError

This function gets error codes in the `kCFStreamErrorDomainSOCKS` domain from the `CFStreamError` returned by a stream operation.

```
SInt32 CFSocketStreamSOCKSGetError(CFStreamError* error);
```

Parameters

error

The error value to decode.

Discussion

Error codes in the `kCFStreamErrorDomainSOCKS` domain can come from multiple parts of the protocol stack, many of which define their own error values as part of outside specifications such as the HTTP specification.

To avoid confusion from conflicting error numbers, error codes in the `kCFStreamErrorDomainSOCKS` domain contain two parts: a subdomain, which tells which part of the protocol stack generated the error, and the error code itself.

Calling `CFSocketStreamSOCKSGetError` (page 114) returns the error code itself, which must be interpreted in the context of the result of a call to `CFSocketStreamSOCKSGetErrorSubdomain` (page 115). Possible return values (beyond subdomain-specific values such as client versions and HTTP error codes) are listed in "CFStream Errors" (page 126).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CFSocketStream.h`

CFSocketStreamSOCKSGetErrorSubdomain

Gets the error subdomain associated with errors in the `kCFStreamErrorDomainSOCKS` domain from the `CFStreamError` returned by a stream operation.

```
SInt32 CFSocketStreamSOCKSGetErrorSubdomain(CFStreamError* error);
```

Parameters

error

The error value to decode.

Discussion

Error codes in the `kCFStreamErrorDomainSOCKS` domain can come from multiple parts of the protocol stack, many of which define their own error values as part of outside specifications such as the HTTP specification.

To avoid confusion from conflicting error numbers, error codes in the `kCFStreamErrorDomainSOCKS` domain contain two parts: a subdomain, which tells which part of the protocol stack generated the error, and the error code itself.

Calling `CFSocketStreamSOCKSGetErrorSubdomain` (page 115) returns an identifier that tells which layer of the protocol stack produced the error. The possible values are listed in "Error Subdomains" (page 125). With this information, you can interpret the error codes returned by `CFSocketStreamSOCKSGetError` (page 114).

Availability

Available in Mac OS X v10.2 and later.

Declared In
CFSocketStream.h

CFStreamCreatePairWithSocketToCFHost

Creates readable and writable streams connected to a given CFHost object.

```
void CFStreamCreatePairWithSocketToCFHost (
   CFAllocatorRef alloc,
   CFHostRef host,
   SInt32 port,
   CFReadStreamRef *readStream,
   CFWriteStreamRef *writeStream
);
```

Parameters

alloc

The allocator to use to allocate memory for the CFReadStream and CFWriteStream objects. Pass NULL or kCFAllocatorDefault to use the current default allocator.

host

A CFHost object to which the streams are connected. If unresolved, the host will be resolved prior to connecting.

port

The TCP port number to which the socket streams should connect.

readStream

Upon return, contains a CFReadStream object connected to the host *host* on port port, or NULL if there is a failure during creation. If you pass NULL, the function will not create a readable stream. Ownership follows the Create Rule.

writeStream

Upon return, contains a CFWriteStream object connected to the host *host* on port port, or NULL if there is a failure during creation. If you pass NULL, the function will not create a writable stream. Ownership follows the Create Rule.

Discussion
The streams do not open a connection to the specified host until one of the streams is opened.

Most properties are shared by both streams. Setting the property for one stream automatically sets the property for the other.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CFSocketStream.h

CFStreamCreatePairWithSocketToNetService

Creates a pair of streams for a CFNetService.

```
void CFStreamCreatePairWithSocketToNetService (
   CFAllocatorRef alloc,
   CFNetServiceRef service,
   CFReadStreamRef *readStream,
   CFWriteStreamRef *writeStream
);
```

Parameters

alloc

The allocator to use to allocate memory for the `CFReadStream` and `CFWriteStream` objects. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

service

Reference to the `CFNetService` to which the streams are to be connected. If the service is not resolved, the service will be resolved before the streams are connected.

readstream

Upon return, contains a `CFReadStream` object connected to the service specified by *service*, or `NULL` if there is a failure during creation. If you pass `NULL`, the function will not create a readable stream. Ownership follows the Create Rule.

writeStream

Upon return, contains a `CFWriteStream` object connected to the service specified by *service*, or `NULL` if there is a failure during creation. If you pass `NULL`, the function will not create a writable stream. Ownership follows the Create Rule.

Discussion

Read and write operations on sockets can block. To prevent blocking, you can call `CFReadStreamSetClient` and `CFWriteStreamSetClient` to register to receive stream-related event notifications. Then call `CFReadStreamScheduleWithRunLoop` and `CFWriteStreamScheduleWithRunLoop` to schedule the stream on a run loop for receiving stream-related event notifications. Then call `CFReadStreamOpen` and `CFWriteStreamOpen` to open each stream.

Special Considerations

This function is thread safe.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CFSocketStream.h`

Constants

CFStream Property Keys

Constants for `CFStream` property keys

```
const CFStringRef kCFStreamPropertyShouldCloseNativeSocket;
const CFStringRef kCFStreamPropertySocketSecurityLevel;
const CFStringRef kCFStreamPropertySOCKSProxy;
const CFStringRef kCFStreamPropertySSLPeerCertificates;
const CFStringRef kCFStreamPropertySSLSettings;
const CFStringRef kCFStreamPropertyProxyLocalByPass;
extern const CFStringRef kCFStreamPropertySocketRemoteHost;
extern const CFStringRef kCFStreamPropertySocketRemoteNetService;
```

Constants

`kCFStreamPropertyShouldCloseNativeSocket`

Should Close Native Socket property key.

If set to `kCFBooleanTrue`, the stream will close and release the underlying native socket when the stream is released. If set to `kCFBooleanFalse`, the stream will not close and release the underlying native socket when the stream is released. If a stream is created with a native socket, the default value of this property is `kCFBooleanFalse`. This property is only available for socket streams. It can be set by calling `CFReadStreamSetProperty` and `CFWriteStreamSetProperty`, and it can be copied by `CFReadStreamCopyProperty` and `CFWriteStreamCopyProperty`.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySocketNativeHandle`

Socket Native Handle property key.

Causes `CFReadStreamCopyProperty` or `CFWriteStreamCopyProperty` to return `CFData` object that contains the native handle for a socket stream. This property is only available for socket streams.

Available in Mac OS X v10.1 and later.

Declared in `CFStream.h`.

`kCFStreamPropertySocketSecurityLevel`

Socket Security Level property key.

See CFStream Socket Security Level Constants (page 122) for specific security level constants to use.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySSLPeerCertificates`

SSL Peer Certificates property key for copy operations, which return a `CFArray` object containing `SecCertificateRef` objects.

For more information, see `SSLGetPeerCertificates` in `Security/SecureTransport.h`.

Available in Mac OS X v10.4 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySOCKSProxy`

SOCKS proxy property key.

To set a `CFStream` object to use a SOCKS proxy, call `CFReadStreamSetProperty` or `CFWriteStreamSetProperty` with the property name set to `kCFStreamPropertySOCKSProxy` and its value set to a `CFDictionary` object having at minimum a `kCFStreamPropertySOCKSProxyHost` key and a `kCFStreamPropertySOCKSProxyPort` key. For information on these keys, see CFStream SOCKS Proxy Key Constants (page 123). SystemConfiguration returns a CFDictionary for SOCKS proxies that is usable without modification.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySSLSettings`
SSL Settings property key for set operations.

The key's value is a `CFDictionary` object containing security settings. For information on the dictionary's keys and values, see CFStream Property SSL Settings Constants (page 119). By default, there are no security settings.

Available in Mac OS X v10.4 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertyProxyLocalBypass`
Proxy Local Bypass property key.

The key's value is `CFBoolean` object whose value indicates whether local hostnames should be subject to proxy handling.

Available in Mac OS X v10.4 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySocketRemoteHost`
The key's value is a `CFHostRef` for the remote host if it is known. If not, its value is `NULL`.

Available in Mac OS X version 10.3 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySocketRemoteNetService`
The key's value is a `CFNetServiceRef` for the remote network service if it is known. If not, its value is `NULL`.

Available in Mac OS X version 10.3 and later.

Declared in `CFSocketStream.h`.

Declared In
`CFNetwork/CFSocketStream.h`

CFStream Property SSL Settings Constants

Constants for use in a `CFDictionary` object that is the value of the `kCFStreamPropertySSLSettings` stream property key.

```
const CFStringRef kCFStreamSSLLevel;
const CFStringRef kCFStreamSSLAllowsExpiredCertificates;
const CFStringRef kCFStreamSSLAllowsExpiredRoots;
const CFStringRef kCFStreamSSLAllowsAnyRoot;
const CFStringRef kCFStreamSSLValidatesCertificateChain;
const CFStringRef kCFStreamSSLPeerName;
const CFStringRef kCFStreamSSLCertificates;
const CFStringRef kCFStreamSSLIsServer;
```

Constants
`kCFStreamSSLLevel`
Security property key whose value specifies the stream's security level.

By default, a stream's security level is `kCFStreamSocketSecurityLevelNegotiatedSSL`. For other possible values, see CFStream Socket Security Level Constants (page 122).

Available in Mac OS X v10.4 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSSLAllowsExpiredCertificates`
: Security property key whose value indicates whether expired certificates are allowed.

  By default, the value of this key is `kCFBooleanFalse` (expired certificates are not allowed).

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLAllowsExpiredRoots`
: Security property key whose value indicates whether expired root certificates are allowed.

  By default, the value of this key is `kCFBooleanFalse` (expired root certificates are not allowed).

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLAllowsAnyRoot`
: Security property key whose value indicates whether root certificates should be allowed.

  By default, the value of this key is `kCFBooleanFalse` (root certificates are not allowed).

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLValidatesCertificateChain`
: Security property key whose value indicates whether the certificate chain should be validated.

  By default, the value of this key is `kCFBooleanTrue` (the certificate chain should be validated).

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLPeerName`
: Security property key whose value overrides the name used for certificate verification.

  By default, the host name that was used when the stream was created is used; if no host name was used, no peer name will be used. Set the value of this key to `kCFNull` to prevent name verification.

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLCertificates`
: Security property key whose value is a CFArray of SecCertificateRefs except for the first element in the array, which is a SecIdentityRef.

  For more information, see `SSLSetCertificate()` in `Security/SecureTransport.h`.

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamSSLIsServer`
: Security property key whose value indicates whether the connection is to act as a server in the SSL process.

  By default, the value of this key is `kCFBooleanFalse` (the connection is not to act as a server). If the value of this key is `kCFBooleanTrue`, the `kCFStreamSSLCertificates` key must contain a valid value.

  Available in Mac OS X v10.4 and later.

  Declared in `CFSocketStream.h`.

Discussion
This enumeration defines the constants for keys in a `CFDictionary` object that is the value of the `kCFStreamPropertySSLSettings` key.

Declared In
`CFNetwork/CFSocketStream.h`

CFStream Socket Security Protocol Constants

Specifies constants for setting the security protocol for a socket stream.

```
typedef enum {
    kCFStreamSocketSecurityNone = 0,
    kCFStreamSocketSecuritySSLv2,
    kCFStreamSocketSecuritySSLv3,
    kCFStreamSocketSecuritySSLv23,
    kCFStreamSocketSecurityTLSv1
} CFStreamSocketSecurityProtocol;
```

Constants

`kCFStreamSocketSecurityNone`

Specifies that no security protocol be set for a socket stream. (**Deprecated.** Use `kCFStreamSocketSecurityLevelNone`.)

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.2.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecuritySSLv2`

Specifies that SSL version 2 be set as the security protocol for a socket stream. (**Deprecated.** Use `kCFStreamSocketSecurityLevelSSLv2`.)

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.2.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecuritySSLv3`

Specifies that SSL version 3 be set as the security protocol for a socket stream. (**Deprecated.** Use `kCFStreamSocketSecurityLevelSSLv3`.)

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.2.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecuritySSLv23`

Specifies that SSL version 3 be set as the security protocol for a socket stream pair. If that version is not available, specifies that SSL version 2 be set as the security protocol for a socket stream. (**Deprecated.** Use `kCFStreamSocketSecurityLevelNegotiatedSSL`.)

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.2.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecurityTLSv1`

Specifies that TLS version 1 be set as the security protocol for a socket stream. (**Deprecated.** Use `kCFStreamSocketSecurityLevelTLSv1`.)

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.2.

Declared in `CFSocketStream.h`.

Discussion
This enumeration defines constants for setting the security protocol for a socket stream pair when calling `CFSocketStreamPairSetSecurityProtocol` (page 114).

Special Considerations

This enumeration is deprecated in favor of the constants described in CFStream Socket Security Level Constants (page 122).

Declared In
`CFNetwork/CFSocketStream.h`

CFStream Socket Security Level Constants

Constants for setting the security level of a socket stream.

```
const CFStringRef kCFStreamSocketSecurityLevelNone;
const CFStringRef kCFStreamSocketSecurityLevelSSLv2;
const CFStringRef kCFStreamSocketSecurityLevelSSLv3;
const CFStringRef kCFStreamSocketSecurityLevelTLSv1;
const CFStringRef kCFStreamSocketSecurityLevelNegotiatedSSL;
```

Constants

`kCFStreamSocketSecurityLevelNone`

Specifies that no security level be set.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecurityLevelSSLv2`

Specifies that SSL version 2 be set as the security protocol for a socket stream.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecurityLevelSSLv3`

Specifies that SSL version 3 be set as the security protocol for a socket stream pair.

If SSL version 3 is not available, specifies that SSL version 2 be set as the security protocol for a socket stream.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecurityLevelTLSv1`

Specifies that TLS version 1 be set as the security protocol for a socket stream.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSecurityLevelNegotiatedSSL`
Specifies that the highest level security protocol that can be negotiated be set as the security protocol for a socket stream.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

Discussion
This enumeration defines the preferred constants for setting the security protocol for a socket stream pair when calling `CFReadStreamSetProperty` or `CFWriteStreamSetProperty`.

Declared In
`CFNetwork/CFSocketStream.h`

CFStream SOCKS Proxy Key Constants

Constants for SOCKS Proxy `CFDictionary` keys.

```
const CFStringRef kCFStreamPropertySOCKSProxyHost;
const CFStringRef kCFStreamPropertySOCKSProxyPort;
const CFStringRef kCFStreamPropertySOCKSVersion;
const CFStringRef kCFStreamSocketSOCKSVersion4;
const CFStringRef kCFStreamSocketSOCKSVersion5;
const CFStringRef kCFStreamPropertySOCKSUser;
const CFStringRef kCFStreamPropertySOCKSPassword;
```

Constants
`kCFStreamPropertySOCKSProxyHost`
Constant for the SOCKS proxy host key.

This key contains a CFString object that represents the SOCKS proxy host. Defined to match `kSCPropNetProxiesSOCKSProxy`.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySOCKSProxyPort`
Constant for the SOCKS proxy host port key.

This key contains a `CFNumberRef` object of type `kCFNumberSInt32Type` whose value represents the port on which the proxy listens.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamPropertySOCKSVersion`
Constant for the SOCKS version key.

Its value must be `kCFStreamSocketSOCKSVersion4` or `kCFStreamSocketSOCKSVersion5` to set SOCKS4 or SOCKS5, respectively. If this key is not present, SOCKS5 is used by default.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSOCKSVersion4`
Constant used in the `kCFStreamSockerSOCKSVersion` key to specify SOCKS4 as the SOCKS version for the stream.

Available in Mac OS X v10.2 and later.

Declared in `CFSocketStream.h`.

`kCFStreamSocketSOCKSVersion5`
: Constant used in the `kCFStreamSOCKSVersion` key to specify SOCKS5 as the SOCKS version for the stream.

  Available in Mac OS X v10.2 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamPropertySOCKSUser`
: Constant for the key required to set a user name.

  The value is a `CFString` object containing the user's name.

  Available in Mac OS X v10.2 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamPropertySOCKSPassword`
: Constant for the key required to set a user's password.

  The value is a `CFString` object containing the user's password.

  Available in Mac OS X v10.2 and later.

  Declared in `CFSocketStream.h`.

Discussion
When setting the stream's SOCKS Proxy property, the property's value is a `CFDictionary` object containing at minimum the `kCFStreamPropertySOCKSProxyHost` and `kCFStreamPropertySOCKSProxyPort` keys. The dictionary may also contain the other keys described in this section.

Error Domains

Error domains specific to `CFSocketStream` calls.

```
extern const int kCFStreamErrorDomainSOCKS;
extern const int kCFStreamErrorDomainSSL;
extern const CFIndex kCFStreamErrorDomainWinSock;
```

Constants
`kCFStreamErrorDomainSOCKS`
: This domain returns error codes from the SOCKS layer. The errors are described in

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamErrorDomainSSL`
: This domain returns error codes associated with the SSL layer. For a list of error codes, see the header `SecureTransport.h` in `Security.framework`.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamErrorDomainWinSock`
: When running CFNetwork code on Windows, this domain returns error codes associated with the underlying TCP/IP stack. You should also note that non-networking errors such as `ENOMEM` are delivered through the POSIX domain. See the header `winsock2.h` for relevant error codes.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

Discussion
To determine the source of an error, examine the `userInfo` dictionary included in the `CFError` object returned by a function call or call `CFErrorGetDomain` and pass in the `CFError` object and the domain whose value you want to read.

Error Subdomains

Subdomains used to determine how to interpret an error in the `kCFStreamErrorDomainSOCKS` domain.

```
enum {
    kCFStreamErrorSOCKSSubDomainNone = 0,
    kCFStreamErrorSOCKSSubDomainVersionCode = 1,
    kCFStreamErrorSOCKS4SubDomainResponse = 2,
    kCFStreamErrorSOCKS5SubDomainUserPass = 3,
    kCFStreamErrorSOCKS5SubDomainMethod = 4,
    kCFStreamErrorSOCKS5SubDomainResponse = 5
};
```

Constants

`kCFStreamErrorSOCKSSubDomainNone`
The error code returned is a SOCKS error number.
Available in Mac OS X version 10.5 and later.

`kCFStreamErrorSOCKSSubDomainVersionCode`
The error returned contains the version of SOCKS that the server wishes to use.
Available in Mac OS X version 10.5 and later.

`kCFStreamErrorSOCKS4SubDomainResponse`
The error returned is the status code that the server returned after the last operation.
Available in Mac OS X version 10.5 and later.

`kCFStreamErrorSOCKS5SubDomainUserPass`
This subdomain returns error codes associated with the last authentication attempt.
Available in Mac OS X version 10.5 and later.

`kCFStreamErrorSOCKS5SubDomainMethod`
This subdomain returns the server's desired negotiation method.
Available in Mac OS X version 10.5 and later.

`kCFStreamErrorSOCKS5SubDomainResponse`
This subdomain returns the response code sent by the server when replying to a connection request.
Available in Mac OS X version 10.5 and later.

Discussion
Error codes in the `kCFStreamErrorDomainSOCKS` domain can come from multiple parts of the protocol stack, many of which define their own error values as part of outside specifications such as the HTTP specification.

To avoid confusion from conflicting error numbers, error codes in the `kCFStreamErrorDomainSOCKS` domain contain two parts: a subdomain, which tells which part of the protocol stack generated the error, and the error code itself.

Calling `CFSocketStreamSOCKSGetErrorSubdomain` (page 115) returns an identifier that tells which layer of the protocol stack produced the error. This list of constants contains the possible values that this function will return.

Calling `CFSocketStreamSOCKSGetError` (page 114) returns the actual error code that the subdomain describes.

CFStream Errors

Error codes returned by the `kCFStreamErrorDomainSOCKS` error domain.

```
/* kCFStreamErrorSOCKSSubDomainNone*/
enum {
  kCFStreamErrorSOCKS5BadResponseAddr = 1,
  kCFStreamErrorSOCKS5BadState  = 2,
  kCFStreamErrorSOCKSUnknownClientVersion = 3
};

/* kCFStreamErrorSOCKS4SubDomainResponse*/
enum {
  kCFStreamErrorSOCKS4RequestFailed = 91,
  kCFStreamErrorSOCKS4IdentdFailed = 92,
  kCFStreamErrorSOCKS4IdConflict = 93
};

/* kCFStreamErrorSOCKS5SubDomainMethod*/
enum {
  kSOCKS5NoAcceptableMethod     = 0xFF
};
```

Constants

`kCFStreamErrorSOCKS5BadResponseAddr`

The address returned is not of a known type. This error code is only valid for errors in the `kCFStreamErrorSOCKSSubDomainNone` subdomain.

Available in Mac OS X version 10.5 and later.

Declared in `CFSocketStream.h`.

`kCFStreamErrorSOCKS5BadState`

The stream is not in a state that allows the requested operation. This error code is only valid for errors in the `kCFStreamErrorSOCKSSubDomainNone` subdomain..

Available in Mac OS X version 10.5 and later.

Declared in `CFSocketStream.h`.

`kCFStreamErrorSOCKSUnknownClientVersion`

The SOCKS server rejected access because it does not support connections with the requested SOCKS version. SOCKS client version. You can query the `kCFSOCKSVersionKey` key to find out what version the server requested. This error code is only valid for errors in the `kCFStreamErrorSOCKSSubDomainNone` subdomain.

Available in Mac OS X version 10.5 and later.

Declared in `CFSocketStream.h`.

`kCFStreamErrorSOCKS4RequestFailed`
: Request rejected by the server or request failed. This error is specific to SOCKS4. This error code is only valid for errors in the `kCFStreamErrorSOCKS4SubDomainResponse` subdomain.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamErrorSOCKS4IdentdFailed`
: Request rejected by the server because it could not connect to the `identd` daemon on the client. This error is specific to SOCKS4. This error code is only valid for errors in the `kCFStreamErrorSOCKS4SubDomainResponse` subdomain.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

`kCFStreamErrorSOCKS4IdConflict`
: Request rejected by the server because the client program and the `identd` daemon reported different user IDs. This error is specific to SOCKS4. This error code is only valid for errors in the `kCFStreamErrorSOCKS4SubDomainResponse` subdomain.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

`kSOCKS5NoAcceptableMethod`
: The client and server could not find a mutually agreeable authentication method. This error code is only valid for errors in the `kCFStreamErrorSOCKS5SubDomainMethod` subdomain.

  Available in Mac OS X version 10.5 and later.

  Declared in `CFSocketStream.h`.

Discussion

Error codes in the `kCFStreamErrorDomainSOCKS` domain can come from multiple parts of the protocol stack, many of which define their own error values as part of outside specifications such as the HTTP specification.

To avoid confusion from conflicting error numbers, error codes in the `kCFStreamErrorDomainSOCKS` domain contain two parts: a subdomain, which tells which part of the protocol stack generated the error, and the error code itself.

Calling `CFSocketStreamSOCKSGetErrorSubdomain` (page 115) returns an identifier that tells which layer of the protocol stack produced the error.

Calling `CFSocketStreamSOCKSGetError` (page 114) returns the actual error code that the subdomain describes. This list of constants contains the possible values that this function will return. They must be interpreted within the context of the relevant error subdomain.

MDItem Reference

Derived From:	CFType
Framework:	CoreServices/CoreServices.h
Declared in	MDItem.h
Companion guides	Spotlight Overview Spotlight Query Programming Guide Spotlight Importer Programming Guide Spotlight Metadata Attributes Reference

Overview

MDItem is a CF-compliant object that represents a file and the metadata associated with the file.

For functions that expect an MDItemRef parameter, if this parameter is not a valid MDItemRef, the behavior is undefined. `NULL` is not a valid MDItemRef.

Functions by Task

Creating an MDItem

`MDItemCreate` (page 132)
Creates an MDItem object for a file at the specified path.

Getting the Type Identifier

`MDItemGetTypeID` (page 132)
Returns the type identifier of all MDItem instances.

Retrieving Metadata Attributes

`MDItemCopyAttribute` (page 130)
Returns the value of the specified attribute in the metadata item.

`MDItemCopyAttributes` (page 131)
Returns the values of the specified attributes in the metadata item.

`MDItemCopyAttributeList` (page 130)
Returns the values of the specified attributes in the metadata item.

`MDItemCopyAttributeNames` (page 131)
Returns an array containing the attribute names existing in the metadata item.

Functions

MDItemCopyAttribute

Returns the value of the specified attribute in the metadata item.

```
CFTypeRef MDItemCopyAttribute (
   MDItemRef item,
   CFStringRef name
);
```

Parameters

item
The item to be queried.

name
The name of the requested attribute.

Return Value

A CFTypeRef, or `NULL` if there was a failure reading the attribute or the attribute does not exist.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`MDItem.h`

MDItemCopyAttributeList

Returns the values of the specified attributes in the metadata item.

```
CFDictionaryRef MDItemCopyAttributeList (
   MDItemRef item,
   ...
);
```

Parameters

item
The item to be queried.

...
A comma-separated varargs list of the string attribute names..

Return Value

A CFDictionary containing keys for the requested attribute names, and the corresponding values. If an attribute does not exist, or the attribute is unreadable, there will be no key-value pair for it in the dictionary. Returns `NULL` on failure.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

MDItemCopyAttributeNames

Returns an array containing the attribute names existing in the metadata item.

```
CFArrayRef MDItemCopyAttributeNames (
   MDItemRef item
);
```

Parameters

item

The item to be queried.

Return Value
A CFArray of CFString attribute names, or `NULL` on failure.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

MDItemCopyAttributes

Returns the values of the specified attributes in the metadata item.

```
CFDictionaryRef MDItemCopyAttributes (
   MDItemRef item,
   CFArrayRef names
);
```

Parameters

item

The item to be queried.

names

A CFArray containing the names of the requested attributes.

Return Value
A CFDictionary containing keys for the requested attribute names, and the corresponding values. If an attribute does not exist, or the attribute is unreadable, there will be no key-value pair for it in the dictionary. Returns `NULL` on failure.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

MDItemCreate

Creates an MDItem object for a file at the specified path.

```
MDItemRef MDItemCreate (
   CFAllocatorRef allocator,
   CFStringRef path
);
```

Parameters

allocator

The `CFAllocator` object to be used to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

path

A path to the file from which to create the `MDItem`. The path must exist.

Return Value
An `MDItem` object or `NULL` if there was a problem creating the object.

Discussion
Returns a metadata item for the given path. MDItemRefs are uniqued and can be compared using == or `CFEqual`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

MDItemGetTypeID

Returns the type identifier of all MDItem instances.

```
CFTypeID MDItemGetTypeID (
   void
);
```

Return Value
The type identifier for the `MDItem` opaque type.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

Data Types

MDItemRef

A reference to a MDItem object.

```
typedef struct __MDItem *MDItemRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDItem.h`

Constants

Common Metadata Attribute Keys

Metadata attribute keys that are common to many file types.

```

const CFStringRef kMDItemStarRating;
const CFStringRef kMDItemStateOrProvince;
const CFStringRef kMDItemTextContent;
const CFStringRef kMDItemTitle;
const CFStringRef kMDItemVersion;
const CFStringRef kMDItemWhereFroms;
```

Constants

`kMDItemAttributeChangeDate`

The date and time of the last change made to a metadata attribute. A CFDate.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAudiences`

The audience for which the file is intended. The audience may be determined by the creator or the publisher or by a third party. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAuthors`
: The author, or authors, of the contents of the file. The order of the authors is preserved, but does not represent the main author or relative importance of the authors. A CFArray of CFStrings.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemCity`
: Identifies city of origin according to guidelines established by the provider. For example, "New York", "Cupertino", or "Toronto". A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemComment`
: A comment related to the file. This differs from the Finder comment, `kMDItemFinderComment`. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemContactKeywords`
: A list of contacts that are associated with this document, not including the authors. A CFArray of CFStrings.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemContentCreationDate`
: The date that the contents of the file were created. This is different than the file creation date. Its can be used to store when the file contents were first created, or first modified. A CFDate.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemContentModificationDate`
: The date and time that the contents of the file were last modified. This is not necessarily the file modification date. A CFDate.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemContentType`
: The UTI pedigree of a file. For example, a jpeg image file will have a value of public.jpeg/public.image/public.data. The value of this attribute is set by the MDImporter. Changes to this value are lost when the file attributes are next imported. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemContributors`
: The entities responsible for making contributions to the content of the resource. Examples of a contributor include a person, an organization or a service. A CFArray of CFStrings.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemCopyright`
The copyright owner of the file contents. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemCountry`
The full, publishable name of the country or primary location where the intellectual property of the item was created, according to guidelines of the provider. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemCoverage`
The extent or scope of the content of the resource. Coverage will typically include spatial location (a place name or geographic co-ordinates), temporal period (a period label, date, or date range) or jurisdiction (such as a named administrative entity). Recommended best practice is to select a value from a controlled vocabulary, and that, where appropriate, named places or time periods be used in preference to numeric identifiers such as sets of co-ordinates or date ranges. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemCreator`
Application used to create the document content (e.g. "Word", "AppleWorks", etc.). A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemDescription`
A description of the content of the resource. The description may include an abstract, table of contents, reference to a graphical representation of content or a free-text account of the content. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemDueDate`
Date this item is due. A CFDate.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemDurationSeconds`
The duration, in seconds, of the content of file. A value of 10.5 represents media that is 10 and 1/2 seconds long. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemEmailAddresses`
Email addresses related to this item. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemEncodingApplications`
Application used to convert the original content into it's current form. For example, a PDF file might have an encoding application set to "Distiller". A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFinderComment`
Finder comments for this file. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFonts`
Fonts used in this item. You should store the font's full name, the postscript name, or the font family name, based on the available information. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemHeadline`
A publishable entry providing a synopsis of the contents of the file. For example, "Apple Introduces the iPod Photo". A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemIdentifier`
A formal identifier used to reference the resource within a given context. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemInstantMessageAddresses`
Instant message addresses related to this item. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemInstructions`
Editorial instructions concerning the use of the item, such as embargoes and warnings. For example, "Second of four stories". A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemKeywords`
Keywords associated with this file. For example, “Birthday”, “Important”, etc. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemKind`
A description of the kind of item this file represents. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemLanguages`
Indicates the languages of the intellectual content of the resource. Recommended best practice for the values of the Language element is defined by RFC 3066. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemLastUsedDate`
: The date and time that the file was last used. This value is updated automatically by LaunchServices everytime a file is opened by double clicking, or by asking LaunchServices to open a file. A CFDate.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemNumberOfPages`
: Number of pages in the document. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemOrganizations`
: The company or organization that created the document. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemPageHeight`
: Height of the document page, in points (72 points per inch). For PDF files this indicates the height of the first page only. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemPageWidth`
: Width of the document page, in points (72 points per inch). For PDF files this indicates the width of the first page only. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemPhoneNumbers`
: Phone numbers related to this item. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemProjects`
: The list of projects that this file is part of. For example, if you were working on a movie all of the files could be marked as belonging to the project “My Movie”. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemPublishers`
: The entity responsible for making the resource available. For example, a person, an organization, or a service. Typically, the name of a publisher should be used to indicate the entity. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemRecipients`
: Recipients of this item. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemRights`
: Provides a link to information about rights held in and over the resource. Contains a rights management statement for the resource, or reference a service providing such information. Rights information often encompasses Intellectual Property Rights (IPR), Copyright, and various Property Rights. If this attribute is absent, no assumptions can be made about the status of these and other rights with respect to the resource. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemSecurityMethod`
: The security or encryption method used for the file. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemStarRating`
: User rating of this item. For example, the stars rating of an iTunes track. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemStateOrProvince`
: Identifies the province or state of origin according to guidelines established by the provider. For example, "CA", "Ontario", or "Sussex". A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemTextContent`
: Contains a text representation of the content of the document. Data in multiple fields should be combined using a whitespace character as a separator. An application's Spotlight importer provides the content of this attribute. Applications can search for values in this attribute, but are not able to read the content of this attribute directly. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemTitle`
: The title of the file. For example, this could be the title of a document, the name of an song, or the subject of an email message. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemVersion`
: The version number of this file. A CFString

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemWhereFroms`
: Describes where the file was obtained from. For example, a downloaded file may refer to the URL, files received by email may indicate the sender's email address, message subject, etc. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

Image Metadata Attribute Keys

Metadata attribute keys that are common to image files.

```
const CFStringRef      kMDItemPixelHeight;
const CFStringRef      kMDItemPixelWidth;
const CFStringRef      kMDItemColorSpace;
const CFStringRef      kMDItemBitsPerSample;
const CFStringRef      kMDItemFlashOnOff;
const CFStringRef      kMDItemFocalLength;
const CFStringRef      kMDItemAcquisitionMake;
const CFStringRef      kMDItemAcquisitionModel;
const CFStringRef      kMDItemISOSpeed;
const CFStringRef      kMDItemOrientation;
const CFStringRef      kMDItemLayerNames;
const CFStringRef      kMDItemWhiteBalance;
const CFStringRef      kMDItemAperture;
const CFStringRef      kMDItemProfileName;
const CFStringRef      kMDItemResolutionWidthDPI;
const CFStringRef      kMDItemResolutionHeightDPI;
const CFStringRef      kMDItemExposureMode;
const CFStringRef      kMDItemExposureTimeSeconds;
const CFStringRef      kMDItemEXIFVersion;
const CFStringRef      kMDItemAlbum;
const CFStringRef      kMDItemHasAlphaChannel;
const CFStringRef      kMDItemRedEyeOnOff;
const CFStringRef      kMDItemMeteringMode;
const CFStringRef      kMDItemMaxAperture;
const CFStringRef      kMDItemFNumber;
const CFStringRef      kMDItemExposureProgram;
const CFStringRef      kMDItemExposureTimeString;
```

Constants

`kMDItemPixelHeight`
The height, in pixels, of the contents. For example, the image height or the video frame height. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemPixelWidth`
The width, in pixels, of the contents. For example, the image width or the video frame width. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemColorSpace`
The color space model used by the document contents. For example, “RGB”, “CMYK”, “YUV”, or “YCbCr”. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemBitsPerSample`
The number of bits per sample. For example, the bit depth of an image (8-bit, 16-bit etc...) or the bit depth per audio sample of uncompressed audio data (8, 16, 24, 32, 64, etc..). A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFlashOnOff`
Indicates if a camera flash was used. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFocalLength`
The actual focal length of the lens, in millimeters. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAcquisitionMake`
The manufacturer of the device used to aquire the document contents. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAcquisitionModel`
The model of the device used to aquire the document contents. For example, 100, 200, 400, etc. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemISOSpeed`
The ISO speed used to aquire the document contents. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemOrientation`
The orientation of the document contents. Possible values are 0 (landscape) and 1 (portrait). A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemLayerNames`
The names of the layers in the file. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemWhiteBalance`
The white balance setting used to aquire the document contents. Possible values are 0 (auto white balance) and 1 (manual). A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAperture`
The aperature setting used to aqure the document contents. This unit is the APEX value. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemProfileName`
The name of the color profile used by the document contents. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemResolutionWidthDPI`
Resolution width, in DPI, of this image. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemResolutionHeightDPI`
Resolution height, in DPI, of this image. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemExposureMode`
The exposure mode used to aquire the document contents. Possible values are 0 (auto exposure), 1 (manual exposure) and 2 (auto bracket). A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemExposureTimeSeconds`
The exposure time, in seconds, used to aquire the document contents. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemEXIFVersion`
The version of the EXIF header used to generate the metadata. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAlbum`
The title for a collection of media. This is analagous to a record album, or photo album. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemHasAlphaChannel`
Indicates if this image file has an alpha channel. A CFBoolean.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemRedEyeOnOff`
Indicates if red-eye reduction was used to take the picture. Possible values are 0 (no red-eye reduction mode or unknown) and 1 (red-eye reduction used). A CFBoolean.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemMeteringMode`
The metering mode used to take the image. Possible values are: Unknown, Average, CenterWeightedAverage, Spot, MultiSpot, Pattern, and Partial. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemMaxAperture`
The smallest f-number of the lens. The unit is the APEX?? value. Ordinarily it is given in the range of 00.00 to 99.99. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFNumber`
The diameter of the diaphragm aperture in terms of the effective focal length of the lens.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemExposureProgram`
The class of the exposure program used by the camera to set exposure when the image is taken. Possible values include: Manual, Normal, and Aperture priority.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemExposureTimeString`
The time of the exposure. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

Video Metadata Attribute Keys

Metadata attribute keys that are common to video files.

```
const CFStringRef kMDItemAudioBitRate;
const CFStringRef kMDItemCodecs;
const CFStringRef kMDItemDeliveryType;
const CFStringRef kMDItemMediaTypes;
const CFStringRef kMDItemStreamable;
const CFStringRef kMDItemTotalBitRate;
const CFStringRef kMDItemVideoBitRate;
```

Constants
`kMDItemAudioBitRate`
The audio bit rate. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemCodecs`
: The codecs used to encode/decode the media. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemDeliveryType`
: The delivery type. Values are “Fast start” or “RTSP”. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemMediaTypes`
: The media types present in the content. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemStreamable`
: Whether the content is prepared for streaming. A CFBoolean.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemTotalBitRate`
: The total bit rate, audio and video combined, of the media. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemVideoBitRate`
: The video bit rate. A CFNumber.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

Audio Metadata Attribute Keys

Metadata attribute keys that describe an audio file.

```
const CFStringRef kMDItemAppleLoopDescriptors;
const CFStringRef kMDItemAppleLoopsKeyFilterType;
const CFStringRef kMDItemAppleLoopsLoopMode;
const CFStringRef kMDItemAppleLoopsRootKey;
const CFStringRef kMDItemAudioChannelCount;
const CFStringRef kMDItemAudioEncodingApplication;
const CFStringRef kMDItemAudioSampleRate;
const CFStringRef kMDItemAudioTrackNumber;
const CFStringRef kMDItemComposer;
const CFStringRef kMDItemIsGeneralMIDISequence;
const CFStringRef kMDItemKeySignature;
const CFStringRef kMDItemLyricist;
const CFStringRef kMDItemMusicalGenre;
const CFStringRef kMDItemMusicalInstrumentCategory;
const CFStringRef kMDItemMusicalInstrumentName;
const CFStringRef kMDItemRecordingDate;
const CFStringRef kMDItemRecordingYear;
const CFStringRef kMDItemTempo;
const CFStringRef kMDItemTimeSignature;
```

Constants

`kMDItemAppleLoopDescriptors`

Specifies multiple pieces of descriptive information about a loop. Besides genre and instrument, files can contain descriptive information that help users in refining searches. A CFArray of CFStrings.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAppleLoopsKeyFilterType`

Specifies key filtering information about a loop. Loops are matched against projects that often in a major or minor key. To assist users in identifying loops that will "fit" with their compositions, loops can be tagged with one of the following key filters: "AnyKey" "Minor" "Major" "NeitherKey" "BothKeys". "AnyKey" means that it fits with anything (whether in a major key, minor key or neither). "Minor" fits with compositions in a minor key. "NeitherKey" doesn't work well with compositions that are in major or minor key. "BothKeys" means it fits with major or minor key. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAppleLoopsLoopMode`

Specifies how a file should be played. Tagged files can either be loops or non-loops (e.g., a cymbal crash). "Looping" indicates if the file should be treated as a loop. "Non-looping" indicates the file should not be treated as a loop. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAppleLoopsRootKey`

Specifies the loop's original key. The key is the root note or tonic for the loop, and does not include the scale type. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemAudioChannelCount`
: Number of channels in the audio data contained in the file. This integer value only represents the number of discreet channels of audio data found in the file. It does not indicate any configuration of the data in regards to a user's speaker setup. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemAudioEncodingApplication`
: The name of the application that encoded the data contained in the audio file. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemAudioSampleRate`
: Sample rate of the audio data contained in the file. The sample rate is a float value representing hz (audio_frames/second). For example: 44100.0, 22254.54. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemAudioTrackNumber`
: The track number of a song or composition when it is part of an album. A CFNumber (integer).

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemComposer`
: The composer of the music contained in the audio file. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemIsGeneralMIDISequence`
: Indicates whether the MIDI sequence contained in the file is setup for use with a General MIDI device. A CFBoolean.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemKeySignature`
: The key of the music contained in the audio file. For example: C, Dm, F#m, Bb. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemLyricist`
: The lyricist, or text writer, of the music contained in the audio file. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemMusicalGenre`
: The musical genre of the song or composition contained in the audio file. For example: Jazz, Pop, Rock, Classical. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemMusicalInstrumentCategory`
: Specifies the category of an instrument. Files should have an instrument associated with them ("Other Instrument" is provided as a catch-all). For some categories, such as "Keyboards", there are instrument names which provide a more detailed instrument definition, for example "Piano" or "Organ". A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemMusicalInstrumentName`
: Specifies the name of instrument relative to the instrument category. Files can have an instrument name associated with them if they have certain instrument categories. For example, the "Percussion" category has multiple instruments, including "Conga" and "Bongo". A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemRecordingDate`
: The recording date of the song or composition. This is in contrast to `kMDItemContentCreationDate` which, could indicate the creation date of an edited or 'mastered' version of the original art. A CFDate.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemRecordingYear`
: Indicates the year the item was recorded. For example, 1964, 2003, etc. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemTempo`
: A float value that specifies the beats per minute of the music contained in the audio file. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemTimeSignature`
: The time signature of the musical composition contained in the audio/MIDI file. For example: "4/4", "7/8". A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

File System Metadata Attribute Keys

Metadata attribute keys that describe the file system attributes for a file.

```
const CFStringRef kMDItemDisplayName;
const CFStringRef kMDItemFSContentChangeDate;
const CFStringRef kMDItemFSCreationDate;
const CFStringRef kMDItemFSExists;
const CFStringRef kMDItemFSInvisible;
const CFStringRef kMDItemFSIsExtensionHidden;
const CFStringRef kMDItemFSIsReadable;
const CFStringRef kMDItemFSIsWriteable;
const CFStringRef kMDItemFSLabel;
const CFStringRef kMDItemFSName;
const CFStringRef kMDItemFSNodeCount;
const CFStringRef kMDItemFSOwnerGroupID;
const CFStringRef kMDItemFSOwnerUserID;
const CFStringRef kMDItemFSSize;
const CFStringRef kMDItemPath;
```

Constants

`kMDItemDisplayName`

The localized version of the file name. This is the localized version of the LaunchServices call `LSCopyDisplayNameForURL()`/`LSCopyDisplayNameForRef()`. A CFString.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFSContentChangeDate`

The date the file contents last changed. A CFDate.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFSCreationDate`

The date and time that the file was created. A CFDate.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFSExists`

This attribute is deprecated and was never implemented.

Deprecated in Mac OS X v10.4.

Declared in `MDItem.h`.

`kMDItemFSInvisible`

Indicates whether the file is invisible. A CFBoolean.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFSIsExtensionHidden`

Indicates whether the file extension of the file is hidden. A CFBoolean.

Available in Mac OS X v10.4 and later.

Declared in `MDItem.h`.

`kMDItemFSIsReadable`

This attribute is deprecated and was never implemented.

Deprecated in Mac OS X v10.4.

Declared in `MDItem.h`.

`kMDItemFSIsWriteable`
: This attribute is deprecated and was never implemented.

  Deprecated in Mac OS X v10.4.

  Declared in `MDItem.h`.

`kMDItemFSLabel`
: Index of the Finder label of the file. Possible values are 0 through 7. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemFSName`
: The file name of the item. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemFSNodeCount`
: Number of files in a directory. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemFSOwnerGroupID`
: The group ID of the owner of the file. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemFSOwnerUserID`
: The user ID of the owner of the file. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemFSSize`
: The size, in bytes, of the file on disk. A CFNumber.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

`kMDItemPath`
: The complete path to the file. A CFString.

  Available in Mac OS X v10.4 and later.

  Declared in `MDItem.h`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`MDItem.h`

MDQuery Reference

Derived From:	CFType
Framework:	CoreServices/CoreServices.h
Declared in	MDQuery.h
Companion guides	Spotlight Overview Spotlight Query Programming Guide

Overview

MDQuery is a CF-compliant object, follows the CF conventions, and can be used with the CF polymorphic functions, such as `CFRetain`. MDQuery encapsulates queries against the System store of the file metadata.

An MDQuery normally executes asynchronously and posts progress notifications as the results are collected. During the gathering phase the query results conform to the specified value lists and sorting.

MDQuery gathers results and processes updates only while the current thread's run loop is running.

For functions that take an MDQueryRef parameter, if this parameter is not a valid MDQueryRef, the behavior is undefined. `NULL` is not a valid MDQueryRef.

For functions that take CF*Ref parameters, such as CFStringRef and CFArrayRef, if this parameter is not a valid CF object of the correct type, the behavior is undefined. `NULL` is not a valid CF*Ref.

Functions by Task

Creating Queries

`MDQueryCreate` (page 155)
Creates a new query instance.

`MDQueryCreateSubset` (page 155)
Creates a new query that is a subset of the specified parentquery.

`MDQuerySetSearchScope` (page 164)
Sets the search scope for a query instance.

Getting and Setting Query Parameters

`MDQueryGetBatchingParameters` (page 158)
Returns the current parameters that control the batching of progress notifications.

`MDQueryCopyValueListAttributes` (page 154)
Returns the list of attribute names for which values are being collected by the query.

`MDQueryCopySortingAttributes` (page 153)
Returns the list of attribute names used to sort the results.

`MDQueryCopyQueryString` (page 153)
Returns the query string of the query.

`MDQuerySetBatchingParameters` (page 161) Deprecated in Mac OS X v10.2
Set the query batching parameters.

Setting Callback Functions

`MDQuerySetCreateResultFunction` (page 162)
Sets the function used to create the result objects of the MDQuery.

`MDQuerySetSortComparator` (page 165)
Sets the function used to sort the results of an MDQuery.

`MDQuerySetCreateValueFunction` (page 163)
Sets the function used to create the value objects of the MDQuery.

Starting, Stopping and Pausing Queries

`MDQueryExecute` (page 157)
Run the query, and populate the query with the results.

`MDQueryStop` (page 165)
Stops the query from generating more results.

`MDQueryDisableUpdates` (page 156)
Disables updates to the query result list.

`MDQueryEnableUpdates` (page 156)
Enables updates to the query result list.

`MDQueryIsGatheringComplete` (page 161)
Returns true if the first phase of a query, the initial result gathering, has finished.

Getting Query Result Values

`MDQueryCopyValuesOfAttribute` (page 154)
Returns the list of values from the results of the query for the specified attribute.

`MDQueryGetAttributeValueOfResultAtIndex` (page 158)
Returns the value of the named attribute for the result at the given index.

`MDQueryGetCountOfResultsWithAttributeValue` (page 158)
Returns the number of results which have the given attribute and attribute value.

`MDQueryGetIndexOfResult` (page 159)
Returns the current index of the given result.

`MDQueryGetResultAtIndex` (page 160)
Returns the current result at the given index.

`MDQueryGetResultCount` (page 160)
Returns the number of results currently collected by the query.

Getting the Type Identifier

`MDQueryGetTypeID` (page 161)
Returns the type identifier of all MDQuery instances

Functions

MDQueryCopyQueryString

Returns the query string of the query.

```
CFStringRef MDQueryCopyQueryString (
   MDQueryRef query
);
```

Parameters

query
The query.

Return Value
A CFStringRef containing the query string.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryCopySortingAttributes

Returns the list of attribute names used to sort the results.

```
CFArrayRef MDQueryCopySortingAttributes (
   MDQueryRef query
);
```

Parameters

query
The query.

Return Value
A CFArrayRef containing the attribute names used to sort the query results.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryCopyValueListAttributes

Returns the list of attribute names for which values are being collected by the query.

```
CFArrayRef MDQueryCopyValueListAttributes (
   MDQueryRef query
);
```

Parameters

query
The query.

Return Value
A CFArrayRef containing the attribute names of the collected values.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryCopyValuesOfAttribute

Returns the list of values from the results of the query for the specified attribute.

```
CFArrayRef MDQueryCopyValuesOfAttribute (
   MDQueryRef query,
   CFStringRef name
);
```

Parameters

query
The query.

name
The attribute name to return the value of. If the attribute is not one of those requested when the query was created the behavior is undefined

Return Value
A CFArrayRef containing the value objects for the specified attribute. The array contents are not ordered and contain only one occurrence of each value. The array contents may change over time if the query is configured for live-updates.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryCreate

Creates a new query instance.

```
MDQueryRef MDQueryCreate (
   CFAllocatorRef allocator,
   CFStringRef queryString,
   CFArrayRef valueListAttrs,
   CFArrayRef sortingAttrs
);
```

Parameters

allocator

The CFAllocator object to be used to allocate memory for the new object. Pass `NULL` or `kCFAllocatorDefault` to use the current default allocator.

queryString

The query expression string for this query.

valueListAttrs

An optional array of attribute names. The query will collect the values of these attributes into uniqued lists that can be used to summarize the results of the query and allow the user to further qualify the search. This parameter may be `NULL` if no value lists are required. Value list collection increases CPU usage and significantly increases the memory usage of an MDQuery. The attribute names are CFStrings.

sortingAttrs

A n array of attribute names used to sort the results, or `NULL` if no sorting is required. The first name in the array is used as the primary sort key, the second as the secondary key, and so on. The comparison of like-typed values is a simple, literal comparison. Sorting increases memory usage and significantly increases the CPU usage of an MDQuery. It is usually more efficent to allow the MDQuery to sort the results than retrieiving the values and sorting the results yourself. The attribute names are CFStrings.

Return Value

An MDQueryRef, or `NULL` on failure. If the query string is empty or malformed the function returns NULL.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`MDQuery.h`

MDQueryCreateSubset

Creates a new query that is a subset of the specified parentquery.

```
MDQueryRef MDQueryCreateSubset (
   CFAllocatorRef allocator,
   MDQueryRef query,
   CFStringRef queryString,
   CFArrayRef valueListAttrs,
   CFArrayRef sortingAttrs
);
```

Parameters

allocator

The CFAllocator object to be used to allocate memory for the new object. Pass NULL or `kCFAllocatorDefault` to use the current default allocator.

query
The parent query

queryString
The query expression string for this query.

valueListAttrs
An optional array of attribute names. The query will collect the values of these attributes into uniqued lists that can be used to summarize the results of the query and allow the user to further qualify the search. This parameter may be `NULL` if no value lists are required. Value list collection increases CPU usage and significantly increases the memory usage of an MDQuery. The attribute names are CFStrings.

sortingAttrs
A n array of attribute names used to sort the results, or `NULL` if no sorting is required. The first name in the array is used as the primary sort key, the second as the secondary key, and so on. The comparison of like-typed values is a simple, literal comparison. Sorting increases memory usage and significantly increases the CPU usage of an MDQuery. It is usually more efficent to allow the MDQuery to sort the results than retrieiving the values and sorting the results yourself. The attribute names are CFStrings.

Return Value
An MDQueryRef, or `NULL` on failure. If the query string is empty or malformed the function returns NULL.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryDisableUpdates

Disables updates to the query result list.

```
void MDQueryDisableUpdates (
   MDQueryRef query
);
```

Parameters

query
The query.

Discussion
This function should be called before iterating over query results that could change due to live-updates. The disabled state is a counter and disabling can be done recursively and from different threads.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryEnableUpdates

Enables updates to the query result list.

```
void MDQueryEnableUpdates (
   MDQueryRef query
);
```

Parameters

query

The query.

Discussion
This function should be called when finished iterating through the list of results. Live-updates to the query results will continue when all the disables have been matched by a corresponding enable.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryExecute

Run the query, and populate the query with the results.

```
Boolean MDQueryExecute (
   MDQueryRef query,
   CFOptionFlags optionFlags
);
```

Parameters

query

The query to execute.

optionFlags

A bitwise OR of the `MDQueryOptionFlags` to be used by the query.

Return Value
Returns `TRUE` if the query was started, `FALSE` otherwise. Queries cannot be executed more than once.

Discussion
Queries only gather results or process updates while the current thread's run loop is running.

Queries have two phases: the initial gathering phase that collects all currently matching results and a second live-update phase. Updates occur during the live-update phase if a change in a file occurs such that it no longer matches the query or if it begins to match the query. Files which begin to match the query are added to the result list, and files which no longer match the query expression are removed from the result list.

Query notifications are posted within the context of the same thread which executes the query.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryGetAttributeValueOfResultAtIndex

Returns the value of the named attribute for the result at the given index.

```
void * MDQueryGetAttributeValueOfResultAtIndex (
   MDQueryRef query,
   CFStringRef name,
   CFIndex idx
);
```

Parameters

query

The query.

name

The attribute name to return the values of. If the attribute is not one of those requested in the *valueListAttrs* or *sortingAttrs* parameters to one of the query creation functions, the result will be `NULL`.

idx

The index into the query's result list. If the index is negative or is equal to or larger than the current number of results in the query, the behavior is undefined.

Return Value

The value of the attribute, or `NULL` if the attribute doesn't exist for the specidied result.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`MDQuery.h`

MDQueryGetBatchingParameters

Returns the current parameters that control the batching of progress notifications.

```
MDQueryBatchingParams MDQueryGetBatchingParameters (
   MDQueryRef query
);
```

Parameters

query

The query.

Return Value

An MDQueryBatchingParams structure with the current batching parameters.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`MDQuery.h`

MDQueryGetCountOfResultsWithAttributeValue

Returns the number of results which have the given attribute and attribute value.

```
CFIndex MDQueryGetCountOfResultsWithAttributeValue (
   MDQueryRef query,
   CFStringRef name,
   CFTypeRef value
);
```

Parameters

query

The query.

name

The attribute name to return the result count of. If the attribute is not one of those requested in the *valueListAttrs* parameter, the behavior is undefined.

value

The attribute value for which to return the number of results with that value. This parameter may be `NULL`, in which case the number of results that do not contain the specified attribute is returned.

Return Value
The number of results containing that attribute and value.

Discussion
This count may change over time if the query allows live-updates.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryGetIndexOfResult

Returns the current index of the given result.

```
CFIndex MDQueryGetIndexOfResult (
   MDQueryRef query,
   const void *result
);
```

Parameters

query

The query.

result

The result object to search for. If a custom create-result function has been set and this parameter is not a valid result object that the provided callbacks can handle, the behavior is undefined. If a custom create-result function has not been set this parameter must be a valid MDItemRef.

Return Value
The index of the given result, or `kCFNotFound` if the value is not one of the query's existing results. If you provided a custom result creation function result, the result will be objects created by that function.

Discussion
If a result-create function has been set, and the equal callback is non-`NULL`, it will be used to test the query's results against the candidate result.

Note that the index of a result can change over time if the query allows live-updates.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryGetResultAtIndex

Returns the current result at the given index.

```
const void * MDQueryGetResultAtIndex (
   MDQueryRef query,
   CFIndex idx
);
```

Parameters

query

The query.

idx

The index into the query's result list. If the index is negative, or is equal to or larger than the current number of results in the query, the behavior is undefined.

Return Value
Returns the MDItemRef currently at the given index, or if a result-creation function has been set, returns the result returned by that function.

Discussion
This function causes the result object to be created if it hasn't been created already. For performance reasons you should only request objects that you require. If possible, call this function to fetch only the results you need to display or otherwise process.

Note that the index of a particular result can change over time if the query is configured to allow live-updates.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryGetResultCount

Returns the number of results currently collected by the query.

```
CFIndex MDQueryGetResultCount (
   MDQueryRef query
);
```

Parameters

query

The query.

Return Value
The number of results in the query.

Discussion
Note that the number of results in a query will change over time as the query's result list is updated.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryGetTypeID

Returns the type identifier of all MDQuery instances

```
CFTypeID MDQueryGetTypeID (
   void
);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryIsGatheringComplete

Returns true if the first phase of a query, the initial result gathering, has finished.

```
Boolean MDQueryIsGatheringComplete (
   MDQueryRef query
);
```

Parameters

query
The query.

Return Value
Returns `TRUE` if the first phase of a query has completed, otherwise `FALSE`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQuerySetBatchingParameters

Set the query batching parameters.

```
void MDQuerySetBatchingParameters (
   MDQueryRef query,
   MDQueryBatchingParams params
);
```

Parameters

query

The query.

params

An MDQueryBatchingParams structure with the batching parameters to set.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQuerySetCreateResultFunction

Sets the function used to create the result objects of the MDQuery.

```
void MDQuerySetCreateResultFunction (
   MDQueryRef query,
   MDQueryCreateResultFunction func,
   void *context,
   const CFArrayCallBacks *cb
);
```

Parameters

query

The query.

func

The callback function the MDQuery will use to create its results, such as those returned by the function `MDQueryGetResultAtIndex`. This parameter may be `NULL`, in which case any previous result creation settings are cancelled and the MDQuery will subsequently produce MDItemRefs. If a function is specified and is not of type `MDQueryCreateResultFunction` or does not behave as a `MDQueryCreateResultFunction` must, the behavior is undefined.

context

A pointer-sized user-defined value, that is passed as the third parameter to the create function. MDQuery does not use this value, does not retain the context in any way, and requires that the context be valid for the lifetime of the query. If the context is not what is expected by the create function, the behavior is undefined.

cb

A pointer to a `CFArrayCallBacks` structure initialized with the callbacks for the query to use to manage the created result objects. A copy of the contents of the callbacks structure is made, so that a pointer to a structure on the stack can be passed in, or can be reused for multiple query creations. Only version 0 of the `CFArrayCallBacks` is supported. The retain field may be `NULL`, in which case the MDQuery will not add a retain to the created results for the query. The release field may be `NULL`, in which case the MDQuery will not remove the query's retain (such as the one it gets from the create function) on the result objects when the query is destroyed. If the *`copyDescription`* field is `NULL`, the query will create a simple description for the result objects. If the *`equal`* field is `NULL`, the query will use pointer equality to test for equality of results. This callbacks parameter itself may be `NULL` in which case it is treated as a valid version 0 structure with all fields NULL. Otherwise, if any of the fields are not valid pointers to functions of the correct type, or this parameter is not a valid pointer to a `CFArrayCallBacks` callbacks structure, the behavior is undefined. If any of the value values returned from the create function is not one understood by one or more of the callback functions, the behavior when those callback functions are used is undefined. For example, if the create function can return `NULL`, then `NULL` must be understood by the callback functions as a possible parameter. The retain and release callbacks must be a matched set, you should not assume that the retain function will be unused or that additional reference counts will not be taken on the created results.

Discussion
If no create function is specified for an MDQuery, the default result objects are MDItemRefs. Results created after the function `MDQuerySetCreateResultFunction` is called are created through the specified create function, but values created before the function was set, or after it is unset, are not modified. It is not advisable to change this function after the function `MDQueryExecute` has been called. The create-result function is called lazily as results are requested from a query, it is not called on all results, and may not be called at all. This avoids the cost of creating potentially hundreds of thousands of what might be temporary objects.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQuerySetCreateValueFunction

Sets the function used to create the value objects of the MDQuery.

```
void MDQuerySetCreateValueFunction (
   MDQueryRef query,
   MDQueryCreateValueFunction func,
   void *context,
   const CFArrayCallBacks *cb
);
```

Parameters

query

The query.

func

The callback function the MDQuery should use to create the value list values, such as those returned by the function `MDQueryCopyValuesOfAttribute`. This parameter may be `NULL`, in which case any previous value creation settings are cancelled and the MDQuery will subsequently produce the default CFTypeRefs. If a function is specified and is not of type `MDQueryCreateValueFunction` or does not behave as a `MDQueryCreateValueFunction` must, the behavior is undefined.

context

A pointer-sized user-defined value, that is passed as the third parameter to the create function. MDQuery does not use this value, does not retain the context in any way, and requires that the context be valid for the lifetime of the query. If the context is not what is expected by the create function, the behavior is undefined.

cb

A pointer to a CFArrayCallBacks structure initialized with the callbacks for the query to use to manage the created value objects. A copy of the contents of the callbacks structure is made, so that a pointer to a structure on the stack can be passed in, or can be reused for multiple query creations. Only version 0 of the `CFArrayCallBacks` is supported. The retain field may be `NULL`, in which case the MDQuery will not add a retain to the created values. The release field may be `NULL`, in which case the MDQuery will do nothing to remove the query's retain (such as the one it gets from the create function) on the value objects when the query is destroyed. If the *copyDescription* field is `NULL`, the query will create a simple description for the value objects. If the *equal* field is `NULL`, the query will use pointer equality to test for equality of values. This callbacks parameter itself may be `NULL` in which case it is treated as a valid version 0 structure with all fields `NULL`. Otherwise, if any of the fields are not valid pointers to functions of the correct type, or this parameter is not a valid pointer to a `CFArrayCallBacks` callbacks structure, the behavior is undefined. If any of the value values returned from the create function is not one understood by one or more of the callback functions, the behavior when those callback functions are used is undefined. For example, if the create function can return `NULL`, then `NULL` must be understood by the callback functions as a possible parameter. The retain and release callbacks must be a matched set, you should not assume that the retain function will be unused or that additional reference counts will not be taken on the created results.

Discussion
Values created after a create function is set will be created using the newly specified function, but existing values are not modified. It is not advisable to change this function after `MDQueryExecute` has been called with the query.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQuerySetSearchScope

Sets the search scope for a query instance.

```
void MDQuerySetSearchScope (
   MDQueryRef query,
   CFArrayRef scopeDirectories,
   OptionBits scopeOptions
);
```

Parameters

query

The query object to modify.

scopeDirectories

A CFArray of CFStringRef or CFURLRef objects which specify where to search. For convenience the `kMDQueryScopeHome`, `kMDQueryScopeComputer` and `kMDQueryScopeNetwork` constants may also be included in the array.

scopeOptions
Additional options for modifying the search. Currently you must pass 0.

Discussion

Availability
Available in Mac OS X v10.4 and later.

Declared In
MDQuery.h

MDQuerySetSortComparator

Sets the function used to sort the results of an MDQuery.

```
void MDQuerySetSortComparator (
   MDQueryRef query,
   MDQuerySortComparatorFunction comparator,
   void *context
);
```

Parameters

query
The query.

comparator
The callback function the MDQuery uses to sort the results list. This parameter may be `NULL` which cancels previous sort comparator settings. If a function is specified and is not of type `MDQuerySortComparatorFunction` or does not behave as a `MDQuerySortComparatorFunction` must, the behavior is undefined.

context
A pointer-sized user-defined value, that is passed as the third parameter to the create function. MDQuery does not use this value, does not retain the context in any way, and requires that the context be valid for the lifetime of the query. If the context is not what is expected by the create function, the behavior is undefined.

Availability
Available in Mac OS X v10.4 and later.

Declared In
MDQuery.h

MDQueryStop

Stops the query from generating more results.

```
void MDQueryStop (
   MDQueryRef query
);
```

Parameters

query
The query.

Discussion
Queries may be executed only once and cannot be restarted. The query will first complete processing any unprocessed results.do. That may trigger a progress notification, so be aware of that if you are stopping a query from within your progress note handler; that is, during this function, a recursive progress and/or finished notification might occur, which might recursively call your notification handler. It is safe to call this function recursively. You would call this function to stop a query that is generating way too many results to be useful, but still want to access the results that have come in so far. If a query is stopped before the gathering phase finishes, it will not report itself as finished, nor will it send out a finished notification.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

Callbacks

MDQueryCreateResultFunction

Callback function used to create the result objects stored and returned by a query.

```
typedef const void * (*MDQueryCreateResultFunction) (
 MDQueryRef query,
 MDItemRef item,
 void *context
);

forthcoming
```

Parameters

query
The query instance.

item
The default MDItemRef for the result.

context
The user-defined context parameter provided to the `MDQuerySetCreateResultFunction` function.

Return Value
The function must return a pointer-sized value that can be managed with the callbacks which were set at the same time the create function was given to the query. The value must be returned with a reference (such as if the retain callback had been called on it), as implied by the Create name. If this function doesn't wish to create a new object it can return the given MDItemRef, but must also return it with a new retain, and the callbacks must be able to handle an MDItemRef as an input value. If this function returns NULL, NULL will be stored for the moment in the query, MDQueryGetResultAtIndex() may return NULL for that result, and the next time the query wants the result, it will call this function again.

Discussion
The function may hold onto the given attribute name and/or value in some other data structure, but must retain them for them to remain valid.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQueryCreateValueFunction

Callback function used to create the value objects stored and returned by a query.

```
typedef const void * (*MDQueryCreateValueFunction) (
 MDQueryRef query,
 CFStringRef attrName,
 CFTypeRef attrValue,
 void *context
);

forthcoming
```

Parameters

query
The query instance.

attrName
The attribute name of the value.

attrValue
The default value of the value.

context
The user-defined context parameter provided in the `MDQuerySetCreateValueFunction` function.

Return Value
The function must return a pointer-sized value that can be managed with the callbacks which were set at the same time the create function was given to the query. The value must be returned with a reference (such as if the retain callback had been called on it), as implied by the Create name. If this function doesn't wish to create a new object, it can return the given CFTypeRef, but must also return it with a new retain, and the callbacks must be able to handle a CFTypeRef as an input value.

Discussion
The function may hold onto the given attribute name and/or value in some other data structure, but must retain them for them to remain valid

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

MDQuerySortComparatorFunction

Callback function used to sort the results of a query.

```
typedef CFComparisonResult (*MDQuerySortComparatorFunction) (
 const CFTypeRef attrs1[],
 const CFTypeRef attrs2[],
 void *context
);

asdfasdfasdfasdfadsf
```

Parameters

query

The query instance.

attrs1

A C array of attribute values for a result. The values occur in the array in the same order and position that the attribute names were passed in the `sortingAttrs` array when the query was created. The values of the attributes will be `NULL` if the attribute doesn't exist for a result or if read access to that attribute is not allowed.

attrs2

A C array of attribute values for a result. The values occur in the array in the same order and position that the attribute names were passed in the `sortingAttrs` array when the query was created. The values of the attributes will be `NULL` if the attribute doesn't exist for a result or if read access to that attribute is not allowed.

context

The user-defined context parameter provided in the function `MDQuerySetSortComparator`.

Return Value

The function must return one of the CFComparisonResults `kCFCompareLessThan`, `kCFCompareEqualTo`, or `kCFCompareGreaterThan`. There is no provision for unordered results. The comparison should be a total order relation and produce the same results for the same inputs.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`MDQuery.h`

Data Types

Batching Parameters

MDQueryBatchingParams

Structure containing the progress notification batching parameters of a MDQuery.

```
typedef struct {
    size_t first_max_num;
    size_t first_max_ms;
    size_t progress_max_num;
    size_t progress_max_ms;
    size_t update_max_num;
    size_t update_max_ms;
} MDQueryBatchingParams;
```

Fields

`first_max_num`

The maximum number of results that can accumulate before the first progress notification is sent. This value is used only during the initial result-gathering phase of a query.

`first_max_ms`

The maximum number of milliseconds that can pass before the first progress notification is sent. This value is advisory, in that the notification will be triggered at some point after `first_max_ms` milliseconds have passed since the query began accumulating results. This value is used only during the initial result-gathering phase of a query.

`progress_max_num`

The maximum number of results that can accumulate before additional progress notifications are sent. This value is used only during the initial result-gathering phase of a query.

`progress_max_ms`

The maximum number of milliseconds that can pass before additional progress notifications are sent. This value is advisory, in that the notification will be triggered at some point after `progress_max_ms` milliseconds have passed since the query began accumulating results. This value is used only during the initial result-gathering phase of a query.

`update_max_num`

The maximum number of results that can accumulate before an update notification is sent. This value is used only during the live-update phase of a query.

`update_max_ms`

The maximum number of milliseconds that can pass before an update notification is sent. This value is advisory, in that the notification will be triggered at some point after `update_max_ms` milliseconds have passed since the query began accumulating results. This value is used only during the live-update phase of a query.

Discussion

The default batching parameters are undefined and subject to change.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`MDQuery.h`

Miscellaneous

MDQueryRef

A reference to a MDQuery object.

```
typedef struct __MDQuery *MDQueryRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MDQuery.h`

Constants

Query Option Flags

MDQueryOptionsFlags

Specify the execution mode for a query.

```
typedef enum {
    kMDQuerySynchronous = 1,
    kMDQueryWantsUpdates = 4,
} MDQueryOptionFlags;
```

Constants

`kMDQuerySynchronous`
Specifies that a query should block during the initial gather phase. The query's run loop will run in the default mode. If this option is not specified the query function returns immediately after starting the query asynchronously.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

`kMDQueryWantsUpdates`
Specifies that a query should provide live-updates to the result list after the initial gathering phase. Updates occur during the live-update phase if a change in a file occurs such that it no longer matches the query or if it begins to match the query. Files which begin to match the query are added to the result list, and files which no longer match the query expression are removed from the result list. Currently, this option is ignored if the `kMDQuerySynchronous` parameter is specified. This is subject to change, and you should always pass the value appropraite to the required behavior.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

Notifications

kMDQueryDidFinishNotification

Indicates that a query has finished with the initial result-gathering phase.

```
const CFStringRef kMDQueryDidFinishNotification;
```

Constants
`kMDQueryDidFinishNotification`
Posted to indicate that the query has finished the initial result-gathering phase.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

Discussion
The query results list is not updated as a result of this notification.

This notification is only sent to the application's notification center.

kMDQueryDidUpdateNotification

Indicates that a query's results list has change during the live-update phase of a query.

```
const CFStringRef kMDQueryDidUpdateNotification;
```

Constants
`kMDQueryDidUpdateNotification`
Notification posted to indicate that a change has occured to the query's resuls list during the live-update phase of a query's execution.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

Discussion
The info dictionary of the notification can contain `kMDQueryUpdateAddedItems`, `kMDQueryUpdateChangedItems`, and `kMDQueryUpdateRemovedItems` keys.

This notification is only sent to the application's notification center.

kMDQueryProgressNotification

Indicates that a query's results list has change during the initial result-gathering phase of a query.

```
const CFStringRef kMDQueryProgressNotification;
```

Constants
`kMDQueryProgressNotification`
Notification posted to indicate that a change has occurred to the query's results list during the initial result-gathering phase of execution.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

Discussion
New items are typically added during this phase, however it is possible for items to be removed or updated, if the original file is changed. The info dictionary of the notification can contain `kMDQueryUpdateChangedItems` and `kMDQueryUpdateRemovedItems` keys.

For performance reasons added results are not indicated in progress notifications, to avoid the cost of creating the result objects.

This notification is only sent to the application's notification center.

Notification Info Keys

Query Result Change Keys

Specify the items that have changed in the query results.

```
const CFStringRef kMDQueryUpdateAddedItems;
const CFStringRef kMDQueryUpdateChangedItems;
const CFStringRef kMDQueryUpdateRemovedItems;
```

Constants

`kMDQueryUpdateAddedItems`

An array that identifies the items that have been added to the query results. This list only contains result objects that have previously been created, result objects that have not been created are not included.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

`kMDQueryUpdateChangedItems`

An array that identifies the items that have changed in the query results. This list only contains result objects that have previously been created, result objects that have not been created are not included.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

`kMDQueryUpdateRemovedItems`

An array that identifies the items that have been removed from the query results. This list only contains result objects that have previously been created, result objects that have not been created are not included.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

Query Search Scope Keys

Specify the scope of a query's search.

```
const CFStringRef kMDQueryScopeHome;
const CFStringRef kMDQueryScopeComputer;
const CFStringRef kMDQueryScopeNetwork;
```

Constants

`kMDQueryScopeHome`

Specifies that the query should be restricted to the volume and directory that contains the current user's home directory.

Available in Mac OS X v10.4 and later.

Declared in `MDQuery.h`.

`kMDQueryScopeComputer`
: Specifies that the query should be restricted to all locally mounted volumes, plus the user's home directory (which may be on a remote volume).

  Available in Mac OS X v10.4 and later.

  Declared in `MDQuery.h`.

`kMDQueryScopeNetwork`
: Specifies that the query should include all user mounted remote volumes.

  Available in Mac OS X v10.4 and later.

  Declared in `MDQuery.h`.

Discussion
These constants can be passed in the *`scopeDirectories`* array to the function `MDQuerySetSearchScope`.

Result Relevance Sorting Key

Key used in a user notification's description dictionary that indicates the relevance of a result.

```
const CFStringRef kMDQueryResultContentRelevance;
```

Constants
`kMDQueryResultContentRelevance`
: A CFNumberRef with a floating point value between 0.0 and 1.0 inclusive.

  Available in Mac OS X v10.4 and later.

  Declared in `MDQuery.h`.

Discussion
The relevance value indicates the relevance of the content of a result object. The relevance is computed based on the value of the result itself, not on its relevance to the other results returned by the query.

The relevance value is for the content of the object only, not on the result item as a whole, and may not be computed if the item matches theq uery through evaluation of other attributes

If the value is not computed it is treated as an attribute on the item that does not exist.

Managers

Alias Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Aliases.h

Overview

The Alias Manager creates and resolves alias records, which are data structures that describe file system objects (files, directories, and volumes.) An alias record contains a "fingerprint" of a file system object. You can store the alias record instead of a file system reference, and use the Alias Manager to find the object again when it's needed. The Alias Manager contains algorithms for locating objects that have been moved, renamed, copied, or restored from backup.

The exact makeup of an alias record depends on the file system in which the object resides. The Alias Manager takes advantage of persistent object ids, creation dates, file types, creator codes and the like if they are available. By default, an object at the location stored in the alias record will be considered a stronger match than an object with the same file id in a different location. (You can alter this behavior by passing flags to the functions that resolve the alias.)

The Alias Manager supports two types of alias records. The standard alias contains as much information as the Alias Manager can gather from the underlying file system. The minimal alias only stores a subset of the information in a standard alias record. A minimal alias may be used when the object is unlikely to move, the reference is to be short-lived, or space is a critical issue (the exact space savings depends on the underlying file system format.) The standard alias is the preferred format because it is more robust.

The Finder supports the creation and use of alias files that contain alias records. Currently, Mac OS X does not provide a way for other applications to create these alias files. The Alias Manager can identify and resolve Finder alias files, but it cannot create them.

Functions by Task

Creating and Updating Alias Records

`FSNewAlias` (page 188)
Creates a new alias record, given a target file or directory.

`FSNewAliasUnicode` (page 191)
Creates a new alias record, given the Unicode name and parent directory of the target.

`FSNewAliasFromPath` (page 189)
Creates a new alias record, given the pathname of the target file or directory.

`FSNewAliasMinimal` (page 190)
Creates a new minimal alias record, given a target file or directory.

`FSNewAliasMinimalUnicode` (page 190)
Creates a minimal alias, given the Unicode name and parent directory of the target.

`FSUpdateAlias` (page 196)
Updates an alias record for a specified target.

Getting Alias Size

`GetAliasSize` (page 198)
Gets the size of an alias record referenced by a handle.

`GetAliasSizeFromPtr` (page 198)
Gets the size of an alias record referenced by a pointer.

Getting and Setting Alias User Types

`GetAliasUserType` (page 198)
Gets the user type for an alias record referenced by a handle.

`SetAliasUserType` (page 212)
Sets the user type for an alias record referenced by a handle.

`GetAliasUserTypeFromPtr` (page 199)
Gets the user type for the alias record referenced by a pointer.

`SetAliasUserTypeWithPtr` (page 212)
Sets the user type for the alias record referenced by a pointer.

Resolving and Reading Alias Records

`FSCopyAliasInfo` (page 181)
Returns information from an alias handle.

`FSMatchAliasBulk` (page 185)
Identifies a list of possible matches for an alias.

`FSResolveAlias` (page 192)
Returns an `FSRef` to the single most likely target of an alias record.

`FSResolveAliasWithMountFlags` (page 195)
Returns an `FSRef` to the target of an alias.

`FSMatchAlias` (page 184) Deprecated in Mac OS X v10.5
Identifies a list of possible matches for an alias. (Deprecated. Use `FSMatchAliasBulk` (page 185) instead.)

`FSMatchAliasNoUI` (page 187) Deprecated in Mac OS X v10.5
Identifies a list of possible matches for an alias without any user interaction. (Deprecated. Use `FSMatchAliasBulk` (page 185) with the `kARMNoUI` flag instead.)

Working With Finder Alias Files

`FSFollowFinderAlias` (page 182)
Resolves an alias record obtained from a Finder alias file.

`FSIsAliasFile` (page 183)
Determines whether a file system object is an alias file, a data file, or a folder.

`FSResolveAliasFile` (page 193)
Resolves an alias contained in an alias file.

`FSResolveAliasFileWithMountFlags` (page 194)
Resolves an alias contained in an alias file.

Working With Universal Procedure Pointers to Alias Manager Callbacks

`NewAliasFilterUPP` (page 204)
Creates a new universal procedure pointer (UPP) to an alias filtering callback function.

`DisposeAliasFilterUPP` (page 180)
Disposes of a universal procedure pointer (UPP) to an alias filtering callback function.

`InvokeAliasFilterUPP` (page 199)
Calls your alias filtering callback function.

Deprecated Functions

Alias Manager functions that use the `FSSpec` data type have been deprecated. Instead, you should use the equivalent `FSRef`–based functions, which include support for features such as unicode and long filenames. For more information on `FSSpec` and `FSRef` types, see *File Manager Reference*.

`GetAliasInfo` (page 197) Deprecated in Mac OS X v10.3
Gets information from an alias record without actually resolving the record. (Deprecated. Use `FSCopyAliasInfo` (page 181) instead.)

`FollowFinderAlias` (page 181) Deprecated in Mac OS X v10.5
Resolves an alias record obtained from a Finder alias file. (Deprecated. Use `FSFollowFinderAlias` (page 182) instead.)

`MatchAliasNoUI` (page 202) Deprecated in Mac OS X v10.5
Identifies a list of possible matches for an alias without any user interaction. (Deprecated. Use `FSMatchAliasBulk` (page 185) with the `kARMNoUI` flag instead.)

`ResolveAliasFileWithMountFlags` (page 209) Deprecated in Mac OS X v10.5
Resolves an alias contained in an alias file. (Deprecated. Use `FSResolveAliasFileWithMountFlags` (page 194) instead.)

`IsAliasFile` (page 200) Deprecated in Mac OS X v10.4
Determines whether a file system object is an alias file, a data file, or a folder. (Deprecated. Use `FSIsAliasFile` (page 183) instead.)

`MatchAlias` (page 201) Deprecated in Mac OS X v10.4
Identifies a list of possible matches for an alias and passes the list through an optional selection filter. The filter can return more than one possible match. (Deprecated. Use `FSMatchAliasBulk` (page 185) instead.)

`NewAlias` (page 203) Deprecated in Mac OS X v10.4
Creates a complete alias record. (Deprecated. Use `FSNewAlias` (page 188) instead.)

`NewAliasMinimal` (page 205) Deprecated in Mac OS X v10.4
Creates a short alias record quickly. (Deprecated. Use `FSNewAliasMinimal` (page 190) instead.)

`NewAliasMinimalFromFullPath` (page 205) Deprecated in Mac OS X v10.4
Creates an alias record that contains only the full pathname of the target. (Deprecated. Use `FSNewAliasMinimal` (page 190) or `FSNewAliasMinimalUnicode` (page 190) instead.)

`ResolveAlias` (page 206) Deprecated in Mac OS X v10.4
Identifies the single most likely target of an alias record. (Deprecated. Use `FSResolveAlias` (page 192) instead.)

`ResolveAliasFile` (page 208) Deprecated in Mac OS X v10.4
Resolves an alias contained in an alias file. (Deprecated. Use `FSResolveAliasFile` (page 193) instead.)

`ResolveAliasFileWithMountFlagsNoUI` (page 210) Deprecated in Mac OS X v10.4
Resolves an alias file without any user interaction. (Deprecated. Use `FSResolveAliasFileWithMountFlags` (page 194) with the `kResolveAliasFileNoUI` flag instead.)

`ResolveAliasWithMountFlags` (page 211) Deprecated in Mac OS X v10.4
Identifies the target of an alias. (Deprecated. Use `FSResolveAliasWithMountFlags` (page 195) instead.)

`UpdateAlias` (page 213) Deprecated in Mac OS X v10.4
Updates an alias record. (Deprecated. Use `FSUpdateAlias` (page 196) instead.)

Functions

DisposeAliasFilterUPP

Disposes of a universal procedure pointer (UPP) to an alias filtering callback function.

```
void DisposeAliasFilterUPP (
   AliasFilterUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion

See `AliasFilterProcPtr` (page 215) for more information on alias filtering callback functions.

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`Aliases.h`

FollowFinderAlias

Resolves an alias record obtained from a Finder alias file. (Deprecated in Mac OS X v10.5. Use `FSFollowFinderAlias` (page 182) instead.)

```
OSErr FollowFinderAlias (
   const FSSpec *fromFile,
   AliasHandle alias,
   Boolean logon,
   FSSpec *target,
   Boolean *wasChanged
);
```

Parameters

fromFile

A pointer to a file system specification specifying a file for a first attempt at a relative resolution; pass a pointer to the alias file's `FSSpec` forthis parameter.

alias

A handle to the alias record taken from the alias file's resources.

logon

If `true`, the Alias Manager attempts to mount a volume if necessary to complete the resolution of the alias.

target

A pointer to an `FSSpec` structure. On return, this `FSSpec` refers to the target found by the resolution.

wasChanged

A pointer to a Boolean value. `FollowFinderAlias` sets this value to `true` if it has updated the alias record. If the alias has been updated, you should call `ChangedResource` and `WriteResource` if the updated record should be saved in the resource file.

Return Value

A result code.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Aliases.h`

FSCopyAliasInfo

Returns information from an alias handle.

```
OSStatus FSCopyAliasInfo (
   AliasHandle inAlias,
   HFSUniStr255 *targetName,
   HFSUniStr255 *volumeName,
   CFStringRef *pathString,
   FSAliasInfoBitmap *whichInfo,
   FSAliasInfo *info
);
```

Parameters

inAlias

A handle to the alias record from which to get information.

targetName

A pointer to a string that, on return, contains the name of the target item. Pass `NULL` if you do not want this information returned.

volumeName

A pointer to a string that, on return, contains the name of the volume the target resides on. Pass `NULL` if you do not want this information returned.

pathString

A pointer a CFString that, on return, contains the POSIX path to the target. Pass `NULL` if you do not want this information returned.

whichInfo

A pointer to a variable of type `FSAliasInfoBitmap`. On return, this field indicates which fields in the alias information block, specified in the `info` parameter, contain valid data. See "Alias Information Masks" (page 218) for a description of the values that may be returned here. This parameter may be `NULL`.

info

A pointer to a structure of type `FSAliasInfo` (page 217). On return, this structure contains information about the alias. Pass `NULL` if you do not want this information returned.

Return Value
A result code.

Discussion
This function returns the requested information from the alias handle passed in the *inAlias* parameter. The information is gathered only from the alias record, so it may not match what is on disk. No disk input/output is performed.

The `FSCopyAliasInfo` function adds support for unicode filenames and filenames longer than 32 bytes. It replaces the `GetAliasInfo` function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Aliases.h`

FSFollowFinderAlias

Resolves an alias record obtained from a Finder alias file.

```
OSErr FSFollowFinderAlias (
   FSRef *fromFile,
   AliasHandle alias,
   Boolean logon,
   FSRef *target,
   Boolean *wasChanged
);
```

Parameters

fromFile

A pointer to the file to use for a first attempt at a relative resolution; pass a pointer to the alias file's `FSRef` for this parameter.

alias

A handle to the alias record taken from the alias file's resources.

logon

If `true`, the Alias Manager attempts to mount a volume if necessary to complete the resolution of the alias.

target

A pointer to an `FSRef` structure. On return, this `FSRef` refers to the target found by the resolution.

wasChanged

A pointer to a Boolean value. `FSFollowFinderAlias` sets this value to `true` if it has updated the alias record.

Return Value
A result code.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Aliases.h`

FSIsAliasFile

Determines whether a file system object is an alias file, a data file, or a folder.

```
OSErr FSIsAliasFile (
   const FSRef *fileRef,
   Boolean *aliasFileFlag,
   Boolean *folderFlag
);
```

Parameters

fileRef

A pointer to the file system object to test.

aliasFileFlag

A pointer to a Boolean variable. On return, a value of `TRUE` indicates that the object specified in the *fileRef* parameter is an alias file. A value of `FALSE` indicates that the object is not an alias file.

folderFlag

A pointer to a Boolean variable. On return, a value of `TRUE` indicates that the object specified in the *fileRef* parameter is a folder. A value of `FALSE` indicates that the object is a file.

Return Value
A result code.

Discussion
Table 10-1 summarizes the information that this function provides about the object specified in the `fileRef` parameter:

Table 10-1 Information about a file system object

Alias flag	Folder flag	Object kind
T	F	Alias file
F	F	Data file
F	T	Folder

Note that if `fileRef` is an alias file, this function does not provide any information about the object to which the alias refers. To find out whether this object is a file or a folder, you can use `FSResolveAliasFile` (page 193).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`Aliases.h`

FSMatchAlias

Identifies a list of possible matches for an alias. (Deprecated in Mac OS X v10.5. Use `FSMatchAliasBulk` (page 185) instead.)

```
OSErr FSMatchAlias (
   const FSRef *fromFile,
   unsigned long rulesMask,
   AliasHandle inAlias,
   short *aliasCount,
   FSRef *aliasList,
   Boolean *needsUpdate,
   AliasFilterUPP aliasFilter,
   void *yourDataPtr
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. You may pass `NULL` if you do not want this function to perform a relative search.

rulesMask

A set of rules to guide the resolution. Pass the sum of all of the rules you want to invoke. For a description of the values you can use in this parameter, see "Matching Constants" (page 220).

inAlias
A handle to the alias record to be resolved.

aliasCount
On input, a pointer to the maximum number of possible matches to return. On output, the actual number of matches returned.

aliasList
A pointer to an array of FSRef structures. On return, this array holds the results of the search, a list of possible candidates.

needsUpdate
A pointer to a Boolean flag that, on return, indicates whether the alias record needs to be updated.

aliasFilter
An application-defined filter function. The Alias Manager executes this function each time it identifies a possible match. Your filter function returns a Boolean value that determines whether the possible match is discarded (true) or added to the list of possible targets (false). It can also terminate the search by setting the variable parameter quitFlag. See AliasFilterProcPtr (page 215) for a description of the filter function.

yourDataPtr
A pointer to data to be passed to the filter function. The yourDataPtr parameter can point to any data your application might need in the filter function.

Return Value
A result code. When it finds the specified volume and parent directory but fails to find the target file or directory in that location, FSMatchAlias returns fnfErr. Note that the file system objects in the aliasList parameter are not valid in this case.

Discussion
After it identifies a target, FSMatchAlias compares some key information about the target with the same information in the record. If the information does not match, FSMatchAlias sets the *needsUpdate* flag to true.

The FSMatchAlias function also sets the *needsUpdate* flag to true if it identifies a list of possible matches rather than a single match or if kARMsearchRelFirst is set in the *rulesMask* parameter but the target is identified through either an absolute search or an exhaustive search. Otherwise, the FSMatchAlias function sets the *needsUpdate* flag to false. FSMatchAlias always sets the *needsUpdate* flag to false when resolving an alias created by FSNewAliasMinimal. If you want to update the alias record to reflect the final results of the resolution, call FSUpdateAlias.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Aliases.h

FSMatchAliasBulk

Identifies a list of possible matches for an alias.

```
OSStatus FSMatchAliasBulk (
    const FSRef *fromFile,
    unsigned long rulesMask,
    AliasHandle inAlias,
    short *aliasCount,
    FSRef *aliasList,
    Boolean *needsUpdate,
    FSAliasFilterProcPtr aliasFilter,
    void *yourDataPtr
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. You may pass `NULL` if you do not want this function to perform a relative search. By default, this function performs a relative search only if the absolute search does not find a match. If you want to perform the relative search first, you should pass `kARMSearchRelFirst` in the `rulesMask` parameter.

rulesMask

A set of rules to guide the resolution. Pass the sum of all of the rules you want to invoke. For a description of the values you can use in this parameter, see "Matching Constants" (page 220).

inAlias

A handle to the alias record to be resolved.

aliasCount

On input, a pointer to the maximum number of possible matches to return. On output, the actual number of matches returned.

aliasList

A pointer to an array of `FSRef` structures. On output, this array holds the results of the search, a list of possible candidates.

needsUpdate

A pointer to a Boolean flag that, on output, indicates whether the alias record needs to be updated. For more information about this parameter, see the Discussion.

aliasFilter

An optional application-defined filter function. The Alias Manager calls your filter function each time it identifies a possible match or after the search has continued for three seconds without a match. Your filter function returns a Boolean value that determines whether the possible match is discarded (`true`) or added to the list of possible targets (`false`). It can also terminate the search by setting the variable parameter `quitFlag`. See `FSAliasFilterProcPtr` (page 215) for a description of the filter function.

yourDataPtr

A pointer to data to be passed to the filter function, or `NULL`. The `yourDataPtr` parameter can point to any data your application might need in the filter function.

Return Value

A result code. If the Alias Manager finds the specified volume and parent directory but fails to find the target file or directory in that location, the return value is `fnfErr` and the elements in the `aliasList` parameter are not valid.

Discussion

After it identifies a target, this function compares some key information about the target with the same information in the record. If the information does not match, this function sets the *needsUpdate* flag to `true`. This function also sets the *needsUpdate* flag to `true` if it identifies a list of possible matches rather than a single match or if `kARMsearchRelFirst` is set in the *rulesMask* parameter but the target is identified

through either an absolute search or an exhaustive search. Otherwise, this function sets the *needsUpdate* flag to false. This function always sets the *needsUpdate* flag to false when resolving an alias created by FSNewAliasMinimal. To update the alias record to reflect the final results of the resolution, use the function FSUpdateAlias (page 196).

Availability
Available in Mac OS X v10.5 and later.

Declared In
Aliases.h

FSMatchAliasNoUI

Identifies a list of possible matches for an alias without any user interaction. (Deprecated in Mac OS X v10.5. Use FSMatchAliasBulk (page 185) with the kARMNoUI flag instead.)

```
OSErr FSMatchAliasNoUI (
   const FSRef *fromFile,
   unsigned long rulesMask,
   AliasHandle inAlias,
   short *aliasCount,
   FSRef *aliasList,
   Boolean *needsUpdate,
   AliasFilterUPP aliasFilter,
   void *yourDataPtr
);
```

Parameters

fromFile
A pointer to the starting point for a relative search. You may pass NULL if you do not want this function to perform a relative search.

rulesMask
A set of rules to guide the resolution. Pass the sum of all of the rules you want to invoke. For a description of the values you can use in this parameter, see "Matching Constants" (page 220).

inAlias
A handle to the alias record to be resolved.

aliasCount
On input, a pointer to the maximum number of possible matches to return. On output, the actual number of matches returned.

aliasList
A pointer to an array of FSRef structures. On return, this array holds the results of the search, a list of possible candidates.

needsUpdate
A pointer to a Boolean flag that, on return, indicates whether the alias record needs to be updated.

aliasFilter
An application-defined filter function. The Alias Manager executes this function each time it identifies a possible match. Your filter function returns a Boolean value that determines whether the possible match is discarded (true) or added to the list of possible targets (false). It can also terminate the search by setting the variable parameter quitFlag. See AliasFilterProcPtr (page 215) for a description of the filter function.

yourDataPtr

A pointer to data to be passed to the filter function. The `yourDataPtr` parameter can point to any data your application might need in the filter function.

Return Value
A result code.

Discussion
The `FSMatchAliasNoUI` function operates in much the same way as the `FSMatchAlias` function; however, it does not present an interface to the user. Additionally, the `FSMatchAliasNoUI` function does not mount network volumes, even when it is possible to mount the volume without user interaction. See the discussion of `FSMatchAlias` (page 184) for more information.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Aliases.h`

FSNewAlias

Creates a new alias record, given a target file or directory.

```
OSErr FSNewAlias (
   const FSRef *fromFile,
   const FSRef *target,
   AliasHandle *inAlias
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. You may pass `NULL` if you do not need relative search information in the alias record. The files or directories specified in the *fromFile* and *target* parameters must reside on the same volume.

target

A pointer to the target file or directory of the alias.

inAlias

A pointer to an alias handle. On return, this handle refers to the newly created alias record. If the function fails to create an alias record, it sets *inAlias* to `NULL`.

Return Value
A result code. If the specified target is valid, this function creates an alias record for the target and returns `noErr`. Any other return value indicates that this function did not create an alias record.

Discussion
The `FSNewAlias` function creates an alias record that describes the specified target. It allocates the storage, fills in the record, and puts a record handle to that storage in the *inAlias* parameter. `FSNewAlias` records the full pathname of the target and a collection of other information relevant to locating the target, verifying the target, and mounting the target's volume, if necessary. You can have `FSNewAlias` store relative search information as well by supplying a starting point for a relative search.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`Aliases.h`

FSNewAliasFromPath

Creates a new alias record, given the pathname of the target file or directory.

```
OSErr FSNewAliasFromPath (
   const char *fromFilePath,
   const char *targetPath,
   OptionBits flags,
   AliasHandle *inAlias,
   Boolean *isDirectory
);
```

Parameters

fromFilePath
A C string that specifies the starting point for a relative search. The string should contain a UTF-8 pathname. You may pass `NULL` if you do not need relative search information in the alias record.

targetPath
A C string that contains the full UTF-8 pathname of the target object.

flags
Reserved for future use. Currently, you should pass 0.

inAlias
A pointer to an alias handle. On output, this handle refers to the newly created alias record.

isDirectory
A pointer to a Boolean value. On input, if the target does not exist, set the value to `true` if the target is a directory or `false` if it is not. (Pass `NULL` if you are not sure whether the target is a directory.) On output, if the target exists, the value is `true` if the target is a directory, `false` if it is not.

Return Value
A result code. For more information, see the Discussion.

Discussion
If the specified target exists, this function creates an alias record for the target and returns `noErr`. If the parent directory specified in the target pathname exists but the target itself does not exist, this function creates an alias record for the target and returns `fnfErr`. Any other return value indicates that this function did not create an alias record.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Aliases.h`

FSNewAliasMinimal

Creates a new minimal alias record, given a target file or directory.

```
OSErr FSNewAliasMinimal (
   const FSRef *target,
   AliasHandle *inAlias
);
```

Parameters

target

A pointer to the target of the alias record.

inAlias

A pointer to an alias handle. On return, this handle refers to the newly created alias record. If the function fails to create an alias record, it sets `inAlias` to `NULL`.

Return Value

A result code. If the specified target is valid, this function creates an alias record for the target and returns `noErr`. Any other return value indicates that this function did not create an alias record.

Discussion

The `FSNewAliasMinimal` function creates an alias record that contains only the minimum information necessary to describe the target. The `FSNewAliasMinimal` function uses the standard alias record data structure, but it fills in only parts of the record.

The `FSResolveAlias` (page 192) function never updates a minimal alias record.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Aliases.h`

FSNewAliasMinimalUnicode

Creates a minimal alias, given the Unicode name and parent directory of the target.

```
OSErr FSNewAliasMinimalUnicode (
   const FSRef *targetParentRef,
   UniCharCount targetNameLength,
   const UniChar *targetName,
   AliasHandle *inAlias,
   Boolean *isDirectory
);
```

Parameters

targetParentRef

A pointer to the parent directory of the target.

targetNameLength

The number of Unicode characters in the target's name.

targetName

A pointer to the Unicode name of the target.

inAlias

A pointer to an alias handle. On return, this handle refers to the newly created alias record.

isDirectory
A pointer to a Boolean value. On input, if the target does not exist, set the value to `true` if the target is a directory or `false` if it is not. (Pass `NULL` if you are not sure whether the target is a directory.) On output, if the target exists, the value is `true` if the target is a directory, `false` if it is not.

Return Value
A result code. For more information, see the Discussion.

Discussion
If the specified target exists, this function creates an alias record for the target and returns `noErr`. If the parent directory exists but the target itself does not exist, this function creates an alias record for the target and returns `fnfErr`. Any other return value indicates that this function did not create an alias record.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Aliases.h`

FSNewAliasUnicode

Creates a new alias record, given the Unicode name and parent directory of the target.

```
OSErr FSNewAliasUnicode (
    const FSRef *fromFile,
    const FSRef *targetParentRef,
    UniCharCount targetNameLength,
    const UniChar *targetName,
    AliasHandle *inAlias,
    Boolean *isDirectory
);
```

Parameters

fromFile
A pointer to the starting point for a relative search. You may pass `NULL` if you do not need relative search information in the alias record.

targetParentRef
A pointer to the parent directory of the target.

targetNameLength
The number of Unicode characters in the target's name.

targetName
A pointer to the Unicode name of the target.

inAlias
A pointer to an alias handle. On return, this handler refers to the newly created alias record.

isDirectory
A pointer to a Boolean value. On input, if the target does not exist, set the value to `true` if the target is a directory or `false` if it is not. (Pass `NULL` if you are not sure whether the target is a directory.) On output, if the target exists, the value is `true` if the target is a directory, `false` if it is not.

Return Value
A result code. For more information, see the Discussion.

Discussion
If the specified target exists, this function creates an alias record for the target and returns `noErr`. If the parent directory exists but the target itself does not exist, this function creates an alias record for the target and returns `fnfErr`. Any other return value indicates that this function did not create an alias record.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Aliases.h`

FSResolveAlias

Returns an `FSRef` to the single most likely target of an alias record.

```
OSErr FSResolveAlias (
   const FSRef *fromFile,
   AliasHandle alias,
   FSRef *target,
   Boolean *wasChanged
);
```

Parameters

`fromFile`

A pointer to the starting point for a relative search. If you pass `NULL` in this parameter, `FSResolveAlias` performs only an absolute search. If you pass a pointer to a valid `FSRef` in the `fromFile` parameter, `FSResolveAlias` performs a relative search for the target, followed by an absolute search only if the relative search fails. If you want to perform an absolute search followed by a relative search, you should use the function `FSMatchAliasBulk` (page 185).

`alias`

A handle to the alias record to be resolved and, if necessary, updated.

`target`

A pointer to an `FSRef`. On successful return, this `FSRef` describes the target of the alias record. This parameter must point to a valid `FSRef` structure.

`wasChanged`

A pointer to a Boolean value indicating, on return, whether the alias record in the *`alias`* parameter was updated because it contained some outdated information about the target. If it updates the alias record, `FSResolveAlias` sets the `wasChanged` parameter to `true`. Otherwise, it sets it to `false`. (`FSResolveAlias` never updates a minimal alias, so it never sets `wasChanged` to `true` when resolving a minimal alias.

Return Value
A result code. When it finds the specified volume and parent directory but fails to find the target file or directory in that location, `FSResolveAlias` returns `fnfErr`. Note that the `FSRef` in the `alias` parameter is not valid in this case.

Discussion
The `FSResolveAlias` function performs a fast search for the target of the alias. If the resolution is successful, `FSResolveAlias` returns (in the *`target`* parameter) the `FSRef` for the target file system object, updates the alias record if necessary, and reports (through the *`wasChanged`* parameter) whether the record was updated. If the target is on an unmounted AppleShare volume, `FSResolveAlias` automatically mounts the volume. If the target is on an unmounted ejectable volume, `FSResolveAlias` asks the user to insert the volume. The `FSResolveAlias` function exits after it finds one acceptable target.

After it identifies a target, FSResolveAlias compares some key information about the target with the information in the alias record. If the information differs, FSResolveAlias updates the record to match the target.

The FSResolveAlias function displays the standard dialogs when it needs input from the user, such as a name and password for mounting a remote volume. The user can cancel the resolution through these dialogs.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
Aliases.h

FSResolveAliasFile

Resolves an alias contained in an alias file.

```
OSErr FSResolveAliasFile (
   FSRef *theRef,
   Boolean resolveAliasChains,
   Boolean *targetIsFolder,
   Boolean *wasAliased
);
```

Parameters

theRef

A pointer to the alias file you plan to open. If the function completes successfully, this FSRef describes to the file or the directory referred to by the alias file.

resolveAliasChains

A Boolean value. Set this parameter to TRUE if you want FSResolveAliasFile to resolve all aliases in a chain (for example, an alias file that refers to an alias file and so on), stopping only when it reaches the target file. Set this parameter to FALSE if you want to resolve only one alias file, even if the target is another alias file.

targetIsFolder

A pointer to a Boolean value. The FSResolveAliasFile function returns TRUE in this parameter if the FSRef in the parameter theRef points to a directory or a volume; otherwise, FSResolveAliasFile returns FALSE in this parameter.

wasAliased

A pointer to a Boolean value. The FSResolveAliasFile function returns TRUE in this parameter if the FSRef in the parameter theRef points to an alias; otherwise, FSResolveAliasFile returns FALSE in this parameter.

Return Value
A result code. When it finds the specified volume and parent directory but fails to find the target file or directory in that location, FSResolveAliasFile returns fnfErr.

Discussion
If your application bypasses the Finder when manipulating documents, it should check for and resolve aliases itself by using the FSResolveAliasFile function.

The FSResolveAliasFile function first checks the catalog file for the file or directory specified in the parameter *theRef* to determine whether it is an alias and whether it is a file or a directory. If the object is not an alias, FSResolveAliasFile leaves *theRef* unchanged, sets the *targetIsFolder* parameter to TRUE for a directory or volume and FALSE for a file, sets *wasAliased* to FALSE, and returns noErr. If the object is an alias, FSResolveAliasFile resolves it, places the target in the parameter *theRef*, and sets the *wasAliased* flag to TRUE.

If FSResolveAliasFile receives an error code while resolving an alias, it leaves the input parameters as they are and exits, returning an error code. FSResolveAliasFile can return any Resource Manager or File Manager errors.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Aliases.h

FSResolveAliasFileWithMountFlags

Resolves an alias contained in an alias file.

```
OSErr FSResolveAliasFileWithMountFlags (
   FSRef *theRef,
   Boolean resolveAliasChains,
   Boolean *targetIsFolder,
   Boolean *wasAliased,
   unsigned long mountFlags
);
```

Parameters

theRef

A pointer to the alias file you plan to open. If the function completes successfully, this FSRef describes the file or the directory referred to by the alias file.

resolveAliasChains

A Boolean value. Set this parameter to TRUE if you want FSResolveAliasFileWithMountFlags to resolve all aliases in a chain (for example, an alias file that refers to an alias file and so on), stopping only when it reaches the target file. Set this parameter to FALSE if you want to resolve only one alias file, even if the target is another alias file.

targetIsFolder

A pointer to a Boolean value. The FSResolveAliasFileWithMountFlags function returns TRUE in this parameter if the FSRef in the parameter theRef points to a directory or a volume; otherwise, FSResolveAliasFileWithMountFlags returns FALSE in this parameter.

wasAliased

A pointer to a Boolean value. The FSResolveAliasFileWithMountFlags function returns TRUE in this parameter if the FSRef in the parameter theRef points to an alias; otherwise, FSResolveAliasFileWithMountFlags returns FALSE in this parameter.

mountFlags

Options controlling how the alias file is resolved. See "Volume Mount Options" (page 220) for a description of the values you can use here. Set this parameter to kResolveAliasFileNoUI to prevent any user interaction, including disk switch alerts, while the alias is being resolved.

Return Value
A result code.

Discussion
The function `FSResolveAliasFileWithMountFlags` is identical to `FSResolveAliasFile` (page 193) with the exception that it provides the *`mountFlags`* parameter, allowing callers additional control over how the alias file is resolved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Aliases.h`

FSResolveAliasWithMountFlags

Returns an `FSRef` to the target of an alias.

```
OSErr FSResolveAliasWithMountFlags (
   const FSRef *fromFile,
   AliasHandle inAlias,
   FSRef *target,
   Boolean *wasChanged,
   unsigned long mountFlags
);
```

Parameters

`fromFile`
A pointer to the starting point for a relative search. If you pass `NULL` in this parameter, `FSResolveAliasWithMountFlags` performs an absolute search. If you pass a pointer to a valid `FSRef` in the `fromFile` parameter, `FSResolveAliasWithMountFlags` performs a relative search for the target, followed by an absolute search only if the relative search fails. If you want to perform an absolute search followed by a relative search, you should use the function `FSMatchAliasBulk` (page 185).

`inAlias`
A handle to the alias record to be resolved and, if necessary, updated.

`target`
A pointer to an `FSRef` structure. On successful return, this `FSRef` refers to the target of the alias record. This parameter must point to a valid `FSRef` structure.

`wasChanged`
A pointer to a Boolean value indicating, on return, whether the alias record to be resolved was updated because it contained some outdated information about the target. If it updates the alias record, `FSResolveAliasWithMountFlags` sets the `wasChanged` parameter to `true`. Otherwise, it sets it to `false`. (`FSResolveAliasWithMountFlags` never updates a minimal alias, so it never sets `wasChanged` to `true` when resolving a minimal alias.

`mountFlags`
Options controlling how the alias is resolved. See "Volume Mount Options" (page 220) for a description of the values you can use here. Set this parameter to `kResolveAliasFileNoUI` to prevent any user interaction while the alias is being resolved.

Return Value
A result code.

Discussion
The function `FSResolveAliasWithMountFlags` is identical to `FSResolveAlias` (page 192) with the exception that it provides the `mountFlags` parameter, allowing callers additional control over how the alias is resolved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Aliases.h`

FSUpdateAlias

Updates an alias record for a specified target.

```
OSErr FSUpdateAlias (
   const FSRef *fromFile,
   const FSRef *target,
   AliasHandle alias,
   Boolean *wasChanged
);
```

Parameters

`fromFile`
A pointer to the starting point for a relative search. You may pass `NULL` if you do not need relative search information in the alias record. The two files or directories specified in the `fromFile` and `target` parameters must reside on the same volume.

`target`
A pointer to the target of the alias record.

`alias`
A handle to the alias record to be updated.

`wasChanged`
A pointer to a Boolean value that, on output, indicates whether the newly constructed alias record is different from the old one. If the new record is exactly the same as the old one, the value is `false`. Otherwise, the value is `true`. Check this parameter to determine whether you need to save an updated record.

Return Value
A result code.

Discussion
This function rebuilds the entire alias record and fills it in as the `FSNewAlias` function would. The `FSUpdateAlias` function always creates a complete alias record. When you use `FSUpdateAlias` to update a minimal alias record, you convert the minimal record to a complete record.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Aliases.h`

GetAliasInfo

Gets information from an alias record without actually resolving the record. (Deprecated in Mac OS X v10.3. Use `FSCopyAliasInfo` (page 181) instead.)

```
OSErr GetAliasInfo (
   AliasHandle alias,
   AliasInfoType index,
   Str63 theString
);
```

Parameters

alias

A handle to the alias record to be read.

index

The kind of information to be retrieved. If the value of `index` is a positive integer, `GetAliasInfo` retrieves the parent directory that has the same hierarchical level above the target as the index parameter (for example, an `index` value of 2 returns the name of the parent directory of the target's parent directory). You can therefore assemble the names of the target and all of its parent directories by making repeated calls to `GetAliasInfo` with incrementing index values, starting with a value of 0. When the value of `index` is greater than the number of levels between the target and the root, `GetAliasInfo` returns an empty string. You can also set the `index` parameter to one of the values described in "Information Type Constants" (page 222).

theString

A string that, on return, holds the requested information.

Return Value

A result code.

Discussion

The `GetAliasInfo` function returns the information stored in the alias record, which might not be current. To ensure that the information is current, you can resolve and update the alias record before calling `GetAliasInfo`.

The `GetAliasInfo` function cannot provide all kinds of information about a minimal alias.

Special Considerations

Use the `FSCopyAliasInfo` (page 181) function instead of `GetAliasInfo`. `GetAliasInfo` does not reliably return information for aliases to items on POSIX file systems. In addition, `GetAliasInfo` does not support unicode names or names longer than 32 bytes. If the name of the alias target is longer than 32 bytes, the name is truncated and the file ID and extension (if any) are appended before the name is returned by `GetAliasInfo`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`Aliases.h`

GetAliasSize

Gets the size of an alias record referenced by a handle.

```
Size GetAliasSize (
   AliasHandle alias
);
```

Parameters

alias

A handle to the alias record from which to get the information.

Return Value

The size of the alias record.

Discussion

The returned size is smaller than the size returned by the function `GetHandleSize` if any custom data is added. This routine is thread safe.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`Aliases.h`

GetAliasSizeFromPtr

Gets the size of an alias record referenced by a pointer.

```
Size GetAliasSizeFromPtr (
   const AliasRecord *alias
);
```

Parameters

alias

A pointer to the alias record from which to get the information.

Return Value

The size of the alias record.

Discussion

This routine is thread safe.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`Aliases.h`

GetAliasUserType

Gets the user type for an alias record referenced by a handle.

```
OSType GetAliasUserType (
   AliasHandle alias
);
```

Parameters

alias

A handle to the alias record from which to get the user type.

Return Value
The user type associated with the alias.

Discussion
This routine is thread safe.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Aliases.h`

GetAliasUserTypeFromPtr

Gets the user type for the alias record referenced by a pointer.

```
OSType GetAliasUserTypeFromPtr (
   const AliasRecord *alias
);
```

Parameters

alias

A pointer to the alias record from which to get the user type.

Return Value
The user type associated with the alias.

Discussion
This routine is thread safe.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Aliases.h`

InvokeAliasFilterUPP

Calls your alias filtering callback function.

```
Boolean InvokeAliasFilterUPP (
   CInfoPBPtr cpbPtr,
   Boolean *quitFlag,
   Ptr myDataPtr,
   AliasFilterUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeAliasFilterUPP`, as the system calls your alias filtering callback for you.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Aliases.h`

IsAliasFile

Determines whether a file system object is an alias file, a data file, or a folder. (Deprecated in Mac OS X v10.4. Use `FSIsAliasFile` (page 183) instead.)

```
OSErr IsAliasFile (
   const FSSpec *fileFSSpec,
   Boolean *aliasFileFlag,
   Boolean *folderFlag
);
```

Parameters

fileFSSpec
A pointer to a file specification structure describing a file.

aliasFileFlag
A pointer to a Boolean variable. On return, a value of `TRUE` indicates that the object specified in the *fileRef* parameter is an alias file. A value of `FALSE` indicates that the object is not an alias file.

folderFlag
A pointer to a Boolean variable. On return, a value of `TRUE` indicates that the object specified in the *fileRef* parameter is a folder. A value of `FALSE` indicates that the object is a file.

Return Value
A result code.

Discussion
This function determines whether a file is an alias file.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

MatchAlias

Identifies a list of possible matches for an alias and passes the list through an optional selection filter. The filter can return more than one possible match. (Deprecated in Mac OS X v10.4. Use `FSMatchAliasBulk` (page 185) instead.)

```
OSErr MatchAlias (
   const FSSpec *fromFile,
   unsigned long rulesMask,
   AliasHandle alias,
   short *aliasCount,
   FSSpecArrayPtr aliasList,
   Boolean *needsUpdate,
   AliasFilterUPP aliasFilter,
   void *yourDataPtr
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. If you do not want `MatchAlias` to perform a relative search, set `fromFile` to `NULL`. If you want `MatchAlias` to perform a relative search, pass a pointer to a file system specification structure that describes the starting point for the search.

rulesMask

A set of rules to guide the resolution. Pass the sum of all of the rules you want to invoke. For a description of the values you can use in this parameter, see "Matching Constants" (page 220).

alias

A handle to the alias record to be resolved.

aliasCount

On input, a pointer to the maximum number of possible matches to return. On output, the actual number of matches returned.

aliasList

A pointer to the array that holds the results of the search, a list of possible candidates.

needsUpdate

A pointer to a Boolean flag that indicates whether the alias record to be resolved needs to be updated.

aliasFilter

An application-defined filter function. The Alias Manager executes this function each time it identifies a possible match and after the search has continued for three seconds without a match. Your filter function returns a Boolean value that determines whether the possible match is discarded (`true`) or added to the list of possible targets (`false`). It can also terminate the search by setting the variable parameter `quitFlag`. See `AliasFilterProcPtr` (page 215) for a description of the filter function.

yourDataPtr

A pointer to data to be passed to the filter function. The `yourDataPtr` parameter can point to any data your application might need in the filter function.

Return Value

A result code.

Discussion

If `MatchAlias` finds the parent directory on the correct volume but does not find the target, it sets the *aliasCount* parameter to 1, puts the file system specification structure for the target in the results list, and returns `fnfErr`. The `FSSpec` structure is valid, although the object it describes does not exist. This information

is intended as a "hint" that lets you explore possible solutions to the resolution failure. You can, for example, use the `FSSpec` structure and the File Manager function `FSpCreate` to create a replacement for a missing file.

After it identifies a target, `MatchAlias` compares some key information about the target with the same information in the record. If the information does not match, `MatchAlias` sets the *`needsUpdate`* flag to `true`. The key information is

- the name of the target
- the directory ID of the target's parent
- the file ID or directory ID of the target
- the name and creation date of the volume on which the target resides

The `MatchAlias` function also sets the *`needsUpdate`* flag to `true` if it identifies a list of possible matches rather than a single match or if `kARMsearchRelFirst` is set in the `rulesMask` parameter but the target is identified through either an absolute search or an exhaustive search. Otherwise, the `MatchAlias` function sets the *`needsUpdate`* flag to `false`. `MatchAlias` always sets the *`needsUpdate`* flag to `false` when resolving an alias created by `NewAliasMinimal`. If you want to update the alias record to reflect the final results of the resolution, call `UpdateAlias`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

MatchAliasNoUI

Identifies a list of possible matches for an alias without any user interaction. (Deprecated in Mac OS X v10.5. Use `FSMatchAliasBulk` (page 185) with the `kARMNoUI` flag instead.)

```
OSErr MatchAliasNoUI (
   const FSSpec *fromFile,
   unsigned long rulesMask,
   AliasHandle alias,
   short *aliasCount,
   FSSpecArrayPtr aliasList,
   Boolean *needsUpdate,
   AliasFilterUPP aliasFilter,
   void *yourDataPtr
);
```

Parameters

`fromFile`

A pointer to the starting point for a relative search. If you do not want `MatchAliasNoUI` to perform a relative search, set `fromFile` to `NULL`. If you want `MatchAliasNoUI` to perform a relative search, pass a pointer to a file system specification structure that describes the starting point for the search.

rulesMask
: A set of rules to guide the resolution. Pass the sum of all of the rules you want to invoke. For a description of the values you can use in this parameter, see "Matching Constants" (page 220).

alias
: A handle to the alias record to be resolved.

aliasCount
: On input, a pointer to the maximum number of possible matches to return. On output, the actual number of matches returned.

aliasList
: A pointer to the array of `FSSpec` structures that holds, on return, the results of the search, a list of possible candidates.

needsUpdate
: A pointer to a Boolean flag that, on return, indicates whether the alias record needs to be updated.

aliasFilter
: An application-defined filter function. The Alias Manager executes this function each time it identifies a possible match and after the search has continued for three seconds without a match. Your filter function returns a Boolean value that determines whether the possible match is discarded (`true`) or added to the list of possible targets (`false`). It can also terminate the search by setting the variable parameter `quitFlag`. See `AliasFilterProcPtr` (page 215) for a description of the filter function.

yourDataPtr
: A pointer to data to be passed to the filter function. The `yourDataPtr` parameter can point to any data your application might need in the filter function.

Return Value
A result code.

Discussion
The `MatchAliasNoUI` function operates in the same way as the `MatchAlias` function; however, it does not present an interface to the user. See the discussion of `MatchAlias` (page 201) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Aliases.h`

NewAlias

Creates a complete alias record. (Deprecated in Mac OS X v10.4. Use `FSNewAlias` (page 188) instead.)

```
OSErr NewAlias (
   const FSSpec *fromFile,
   const FSSpec *target,
   AliasHandle *alias
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. If you do not need relative search information in the alias record, pass a `fromFile` value of `NULL`. If you want `NewAlias` to record relative search information, pass a pointer to a valid `FSSpec` structure in this parameter. The files or directories specified in the `fromFile` and `target` parameters must reside on the same volume.

target

A pointer to an `FSSpec` structure for the target of the alias record.

alias

A pointer to an alias handle. On return, this handle refers to the newly created alias record. If the function fails to create an alias record, it sets *alias* to `NULL`.

Return Value
A result code.

Discussion
The `NewAlias` function creates an alias record that describes the specified target. It allocates the storage, fills in the record, and puts a record handle to that storage in the *alias* parameter. `NewAlias` always records the name and file or directory ID of the target, its creation date, the parent directory name and ID, and the volume name and creation date. It also records the full pathname of the target and a collection of other information relevant to locating the target, verifying the target, and mounting the target's volume, if necessary. You can have `NewAlias` store relative search information as well by supplying a starting point for a relative search.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

NewAliasFilterUPP

Creates a new universal procedure pointer (UPP) to an alias filtering callback function.

```
AliasFilterUPP NewAliasFilterUPP (
   AliasFilterProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your alias filtering callback function. For more information, see `AliasFilterProcPtr` (page 215).

Return Value
On return, a UPP to the alias filtering callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Aliases.h`

NewAliasMinimal

Creates a short alias record quickly. (Deprecated in Mac OS X v10.4. Use `FSNewAliasMinimal` (page 190) instead.)

```
OSErr NewAliasMinimal (
   const FSSpec *target,
   AliasHandle *alias
);
```

Parameters

target
A pointer to the target of the alias record.

alias
A pointer to an alias handle. On return, this handle refers to the newly created alias record. If the function fails to create an alias record, it sets `alias` to `NULL`.

Return Value
A result code.

Discussion
The `NewAliasMinimal` function creates an alias record that contains only the minimum information necessary to describe the target: the target name, the parent directory ID, the volume name and creation date, and the volume mounting information. The `NewAliasMinimal` function uses the standard alias record data structure, but it fills in only parts of the record.

The `ResolveAlias` (page 206) function never updates a minimal alias record.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

NewAliasMinimalFromFullPath

Creates an alias record that contains only the full pathname of the target. (Deprecated in Mac OS X v10.4. Use `FSNewAliasMinimal` (page 190) or `FSNewAliasMinimalUnicode` (page 190) instead.)

```
OSErr NewAliasMinimalFromFullPath (
   short fullPathLength,
   const void *fullPath,
   ConstStr32Param zoneName,
   ConstStr31Param serverName,
   AliasHandle *alias
);
```

Parameters

fullPathLength

The number of characters in the full pathname of the target.

fullPath

A pointer to a buffer that contains the full pathname of the target. The full pathname starts with the name of the volume, includes all of the directory names in the path to the target, and ends with the target name. (For a description of pathnames, see the documentation for the File Manager.)

zoneName

The AppleTalk zone name of the AppleShare volume on which the target resides. Set this parameter to a null string if you do not need it.

serverName

The AppleTalk server name of the AppleShare volume on which the target resides. Set this parameter to a null string if you do not need it.

alias

A pointer to an alias handle. On return, this handle refers to the newly created alias record. If the function fails to create an alias record, it sets `alias` to `NULL`.

Return Value
A result code.

Discussion
The `NewAliasMinimalFromFullPath` function creates an alias record that identifies the target by full pathname. You can call `NewAliasMinimalFromFullPath` to create an alias record for a file that doesn't exist or that resides on an unmounted volume.

The `NewAliasMinimalFromFullPath` function uses the standard alias record data structure, but it fills in only the information provided in the input parameters. You can therefore use `NewAliasMinimalFromFullPath` to create alias records for targets on unmounted volumes.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

ResolveAlias

Identifies the single most likely target of an alias record. (Deprecated in Mac OS X v10.4. Use `FSResolveAlias` (page 192) instead.)

```
OSErr ResolveAlias (
   const FSSpec *fromFile,
   AliasHandle alias,
   FSSpec *target,
   Boolean *wasChanged
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. If you pass a `fromFile` parameter of `NULL`, `ResolveAlias` performs only an absolute search. If you pass a pointer to a valid `FSSpec` structure in the `fromFile` parameter, `ResolveAlias` performs a relative search for the target, followed by an absolute search only if the relative search fails. If you want to perform an absolute search followed by a relative search, you must use the `MatchAlias` function.

alias

A handle to the alias record to be resolved and, if necessary, updated.

target

A pointer to the target of the alias record. This parameter must be a valid `FSSpec` structure.

wasChanged

A pointer to a Boolean value indicating whether the alias record to be resolved was updated because it contained some outdated information about the target. If it updates the alias record, `ResolveAlias` sets the `wasChanged` parameter to `true`. Otherwise, it sets it to `false`. (`ResolveAlias` never updates a minimal alias, so it never sets `wasChanged` to `true` when resolving a minimal alias.

Return Value
A result code.

Discussion
The `ResolveAlias` function performs a fast search for the target of the alias. If the resolution is successful, `ResolveAlias` returns (in the *`target`* parameter) the `FSSpec` structure for the target file system object, updates the alias record if necessary, and reports (through the *`wasChanged`* parameter) whether the record was updated. If the target is on an unmounted AppleShare volume, `ResolveAlias` automatically mounts the volume. If the target is on an unmounted ejectable volume, `ResolveAlias` asks the user to insert the volume. The `ResolveAlias` function exits after it finds one acceptable target.

After it identifies a target, `ResolveAlias` compares some key information about the target with the information in the alias record. (The description of the `MatchAlias` (page 201) function lists the key information.) If the information differs, `ResolveAlias` updates the record to match the target.

When it finds the specified volume and parent directory but fails to find the target file or directory in that location, `ResolveAlias` returns a result code of `fnfErr` and fills in the *`target`* parameter with a complete `FSSpec` structure describing the target (that is, the volume reference number, parent directory ID, and filename or folder name). The `FSSpec` structure is valid, although the object it describes does not exist. This information is intended as a "hint" that lets you explore possible solutions to the resolution failure. You can, for example, pass the `FSSpec` structure to the File Manager function `FSpCreate` to create a replacement for a missing file.

The `ResolveAlias` function displays the standard dialog boxes when it needs input from the user, such as a name and password for mounting a remote volume. The user can cancel the resolution through these dialog boxes.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Aliases.h`

ResolveAliasFile

Resolves an alias contained in an alias file. (Deprecated in Mac OS X v10.4. Use `FSResolveAliasFile` (page 193) instead.)

```
OSErr ResolveAliasFile (
   FSSpec *theSpec,
   Boolean resolveAliasChains,
   Boolean *targetIsFolder,
   Boolean *wasAliased
);
```

Parameters

theSpec

A pointer to the alias file you plan to open. If the function completes successfully, this `FSSpec` refers to the file or the directory that was referred to by the alias file.

resolveAliasChains

A Boolean value. Set this parameter to `TRUE` if you want `ResolveAliasFile` to resolve all aliases in a chain (for example, an alias file that refers to an alias file and so on), stopping only when it reaches the target file. Set this parameter to `FALSE` if you want to resolve only one alias file, even if the target is another alias file.

targetIsFolder

A return parameter only. The `ResolveAliasFile` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to a directory or a volume; otherwise, `ResolveAliasFile` returns `FALSE` in this parameter.

wasAliased

A return parameter only. The `ResolveAliasFile` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to an alias; otherwise, `ResolveAliasFile` returns `FALSE` in this parameter.

Return Value
A result code.

Discussion
If your application bypasses the Finder when manipulating documents, it should check for and resolve aliases itself by using the `ResolveAliasFile` function.

The `ResolveAliasFile` function first checks the catalog file for the file or directory specified in the parameter *theSpec* to determine whether it is an alias and whether it is a file or a directory. If the object is not an alias, `ResolveAliasFile` leaves *theSpec* unchanged, sets the *targetIsFolder* parameter to `TRUE` for a directory or volume and `FALSE` for a file, sets *wasAliased* to `FALSE`, and returns `noErr`. If the object is an alias, `ResolveAliasFile` resolves it, places the target in the parameter *theSpec*, and sets the *wasAliased* flag to `TRUE`.

When `ResolveAliasFile` finds the specified volume and parent directory but fails to find the target file or directory in that location, `ResolveAliasFile` returns a result code of `fnfErr` and fills in the parameter *theSpec* with a complete file system specification structure describing the target (that is, its volume reference number, parent directory ID, and filename or folder name). The file system specification structure is valid,

although the object it describes does not exist. This information is intended as a "hint" that lets you explore possible solutions to the resolution failure. You can, for example, use the file system specification structure to create a replacement for a missing file with the File Manager function `FSpCreate`.

If `ResolveAliasFile` receives an error code while resolving an alias, it leaves the input parameters as they are and exits, returning an error code. `ResolveAliasFile` can return any Resource Manager or File Manager errors.

Special Considerations

Before calling the `ResolveAliasFile` function, you should make sure that it is available by using the `Gestalt` function with the `gestaltAliasMgrAttr` selector.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Aliases.h`

ResolveAliasFileWithMountFlags

Resolves an alias contained in an alias file. (Deprecated in Mac OS X v10.5. Use `FSResolveAliasFileWithMountFlags` (page 194) instead.)

```
OSErr ResolveAliasFileWithMountFlags (
   FSSpec *theSpec,
   Boolean resolveAliasChains,
   Boolean *targetIsFolder,
   Boolean *wasAliased,
   unsigned long mountFlags
);
```

Parameters

`theSpec`

A pointer to the alias file you plan to open. If the function completes successfully, this `FSSpec` refers to the file or the directory that was referred to by the alias file.

`resolveAliasChains`

A Boolean value. Set this parameter to `TRUE` if you want `ResolveAliasFileWithMountFlags` to resolve all aliases in a chain (for example, an alias file that refers to an alias file and so on), stopping only when it reaches the target file. Set this parameter to `FALSE` if you want to resolve only one alias file, even if the target is another alias file.

`targetIsFolder`

A return parameter only. The `ResolveAliasFileWithMountFlags` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to a directory or a volume; otherwise, `ResolveAliasFileWithMountFlags` returns `FALSE` in this parameter.

`wasAliased`

A return parameter only. The `ResolveAliasFileWithMountFlags` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to an alias; otherwise, `ResolveAliasFileWithMountFlags` returns `FALSE` in this parameter.

mountFlags

Options controlling how the alias file is resolved. See "Volume Mount Options" (page 220) for a description of the values you can use here. Set this parameter to `kResolveAliasFileNoUI` to prevent any user interaction while the alias is being resolved.

Return Value
A result code.

Discussion
The function `ResolveAliasFileWithMountFlags` is identical to `ResolveAliasFile` (page 208) with the exception that it provides the *mountFlags* parameter.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Aliases.h`

ResolveAliasFileWithMountFlagsNoUI

Resolves an alias file without any user interaction. (Deprecated in Mac OS X v10.4. Use `FSResolveAliasFileWithMountFlags` (page 194) with the `kResolveAliasFileNoUI` flag instead.)

```
OSErr ResolveAliasFileWithMountFlagsNoUI (
   FSSpec *theSpec,
   Boolean resolveAliasChains,
   Boolean *targetIsFolder,
   Boolean *wasAliased,
   unsigned long mountFlags
);
```

Parameters

theSpec

A pointer to the alias file you plan to open. If the function completes successfully, this `FSSpec` refers to the file or the directory that was referred to by the alias file.

resolveAliasChains

A Boolean value. Set this parameter to `TRUE` if you want `ResolveAliasFileWithMountFlagsNoUI` to resolve all aliases in a chain (for example, an alias file that refers to an alias file and so on), stopping only when it reaches the target file. Set this parameter to `FALSE` if you want to resolve only one alias file, even if the target is another alias file.

targetIsFolder

A return parameter only. The `ResolveAliasFileWithMountFlagsNoUI` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to a directory or a volume; otherwise, `ResolveAliasFileWithMountFlagsNoUI` returns `FALSE` in this parameter.

wasAliased

A return parameter only. The `ResolveAliasFileWithMountFlagsNoUI` function returns `TRUE` in this parameter if the file specification structure in the parameter `theSpec` points to an alias; otherwise, `ResolveAliasFileWithMountFlagsNoUI` returns `FALSE` in this parameter.

mountFlags

Options controlling how the alias file is resolved. See "Volume Mount Options" (page 220) for a description of the values you can use here. Set this parameter to `kResolveAliasFileNoUI` to prevent any user interaction, including disk switch alerts, while the alias is being resolved.

Return Value
A result code.

Discussion
The function `ResolveAliasFileWithMountFlagsNoUI` is identical to `ResolveAliasFile` (page 208) with the exception that it presents no interface to the user.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

ResolveAliasWithMountFlags

Identifies the target of an alias. (Deprecated in Mac OS X v10.4. Use `FSResolveAliasWithMountFlags` (page 195) instead.)

```
OSErr ResolveAliasWithMountFlags (
   const FSSpec *fromFile,
   AliasHandle alias,
   FSSpec *target,
   Boolean *wasChanged,
   unsigned long mountFlags
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. If you pass `NULL` in this parameter, `ResolveAliasWithMountFlags` performs only an absolute search. If you pass a pointer to a valid `FSSpec` structure in the `fromFile` parameter, `ResolveAliasWithMountFlags` performs a relative search for the target, followed by an absolute search only if the relative search fails. If you want to perform an absolute search followed by a relative search, you must use the `MatchAlias` function.

alias

A handle to the alias record to be resolved and, if necessary, updated.

target

A pointer to an `FSSpec` structure. On return, this `FSSpec` identifies the target of the alias record. This parameter must point to a valid `FSSpec` structure.

wasChanged

A pointer to a Boolean value indicating, on return, whether the alias record to be resolved was updated because it contained some outdated information about the target. If it updates the alias record, `ResolveAliasWithMountFlags` sets the `wasChanged` parameter to `true`. Otherwise, it sets it to `false`. (`ResolveAliasWithMountFlags` never updates a minimal alias, so it never sets `wasChanged` to `true` when resolving a minimal alias.

mountFlags
Options controlling how the alias is resolved. See "Volume Mount Options" (page 220) for a description of the values you can use here. Set this parameter to `kResolveAliasFileNoUI` to prevent any user interaction while the alias is being resolved.

Return Value
A result code.

Discussion
The function `ResolveAliasWithMountFlags` is identical to `ResolveAlias` (page 206) with the exception that it provides the `mountFlags` parameter, allowing callers additional control over how the alias is resolved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Aliases.h`

SetAliasUserType

Sets the user type for an alias record referenced by a handle.

```
void SetAliasUserType (
   AliasHandle alias,
   OSType userType
);
```

Parameters
alias
A handle to the alias record for which to set the user type.
userType
The user type associated with the alias.

Discussion
This routine is thread safe.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Aliases.h`

SetAliasUserTypeWithPtr

Sets the user type for the alias record referenced by a pointer.

```
void SetAliasUserTypeWithPtr (
   AliasPtr alias,
   OSType userType
);
```

Parameters

alias

A pointer to the alias record for which to set the user type.

userType

The user type associated with the alias.

Discussion
This routine is thread safe.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Aliases.h`

UpdateAlias

Updates an alias record. (Deprecated in Mac OS X v10.4. Use `FSUpdateAlias` (page 196) instead.)

```
OSErr UpdateAlias (
   const FSSpec *fromFile,
   const FSSpec *target,
   AliasHandle alias,
   Boolean *wasChanged
);
```

Parameters

fromFile

A pointer to the starting point for a relative search. If you do not need relative search information in the record, pass a `fromFile` value of `NULL`. If you want `UpdateAlias` to record relative search information, pass a pointer to a valid `FSSpec` structure in this parameter.

target

A pointer to the target of the alias record.

alias

A handle to the alias record to be updated.

wasChanged

A pointer to a Boolean value indicating whether the newly constructed alias record is exactly the same as the old one. If the new record is the same as the old one, `UpdateAlias` sets the `wasChanged` parameter to `false`. Otherwise, it sets it to `true`. Check this parameter to determine whether you need to save an updated record.

Return Value
A result code.

Discussion
The `UpdateAlias` function rebuilds the entire alias record and fills it in as the `NewAlias` function would.

The `UpdateAlias` function always creates a complete alias record. When you use `UpdateAlias` to update a minimal alias record, you convert the minimal record to a complete record.

Special Considerations

The two files or directories, specified in the `fromFile` and `target` parameters, must reside on the same volume.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Aliases.h`

Callbacks

AliasFilterProcPtr

Defines a pointer to an alias filtering callback function that filters out possible targets identified by the `FSMatchAlias` (page 184) function.

```
typedef Boolean (*AliasFilterProcPtr) (
    CInfoPBPtr cpbPtr,
    Boolean * quitFlag,
    Ptr myDataPtr
);
```

If you name your function `MyAliasFilterCallback`, you would declare it like this:

```
Boolean MyAliasFilterCallback (
    CInfoPBPtr cpbPtr,
    Boolean * quitFlag,
    Ptr myDataPtr
);
```

Parameters

`cpbPtr`

A pointer to a catalog information parameter block. When your function is called, the `cpbPtr` parameter points to the catalog information parameter block of the possible match (returned by the File Manager function `PBGetCatInfo`).

`quitFlag`

On exit, set this to `true` if you want to terminate the search.

`myDataPtr`

A pointer to any customized data that your application passed when it called `FSMatchAlias` (page 184). This parameter allows your filter function to access any data that your application has set up on its own.

Return Value
Your function should return `true` to indicate that the possible match is to be discarded, or `false` to indicate that the possible match is to be added to the list of possible targets.

Discussion
You can write your own filter function to examine possible targets identified by the `FSMatchAlias` function. The `FSMatchAlias` function calls your filter function each time it identifies a possible match.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Aliases.h`

FSAliasFilterProcPtr

Defines a pointer to an alias filtering callback function that filters out possible targets identified by the `FSMatchAliasBulk` (page 185) function.

```
typedef Boolean (*FSAliasFilterProcPtr) (
    FSRef *ref,
    Boolean *quitFlag,
    Ptr myDataPtr
);
```

If you name your function `MyFSAliasFilterCallback`, you would declare it like this:

```
Boolean MyAliasFilterCallback (
    FSRef *ref,
    Boolean *quitFlag,
    Ptr myDataPtr
);
```

Parameters

ref
A pointer to a file system object. When your function is called, the *ref* parameter points to the possible match.

quitFlag
On output, set this Boolean flag to `true` if you want to terminate the search.

myDataPtr
A pointer to any customized data that your application passed when it called `FSMatchAliasBulk` (page 185). This parameter allows your filter function to access any data that your application has set up on its own.

Return Value
Your function should return `true` to indicate that the possible match is to be discarded, or `false` to indicate that the possible match is to be added to the list of possible targets.

Discussion
You can write your own filter function to examine possible targets identified by the `FSMatchAliasBulk` function. The `FSMatchAliasBulk` function calls your filter function each time it identifies a possible match.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Aliases.h`

Data Types

AliasInfoType

Defines the alias record information type used in the index parameter of `GetAliasInfo`.

```
typedef short AliasInfoType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Aliases.h`

AliasFilterUPP

Defines a universal procedure pointer (UPP) to an alias filtering function.

```
typedef AliasFilterProcPtr AliasFilterUPP;
```

Discussion
See `AliasFilterProcPtr` (page 215) for more information on alias filtering functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Aliases.h`

AliasRecord

Defines an alias record.

```
struct AliasRecord {
    OSType userType;
    unsigned short aliasSize;
};
typedef struct AliasRecord              AliasRecord;
typedef AliasRecord *                   AliasPtr;
typedef AliasPtr *                      AliasHandle;
```

Fields

`userType`

A 4-byte field that can contain application-specific data. When an alias record is created, this field contains 0. Your application can use this field for its own purposes.

`aliasSize`

The size, in bytes, assigned to the alias record at the time of its creation or updating. This is the total size of the record, including the `userType` and `aliasSize` fields, as well as the variable-length data that is private to the Alias Manager.

Discussion

The Alias Manager uses alias records to store information that allows it to locate an object in the file system.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Aliases.h`

FSAliasInfo

Defines an information block passed to the `FSCopyAliasInfo` function.

```
struct FSAliasInfo {
    UTCDateTime volumeCreateDate;
    UTCDateTime targetCreateDate;
    OSType fileType;
    OSType fileCreator;
    UInt32 parentDirID;
    UInt32 nodeID;
    UInt16 filesystemID;
    UInt16 signature;
    Boolean volumeIsBootVolume;
    Boolean volumeIsAutomounted;
    Boolean volumeIsEjectable;
    Boolean volumeHasPersistentFileIDs;
    Boolean isDirectory;
};
typedef struct FSAliasInfo FSAliasInfo;
typedef FSAliasInfo * FSAliasInfoPtr;
```

Fields

`volumeCreateDate`

The creation date of the volume on which the alias target resides.

`targetCreateDate`

The creation date of the alias target.

`fileType`
The file type of the target.

`fileCreator`
The creator code of the target.

`parentDirID`
The directory ID of the target's parent directory.

`nodeID`
The ID of the file or directory that is the alias target.

`filesystemID`
The filesystem ID.

`signature`
The volume signature of the volume on which the target resides.

`volumeIsBootVolume`
A Boolean value indicating whether the volume is the boot volume.

`volumeIsAutomounted`
A Boolean value indicating whether the volume is automounted.

`volumeIsEjectable`
A Boolean value indicating whether the volume is ejectable.

`volumeHasPersistentFileIDs`
A Boolean value indicating whether the volume has persistent file ID's.

`isDirectory`
A Boolean value indicating whether the alias target is a directory.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Aliases.h`

Constants

Alias Information Masks

Returned by the `FSCopyAliasInfo` function to indicate which fields of the alias information structure contain valid data.

```
typedef UInt32 FSAliasInfoBitmap;
enum {
    kFSAliasInfoNone = 0x00000000,
    kFSAliasInfoVolumeCreateDate = 0x00000001,
    kFSAliasInfoTargetCreateDate = 0x00000002,
    kFSAliasInfoFinderInfo = 0x00000004,
    kFSAliasInfoIsDirectory = 0x00000008,
    kFSAliasInfoIDs = 0x00000010,
    kFSAliasInfoFSInfo = 0x00000020,
    kFSAliasInfoVolumeFlags = 0x00000040
};
```

Constants

`kFSAliasInfoNone`
None of the alias information is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoVolumeCreateDate`
The volume creation date in the `volumeCreateDate` field is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoTargetCreateDate`
The creation date of the alias target, in the `targetCreateDate` field, is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoFinderInfo`
The file type and creator information, in the `fileType` and `fileCreator` fields, is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoIsDirectory`
The information in the `isDirectory` field is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoIDs`
The parent directory ID and alias target ID, in the `parentDirID` and `nodeID` fields, are valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoFSInfo`
The filesystem ID and signature, in the `filesystemID` and `signature` fields, are valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

`kFSAliasInfoVolumeFlags`
The volume information, in the `volumeIsBootVolume`, `volumeIsAutomounted`, `volumeIsEjectable`, and `volumeHasPersistentFileIDs` fields, is valid.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

Volume Mount Options

Specify how an alias should be resolved.

```
enum {
    kResolveAliasFileNoUI = 0x00000001,
    kResolveAliasTryFileIDFirst = 0x00000002
};
```

Constants

`kResolveAliasFileNoUI`

The Alias Manager should resolve the alias without presenting a user interface.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`kResolveAliasTryFileIDFirst`

The Alias Manager should search for the alias target using file IDs before searching using the path.

Available in Mac OS X v10.2 and later.

Declared in `Aliases.h`.

Discussion

The `FSResolveAliasWithMountFlags` (page 195), `FSResolveAliasFileWithMountFlags` (page 194), `ResolveAliasWithMountFlags` (page 211), `ResolveAliasFileWithMountFlags` (page 209), and `ResolveAliasFileWithMountFlagsNoUI` (page 210) functions take these constants in the `mountFlags` parameter, allowing you to specify how the alias should be resolved.

Matching Constants

Specify the matching criteria for the alias matching functions.

```
enum {
    kARMMountVol = 0x00000001,
    kARMNoUI = 0x00000002,
    kARMMultVols = 0x00000008,
    kARMSearch = 0x00000100,
    kARMSearchMore = 0x00000200,
    kARMSearchRelFirst = 0x00000400,
    kARMTryFileIDFirst = 0x00000800
};
```

Constants

`kARMMountVol`

Automatically try to mount the target's volume if it is not mounted.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`kARMNoUI`

Stop if a search requires user interaction, such as a password dialog box when mounting a remote volume. If user interaction is needed and `kARMNoUI` is in effect, the search fails.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`kARMMultVols`
: Search all mounted volumes. The search begins with the volume on which the target resided when the record was created. When you specify a fast search of all mounted volumes, `MatchAlias` performs a formal fast search only on the volume described in the alias record. On all other volumes it looks for the target by ID or by name in the directory with the specified parent directory ID. When you specify an exhaustive search of multiple volumes, `MatchAlias` performs the same search on all volumes. When resolving an alias record created by `NewAliasMinimalFromFullPath`, `MatchAlias` ignores this flag.

  Available in Mac OS X v10.0 and later.

  Declared in `Aliases.h`.

`kARMSearch`
: Perform a fast search for the alias target. If `kARMSearchRelFirst` is not set, perform an absolute search first, followed by a relative search only if the value of the `fromFile` parameter is not `NULL` and the list of matches is not full.

  Available in Mac OS X v10.0 and later.

  Declared in `Aliases.h`.

`kARMSearchMore`
: Perform an exhaustive search for the alias target. On HFS volumes, the exhaustive search uses the File Manager function `PBCatSearch` to identify candidates with matching creation date, type, and creator. The `PBCatSearch` function is available only on HFS volumes and only on systems running version 7.0 or later. On MFS volumes or HFS volumes that do not support `PBCatSearch`, the exhaustive search makes a series of indexed calls to File Manager functions, using the same search criteria. If you set `kARMSearchMore` and either or both of `kARMSearch` and `kARMSearchRelFirst`, `MatchAlias` performs the fast search first.

  Available in Mac OS X v10.0 and later.

  Declared in `Aliases.h`.

`kARMSearchRelFirst`
: If `kARMSearch` is also set, perform a relative search before the absolute search. (If `kARMSearch` is also set and the target is found through the absolute search, `MatchAlias` sets the `needsUpdate` flag to `true`.) If neither `kARMSearch` nor `kARMSearchMore` is set, perform only a relative search. If `kARMSearch` is not set but `kARMSearchMore` is set, perform a relative search followed by an exhaustive search.

  Available in Mac OS X v10.0 and later.

  Declared in `Aliases.h`.

`kARMTryFileIDFirst`
: Perform a search using the file ID of the target before searching using the path.

  Available in Mac OS X v10.2 and later.

  Declared in `Aliases.h`.

Discussion
The `FSMatchAlias` (page 184), `FSMatchAliasNoUI` (page 187), `MatchAliasNoUI` (page 202) and `MatchAlias` (page 201) functions use these constants to specify the matching criteria by passing a sum of these constants in the *`rulesMask`* parameter. You must specify at least one of the last three parameters: `kARMSearch`, `kARMSearchMore`, and `kARMSearchRelFirst`.

Alias Resource Type

Specifies the file type of an alias resource file.

```
enum {
    rAliasType = 'alis'
};
```

Information Type Constants

The `GetAliasInfo` function uses these constants in the `index` parameter.

```
enum {
    asiZoneName = -3,
    asiServerName = -2,
    asiVolumeName = -1,
    asiAliasName = 0,
    asiParentName = 1
};
```

Constants

`asiZoneName`
If the record represents a target on an AppleShare volume, retrieve the server's zone name. Otherwise, return an empty string.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`asiServerName`
If the record represents a target on an AppleShare volume, retrieve the server name. Otherwise, return an empty string.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`asiVolumeName`
Return the name of the volume on which the target resides.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`asiAliasName`
Return the name of the target.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

`asiParentName`
Return the name of the parent directory of the target of the record. If the target is a volume, return the volume name.

Available in Mac OS X v10.0 and later.

Declared in `Aliases.h`.

Gestalt Constants

You can check for version and feature availability information by using the Alias Manager selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Code Fragment Manager Reference

Framework: CoreServices/CoreServices.h
Declared in CodeFragments.h

Overview

This chapter describes the Code Fragment Manager, the part of the Mac OS that loads fragments into memory and prepares them for execution. A fragment can be an application, an import library, a system extension, or any other block of executable code and its associated data.

The Code Fragment Manager is intended to operate transparently to most applications and other software. You need to use the Code Fragment Manager explicitly only if

- you need to load code modules dynamically during the execution of your application or other software
- you want to unload code modules before the termination of your application
- you want to obtain information about the symbols exported by a fragment

For example, if your application supports dynamic loading of tools, filters, or other software modules contained in fragments, you'll need to use the Code Fragment Manager to load and prepare them for execution.

Carbon supports the Code Fragment Manager.

Functions by Task

Finding Symbols

`CountSymbols` (page 225) Deprecated in Mac OS X v10.5
Determines how many symbols are exported from a specified fragment.

`FindSymbol` (page 226) Deprecated in Mac OS X v10.5
Searches for a specific exported symbol.

`GetIndSymbol` (page 229) Deprecated in Mac OS X v10.5
Gets information about the exported symbols in a fragment.

Loading Fragments

`GetDiskFragment` (page 227) Deprecated in Mac OS X v10.5
Locates and possibly also loads a fragment contained in a file's data fork into your application's context.

`GetMemFragment` (page 229) Deprecated in Mac OS X v10.5
Prepares a memory-based fragment for subsequent execution.

`GetSharedLibrary` (page 231) Deprecated in Mac OS X v10.5
Locates and possibly also loads an import library into your application's context.

Unloading Fragments

`CloseConnection` (page 224) Deprecated in Mac OS X v10.5
Closes a connection to a fragment.

Converting a Bundle Prelocator

`ConvertBundlePreLocator` (page 225) Deprecated in Mac OS X v10.5
Converts a bundle prelocator to a Core Foundation bundle locator.

Functions

CloseConnection

Closes a connection to a fragment. (Deprecated in Mac OS X v10.5.)

```
OSErr CloseConnection (
   CFragConnectionID *connID
);
```

Parameters

connID
A pointer to a connection ID.

Return Value
A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion
The `CloseConnection` function closes the connection to a fragment indicated by the `connID` parameter. `CloseConnection` decrements the count of existing connections to the specified fragment and, if the resulting count is 0, calls the fragment's termination function and releases the memory occupied by the code and data sections of the fragment. If the resulting count is not 0, any per-connection data is released but the code section remains in memory.

When a fragment is unloaded as a result of its final connection having been closed, all libraries that depend on that fragment are also released, provided that their usage counts are also 0.

The Code Fragment Manager automatically closes any connections that remain open at the time `ExitToShell` is called for your application, so you need to call `CloseConnection` only for fragments you wish to unload before your application terminates.

Special Considerations

You can close a connection only to the root of a loading sequence (that is, the fragment whose loading triggered the entire load chain).

Availability
Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

ConvertBundlePreLocator

Converts a bundle prelocator to a Core Foundation bundle locator. (Deprecated in Mac OS X v10.5.)

```
OSErr ConvertBundlePreLocator (
   CFragSystem7LocatorPtr initBlockLocator
);
```

Parameters

`initBlockLocator`
A pointer to a fragment locator structure. On input, the structure contains a System 7 locator. On output, the structure contains a `CFragCFBundleLocator`.

Return Value
A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion
This function can be used by initialization routines.

Availability
Available in Mac OS X 10.1 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CountSymbols

Determines how many symbols are exported from a specified fragment. (Deprecated in Mac OS X v10.5.)

```
OSErr CountSymbols (
   CFragConnectionID connID,
   long *symCount
);
```

Parameters

connID

A connection ID.

symCount

On return, a pointer to the number of exported symbols in the fragment whose connection ID is `connID`. You can use the value returned in `symCount` to index through all the exported symbols in a particular fragment (using the `GetIndSymbol` function).

Return Value

A result code. See "Code Fragment Manager Result Codes" (page 259).

Availability

Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CodeFragments.h`

FindSymbol

Searches for a specific exported symbol. (Deprecated in Mac OS X v10.5.)

```
OSErr FindSymbol (
   CFragConnectionID connID,
   ConstStr255Param symName,
   Ptr *symAddr,
   CFragSymbolClass *symClass
);
```

Parameters

connID

A connection ID.

symName

A symbol name.

symAddr

On return, a pointer to the address of the symbol whose name is `symName`.

symClass

On return, a pointer to the class of the symbol whose name is `symName`. The currently recognized symbol classes are defined by the "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

Return Value

A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion
The `FindSymbol` function searches the code fragment identified by the `connID` parameter for the symbol whose name is specified by the `symName` parameter. If that symbol is found, `FindSymbol` returns the address of the symbol in the `symAddr` parameter and the class of the symbol in the `symClass` parameter.

Because a fragment's code is normally exported through transition vectors to that code, the value `kCodeSymbol` is not returned in the PowerPC environment. You can use the other two constants to distinguish exports that represent code (of class `kTVectSymbol`) from those that represent general data (of class `kDataSymbol`).

Availability
Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

GetDiskFragment

Locates and possibly also loads a fragment contained in a file's data fork into your application's context. (Deprecated in Mac OS X v10.5.)

```
OSErr GetDiskFragment (
   const FSSpec *fileSpec,
   UInt32 offset,
   UInt32 length,
   ConstStr63Param fragName,
   CFragLoadOptions options,
   CFragConnectionID *connID,
   Ptr *mainAddr,
   Str255 errMessage
);
```

Parameters

fileSpec
A pointer to a file system specification that identifies the disk-based fragment to load.

offset
The number of bytes from the beginning of the file's data fork at which the beginning of the fragment is located.

length
The length (in bytes) of the fragment. Specify the constant `kWholeFork` for this parameter if the fragment extends to the end-of-file of the data fork. Specify a nonzero value for the exact length of the fragment.

fragName
An optional name of the fragment. (This information is used primarily to allow you to identify the fragment during debugging.

loadFlags
A flag that specifies the operation to perform on the fragment.The Code Fragment Manager recognizes the constants described in "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

connID

On return, a pointer to the connection ID that identifies the connection to the fragment. You can pass this ID to other Code Fragment Manager functions.

mainAddr

On return, a pointer to the main address of the fragment. The value returned is specific to the fragment itself. Your application can use this parameter for its own purposes.

errMessage

On return, the name of the fragment that could not successfully be loaded. This parameter is meaningful only if the call to `GetDiskFragment` fails.

Return Value

A result code. See "Code Fragment Manager Result Codes" (page 259). The `kFindLib` constant in the `loadFlags` parameter specifies that the Code Fragment Manager search for the specified fragment. If the fragment is already prepared and connected to your application, `GetDiskFragment` returns `fragNoErr`. If the specified fragment is not found, `GetDiskFragment` returns the result code `fragLibNotFound`. If the specified fragment is found but could not be connected to your application, the function returns `fragLibConnErr`.

Discussion

Loading involves finding the specified fragment, reading it into memory (if it is not already in memory), and preparing it for execution. The Code Fragment Manager attempts to resolve all symbols imported by the fragment; to do so may involve loading import libraries.

If the fragment loading fails, the Code Fragment Manager returns an error code. Note, however, that the error encountered is not always in the fragment you asked to load. Rather, the error might have occurred while attempting to load an import library that the fragment you want to load depends on. For this reason, the Code Fragment Manager also returns, in the `errMessage` parameter, the name of the fragment that caused the load to fail. Although fragment names are restricted to 63 characters, the `errMessage` parameter is declared as type `Str255`; doing this allows future versions of the Code Fragment Manager to return a more informative message in the `errMessage` parameter.

Availability

Modified in Carbon. Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Carbon Porting Notes

On Mac OS X, `GetDiskFragment` does not include the folder containing the root fragment (assuming that it is different from the application fragment) in its search path for import libraries. For example, say your application used a special folder to store plugins. If that folder also contained special libraries for those plugins, then calling `GetDiskFragment` to load a plugin would not find those libraries.

The workaround is to make sure that any import libraries you require are in the Code Fragment Manager's search path (such as by designating an application library subfolder in the code fragment resource, or placing the libraries in the application's container). For more details of how the Code Fragment Manager searches for import libraries, see Mac OS Runtime Architectures.

Declared In

`CodeFragments.h`

GetIndSymbol

Gets information about the exported symbols in a fragment. (Deprecated in Mac OS X v10.5.)

```
OSErr GetIndSymbol (
   CFragConnectionID connID,
   long symIndex,
   Str255 symName,
   Ptr *symAddr,
   CFragSymbolClass *symClass
);
```

Parameters

connID

A connection ID.

symIndex

A symbol index. This index is zero-based. That is, the value of this parameter should be between zero and the number of symbols -1 (where the number of symbols is determined by calling the `CountSymbols` (page 225) function).

symName

On return, the name of the indicated symbol.

symAddr

On return, a pointer to the address of the indicated symbol.

symClass

On return, a pointer to the class of the indicated symbol. See "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

Return Value

A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion

If `GetIndSymbol` executes successfully, it returns the symbol's name, starting address, and class in the `symName`, `symAddr`, and `symClass` parameters, respectively. A fragment's exported symbols are retrieved in no predetermined order.

Availability

Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CodeFragments.h`

GetMemFragment

Prepares a memory-based fragment for subsequent execution. (Deprecated in Mac OS X v10.5.)

```
OSErr GetMemFragment (
   void *memAddr,
   UInt32 length,
   ConstStr63Param fragName,
   CFragLoadOptions options,
   CFragConnectionID *connID,
   Ptr *mainAddr,
   Str255 errMessage
);
```

Parameters

memAddr

The address of the fragment.

length

The size, in bytes, of the fragment.

fragName

The name of the fragment. (This information is used primarily to allow you to identify the fragment during debugging.

loadFlags

A flag that specifies the operation to perform on the fragment. The Code Fragment Manager recognizes the constants described in "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

connID

On return, a pointer to the connection ID that identifies the connection to the fragment. You can pass this ID to other Code Fragment Manager functions (for example, `CloseConnection`).

mainAddr

On return, a pointer to the main address of the fragment. The value returned is specific to the fragment itself.

errMessage

On return, the name of the fragment that could not successfully be loaded. This parameter is meaningful only if the call to `GetMemFragment` fails.

Return Value

A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion

The `GetMemFragment` is most useful for handling code that is contained in a resource. You can read the resource data into memory using normal Resource Manager functions (for example, `Get1Resource`) and then call `GetMemFragment` to complete the processing required to prepare it for use (for example, to resolve any imports and execute the fragment's initialization function).

You must lock the resource-based fragment into memory (for example, by calling `HLock`) before calling `GetMemFragment`. You must not unlock the memory until you have closed the connection to the fragment (by calling `CloseConnection`).

Loading involves finding the specified fragment, reading it into memory (if it is not already in memory), and preparing it for execution. The Code Fragment Manager attempts to resolve all symbols imported by the fragment; to do so may involve loading import libraries.

If the fragment loading fails, the Code Fragment Manager returns an error code. Note, however, that the error encountered is not always in the fragment you asked to load. Rather, the error might have occurred while attempting to load an import library that the fragment you want to load depends on. For this reason, the Code Fragment Manager also returns, in the `errMessage` parameter, the name of the fragment that

caused the load to fail. Although fragment names are restricted to 63 characters, the `errMessage` parameter is declared as type `Str255`; doing this allows future versions of the Code Fragment Manager to return a more informative message in the `errMessage` parameter.

Availability
Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

GetSharedLibrary

Locates and possibly also loads an import library into your application's context. (Deprecated in Mac OS X v10.5.)

```
OSErr GetSharedLibrary (
   ConstStr63Param libName,
   CFragArchitecture archType,
   CFragLoadOptions options,
   CFragConnectionID *connID,
   Ptr *mainAddr,
   Str255 errMessage
);
```

Parameters

libName
The name of an import library.

archType
The instruction set architecture of the import library. For the PowerPC architecture, use the constant `kPowerPCArch`. For the 680x0 architecture, use the constant `kMotorola68KArch`.

loadFlags
A flag that specifies the operation to perform on the import library. The Code Fragment Manager recognizes the constants described in "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

connID
On return, a pointer to the connection ID that identifies the connection to the import library. You can pass this ID to other Code Fragment Manager functions.

mainAddr
On return, a pointer to the main address of the import library. The value returned is specific to the import library itself and is not used by the Code Fragment Manager.

errMessage
On return, the name of the fragment that could not successfully be loaded. This parameter is meaningful only if the call to `GetSharedLibrary` fails.

Return Value
A result code. See "Code Fragment Manager Result Codes" (page 259).

Discussion
The `GetSharedLibrary` function locates the import library named by the `libName` parameter and possibly also loads that import library into your application's context. The actions of `GetSharedLibrary` depend on the action flag you pass in the `loadFlags` parameter; pass `kFindLib` to get the connection ID of an existing connection to the specified fragment, `kLoadLib` to load the specified fragment, or `kLoadNewCopy` to load the fragment with a new copy of the fragment's data section.

The `GetSharedLibrary` function does not resolve any unresolved imports in your application. In particular, you cannot use it to resolve any weak imports in your code fragment.

Loading involves finding the specified fragment, reading it into memory (if it is not already in memory), and preparing it for execution. The Code Fragment Manager attempts to resolve all symbols imported by the fragment; to do so may involve loading import libraries.

If the fragment loading fails, the Code Fragment Manager returns an error code. Note, however, that the error encountered is not always in the fragment you asked to load. Rather, the error might have occurred while attempting to load an import library that the fragment you want to load depends on. For this reason, the Code Fragment Manager also returns, in the `errMessage` parameter, the name of the fragment that caused the load to fail. Although fragment names are restricted to 63 characters, the `errMessage` parameter is declared as type `Str255`; doing this allows future versions of the Code Fragment Manager to return a more informative message in the `errMessage` parameter.

Availability
Available in CarbonLib 1.0 and later when Code Fragment Manager 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

Callbacks

CFragInitFunction

Defines a fragment initialization function that is executed by the Code Fragment Manager when the fragment is first loaded into memory and prepared for execution.

```
typedef OSErr (*CFragInitFunction) (
    const CFragInitBlock * initBlock
);
```

If you name your function `MyCFragInitFunction`, you would declare it like this:

```
OSErr MyCFragInitFunction (
    const CFragInitBlock * initBlock
);
```

Parameters
`initBlock`
A pointer to a fragment initialization block specifying information about the fragment.

Return Value
A result code. See "Code Fragment Manager Result Codes" (page 259). Your initialization function should return `noErr` if it executes successfully, and some other result code if it does not. If your initialization function returns any result code other than `noErr`, the entire load fails and the error `fragUserInitProcErr` is returned to the code that requested the root load.

Discussion
A fragment's initialization function is executed immediately before the fragment's main function (if it has one) is executed. The initialization function is passed a pointer to an initialization block, which contains information about the fragment, such as its location and connection ID. See `InitBlock` (page 245) for a description of the fields of the initialization block.

You can use the initialization function to perform any tasks that need to be performed before any of the code or data in the fragment is accessed. For example, you might want to open the fragment's resource fork (if it has one). You can determine the location of the fragment's container from the `FragmentLocator` field of the fragment initialization block whose address is passed to your initialization function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragTermProcedure

Defines a pointer to a fragment termination function that is executed by the Code Fragment Manager when the fragment is unloaded from memory.

```
typedef void (*CFragTermProcedure) (
);
```

If you name your function `MyCFragTermProcedure`, you would declare it like this:

```
void MyCFragTermProcedure ();
```

Discussion
A fragment's termination function is executed immediately before the fragment is unloaded from memory. You can use the termination function to perform any necessary clean-up tasks, such as closing open resource files or disposing of any memory allocated by the fragment.

Note that a termination function is not passed any parameters and does not return any result. You are expected to maintain any information about the fragment (such as file reference numbers of any open files) in its static data area.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

Data Types

CFragCFBundleLocator

```
struct CFragCFBundleLocator {
    CFBundleRef fragmentBundle;
    UInt32 offset;
    UInt32 length;
};
typedef struct CFragCFBundleLocator CFragCFBundleLocator;
```

Fields

`fragmentBundle`

`offset`

`length`

```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

CFragInitBlock

```
typedef CFragSystem7InitBlock CFragInitBlock;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CodeFragments.h

CFragInitBlockPtr

```
typedef CFragSystem7InitBlockPtr CFragInitBlockPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CodeFragments.h

CFragResource

```
struct CFragResource {
    UInt32 reservedA;
    UInt32 reservedB;
    UInt16 reservedC;
    UInt16 version;
    UInt32 reservedD;
    UInt32 reservedE;
    UInt32 reservedF;
    UInt32 reservedG;
    UInt16 reservedH;
    UInt16 memberCount;
    CFragResourceMember firstMember;
};
typedef struct CFragResource CFragResource;
typedef CFragResource * CFragResourcePtr;
typedef CFragResourcePtr * CFragResourceHandle;
```

Fields

`reservedA`
This field is reserved for future use. Set this field to 0.

`reservedB`
This field is reserved for future use. Set this field to 0.

`reservedC`
This field is reserved for future use. Set this field to 0.

`version`

`reservedD`
This field is reserved for future use. Set this field to 0.

`reservedE`
This field is reserved for future use. Set this field to 0.

`reservedF`
This field is reserved for future use. Set this field to 0.

`reservedG`
This field is reserved for future use. Set this field to 0.

`reservedH`
This field is reserved for future use. Set this field to 0.

`memberCount`

`firstMember`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragResourceExtensionHeader

```
struct CFragResourceExtensionHeader {
    UInt16 extensionKind;
    UInt16 extensionSize;
};
typedef struct CFragResourceExtensionHeader CFragResourceExtensionHeader;
typedef CFragResourceExtensionHeader * CFragResourceExtensionHeaderPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragResourceMember

```
struct CFragResourceMember {
    CFragArchitecture architecture;
    UInt16 reservedA;
    UInt8 reservedB;
    UInt8 updateLevel;
    CFragVersionNumber currentVersion;
    CFragVersionNumber oldDefVersion;
    CFragUsage1Union uUsage1;
    CFragUsage2Union uUsage2;
    CFragUsage usage;
    CFragLocatorKind where;
    UInt32 offset;
    UInt32 length;
    CFragWhere1Union uWhere1;
    CFragWhere2Union uWhere2;
    UInt16 extensionCount;
    UInt16 memberSize;
    unsigned char name[16];
};
typedef struct CFragResourceMember CFragResourceMember;
typedef CFragResourceMember * CFragResourceMemberPtr;
```

Fields
`architecture`
`reservedA`
This field is reserved. Set to 0.
`reservedB`
This field is reserved. Set to 0.

`updateLevel`
`currentVersion`
`oldDefVersion`
`uUsage1`
`uUsage2`
`usage`
`where`
`offset`
`length`
`uWhere1`
`uWhere2`
`extensionCount`
Specifies the number of extensions beyond the name.

`memberSize`
Specifies the size in bytes, including all extensions.

`name`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragResourceSearchExtension

```
struct CFragResourceSearchExtension {
    CFragResourceExtensionHeader header;
    OSType libKind;
    unsigned char qualifiers[1];
};
typedef struct CFragResourceSearchExtension CFragResourceSearchExtension;
typedef CFragResourceSearchExtension * CFragResourceSearchExtensionPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragSystem7DiskFlatLocator

Defines a disk location structure.

```
struct CFragSystem7DiskFlatLocator {
    FSSpec * fileSpec;
    UInt32 offset;
    UInt32 length;
};
typedef struct CFragSystem7DiskFlatLocator CFragSystem7DiskFlatLocator;
typedef CFragSystem7DiskFlatLocator DiskFragment;
```

Fields

`fileSpec`
: A pointer to a file specification structure (a data structure of type `FSSpec`) for the data fork of a file. This pointer is valid only while the initialization function is executing. If you need to access the information in the file specification structure at any later time, you must make a copy of that structure.

`offset`
: The offset, in bytes, from the beginning of the file's data fork to the beginning of the fragment.

`length`
: The length, in bytes, of the fragment. If this field contains the value 0, the fragment extends to the end-of-file.

Discussion

For fragments located in the data fork of a file on disk, the `onDisk` field of a fragment location structure contains a disk location structure, which specifies the location of the fragment.

The fields of a fragment initialization block are aligned in memory in accordance with 680x0 alignment conventions.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CodeFragments.h`

CFragSystem7InitBlock

```
struct CFragSystem7InitBlock {
    CFragContextID contextID;
    CFragClosureID closureID;
    CFragConnectionID connectionID;
    CFragSystem7Locator fragLocator;
    StringPtr libName;
    UInt32 reservedA;
};
typedef struct CFragSystem7InitBlock CFragSystem7InitBlock;
typedef CFragSystem7InitBlock * CFragSystem7InitBlock;
typedef CFragSystem7InitBlock CFragInitBlock;
```

Fields

`contextID`
: A context ID.

`closureID`
: A closure ID.

`connectionID`
A connection ID.

`fragLocator`
A fragment location structure, `CFragSystem7Locator` (page 241) that specifies the location of the fragment.

`libName`
A pointer to the name of the fragment being initialized. The name is a Pascal string (a length byte followed by the name itself).

`reservedA`
Reserved for use by Apple Computer.

Discussion
The Code Fragment Manager passes to your fragment's initialization function a pointer to a fragment initialization block, which contains information about the fragment. A fragment initialization block is defined by the `InitBlock` data type.

The fields of a fragment initialization block are aligned in memory in accordance with 680x0 alignment conventions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragSystem7Locator

Defines a fragment location structure.

```
struct CFragSystem7Locator {
    SInt32 where
    union {
        CFragSystem7DiskFlatLocator onDisk;
        CFragSystem7MemoryLocator inMem;
        CFragSystem7SegmentedLocator inSegs;
        CFragCFBundleLocator inBundle;
    } u;
};
typedef struct CFragSystem7Locator CFragSystem7Locator;
typedef CFragSystem7Locator * CFragSystem7LocatorPtr;
typedef CFragSystem7Locator FragmentLocator;
```

Fields
`where`
A selector that determines which member of the following union is relevant. This field can contain one of the constants described in "Load Flag, Symbol Class, and Fragment Locator Constants" (page 252).

`u`
If the `where` field has the value `kOnDiskFlat`, a disk location structure.

Discussion
The `fragLocator` field of an initialization block contains a fragment location structure that provides information about the location of a fragment.

The fields of a fragment initialization block are aligned in memory in accordance with 680x0 alignment conventions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragSystem7MemoryLocator

Defines a memory location structure.

```
struct CFragSystem7MemoryLocator {
    LogicalAddress address;
    UInt32 length;
    Boolean inPlace;
    UInt8 reservedA;
    UInt16 reservedB;
};
typedef struct CFragSystem7MemoryLocator CFragSystem7MemoryLocator;
typedef CFragSystem7MemoryLocator MemFragment;
```

Fields

`address`
: A pointer to the beginning of the fragment in memory.

`length`
: The length, in bytes, of the fragment.

`inPlace`
: A Boolean value that specifies whether the container's data section is instantiated in place (`true`) or elsewhere (`false`).

`reservedA`
: This field is reserved for future use. Set to 0.

`reservedB`
: This field is reserved for future use. Set to 0.

Discussion
For fragments located in memory, the `inMem` field of a fragment location structure contains a memory location structure, which specifies the location of the fragment in memory.

The fields of a fragment initialization block are aligned in memory in accordance with 680x0 alignment conventions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragSystem7SegmentedLocator

Defines a segment location structure.

```
struct CFragSystem7SegmentedLocator {
    FSSpec * fileSpec;
    OSType rsrcType;
    SInt16 rsrcID;
    UInt16 reservedA;
};
typedef struct CFragSystem7SegmentedLocator CFragSystem7SegmentedLocator;
typedef CFragSystem7SegmentedLocator SegmentedFragment;
```

Fields

`fileSpec`
: A pointer to a file specification structure (a data structure of type `FSSpec`) for the resource fork of a file. This pointer is valid only while the initialization function is executing. If you need to access the information in the file specification structure at any later time, you must make a copy of that structure.

`rsrcType`
: The resource type of the resource containing the fragment.

`rsrcID`
: The resource ID of the resource containing the fragment.

`reservedA`
: This field is reserved for future use.

Discussion

For fragments located in the resource fork of a file on disk, the `inSegs` field of a fragment location structure contains a segment location structure, which specifies the location of the fragment.

The fields of a fragment initialization block are aligned in memory in accordance with 680x0 alignment conventions.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CodeFragments.h`

CFragUsage1Union

```
union CFragUsage1Union {
    UInt32 appStackSize;
};
typedef union CFragUsage1Union CFragUsage1Union;
```

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CodeFragments.h`

CFragUsage2Union

```
union CFragUsage2Union {
    SInt16 appSubdirID;
    UInt16 libFlags;
};
typedef union CFragUsage2Union CFragUsage2Union;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragWhere1Union

```
union CFragWhere1Union {
    UInt32 spaceID;
};
typedef union CFragWhere1Union CFragWhere1Union;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

CFragWhere2Union

```
union CFragWhere2Union {
    UInt16 reserved;
};
typedef union CFragWhere2Union CFragWhere2Union;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CodeFragments.h`

ConnectionID

```
typedef CFragConnectionID ConnectionID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

DiskFragment

A CFragSystem7DiskFlatLocator structure.

```
typedef CFragSystem7DiskFlatLocator DiskFragment;
```

Discussion
See CFragSystem7DiskFlatLocator (page 239).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

FragmentLocator

A CFragSystem7Locator structure.

```
typedef CFragSystem7Locator FragmentLocator;
```

Discussion
See CFragSystem7Locator (page 241).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

FragmentLocatorPtr

```
typedef CFragSystem7LocatorPtr FragmentLocatorPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

InitBlock

```
typedef CFragInitBlock InitBlock;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

InitBlockPtr

```
typedef CFragInitBlockPtr InitBlockPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

LoadFlags

```
typedef CFragLoadOptions LoadFlags;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

MemFragment

A `CFragSystem7MemoryLocator` structure.

```
typedef CFragSystem7MemoryLocator MemFragment;
```

Discussion
See `CFragSystem7MemoryLocator` (page 242).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CodeFragments.h

SegmentedFragment

A `CFragSystem7SegmentedLocator` structure.

```
typedef CFragSystem7SegmentedLocator SegmentedFragment;
```

Discussion
See `CFragSystem7SegmentedLocator` (page 243).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CodeFragments.h`

SymClass

```
typedef CFragSymbolClass SymClass;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CodeFragments.h`

Constants

Architecture Constants

```
typedef OSType CFragArchitecture;
enum {
    kPowerPCCFragArch = 'pwpc',
    kMotorola68KCFragArch = 'm68k',
    kAnyCFragArch = 0x3F3F3F3F
};
```

Constants

`kPowerPCCFragArch`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kMotorola68KCFragArch`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kAnyCFragArch`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Code Fragment Kind

```
enum {
    kIsCompleteCFrag = 0,
    kFirstCFragUpdate = 1
};
```

Constants

`kIsCompleteCFrag`

Indicates a base fragment rather than an update.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

`kFirstCFragUpdate`

Indicates the first update, others are numbered starting with 2.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

Current Resource Version

```
enum {
    kCurrCFragResourceVersion = 1
};
```

Default Name Length

```
enum {
    kDefaultCFragNameLen = 16
};
```

File Location

```
#define IsFileLocation CFragHasFileLocation;
```

kCFragGoesToEOF

```
enum {
    kCFragGoesToEOF = 0
};
```

kCFragLibUsageMapPrivatelyMask

```
enum {
    kCFragLibUsageMapPrivatelyMask = 0x0001
};
```

Constants

`kCFragLibUsageMapPrivatelyMask`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

kCFragResourceSearchExtensionKind

```
enum {
    kCFragResourceSearchExtensionKind = 0x30EE
};
```

kCFragResourceType

```
enum {
    kCFragResourceType = 'cfrg',
    kCFragResourceID = 0,
    kCFragLibraryFileType = 'shlb',
    kCFragAllFileTypes = 0xFFFFFFFF
};
```

Constants

`kCFragResourceType`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kCFragResourceID`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kCFragLibraryFileType`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kCFragAllFileTypes`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

kCompiledCFragArch

```
enum {
    kCompiledCFragArch = 'kPowerPCCFragArch'
};
```

Constants

`kCompiledCFragArch`
The value for this constant is `'kPowerPCCFragArch'` if you have defined `TARGET_CPU_PPC`. If you define `TARGET_CPU_X86`, then the value of this constant is `'none'`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

kLoadCFrag

```
enum {
    kLoadCFrag = kReferenceCFrag
};
```

Constants

`kLoadCFrag`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

kPowerPC

```
enum {
    kPowerPC = kPowerPCCFragArch,
    kMotorola68K = kMotorola68KCFragArch
};
```

Constants

`kPowerPC`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kMotorola68K`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

Load Flag, Symbol Class, and Fragment Locator Constants

```
enum {
    kPowerPCArch = kPowerPCCFragArch,
    kMotorola68KArch = kMotorola68KCFragArch,
    kAnyArchType = kAnyCFragArch,
    kNoLibName = 0,
    kNoConnectionID = 0,
    kLoadLib = kLoadCFrag,
    kFindLib = kFindCFrag,
    kNewCFragCopy = kPrivateCFragCopy,
    kLoadNewCopy = kPrivateCFragCopy,
    kUseInPlace = 0x80,
    kCodeSym = kCodeCFragSymbol,
    kDataSym = kDataCFragSymbol,
    kTVectSym = kTVectorCFragSymbol,
    kTOCSym = kTOCCFragSymbol,
    kGlueSym = kGlueCFragSymbol,
    kInMem = kMemoryCFragLocator,
    kOnDiskFlat = kDataForkCFragLocator,
    kOnDiskSegmented = kResourceCFragLocator,
    kIsLib = kImportLibraryCFrag,
    kIsApp = kApplicationCFrag,
    kIsDropIn = kDropInAdditionCFrag,
    kFullLib = kIsCompleteCFrag,
    kUpdateLib = kFirstCFragUpdate,
    kWholeFork = kCFragGoesToEOF,
    kCFMRsrcType = kCFragResourceType,
    kCFMRsrcID = kCFragResourceID,
    kSHLBFileType = kCFragLibraryFileType,
    kUnresolvedSymbolAddress = kUnresolvedCFragSymbolAddress
};
```

Constants

`kPowerPCArch`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kMotorola68KArch`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kAnyArchType`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kNoLibName`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kNoConnectionID`

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kLoadLib`
Specifies that the Code Fragment Manager search for the specified fragment.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kFindLib`
Specifies that the Code Fragment Manager search for the specified fragment and, if it finds it, load it into memory. If the fragment has already been loaded, it is not loaded again. The Code Fragment Manager uses the data-instantiation method specified in the fragment's container (which is either global or per-connection instantiation).

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kNewCFragCopy`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kLoadNewCopy`
Specifies that the Code Fragment Manager load the specified fragment, creating a new copy of any writable data maintained by the fragment. You specify `kLoadNewCopy` to obtain one instance per load of the fragment's data and to override the data-instantiation method specified in the container itself. This is most useful for application extensions (for example, drop-in tools).

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kUseInPlace`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kCodeSym`
Specifies a code symbol.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kDataSym`
Specifies a data symbol.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kTVectSym`
Specifies a transition vector symbol.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kTOCSym`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kGlueSym`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kInMem`
Specifies that the container is in memory. If used in the `where` parameter of a `FragmentLocator` structure, the relevant member of the union is a `CFragSystem7SegmentedLocator` (page 243) structure.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kOnDiskFlat`
Specifies that the container is in a data fork. If used in the `where` parameter of a `FragmentLocator` structure, the relevant member of the union is a `CFragSystem7SegmentedLocator` (page 243) structure.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kOnDiskSegmented`
Specifies that the container is in a resource. If used in the `where` parameter of a `FragmentLocator` structure, the relevant member of the union is a `CFragSystem7SegmentedLocator` (page 243) structure.

Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kIsLib`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kIsApp`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kIsDropIn`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kFullLib`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kUpdateLib`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kWholeFork`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kCFMRsrcType`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kCFMRsrcID`
Available in Mac OS X v10.0 and later.

Declared in `CodeFragments.h`.

`kSHLBFileType`
Available in Mac OS X v10.0 and later.
Declared in `CodeFragments.h`.

`kUnresolvedSymbolAddress`
Available in Mac OS X v10.0 and later.
Declared in `CodeFragments.h`.

Discussion
The load flag constants (`kLoadLib`, `kFindLib`, and `kLoadNewCopy`) are used in the `loadFlags` parameter of the `GetDiskFragment` (page 227), `GetMemFragment` (page 229), and `GetSharedLibrary` (page 231) functions to specify the action taken by those functions.

The symbol class constants (`kCodeSym`, `kDataSym`, and `kTVectSym`) are returned in the `symClass` parameter of the `FindSymbol` (page 226) function to specify the class of the specified symbol.

The fragment locator constants (`kInMem`, `kOnDiskFlat`, and `kOnDiskSegmented`) are used in the where field of the `FragmentLocator` (page 245) structure to indicate which member of the union `u` is relevant.

Load Options

```
typedef OptionBits CFragLoadOptions;
enum {
    kReferenceCFrag = 0x0001,
    kFindCFrag = 0x0002,
    kPrivateCFragCopy = 0x0005
};
```

Constants
`kReferenceCFrag`
Try to use existing copy, increment reference counts.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kFindCFrag`
Try find an existing copy, do not increment reference counts.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kPrivateCFragCopy`
Prepare a new private copy.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Locator Kind

```
typedef UInt8 CFragLocatorKind;
enum {
    kMemoryCFragLocator = 0,
    kDataForkCFragLocator = 1,
    kResourceCFragLocator = 2,
    kNamedFragmentCFragLocator = 4,
    kCFBundleCFragLocator = 5,
    kCFBundlePreCFragLocator = 6
};
```

Constants

`kMemoryCFragLocator`
Indicates the container is in memory.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kDataForkCFragLocator`
Indicates the container is in a file's data fork.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kResourceCFragLocator`
Indicates the container is in a file's resource fork.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kNamedFragmentCFragLocator`
This constant is reserved for future use.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kCFBundleCFragLocator`
Indicates the container is in the executable of a `CFBundle`.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kCFBundlePreCFragLocator`
Indicates it was passed to the initialization routines in lieu of `kCFBundleCFragLocator`
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Symbol Class Constants

```
typedef UInt8 CFragSymbolClass;
enum {
    kCodeCFragSymbol = 0,
    kDataCFragSymbol = 1,
    kTVectorCFragSymbol = 2,
    kTOCCFragSymbol = 3,
    kGlueCFragSymbol = 4
};
```

Constants

`kCodeCFragSymbol`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kDataCFragSymbol`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kTVectorCFragSymbol`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kTOCCFragSymbol`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kGlueCFragSymbol`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Unresolved Symbol Address

```
enum {
    kUnresolvedCFragSymbolAddress = 0
};
```

Constants

`kUnresolvedCFragSymbolAddress`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Usage Constants

```
typedef UInt8 CFragUsage;
enum {
    kImportLibraryCFrag = 0,
    kApplicationCFrag = 1,
    kDropInAdditionCFrag = 2,
    kStubLibraryCFrag = 3,
    kWeakStubLibraryCFrag = 4
};
```

Constants

`kImportLibraryCFrag`
Indicates a standard CFM import library.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kApplicationCFrag`
Indicates a MacOS application.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kDropInAdditionCFrag`
Indicates an application or library private extension/plug-in.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kStubLibraryCFrag`
Indicates an import library used for linking only
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

`kWeakStubLibraryCFrag`
Indicates an import library used for linking only and will be automatically weak linked
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CodeFragments.h`.

Version Number

```
typedef UInt32 CFragVersionNumber;
enum {
    kNullCFragVersion = 0,
    kWildcardCFragVersion = 0xFFFFFFFF
};
```

Constants

`kNullCFragVersion`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

`kWildcardCFragVersion`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CodeFragments.h`.

Result Codes

The most common result codes returned by Code Fragment Manager are listed in the table below. The Code Fragment Manager may also return `paramErr` (-50).

Result Code	Value	Description
`cfragContextIDErr`	-2800	The context ID was not valid. Available in Mac OS X v10.0 and later.
`cfragFirstErrCode`	-2800	The first value in the range of CFM errors. Available in Mac OS X v10.0 and later.
`cfragConnectionIDErr`	-2801	The connection ID was not valid. Available in Mac OS X v10.0 and later.
`cfragNoSymbolErr`	-2802	The specified symbol was not found. Available in Mac OS X v10.0 and later.
`cfragNoSectionErr`	-2803	The specified section was not found. Available in Mac OS X v10.0 and later.
`cfragNoLibraryErr`	-2804	The named library was not found. Available in Mac OS X v10.0 and later.
`cfragDupRegistrationErr`	-2805	The registration name was already in use. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
cfragFragmentFormatErr	-2806	A fragment's container format is unknown. Available in Mac OS X v10.0 and later.
cfragUnresolvedErr	-2807	A fragment had "hard" unresolved imports. Available in Mac OS X v10.0 and later.
cfragNoPositionErr	-2808	The registration insertion point was not found. Available in Mac OS X v10.0 and later.
cfragNoPrivateMemErr	-2809	Out of memory for internal bookkeeping. Available in Mac OS X v10.0 and later.
cfragNoClientMemErr	-2810	Out of memory for fragment mapping or section instances. Available in Mac OS X v10.0 and later.
cfragNoIDsErr	-2811	No more CFM IDs for contexts, connections, etc. Available in Mac OS X v10.0 and later.
cfragInitOrderErr	-2812	Available in Mac OS X v10.0 and later.
cfragImportTooOldErr	-2813	An import library was too old for a client. Available in Mac OS X v10.0 and later.
cfragImportTooNewErr	-2814	An import library was too new for a client. Available in Mac OS X v10.0 and later.
cfragInitLoopErr	-2815	Circularity in required initialization order. Available in Mac OS X v10.0 and later.
cfragInitAtBootErr	-2816	A boot library has an initialization function. (System 7 only) Available in Mac OS X v10.0 and later.
cfragCFMStartupErr	-2818	Internal error during CFM initialization. Available in Mac OS X v10.0 and later.
cfragCFMInternalErr	-2819	An internal inconsistency has been detected. Available in Mac OS X v10.0 and later.
cfragFragmentCorruptErr	-2820	A fragment's container was corrupt (known format). Available in Mac OS X v10.0 and later.
cfragInitFunctionErr	-2821	A fragment's initialization routine returned an error. Available in Mac OS X v10.0 and later.
cfragNoApplicationErr	-2822	No application member found in the cfrg resource. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
cfragArchitectureErr	-2823	A fragment has an unacceptable architecture. Available in Mac OS X v10.0 and later.
cfragFragmentUsageErr	-2824	A semantic error in usage of the fragment. Available in Mac OS X v10.0 and later.
cfragFileSizeErr	-2825	A file was too large to be mapped. Available in Mac OS X v10.0 and later.
cfragNotClosureErr	-2826	The closure ID was actually a connection ID. Available in Mac OS X v10.0 and later.
cfragNoRegistrationErr	-2827	The registration name was not found. Available in Mac OS X v10.0 and later.
cfragContainerIDErr	-2828	The fragment container ID was not valid. Available in Mac OS X v10.0 and later.
cfragClosureIDErr	-2829	The closure ID was not valid. Available in Mac OS X v10.0 and later.
cfragAbortClosureErr	-2830	Used by notification handlers to abort a closure. Available in Mac OS X v10.0 and later.
cfragOutputLengthErr	-2831	An output parameter is too small to hold the value. Available in Mac OS X v10.0 and later.
cfragMapFileErr	-2851	A file could not be mapped. Available in Mac OS X v10.4 and later.
cfragExecFileRefErr	-2854	Bundle does not have valid executable file. Available in Mac OS X v10.4 and later.
cfragStdFolderErr	-2855	Could not find standard CFM folder. Available in Mac OS X v10.4 and later.
cfragRsrcForkErr	-2856	Resource fork could not be opened. Available in Mac OS X v10.4 and later.
cfragCFragRsrcErr	-2857	'cfrg' resource could not be loaded. Available in Mac OS X v10.4 and later.
cfragFirstReservedCode	-2897	Reserved value for internal warnings. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`cfragReservedCode_3`	-2897	Reserved value for internal warnings. Available in Mac OS X v10.0 and later.
`cfragReservedCode_2`	-2898	Reserved value for internal warnings. Available in Mac OS X v10.0 and later.
`cfragLastErrCode`	-2899	The last value in the range of CFM errors. Available in Mac OS X v10.0 and later.
`cfragReservedCode_1`	-2899	Available in Mac OS X v10.0 and later.

Collection Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Collections.h

Overview

The Collection Manager implements an abstract data type that allows you to store multiple pieces of related information. This abstract data type is called a collection object. A collection object, or simply a collection, is an abstract data type that allows you to store information.

A collection is like an array in that it contains a number of individually accessible items. However, a collection offers some advantages over an array:

- A collection allows for a variable number of data items. You can add items to a collection or remove items from a collection during run time, and the Collection Manager automatically resizes the collection.
- A collection allows for variable-size items. Each item in a collection can contain data of any size.

A collection is also similar to a database, in that you can store information and retrieve it using a variety of search mechanisms.

The internal structure of a collection object is private–you must store information in a collection and retrieve information from it by providing a Collection Manager function with a reference to the collection. You use the functions provided by the Collection Manager to

- create and manipulate collection objects
- add information to a collection object
- retrieve information from a collection object
- store a collection object to disk and retrieve a collection object from disk

Carbon fully supports the Collection Manager.

Functions by Task

Adding and Replacing Items in a Collection

`AddCollectionItem` (page 267)
Adds a new item to a collection or to replace an existing item in a collection.

`ReplaceIndexedCollectionItem` (page 295)
Replaces the variable-length data of an item in a collection given the item's index.

Cloning and Copying Collection Objects

`CloneCollection` (page 270)
Clones a collection object—that is, increment its owner count.

`CopyCollection` (page 271)
Creates a copy of an existing collection.

`CountCollectionOwners` (page 272)
Determines the number of existing references to a collection object.

Counting Items in a Collection

`CountCollectionItems` (page 272)
Determines the total number of items in a collection.

`CountTaggedCollectionItems` (page 273)
Obtains the total number of items in a collection that have a specified collection tag.

Creating and Disposing of Collection Objects

`DisposeCollection` (page 274)
Disposes of a collection object.

`NewCollection` (page 291)
Creates a new, empty collection object.

Editing Item Attributes

`SetCollectionItemInfo` (page 299)
Edits the attributes of a specific collection item given the item's collection tag and collection ID.

`SetIndexedCollectionItemInfo` (page 300)
Edits the attributes of a specific collection item given the item's collection index.

Flattening and Unflattening a Collection

`FlattenCollection` (page 275)
Converts a collection object into a stream format suitable for storing and unflattening.

`FlattenPartialCollection` (page 277)
Converts a collection object into a stream format suitable for storage and unflattening.

`UnflattenCollection` (page 301)
Unflattens a collection that was flattened using the `FlattenCollection` or `FlattenPartialCollection` function.

Getting and Setting the Default Attributes for a Collection

`GetCollectionDefaultAttributes` (page 278)
Examines the default attributes of a collection object.

`SetCollectionDefaultAttributes` (page 298)
Alters the default attributes of a collection object.

Getting and Setting the Exception Procedure for a Collection

`GetCollectionExceptionProc` (page 279)
Obtains a pointer to the exception procedure installed in a specified collection.

`SetCollectionExceptionProc` (page 299)
Installs an exception procedure in a collection object.

Getting Information About a Collection Item

`GetCollectionItemInfo` (page 281)
Obtains information about a specific collection item given the item's collection tag and collection ID.

`GetIndexedCollectionItemInfo` (page 285)
Obtains information about a specific collection item given the item's collection index.

`GetTaggedCollectionItemInfo` (page 288)
Obtains information about a specific collection item given the item's collection tag and tag list position.

Getting Information About Collection Tags

`CollectionTagExists` (page 270)
Determines whether any of the items in a specified collection contain a specified collection tag.

`CountCollectionTags` (page 273)
Determines the number of distinct collection tags contained by the items of a specified collection.

`GetIndexedCollectionTag` (page 286)
Examines a specific collection tag contained in a collection.

Reading Collections From Resource Files

`GetNewCollection` (page 287)
Reads a collection in from a collection (`'cltn'`) resource.

Removing Items From a Collection

`EmptyCollection` (page 275)
Removes every item in a collection.

`PurgeCollection` (page 292)
Removes all items in a collection whose attributes match a specified pattern.

`PurgeCollectionTag` (page 293)
Removes all items with a specific collection tag from a collection.

`RemoveCollectionItem` (page 294)
Removes an item from a collection given the item's associated collection tag and collection ID.

`RemoveIndexedCollectionItem` (page 295)
Removes an item from a collection given the item's index.

Retrieving the Variable-Length Data From an Item

`GetCollectionItem` (page 280)
Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and collection ID.

`GetIndexedCollectionItem` (page 283)
Obtains a copy of the variable-length data associated with a collection item given the item's collection index.

`GetTaggedCollectionItem` (page 287)
Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and tag list position.

Working With Macintosh Memory Manager Handles

`AddCollectionItemHdl` (page 268)
Adds a new item to a collection or to replace an existing item in a collection, specifying the item's variable-length data using a handle rather than a pointer and a data size.

`FlattenCollectionToHdl` (page 276)
Flattens a collection into a Macintosh Memory Manager handle.

`GetCollectionItemHdl` (page 281)
Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and collection ID.

`GetIndexedCollectionItemHdl` (page 284)
Copies the variable-length data associated with a collection item into a Macintosh Memory Manager handle, given the item's collection index.

`ReplaceIndexedCollectionItemHdl` (page 297)
Replaces the variable-length data of an item in a collection given the item's collection index, specifying the item's new variable-length data using a handle rather than a pointer and a data size.

`UnflattenCollectionFromHdl` (page 302)
Unflattens a collection that was flattened using the `FlattenCollectionToHdl` utility function.

Working With Universal Procedure Pointers

`NewCollectionExceptionUPP` (page 291)
Creates a new universal procedure pointer (UPP) to an error-handling callback.

`InvokeCollectionExceptionUPP` (page 290)
Calls an error-handling callback.

`DisposeCollectionExceptionUPP` (page 274)
Disposes of a universal procedure pointer (UPP) to an error-handling callback.

`NewCollectionFlattenUPP` (page 292)
Creates a new universal procedure pointer (UPP) to a data-flattening callback.

`InvokeCollectionFlattenUPP` (page 290)
Calls a data-flattening callback.

`DisposeCollectionFlattenUPP` (page 275)
Disposes of a universal procedure pointer (UPP) to a data-flattening callback.

Retaining And Releasing

`RetainCollection` (page 298)
Increments the owner count (the number of existing references) for a collection object.

`GetCollectionRetainCount` (page 283)
Obtains the owner count (the number of existing references) for a collection object.

`ReleaseCollection` (page 294)
Decrements the owner count (the number of existing references) for a collection object.

Functions

AddCollectionItem

Adds a new item to a collection or to replace an existing item in a collection.

```
OSErr AddCollectionItem (
   Collection c,
   CollectionTag tag,
   SInt32 id,
   SInt32 itemSize,
   const void *itemData
);
```

Parameters

c
A reference to the collection you want to add the item to. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag
The collection tag you want to associate with the new item.

id
The collection ID you want to associate with the new item.

itemSize
The size in bytes of the item's variable-length data.

itemData
A pointer to the item's variable-length data.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
The `AddCollectionItem` function adds an item to the collection referenced by the `c` parameter. This new item contains

- the collection tag specified by the `tag` parameter
- the collection ID specified by the `id` parameter
- the attributes specified by the default attributes of the `c` collection
- the variable-length data specified by the `itemSize` and `itemData` parameters

This function copies the information pointed to by the `itemData` parameter into the new item; after calling this function, you may alter this information or free the memory pointed to by this parameter without affecting the collection.

If the `c` collection already contains an item with the same collection tag and collection ID as specified in the `tag` and `id` parameters, this function removes the original item and replaces it with the new one, unless the existing item is locked. If it is locked, this function returns a `collectionItemLockedErr` result code.

The `itemSize` parameter determines how many bytes of information this function copies into the new item. If you specify 0 for this parameter, or provide `NULL` for the `itemData` parameter, this function copies no information into the variable-length data of the new item, or removes the variable-length data if the item already exists.

To lock a collection item, use the functions `SetCollectionItemInfo` (page 299) and `SetIndexedCollectionItemInfo` (page 300).

To replace a collection item using the item's index (rather than the item's tag and ID), use the `ReplaceIndexedCollectionItem` (page 295) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

AddCollectionItemHdl

Adds a new item to a collection or to replace an existing item in a collection, specifying the item's variable-length data using a handle rather than a pointer and a data size.

```
OSErr AddCollectionItemHdl (
   Collection aCollection,
   CollectionTag tag,
   SInt32 id,
   Handle itemData
);
```

Parameters

aCollection

A reference to the collection you want to add the item to. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag you want to associate with the new item.

id

The collection ID you want to associate with the new item.

itemData

A Macintosh Memory Manager handle to the item's variable-length data. This function copies the information referenced by the `itemData` parameter into the new item; after calling this function, you may alter this information or free the memory referenced by this parameter without affecting the collection.

Return Value

A result code. See "Result Codes" (page 313). If the `aCollection` collection already contains an item with the same collection tag and collection ID as specified in the `tag` and `id` parameters, this function removes the variable-length data from the original item and replaces it with the new data, unless the existing item is locked. If it is locked, this function returns a `collectionItemLockedErr` result code.

Discussion

The `AddCollectionItemHdl` function adds an item to the collection referenced by the `aCollection` parameter. This new item contains:

- the collection tag specified by the `tag` parameter
- the collection ID specified by the `id` parameter
- the attributes specified by the default attributes of the aCollection collection
- the variable-length data specified by the `itemData` parameter

To add or replace a collection item using a pointer (rather than a handle) to the item's variable-length data, use the `AddCollectionItem` (page 267) function.

To replace a collection item using the item's collection index (rather than the item's collection tag and collection ID), use the `ReplaceIndexedCollectionItemHdl` (page 297) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

CloneCollection

Clones a collection object—that is, increment its owner count.

```
Collection CloneCollection (
   Collection c
);
```

Parameters

c

A reference to the collection object you want to clone. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value

A reference to the cloned collection. (This result is effectively a copy of the reference you provide in the `c` parameter. See the description of the `Collection` data type.

Discussion

Typically, you use this function to increment a collection object's owner count to represent a new reference to the collection object. For example, if you want two variables in your application to reference a single collection object, you can use this code to maintain the correct owner count:

```
firstReference = NewCollection();
secondReference = CloneCollection(firstReference);
```

Disposing of either reference (using the `DisposeCollection` function) simply decrements the collection's owner count. Disposing of the remaining reference decrements the owner count again and frees the memory associated with the collection.

To decrement the owner count of a collection object, use the `DisposeCollection` (page 274) function. To determine the owner count of an existing collection object, use the `CountCollectionOwners` (page 272) function.

To copy a collection object, use the `CopyCollection` (page 271) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

CollectionTagExists

Determines whether any of the items in a specified collection contain a specified collection tag.

```
Boolean CollectionTagExists (
   Collection c,
   CollectionTag tag
);
```

Parameters

c

A reference to the collection object you want to search for a specific collection tag. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag to search for in the collection.

Return Value
`True` if the `c` collection contains any items that contain the specified tag.

Discussion
For information about data types related to collection tags, see `CollectionTag` (page 306).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

CopyCollection

Creates a copy of an existing collection.

```
Collection CopyCollection (
   Collection srcCollection,
   Collection dstCollection
);
```

Parameters

srcCollection

A reference to the collection object you want to copy. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

dstCollection

A reference to a collection object to contain the copied collection items. You may provide `NULL` for this parameter to request that the Collection Manager create a new collection object to hold the copied information.

Return Value
A reference to the collection object containing the copied information. See the description of the `Collection` data type.

Discussion
The `CopyCollection` function copies all of the information (except the owner count and exception procedure) from the collection object referenced by the `srcCollection` parameter into the collection object referenced by the `dstCollection` parameter.

If you specify `NULL` for the `dstCollection` parameter, this function creates a new collection object to copy the information into. (This function does not return an error code; it returns `NULL` if it cannot create a new collection object.)

To clone a collection object, use the `DisposeCollection` (page 274) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

CountCollectionItems

Determines the total number of items in a collection.

```
SInt32 CountCollectionItems (
   Collection c
);
```

Parameters

c

A reference to the collection object whose items you want to count. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value

The total number of items in the `c` collection.

Discussion

To count the items in a collection that have a specified collection tag, use the `CountTaggedCollectionItems` (page 273) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

CountCollectionOwners

Determines the number of existing references to a collection object.

```
SInt32 CountCollectionOwners (
   Collection c
);
```

Parameters

c

The collection object whose owner count you want to determine. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value

The owner count of the collection object.

Discussion

To increment the owner count of a collection object, use the `CloneCollection` (page 270) function. To decrement the owner count of a collection object, use the `DisposeCollection` (page 274) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

CountCollectionTags

Determines the number of distinct collection tags contained by the items of a specified collection.

```
SInt32 CountCollectionTags (
   Collection c
);
```

Parameters

c

A reference to the collection object whose collection tags you want to count. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value

The number of distinct collection tags contained by the items of the `c` collection.

Discussion

For information about data types related to collection tags, see `CollectionTag` (page 306).

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

CountTaggedCollectionItems

Obtains the total number of items in a collection that have a specified collection tag.

```
SInt32 CountTaggedCollectionItems (
   Collection c,
   CollectionTag tag
);
```

Parameters

c

A reference to the collection object whose items you want to count. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the items you want to count.

Return Value

The total number of items in the `c` collection whose collection tags match the value specified in the `tag` parameter.

Discussion

To count all of the items in a collection, use the `CountCollectionItems` (page 272) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

DisposeCollection

Disposes of a collection object.

```
void DisposeCollection (
   Collection c
);
```

Parameters

c

A reference to the collection object you want to dispose of. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Discussion

The `DisposeCollection` function decrements the owner count of the collection object referenced by the `c` parameter. If the resulting owner count is 0, this function releases the memory occupied by the collection object, and the collection object reference contained in the `c` parameter becomes invalid.

To create a new collection object, use the `NewCollection` (page 291) function.

To increment the owner count of a collection object, use the `CloneCollection` (page 270) function. To determine the owner count of an existing collection object, use the `CountCollectionOwners` (page 272) function

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

DisposeCollectionExceptionUPP

Disposes of a universal procedure pointer (UPP) to an error-handling callback.

```
void DisposeCollectionExceptionUPP (
   CollectionExceptionUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `CollectionExceptionProcPtr` (page 303) for more information.

Availability

Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

DisposeCollectionFlattenUPP

Disposes of a universal procedure pointer (UPP) to a data-flattening callback.

```
void DisposeCollectionFlattenUPP (
   CollectionFlattenUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `CollectionFlattenProcPtr` (page 304) for more information.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

EmptyCollection

Removes every item in a collection.

```
void EmptyCollection (
   Collection c
);
```

Parameters

c

A reference to the collection object you want to empty. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Discussion

This function removes every item in the collection referenced by the `c` parameter. This function provides the fastest mechanism for emptying a collection.

To remove all of the items in a collection whose attributes match a specified pattern, use the `PurgeCollection` (page 292) function.

To remove all of the items in a collection with a specified collection tag, use the `PurgeCollectionTag` (page 293) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

FlattenCollection

Converts a collection object into a stream format suitable for storing and unflattening.

```
OSErr FlattenCollection (
   Collection c,
   CollectionFlattenUPP flattenProc,
   void *refCon
);
```

Parameters

c

A reference to the collection that you want to flatten. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

flattenProc

A pointer to a callback function you provide to process the flattened stream of bytes.

refCon

A pointer to the reference constant that you want the Collection Manager to pass to your callback function each time that it calls the callback function. You can use this parameter as a pointer to a structure containing information your callback function needs to process the blocks of flattened data.

Return Value
A result code. See "Result Codes" (page 313). This function can return any error returned by the callback function.

Discussion
You could, for example, use this function to copy a collection onto the Clipboard so that it could be pasted into another application.

The `FlattenCollection` function flattens into a stream of bytes the collection you specify with the `c` parameter. As this function flattens the collection, it repeatedly calls the callback function you specify using the `flattenProc` parameter. Each time it calls this function, it provides the callback function with a pointer to a block of memory containing flattened data. It continues to call this function until it has flattened the entire collection. Your callback function can process the flattened data in a number of ways: it could copy the flattened data into a handle-based block of memory, it could write the flattened data to disk, and so on.

When flattening the `c` collection, this function includes only the collection items whose persistence attribute is set.

To create a flattened collection that includes only those collection items whose attributes match a specified pattern, use the `FlattenPartialCollection` (page 277) function.

To unflatten a flattened collection, use the `UnflattenCollection` (page 301) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

FlattenCollectionToHdl

Flattens a collection into a Macintosh Memory Manager handle.

```
OSErr FlattenCollectionToHdl (
   Collection aCollection,
   Handle flattened
);
```

Parameters

aCollection

The collection that you want to flatten into a handle. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

flattened

A handle to contain the flattened data. You must provide a valid Macintosh Memory Manager handle in this parameter. You may specify a handle of size 0; this function resizes the handle as necessary to hold the flattened data.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
This function flattens the collection referenced by the `aCollection` parameter into a block of memory referenced by the handle you provide in the `flattened` parameter.

To flatten a collection directly to disk, use the `FlattenCollection` (page 275) function.

To unflatten a collection from a block of memory referenced by a handle, use the `UnflattenCollectionFromHdl` (page 302) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

FlattenPartialCollection

Converts a collection object into a stream format suitable for storage and unflattening.

```
OSErr FlattenPartialCollection (
   Collection c,
   CollectionFlattenUPP flattenProc,
   void *refCon,
   SInt32 whichAttributes,
   SInt32 matchingAttributes
);
```

Parameters

c

The collection that you want to flatten. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

flattenProc

A pointer to a function to write data.

refCon
A reference constant that you want the Collection Manager to pass to your flatten function each time it calls the flatten function. You can use this parameter as a pointer to a structure containing information your callback function needs to process the blocks of flattened data.

whichAttributes
A mask indicating which attributes you want to test.

matchingAttributes
An `SInt32` word containing the attribute values you want to match.

Return Value
A result code. See "Result Codes" (page 313). This function can return any error returned by the callback function.

Discussion
With this function, you can include in the flattened collection only those items whose attributes match a specified pattern.

The `FlattenPartialCollection` function flattens into a stream of bytes the collection you specify with the `c` parameter. It includes only the collection items whose attributes specified by the `whichAttributes` parameter match the values specified by the `matchingAttributes` parameter.

As this function flattens the collection, it repeatedly calls the callback function you specify using the `flattenProc` parameter. Each time it calls this function, it provides the callback function with a pointer to a block of memory containing flattened data. It continues to call this function until it has flattened the entire collection. Your callback function can process the flattened data in a number of ways: it could copy the flattened data into a handle-based block of memory, it could write the flattened data to disk, and so on.

When flattening the c collection, this function includes only the collection items whose persistence attribute is set, regardless of the values you provide in the `whichAttributes` and `matchingAttributes` parameters.

To create a flattened collection that includes every item in a collection, use the `FlattenCollection` (page 275) function.

To unflatten a flattened collection, use the `UnflattenCollection` (page 301) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionDefaultAttributes

Examines the default attributes of a collection object.

```
SInt32 GetCollectionDefaultAttributes (
   Collection c
);
```

Parameters

c

A reference to the collection object whose default attributes you want to determine. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value
An `SInt32` word containing the bit flags that make up the collection's default attributes.

Discussion
To change the attributes of a collection object, use the `SetCollectionDefaultAttributes` (page 298) function.

To examine the attributes of a specific item in a collection, use `GetCollectionItemInfo` (page 281), `GetIndexedCollectionItemInfo` (page 285), and `GetTaggedCollectionItemInfo` (page 288)

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionExceptionProc

Obtains a pointer to the exception procedure installed in a specified collection.

```
CollectionExceptionUPP GetCollectionExceptionProc (
   Collection c
);
```

Parameters

c

A reference to the collection object whose exception procedure you want to determine. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

Return Value
A pointer to the exception procedure installed in the `c` collection object. See the description of the `CollectionExceptionUPP` data type.

Discussion
To install a new exception procedure in a collection object, use the `SetCollectionExceptionProc` (page 299) function.

For more information about exception procedures, see `CollectionExceptionProcPtr` (page 303).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionItem

Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and collection ID.

```
OSErr GetCollectionItem (
   Collection c,
   CollectionTag tag,
   SInt32 id,
   SInt32 *itemSize,
   void *itemData
);
```

Parameters

c

A reference to the collection object containing the item whose data you want to retrieve. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the item whose data you want to retrieve.

id

The collection ID associated with the item whose data you want to retrieve.

itemSize

A pointer to an `SInt32` value indicating the number of bytes of data you want returned in the `itemData` parameter. On return, this value indicates the size in bytes of the variable-length data associated with the specified item. You may specify the constant `dontWantSize` for this parameter to indicate that you want to copy all the specified item's variable-length data and you do not want to determine the size of this data. You may specify a value for the `itemSize` parameter that is greater than the actual number of bytes in the specified item's variable-length data however, this function never returns in the `itemData` parameter more data than contained in the specified item's variable-length data.

itemData

A pointer to a block of memory to contain the item's data. On return, this memory contains a copy of the data associated with the specified item. You may specify the constant `dontWantData` for this parameter if you do not want a copy of the item's data.

Return Value

A result code. See "Result Codes" (page 313).

Discussion

If you do not know the size of the item you want to retrieve, you typically call this function twice. The first time you provide a pointer in the `itemSize` parameter to determine the size of the specified item's data and you specify `dontWantData` for the `itemData` parameter. Then you allocate a memory block large enough to hold a copy of the item's data. Then you call the function a second time. This time you specify the constant `dontWantSize` for the `itemSize` parameter and provide a pointer to the allocated memory block for the `itemData` parameter. The function then copies the data into the allocated block of memory.

To retrieve the data associated with a collection item given its collection index (rather than its collection tag and ID), use the `GetIndexedCollectionItem` (page 283) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionItemHdl

Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and collection ID.

```
OSErr GetCollectionItemHdl (
   Collection aCollection,
   CollectionTag tag,
   SInt32 id,
   Handle itemData
);
```

Parameters

aCollection
A reference to the collection object containing the item whose data you want to retrieve. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag
The collection tag associated with the item whose data you want to retrieve.

id
The collection ID associated with the item whose data you want to retrieve.

itemData
A handle to a block of memory to contain the item's data. On return, this memory contains a copy of the data associated with the specified item. You must provide a valid Macintosh Memory Manager handle for this function to copy the data into.You may specify the constant `dontWantData` for this parameter if you do not want a copy of the item's data.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
You specify a collection object using the `aCollection` parameter and you specify an item in that collection using the `tag` and `id` parameters.

To retrieve the data associated with a collection item into a block of memory referenced by a pointer (rather than a handle), use the `GetCollectionItem` (page 280) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionItemInfo

Obtains information about a specific collection item given the item's collection tag and collection ID.

```
OSErr GetCollectionItemInfo (
   Collection c,
   CollectionTag tag,
   SInt32 id,
   SInt32 *index,
   SInt32 *itemSize,
   SInt32 *attributes
);
```

Parameters

c

A reference to the collection object containing the item you want to obtain information about. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the item you want to obtain information about.

id

The collection ID associated with the item you want to obtain information about.

index

On return, this value represents the collection index of the specified item. You may specify the constant `dontWantIndex` for this parameter if you do not want to determine the specified item's collection index.

itemSize

On return, this value indicates the size in bytes of the variable-length data associated with the specified item. You may specify the constant `dontWantSize` for this parameter to indicate that you do not want to determine the size of this data.

attributes

On return, this value contains a copy of the attributes associated with the specified item. You may specify the constant `dontWantAttributes` for this parameter if you do not want a copy of the item's attributes.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
This function returns information in the `index`, `itemSize`, and `attributes` parameters:

- If you provide a pointer in the `index` parameter, the function uses this parameter to return the collection index of the specified item. Once you have determined an item's collection index, you can use it to specify the item when calling Collection Manager functions, rather than using the item's collection tag and collection ID. Specifying collection items using their collection index, rather than using the item's collection tag and collection ID, generally results in improved performance.
- If you provide a pointer in the `itemSize` parameter, the function uses this parameter to return the size in bytes of the variable-length data associated with the specified collection item.
- If you provide a pointer in the `attributes` parameter, the function uses this parameter to return a copy of the attributes associated with the specified collection item.

To obtain information about a collection item using the collection index to specify the item, use the `GetIndexedCollectionItemInfo` (page 285) function.

To obtain information about a collection item using the tag and `whichItem` parameters to specify the item, use the `GetTaggedCollectionItemInfo` (page 288) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetCollectionRetainCount

Obtains the owner count (the number of existing references) for a collection object.

```
ItemCount GetCollectionRetainCount (
   Collection c
);
```

Parameters

c

Discussion
This function performs the same operation as `CountCollectionOwners` (page 272), but follows the preferred naming conventions for Carbon and Core Foundation functions.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.1 and later.

Declared In
`Collections.h`

GetIndexedCollectionItem

Obtains a copy of the variable-length data associated with a collection item given the item's collection index.

```
OSErr GetIndexedCollectionItem (
   Collection c,
   SInt32 index,
   SInt32 *itemSize,
   void *itemData
);
```

Parameters

c

A reference to the collection object containing the item whose data you want to retrieve. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index associated with the item whose data you want to retrieve.

itemSize

A pointer to an `SInt32` value indicating the number of bytes of data you want returned in the `itemData` parameter. On return, this value indicates the size in bytes of the variable-length data associated with the specified item. You may specify the constant `dontWantSize` for this parameter to indicate that you want to copy all of the specified item's variable-length data and you do not want to determine the size of this data. You may specify a value for the `itemSize` parameter that is greater than the actual number of bytes in the specified item's variable-length data however, this function never returns in the `itemData` parameter more data than contained in the specified item's variable-length data.

itemData

A pointer to a block of memory to contain the item's data. On return, this memory contains a copy of the data associated with the specified item. You may specify the constant `dontWantData` for this parameter if you do not want a copy of the item's data.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
If you do not know the size of the item you want to retrieve, you typically call this function twice. The first time you provide a pointer in the `itemSize` parameter to determine the size of the specified item's data and you specify the constant `dontWantData` for the `itemData` parameter. Then you allocate a memory block large enough to hold a copy of the item's data. Then you call the function a second time. This time you specify the constant `dontWantSize` for the `itemSize` parameter and provide a pointer to the allocated memory block for the `itemData` parameter. The function then copies the data into the allocated block of memory.

To retrieve the data associated with a collection item given its collection tag and ID (rather than its collection index), use the `GetCollectionItem` (page 280) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetIndexedCollectionItemHdl

Copies the variable-length data associated with a collection item into a Macintosh Memory Manager handle, given the item's collection index.

```
OSErr GetIndexedCollectionItemHdl (
   Collection aCollection,
   SInt32 index,
   Handle itemData
);
```

Parameters

aCollection

A reference to the collection object containing the item whose data you want to retrieve. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index associated with the item whose data you want to retrieve.

itemData

A handle to a block of memory to contain the item's data. On return, this memory contains a copy of the data associated with the specified item.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
To retrieve the data associated with a collection item into a block of memory referenced by a pointer (rather than a handle), use the `GetCollectionItem` (page 280) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetIndexedCollectionItemInfo

Obtains information about a specific collection item given the item's collection index.

```
OSErr GetIndexedCollectionItemInfo (
   Collection c,
   SInt32 index,
   CollectionTag *tag,
   SInt32 *id,
   SInt32 *itemSize,
   SInt32 *attributes
);
```

Parameters

c

A reference to the collection object containing the item you want to obtain information about. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index associated with the item you want to obtain information about.

tag

A pointer to a collection tag. On return, the collection tag associated with the specified item. You may specify the constant `dontWantTag` for this parameter if you do not want to determine the specified item's collection tag.

id

A pointer to an `SInt32` value. On return, the collection ID associated with the specified item. You may specify the constant `dontWantId` for this parameter if you do not want to determine the specified item's collection ID.

itemSize

A pointer to an `SInt32` value. On return, this value indicates the size in bytes of the data associated with the specified item. You may specify the constant `dontWantSize` for this parameter if you do not want to determine the specified item's data size.

attributes

A pointer to an `SInt32` value. On return, this value contains a copy of the attributes associated with the specified item. You may specify the constant `dontWantAttributes` for this parameter if you do not want a copy of the item's attributes.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
To obtain information about a collection item using the collection tag and collection ID to specify the item, use the `GetCollectionItemInfo` (page 281) function.

To obtain information about a collection item using the collection tag and tag list position to specify the item, use the `GetTaggedCollectionItemInfo` (page 288) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetIndexedCollectionTag

Examines a specific collection tag contained in a collection.

```
OSErr GetIndexedCollectionTag (
   Collection c,
   SInt32 tagIndex,
   CollectionTag *tag
);
```

Parameters

c

The collection from which to obtain a specific collection tag. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tagIndex

The position of the desired collection tag in the `c` collection's list of distinct collection tags.

tag

A pointer to a collection tag. On return, the collection tag that lies at the specified position in the list of distinct collection tags contained in the `c` collection.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
Each collection object contains a number of distinct collection tags. By sequentially incrementing the value of the `tagIndex` parameter from 1 to the result of the `CountCollectionTags` (page 273) function, you can use this function to determine every collection tag contained in a collection.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetNewCollection

Reads a collection in from a collection (`'cltn'`) resource.

```
Collection GetNewCollection (
   SInt16 collectionID
);
```

Parameters

collectionID

The resource ID associated with the collection resource from which you want to create the new collection object.

Return Value
A reference to the new collection object. If this function does not find a collection resource with the specified resource ID, it returns `NULL` as the function result. See the description of the `Collection` data type.

Discussion
This function searches the current resource file path for a collection (`'cltn'`) resource with the resource ID specified by the `collectionID` parameter. If it finds such a resource, this function creates a new collection object, initializes it with the information stored in the resource, and returns a reference to it as the function result.

You can use the `MemError` and `ResError` functions to check for other errors after calling this function.

For information about collection resources, see 'cltn'.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetTaggedCollectionItem

Obtains a copy of the variable-length data associated with a collection item given the item's collection tag and tag list position.

```
OSErr GetTaggedCollectionItem (
   Collection c,
   CollectionTag tag,
   SInt32 whichItem,
   SInt32 *itemSize,
   void *itemData
);
```

Parameters

c

A reference to the collection object containing the item whose data you want to retrieve. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag
The collection tag associated with the item whose data you want to retrieve.

whichItem
The tag list position associated with the specific item.

itemSize
A pointer to an `SInt32` value indicating the number of bytes of data you want returned in the `itemData` parameter. On return, this value indicates the size in bytes of the variable-length data associated with the specified item. You may specify the constant `dontWantSize` for this parameter to indicate that you want to copy all of the specified item's variable-length data and you do not want to determine the size of this data.

itemData
A pointer to a block of memory to contain the item's data. On return, this memory contains a copy of the data associated with the specified item. You may specify the constant `dontWantData` for this parameter if you do not want a copy of the item's data.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
Remember that a tag list position is the sequential index that determines an item given a specific collection tag. For example:

- A `whichItem` value of 1 indicates the first item with the specified tag.
- A `whichItem` value of 2 indicates the second item with the specified tag.

By sequentially incrementing the whichItem parameter, you can use this function to step through all of the items in a collection without knowing their collection IDs.

If you do not know the size of the item you want to retrieve, you typically call this function twice. The first time you provide a pointer in the `itemSize` parameter to determine the size of the specified item's data and you specify the constant `dontWantData` for the `itemData` parameter. Then you allocate a memory block large enough to hold a copy of the item's data. Then you call the function a second time. This time you specify the constant `dontWantSize` for the `itemSize` parameter and provide a pointer to the allocated memory block for the `itemData` parameter. The function then copies the data into the allocated block of memory.

To retrieve the data associated with a collection item given its collection tag and ID, use the `GetCollectionItem` (page 280) function.

To retrieve the data associated with a collection item given its collection index, use the `GetIndexedCollectionItem` (page 283) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

GetTaggedCollectionItemInfo

Obtains information about a specific collection item given the item's collection tag and tag list position.

```
OSErr GetTaggedCollectionItemInfo (
   Collection c,
   CollectionTag tag,
   SInt32 whichItem,
   SInt32 *id,
   SInt32 *index,
   SInt32 *itemSize,
   SInt32 *attributes
);
```

Parameters

c

A reference to the collection object containing the item you want to obtain information about. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the item you want to obtain information about.

whichItem

The tag list position of the item you want to obtain information about.

id

A pointer to an `SInt32` value. On return, this value represents the collection ID associated with the specified item. You may specify the constant `dontWantId` for this parameter if you do not want to determine the specified item's collection ID.

index

A pointer to an `SInt32` value. On return, this value represents the collection index of the specified item. You may specify the constant `dontWantIndex` for this parameter if you do not want to determine the specified item's collection index.

itemSize

A pointer to an `SInt32` value. On return, this value indicates the size in bytes of the data associated with the specified item. You may specify the constant `dontWantSize` for this parameter if you do not want to determine the specified item's data size.

attributes

A pointer. On return, this value contains a copy of the attributes associated with the specified item. You may specify the constant `dontWantAttributes` for this parameter if you do not want a copy of the item's attributes.

Return Value

A result code. See "Result Codes" (page 313).

Discussion

Remember that a collection tag and a tag list position uniquely identify a collection item. The tag list position indicates where the collection item would lie in a list made up of all the collection items with the same collection tag. For example:

- A `whichItem` value of 1 indicates the first item with the specified tag.
- A `whichItem` value of 2 indicates the second item with the specified tag.

By sequentially incrementing the `whichItem` parameter, you can use this function to step through all of the items in a collection that share a collection tag without knowing their collection IDs.

To obtain information about a collection item using the collection tag and collection ID to specify the item, use the `GetCollectionItemInfo` (page 281) function.

To obtain information about a collection item using the collection index to specify the item, use the `GetIndexedCollectionItemInfo` (page 285) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

InvokeCollectionExceptionUPP

Calls an error-handling callback.

```
OSErr InvokeCollectionExceptionUPP (
   Collection c,
   OSErr status,
   CollectionExceptionUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeCollectionExceptionUPP`, as the system calls your error-handling callback function for you. See the callback `CollectionExceptionProcPtr` (page 303) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

InvokeCollectionFlattenUPP

Calls a data-flattening callback.

```
OSErr InvokeCollectionFlattenUPP (
   SInt32 size,
   void *data,
   void *refCon,
   CollectionFlattenUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeCollectionFlattenUPP`, as the system calls your data-flattening callback function for you. See the callback `CollectionFlattenProcPtr` (page 304) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

NewCollection

Creates a new, empty collection object.

```
Collection NewCollection (
   void
);
```

Return Value
A reference to the newly created collection object. The new collection contains no items and has an owner count of 1. The `NewCollection` function does not return an error code; it returns `NULL` if it cannot create a new collection object. See the description of the `Collection` data type.

Discussion
The `NewCollection` function allocates memory for a new collection object, initializes it, and returns a reference to it.

To create a copy of an existing collection object, use the `CopyCollection` (page 271) function.

Special Considerations

You are responsible for disposing of collection objects that you create with this function when you no longer need them. To dispose of a collection object, use the `DisposeCollection` (page 274) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

NewCollectionExceptionUPP

Creates a new universal procedure pointer (UPP) to an error-handling callback.

```
CollectionExceptionUPP NewCollectionExceptionUPP (
   CollectionExceptionProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your error-handling callback.

Return Value
On return, a UPP to the error-handling callback. See the description of the `CollectionExceptionUPP` data type.

Discussion
See the callback `CollectionExceptionProcPtr` (page 303) for more information.

Availability
Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

NewCollectionFlattenUPP

Creates a new universal procedure pointer (UPP) to a data-flattening callback.

```
CollectionFlattenUPP NewCollectionFlattenUPP (
   CollectionFlattenProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your data-flattening callback.

Return Value
On return, a UPP to the data-flattening callback. See the description of the `CollectionFlattenUPP` data type.

Discussion
See the callback `CollectionFlattenProcPtr` (page 304) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

PurgeCollection

Removes all items in a collection whose attributes match a specified pattern.

```
void PurgeCollection (
   Collection c,
   SInt32 whichAttributes,
   SInt32 matchingAttributes
);
```

Parameters

c
A reference to the collection object containing the items you want to remove. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

whichAttributes
A mask indicating which attributes you want to test. You should set the bits of the parameter that correspond to the attributes you want to test.

matchingAttributes
An `SInt32` word containing the values of the attributes you want to match.

Discussion
The `PurgeCollection` function removes from the c collection any items whose attributes match the criteria you specify in the `whichAttributes` and `matchingAttributes` parameters.

This function compares the specified attributes of each item in the c collection with the corresponding attributes in the `matchingAttributes` parameter. If the values of all the specified attributes match, the function removes the item. To avoid purging locked items, you should clear the lock attribute in the `whichAttributes` and `matchingAttributes` parameters.

To remove all of the items in a collection with a specified collection tag, use the `PurgeCollectionTag` (page 293) function.

To remove every item in a collection, use the `EmptyCollection` (page 275) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

PurgeCollectionTag

Removes all items with a specific collection tag from a collection.

```
void PurgeCollectionTag (
   Collection c,
   CollectionTag tag
);
```

Parameters

c

A reference to the collection object containing the items you want to remove. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the items to remove.

Discussion
The `PurgeCollectionTag` function removes from the `c` collection all items whose collection tag matches the value of the `tag` parameter. This function removes locked and unlocked items.

To remove all of the items in a collection whose attributes match a specified pattern, use the `PurgeCollection` (page 292) function.

To remove every item in a collection, use the `EmptyCollection` (page 275) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

ReleaseCollection

Decrements the owner count (the number of existing references) for a collection object.

```
OSStatus ReleaseCollection (
   Collection c
);
```

Parameters

c

Return Value

A result code. See "Result Codes" (page 313).

Discussion

This function performs the same operation as `DisposeCollection` (page 274), but follows the preferred naming conventions for Carbon and Core Foundation functions.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.1 and later.

Declared In

`Collections.h`

RemoveCollectionItem

Removes an item from a collection given the item's associated collection tag and collection ID.

```
OSErr RemoveCollectionItem (
   Collection c,
   CollectionTag tag,
   SInt32 id
);
```

Parameters

c

A reference to the collection object from which you want to remove the item. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the item you want to remove.

id

The collection ID associated with the item you want to remove.

Return Value

A result code. See "Result Codes" (page 313). If the `c` collection does not contain an item whose collection tag and collection ID match the values in the `tag` and `id` parameters, this function returns a `collectionItemNotFoundErr` result code.

Discussion

The `RemoveCollectionItem` function removes the item specified by the `tag` and `id` parameters from the collection referenced by the `c` parameter. This function removes the specified item even if its lock attribute is set.

To remove a collection item using the item's index (rather than the item's tag and ID), use the `RemoveIndexedCollectionItem` (page 295) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

RemoveIndexedCollectionItem

Removes an item from a collection given the item's index.

```
OSErr RemoveIndexedCollectionItem (
   Collection c,
   SInt32 index
);
```

Parameters

c

A reference to the collection object from which you want to remove the item. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index of the item you want to remove.

Return Value
A result code. See "Result Codes" (page 313). If the `c` collection does not contain an item whose collection index matches the values in the `index` parameter, this function returns a collectionIndexRangeErr result code.

Discussion
The `RemoveIndexedCollectionItem` function removes the item specified by the `index` parameter from the collection referenced by the `c` parameter. This function removes the specified item even if its lock attribute is set.

To remove a collection item using the item's tag and ID (rather than the item's index), use the `RemoveCollectionItem` (page 294) function.

To replace an item in a collection, use the function `ReplaceIndexedCollectionItem` (page 295).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

ReplaceIndexedCollectionItem

Replaces the variable-length data of an item in a collection given the item's index.

```
OSErr ReplaceIndexedCollectionItem (
   Collection c,
   SInt32 index,
   SInt32 itemSize,
   const void *itemData
);
```

Parameters

c

A reference to the collection containing the item you want to replace. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index associated with the item to replace.

itemSize

The item's size. The `itemSize` parameter determines how many bytes of information this function copies into the new item. If you specify 0 for this parameter, or provide `NULL` for the `itemData` parameter, this function copies no information into the variable-length data of the new item, or removes the variable-length data if the item already exists.

itemData

A pointer to the item's data. This function copies the information pointed to by the `itemData` parameter into the new item; after calling this function, you may alter this information or free the memory pointed to by this parameter without affecting the collection.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
You specify which item to replace using the `index` parameter. If the c collection does not contain an item whose collection index matches the value of the `index` parameter, this function returns a `collectionIndexRangeErr` result code.

If the c collection does contain an item with the specified index, this function replaces that item with a new item (if the existing item is not locked—if it is, this function returns a `collectionItemLockedErr` result code). The new item contains

- the same collection tag as the original item
- the same collection ID as the original item
- the same attributes as the original item
- the variable-length data specified by the `itemSize` and `itemData` parameters

To lock a collection item, use the functions `SetCollectionItemInfo` (page 299) and `SetIndexedCollectionItemInfo` (page 300).

To replace a collection item using the item's tag and ID (rather than the item's index), use the `AddCollectionItem` (page 267) function.

To remove an item from a collection, use the functions `RemoveCollectionItem` (page 294), `RemoveIndexedCollectionItem` (page 295), `PurgeCollection` (page 292), `PurgeCollectionTag` (page 293), and `EmptyCollection` (page 275).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

ReplaceIndexedCollectionItemHdl

Replaces the variable-length data of an item in a collection given the item's collection index, specifying the item's new variable-length data using a handle rather than a pointer and a data size.

```
OSErr ReplaceIndexedCollectionItemHdl (
   Collection aCollection,
   SInt32 index,
   Handle itemData
);
```

Parameters

aCollection

A reference to the collection containing the item you want to replace. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index associated with the item you want to replace.

itemData

A Macintosh Memory Manager handle to the new variable-length data. This function copies the information referenced by the `itemData` parameter into the collection item; after calling this function, you may alter this information or free the memory referenced by this parameter without affecting the collection.

Return Value
A result code. See "Result Codes" (page 313). If the `aCollection` collection does not contain an item whose collection index matches the value of the `index` parameter, this function returns a `collectionIndexRangeErr` result code.

Discussion
If the `aCollection` collection does contain an item with the specified index, this function replaces the data in that item with new data (if the existing item is not locked—if it is, this function returns a `collectionItemLockedErr` result code). The resulting item contains

- the same collection tag as the original item
- the same collection ID as the original item
- the same attributes as the original item
- the variable-length data specified by the `itemData` parameter

To replace a collection item using a pointer (rather than a handle) to the item's variable-length data, use the `ReplaceIndexedCollectionItem` (page 295) function.

To replace a collection item using the item's collection tag and collection ID (rather than the item's collection index), use the `AddCollectionItemHdl` (page 268) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

RetainCollection

Increments the owner count (the number of existing references) for a collection object.

```
OSStatus RetainCollection (
   Collection c
);
```

Parameters

c

Return Value
A result code. See "Result Codes" (page 313).

Discussion
This function performs the same operation as `CloneCollection` (page 270), but follows the preferred naming conventions for Carbon and Core Foundation functions.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.1 and later.

Declared In
`Collections.h`

SetCollectionDefaultAttributes

Alters the default attributes of a collection object.

```
void SetCollectionDefaultAttributes (
   Collection c,
   SInt32 whichAttributes,
   SInt32 newAttributes
);
```

Parameters

c

A reference to the collection object whose default attributes you want to alter. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

whichAttributes

A mask indicating which bit flags in the c collection's default attributes you want to alter. For every bit in the `whichAttributes` parameter, this function takes one of two actions:

- If the bit is set, this function copies the value of the corresponding bit from the `newAttributes` parameter into the corresponding bit of the default attributes of the c collection.
- If the bit is not set, the corresponding bit of the c collection's default attributes remains unchanged.

newAttributes
The new values for the bit flags.

Discussion
To examine the attributes of a collection object, use the `GetCollectionDefaultAttributes` (page 278) function.

To change the attributes of a specific item in a collection, use the functions `SetCollectionItemInfo` (page 299) and `SetIndexedCollectionItemInfo` (page 300).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

SetCollectionExceptionProc

Installs an exception procedure in a collection object.

```
void SetCollectionExceptionProc (
   Collection c,
   CollectionExceptionUPP exceptionProc
);
```

Parameters

c
A reference to the collection object whose exception procedure you want to change. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

exceptionProc
A pointer to the new exception procedure.

Discussion
The `SetCollectionExceptionProc` function copies the function pointer from the `exceptionProc` parameter into the collection object referenced by the `c` parameter.

To obtain a pointer to an existing exception procedure in a collection object, use the `GetCollectionExceptionProc` (page 279) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

SetCollectionItemInfo

Edits the attributes of a specific collection item given the item's collection tag and collection ID.

```
OSErr SetCollectionItemInfo (
   Collection c,
   CollectionTag tag,
   SInt32 id,
   SInt32 whichAttributes,
   SInt32 newAttributes
);
```

Parameters

c

A reference to the collection object containing the item whose attributes you want to edit. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

tag

The collection tag associated with the item whose attributes you want to edit.

id

The collection ID associated with the item whose attributes you want to edit.

whichAttributes

A mask indicating which attributes you want to edit.

newAttributes

An `SInt32` word containing the new settings for the attributes.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
This function copies bit values from the `newAttributes` parameter to the attributes associated with the specified item.

This function uses the `whichAttributes` parameter to determine which bits to copy. For every bit in the `whichAttributes` parameter, this function takes one of two actions:

- If the bit is set, this function copies the value of the corresponding bit from the `newAttributes` parameter into the corresponding bit of the attributes associated with the specified item.
- If the bit is not set, the corresponding bit of the specified item's attributes remains unchanged.

The `whichAttributes` parameter allows you to change the values of specific bits in the specified item's attributes without affecting the values of other bits.

To obtain information about a collection item using the collection index to specify the item, use the `SetIndexedCollectionItemInfo` (page 300) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

SetIndexedCollectionItemInfo

Edits the attributes of a specific collection item given the item's collection index.

```
OSErr SetIndexedCollectionItemInfo (
   Collection c,
   SInt32 index,
   SInt32 whichAttributes,
   SInt32 newAttributes
);
```

Parameters

c

A reference to the collection object containing the item whose attributes you want to edit. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

index

The collection index of the item whose attributes you want to edit.

whichAttributes

A mask indicating which attributes you want to edit.

newAttributes

An `SInt32` word containing the new settings for the attributes.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
The `SetIndexedCollectionItemInfo` function copies bit values from the `newAttributes` parameter to the attributes associated with the specified item.

This function uses the `whichAttributes` parameter to determine which bits to copy. For every bit in the `whichAttributes` parameter, this function takes one of two actions:

- If the bit is set, this function copies the value of the corresponding bit from the `newAttributes` parameter into the corresponding bit of the attributes associated with the specified item.
- If the bit is not set, the corresponding bit of the specified item's attributes remains unchanged.

The `whichAttributes` parameter allows you to change the values of specific bits in the specified item's attributes without affecting the values of other bits.

To edit the attributes of collection item using the collection tag and collection ID (rather than the collection index) to specify the item, use the `SetCollectionItemInfo` (page 299) function.

To examine the attributes of a collection item, use the functions `GetCollectionItemInfo` (page 281), `GetIndexedCollectionItemInfo` (page 285), and `GetTaggedCollectionItemInfo` (page 288).

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

UnflattenCollection

Unflattens a collection that was flattened using the `FlattenCollection` or `FlattenPartialCollection` function.

```
OSErr UnflattenCollection (
   Collection c,
   CollectionFlattenUPP flattenProc,
   void *refCon
);
```

Parameters

c

A reference to the collection object you want to create from the flattened data. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

flattenProc

A pointer to a function to read in flattened data.

refCon

A reference constant that you want the Collection Manager to pass to your callback function each time it calls the callback function. You can use this parameter as a pointer to a structure containing information your callback function needs when reading the blocks of flattened data.

Return Value

A result code. See "Result Codes" (page 313). This function can return any error returned by the callback function.

Discussion

The `UnflattenCollection` function unflattens a stream of bytes into the collection object you specify with the `c` parameter.

As this function unflattens the collection, it repeatedly calls the callback function you specify using the `flattenProc` parameter. Each time it calls this function, it provides the callback function with a pointer to a block of memory and a requested size. The callback function is responsible for reading the next set of bytes from the flattened byte stream and copying the data into the block of memory.

The Collection Manager continues to call your callback function, requesting more of the flattened stream of bytes each time, until it has unflattened the entire collection. Your callback function can read the flattened data from any source you choose: it could read the flattened data from a handle-based block of memory, it could read the flattened data from disk, and so on.

To create a flattened collection that includes only those collection items whose attributes match a specified pattern, use the `FlattenPartialCollection` (page 277) function.

To create a flattened collection that includes every item in a collection, use the `FlattenCollection` (page 275) function.

Availability

Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`Collections.h`

UnflattenCollectionFromHdl

Unflattens a collection that was flattened using the `FlattenCollectionToHdl` utility function.

```
OSErr UnflattenCollectionFromHdl (
   Collection aCollection,
   Handle flattened
);
```

Parameters

aCollection

A reference to a collection object in which to store the unflattened information. The behavior of this function is undefined if you do not provide a reference to a valid collection object.

flattened

A handle to the data that was previously flattened. You must provide a valid Macintosh Memory Manager handle in this parameter.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
To unflatten a collection directly from disk, use the `UnflattenCollection` (page 301) function.

To flatten a collection to a block of memory referenced by a handle, use the `FlattenCollectionToHdl` (page 276) function.

Availability
Available in CarbonLib 1.0 and later when Collections 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`Collections.h`

Callbacks

CollectionExceptionProcPtr

Defines a pointer to an error handling callback function that handles errors that occur when operating on a collection object.

```
typedef OSErr (*CollectionExceptionProcPtr) (  Collection c,  OSErr status );
```

If you name your function `MyCollectionExceptionProc`, you would declare it like this:

```
OSErr MyCollectionExceptionProc (
    Collection c,
    OSErr status
);
```

Parameters

c

A reference to the collection object for which the error occurred.

status

The result code associated with the error that occurred.

Return Value
A result code. See "Result Codes" (page 313).

Discussion
You create this function to install in a collection object using the `SetCollectionExceptionProc` (page 299) function. Subsequently, whenever the Collection Manager is operating on that collection object and an error occurs, the Collection Manager calls this function, sending it a reference to the collection for which the error occurred and the result code associated with the error. You can use this information to handle the error appropriately for your application.

You can use an exception procedure to respond to an error in a number of ways:

- You can change the error from one result code to another by returning as the function result the new result code.
- You can handle the error and return the `noErr` error code, which indicates that the Collection Manager should return control to the place in your application that generated the error, as if no error had occurred.
- You can use the ANSI C functions `setjmp` and `longjmp` to jump out of the exception procedure into code to handle the error.

To install an exception procedure in a collection object, use the `SetCollectionExceptionProc` (page 299) function.

To obtain a pointer to an existing exception procedure in a collection object, use the `GetCollectionExceptionProc` (page 279) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Collections.h`

CollectionFlattenProcPtr

Defines a pointer to a flattening callback function that reads or writes flattened collection data.

```
typedef OSErr (*CollectionFlattenProcPtr)
(
    SInt32 size,
    void * data,
    void * refCon
);
```

If you name your function `MyCollectionFlattenProc`, you would declare it like this:

```
OSErr MyCollectionFlattenProc (
    SInt32 size,
    void * data,
    void * refCon
);
```

Parameters

size

The size of the block of flattened data to read or write.Your function should read or copy the requested number of bytes of flattened data into the block of memory pointed to by the `data` parameter.

data

A pointer to the block of flattened data. When flattening, this pointer points to the data your callback function should write. When unflattening, your callback function should read flattened data into the memory pointed to by this parameter.

refCon

A value you provide to the `FlattenCollection` function or `UnflattenCollection` function that the Collection Manager passes on to your callback function. You can use this parameter as a pointer to a structure containing relevant state information you need when reading or writing the flattened data.

Return Value

A result code. See "Result Codes" (page 313). If the execution of this function results in any fatal error, you should return the error code back to the Collection Manager as the function result. If the function executes successfully, you should return the `noErr` error code as the function result.

Discussion

You create this function to pass to the `FlattenCollection` (page 275), `FlattenPartialCollection` (page 277), and `UnflattenCollection` (page 301) functions when flattening or unflattening a collection.

As the Collection Manager is flattening a collection, it repeatedly calls this callback function to process sequential blocks of flattened data. Each time it calls this function, it provides a pointer to the current block of flattened data in the `data` parameter and the size of the current block in the `size` parameter. You can process this data in a number of ways: appending it to a handle-based block of memory, writing it to disk, and so on.

When unflattening a collection, the Collection Manager repeatedly calls this function to obtain blocks of flattened data.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Collections.h`

Data Types

Collection

Defines defines a reference to an opaque type that your compiler can type-check.

```
typedef struct OpaqueCollection * Collection;
```

Discussion

The Collection Manager provides you with access to a collection object through a `Collection` reference. The `Collection` type defines a reference type that your compiler can type-check; it does not define a pointer to a publicly defined data structure. The contents of the collection object are private; you must use the Collection Manager functions to manipulate collection objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Collections.h`

CollectionExceptionUPP

Defines a universal procedure pointer to an error-handling callback.

```
typedef CollectionExceptionProcPtr CollectionExceptionUPP;
```

Discussion
For more information, see the description of the `CollectionExceptionProcPtr` (page 303) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Collections.h`

CollectionFlattenUPP

Defines a universal procedure pointer to a data-flattening callback.

```
typedef CollectionFlattenProcPtr CollectionFlattenUPP;
```

Discussion
For more information, see the description of the `CollectionFlattenProcPtr` (page 304)callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Collections.h`

CollectionTag

Defines a data type for a collection tag.

```
typedef FourCharCode CollectionTag;
```

Discussion
Each item in a collection is uniquely identified by its collection tag and its collection ID. The collection tag is a four-character identifier, similar to the identifiers used for resources.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Collections.h`

Constants

Attribute Bit Masks

Used to test or set a particular collection item attribute.

```
enum {
    kCollectionUser0Mask = 1L << kCollectionUser0Bit,
    kCollectionUser1Mask = 1L << kCollectionUser1Bit,
    kCollectionUser2Mask = 1L << kCollectionUser2Bit,
    kCollectionUser3Mask = 1L << kCollectionUser3Bit,
    kCollectionUser4Mask = 1L << kCollectionUser4Bit,
    kCollectionUser5Mask = 1L << kCollectionUser5Bit,
    kCollectionUser6Mask = 1L << kCollectionUser6Bit,
    kCollectionUser7Mask = 1L << kCollectionUser7Bit,
    kCollectionUser8Mask = 1L << kCollectionUser8Bit,
    kCollectionUser9Mask = 1L << kCollectionUser9Bit,
    kCollectionUser10Mask = 1L << kCollectionUser10Bit,
    kCollectionUser11Mask = 1L << kCollectionUser11Bit,
    kCollectionUser12Mask = 1L << kCollectionUser12Bit,
    kCollectionUser13Mask = 1L << kCollectionUser13Bit,
    kCollectionUser14Mask = 1L << kCollectionUser14Bit,
    kCollectionUser15Mask = 1L << kCollectionUser15Bit,
    kCollectionReserved0Mask = 1L << kCollectionReserved0Bit,
    kCollectionReserved1Mask = 1L << kCollectionReserved1Bit,
    kCollectionReserved2Mask = 1L << kCollectionReserved2Bit,
    kCollectionReserved3Mask = 1L << kCollectionReserved3Bit,
    kCollectionReserved4Mask = 1L << kCollectionReserved4Bit,
    kCollectionReserved5Mask = 1L << kCollectionReserved5Bit,
    kCollectionReserved6Mask = 1L << kCollectionReserved6Bit,
    kCollectionReserved7Mask = 1L << kCollectionReserved7Bit,
    kCollectionReserved8Mask = 1L << kCollectionReserved8Bit,
    kCollectionReserved9Mask = 1L << kCollectionReserved9Bit,
    kCollectionReserved10Mask = 1L << kCollectionReserved10Bit,
    kCollectionReserved11Mask = 1L << kCollectionReserved11Bit,
    kCollectionReserved12Mask = 1L << kCollectionReserved12Bit,
    kCollectionReserved13Mask = 1L << kCollectionReserved13Bit,
    kCollectionPersistenceMask = 1L << kCollectionPersistenceBit,
    kCollectionLockMask = 1L << kCollectionLockBit
};
```

Discussion

Using the attribute bit numbers, the Collection Manager provides convenient attribute masks for each of the attributes. You can use these attribute masks when testing or setting a particular collection item attribute.

Attribute Bit Masks (Old)

Used to test or set a particular collection item attribute.

```
enum {
    collectionUser0Mask = kCollectionUser0Mask,
    collectionUser1Mask = kCollectionUser1Mask,
    collectionUser2Mask = kCollectionUser2Mask,
    collectionUser3Mask = kCollectionUser3Mask,
    collectionUser4Mask = kCollectionUser4Mask,
    collectionUser5Mask = kCollectionUser5Mask,
    collectionUser6Mask = kCollectionUser6Mask,
    collectionUser7Mask = kCollectionUser7Mask,
    collectionUser8Mask = kCollectionUser8Mask,
    collectionUser9Mask = kCollectionUser9Mask,
    collectionUser10Mask = kCollectionUser10Mask,
    collectionUser11Mask = kCollectionUser11Mask,
    collectionUser12Mask = kCollectionUser12Mask,
    collectionUser13Mask = kCollectionUser13Mask,
    collectionUser14Mask = kCollectionUser14Mask,
    collectionUser15Mask = kCollectionUser15Mask,
    collectionReserved0Mask = kCollectionReserved0Mask,
    collectionReserved1Mask = kCollectionReserved1Mask,
    collectionReserved2Mask = kCollectionReserved2Mask,
    collectionReserved3Mask = kCollectionReserved3Mask,
    collectionReserved4Mask = kCollectionReserved4Mask,
    collectionReserved5Mask = kCollectionReserved5Mask,
    collectionReserved6Mask = kCollectionReserved6Mask,
    collectionReserved7Mask = kCollectionReserved7Mask,
    collectionReserved8Mask = kCollectionReserved8Mask,
    collectionReserved9Mask = kCollectionReserved9Mask,
    collectionReserved10Mask = kCollectionReserved10Mask,
    collectionReserved11Mask = kCollectionReserved11Mask,
    collectionReserved12Mask = kCollectionReserved12Mask,
    collectionReserved13Mask = kCollectionReserved13Mask,
    collectionPersistenceMask = kCollectionPersistenceMask,
    collectionLockMask = kCollectionLockMask
};
```

Discussion
Using the attribute bit numbers, the Collection Manager provides convenient attribute masks for each of the attributes. You can use these attribute masks when testing or setting a particular collection item attribute.

Attribute Bit Numbers

Provides constant names for each of the bits in a collection item attributes.

```
enum {
    kCollectionUser0Bit = 0,
    kCollectionUser1Bit = 1,
    kCollectionUser2Bit = 2,
    kCollectionUser3Bit = 3,
    kCollectionUser4Bit = 4,
    kCollectionUser5Bit = 5,
    kCollectionUser6Bit = 6,
    kCollectionUser7Bit = 7,
    kCollectionUser8Bit = 8,
    kCollectionUser9Bit = 9,
    kCollectionUser10Bit = 10,
    kCollectionUser11Bit = 11,
    kCollectionUser12Bit = 12,
    kCollectionUser13Bit = 13,
    kCollectionUser14Bit = 14,
    kCollectionUser15Bit = 15,
    kCollectionReserved0Bit = 16,
    kCollectionReserved1Bit = 17,
    kCollectionReserved2Bit = 18,
    kCollectionReserved3Bit = 19,
    kCollectionReserved4Bit = 20,
    kCollectionReserved5Bit = 21,
    kCollectionReserved6Bit = 22,
    kCollectionReserved7Bit = 23,
    kCollectionReserved8Bit = 24,
    kCollectionReserved9Bit = 25,
    kCollectionReserved10Bit = 26,
    kCollectionReserved11Bit = 27,
    kCollectionReserved12Bit = 28,
    kCollectionReserved13Bit = 29,
    kCollectionPersistenceBit = 30,
    kCollectionLockBit = 31
};
```

Discussion
The Collection Manager provides the attribute bit numbers enumeration to provide constant names for each of the bits in a collection item's attributes.

The lower 16 bits of the attributes property of a collection item represent the user-defined attributes. You can use these attributes for any purpose suitable to your application.

The upper 16 bits are reserved for use by Apple Computer, Inc. Currently, the 2 high bits are defined: bit 30 represents the persistence attribute and bit 31 represents the lock attribute.

Attribute Bit Numbers (Old)

Provides constant names for each of the bits in a collection item attributes.

```
enum {
    collectionUser0Bit = kCollectionUser0Bit,
    collectionUser1Bit = kCollectionUser1Bit,
    collectionUser2Bit = kCollectionUser2Bit,
    collectionUser3Bit = kCollectionUser3Bit,
    collectionUser4Bit = kCollectionUser4Bit,
    collectionUser5Bit = kCollectionUser5Bit,
    collectionUser6Bit = kCollectionUser6Bit,
    collectionUser7Bit = kCollectionUser7Bit,
    collectionUser8Bit = kCollectionUser8Bit,
    collectionUser9Bit = kCollectionUser9Bit,
    collectionUser10Bit = kCollectionUser10Bit,
    collectionUser11Bit = kCollectionUser11Bit,
    collectionUser12Bit = kCollectionUser12Bit,
    collectionUser13Bit = kCollectionUser13Bit,
    collectionUser14Bit = kCollectionUser14Bit,
    collectionUser15Bit = kCollectionUser15Bit,
    collectionReserved0Bit = kCollectionReserved0Bit,
    collectionReserved1Bit = kCollectionReserved1Bit,
    collectionReserved2Bit = kCollectionReserved2Bit,
    collectionReserved3Bit = kCollectionReserved3Bit,
    collectionReserved4Bit = kCollectionReserved4Bit,
    collectionReserved5Bit = kCollectionReserved5Bit,
    collectionReserved6Bit = kCollectionReserved6Bit,
    collectionReserved7Bit = kCollectionReserved7Bit,
    collectionReserved8Bit = kCollectionReserved8Bit,
    collectionReserved9Bit = kCollectionReserved9Bit,
    collectionReserved10Bit = kCollectionReserved10Bit,
    collectionReserved11Bit = kCollectionReserved11Bit,
    collectionReserved12Bit = kCollectionReserved12Bit,
    collectionReserved13Bit = kCollectionReserved13Bit,
    collectionPersistenceBit = kCollectionPersistenceBit,
    collectionLockBit = kCollectionLockBit
};
```

Discussion
The Collection Manager provides the attribute bit numbers enumeration to provide constant names for each of the bits in a collection item's attributes.

The lower 16 bits of the attributes property of a collection item represent the user-defined attributes. You can use these attributes for any purpose suitable to your application.

The upper 16 bits are reserved for use by Apple Computer, Inc. Currently, the 2 high bits are defined: bit 30 represents the persistence attribute and bit 31 represents the lock attribute.

Attributes Masks

Used to specify attributes for any of the attribute-related Collection Manager functions.

```
enum {
    kCollectionNoAttributes = 0x00000000,
    kCollectionAllAttributes = 0xFFFFFFFF,
    kCollectionUserAttributes = 0x0000FFFF,
    kCollectionDefaultAttributes = 0x40000000
};
```

Constants

`kCollectionNoAttributes`

Specifies a mask in which all collection attributes are clear. You might use this constant when clearing all the attributes of an item or when testing whether all of an item's attributes are clear.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`kCollectionAllAttributes`

Specifies a mask in which all collection attributes are set. You might use this constant as a mask to indicate that you want to edit or test every attribute of an item, or you might use it to set every attribute of an item.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`kCollectionUserAttributes`

Specifies a mask in which the user attributes are set and the reserved attributes are clear. You might use this constant as a mask to indicate that you want to edit or test only the user attributes of an item, or you might use it to set every user attribute of an item.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`kCollectionDefaultAttributes`

Specifies a mask in which the persistent attribute is set and all other attributes are clear. You might use this constant when testing to see if an item's attributes have been edited.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

Discussion

The Collection Manager provides four convenient attributes masks that you can use when specifying attributes for any of the attribute-related Collection Manager functions. You can also use the attribute bit masks as masks for individual attributes.

Attributes Masks (Old)

Used to specify attributes for any of the attribute-related Collection Manager functions.

```
enum {
    noCollectionAttributes = kCollectionNoAttributes,
    allCollectionAttributes = kCollectionAllAttributes,
    userCollectionAttributes = kCollectionUserAttributes,
    defaultCollectionAttributes = kCollectionDefaultAttributes
};
```

Constants

`noCollectionAttributes`
Specifies a mask in which all collection attributes are clear. You might use this constant when clearing all the attributes of an item or when testing whether all of an item's attributes are clear.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`allCollectionAttributes`
Specifies a mask in which all collection attributes are set. You might use this constant as a mask to indicate that you want to edit or test every attribute of an item, or you might use it to set every attribute of an item.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`userCollectionAttributes`
Specifies a mask in which the user attributes are set and the reserved attributes are clear. You might use this constant as a mask to indicate that you want to edit or test only the user attributes of an item, or you might use it to set every user attribute of an item.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

`defaultCollectionAttributes`
Specifies a mask in which the persistent attribute is set and all other attributes are clear. You might use this constant when testing to see if an item's attributes have been edited.

Available in Mac OS X v10.0 and later.

Declared in `Collections.h`.

Discussion
The Collection Manager provides four convenient attributes masks that you can use when specifying attributes for any of the attribute-related Collection Manager functions. You can also use the attribute bit masks as masks for individual attributes.

Optional Return Value Constants

Used to specify that you do not want a particular piece of information.

```
enum {
    kCollectionDontWantTag = 0,
    kCollectionDontWantId = 0,
    kCollectionDontWantSize = 0,
    kCollectionDontWantAttributes = 0,
    kCollectionDontWantIndex = 0,
    kCollectionDontWantData = 0
};
```

Discussion
Many of the Collection Manager functions return multiple pieces of information. For most of these functions, you can specify that you do not want a specific piece of information to be returned by specifying `NULL` for the corresponding parameter when calling the function.

The Collection Manager provides the optional return value constants to make your code easier to read when specifying that you are not interested in obtaining certain types of information. You can use these enumeration constants in place of the more generic constant `NULL` when specifying that you do not want to receive certain optional return values from a function.

Optional Return Value Constants (Old)

Used to specify that you do not want a particular piece of information.

```
enum {
    dontWantTag = kCollectionDontWantTag,
    dontWantId = kCollectionDontWantId,
    dontWantSize = kCollectionDontWantSize,
    dontWantAttributes = kCollectionDontWantAttributes,
    dontWantIndex = kCollectionDontWantIndex,
    dontWantData = kCollectionDontWantData
};
```

Discussion
Many of the Collection Manager functions return multiple pieces of information. For most of these functions, you can specify that you do not want a specific piece of information to be returned by specifying `NULL` for the corresponding parameter when calling the function.

The Collection Manager provides the optional return value constants to make your code easier to read when specifying that you are not interested in obtaining certain types of information. You can use these enumeration constants in place of the more generic constant `NULL` when specifying that you do not want to receive certain optional return values from a function.

Result Codes

The most common result codes returned by the Collection Manager are listed in the table below.

Result Code	Value	Description
`collectionItemLockedErr`	-5750	Available in Mac OS X v10.0 and later.
`collectionItemNotFoundErr`	-5751	Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`collectionIndexRangeErr`	-5752	Available in Mac OS X v10.0 and later.
`collectionVersionErr`	-5753	Available in Mac OS X v10.0 and later.

Component Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Components.h

Overview

You can use the Component Manager to allow your application to find and utilize various software objects (components) at run time. You can create your own components, and you can use the Component Manager to help manage your components. A component is a piece of code that provides a defined set of services to one or more clients. Applications, system extensions, as well as other components can use the services of a component. A component typically provides a specific type of service to its clients. For example, a component might provide image compression or image decompression capabilities; an application could call such a component, providing the image to compress, and the component could perform the desired operation and return the compressed image to the application. The Component Manager provides access to components and manages them by, for example, keeping track of the currently available components and routing requests to the appropriate component.

Functions by Task

Finding Components

`CountComponents` (page 330)
Returns the number of registered components that meet the selection criteria specified by your application.

`FindNextComponent` (page 333)
Returns the component identifier for the next registered component that meets the selection criteria specified by your application.

`GetComponentListModSeed` (page 338)
Allows your application to determine if the list of registered components has changed.

`GetComponentTypeModSeed` (page 341)

`ResolveComponentAlias` (page 353)

Opening and Closing Components

`OpenAComponent` (page 345)

`OpenADefaultComponent` (page 346)

`OpenComponent` (page 346)
Opens a connection to the component with the component identifier specified by your application.

`OpenDefaultComponent` (page 348)
Opens a connection to a registered component of the component type and subtype specified by your application.

`CloseComponent` (page 327)
Terminates your application's connection to a component.

Getting Information About Components

`GetComponentIconSuite` (page 334)
Returns a handle to a component's icon suite to your application.

`GetComponentInfo` (page 335)
Returns to your application the registration information for a component.

`GetComponentPublicIndString` (page 338)

`GetComponentPublicResource` (page 339)

`GetComponentPublicResourceList` (page 339)

`ComponentFunctionImplemented` (page 328) Deprecated in Mac OS X v10.5
Allows your application to determine whether a component supports a specified request.

`GetComponentVersion` (page 341) Deprecated in Mac OS X v10.5
Returns the version number of a component to your application.

Retrieving Component Errors

`GetComponentInstanceError` (page 336)
Returns to your application the last error generated by a specific connection to a component.

Calling Component Functions

`CallComponentOpen` (page 324)

`CallComponentClose` (page 320)

CallComponentCanDo (page 320)

CallComponentVersion (page 326)

CallComponentRegister (page 324)

CallComponentTarget (page 325)

CallComponentUnregister (page 325)

CallComponentDispatch (page 321)

CallComponentGetMPWorkFunction (page 323)

CallComponentGetPublicResource (page 324)

Accessing the Thread Safety Mode

CSSetComponentsThreadMode (page 331)
: Sets whether or not using thread-unsafe components is allowed in the current thread.

CSGetComponentsThreadMode (page 330)
: Indicates whether using thread-unsafe components is allowed in the current thread.

Creating and Managing Universal Procedure Pointers

NewComponentRoutineUPP (page 344)
: Creates a new universal procedure pointer (UPP) to a component routine callback function.

InvokeComponentRoutineUPP (page 342)
: Calls your component routine callback function

DisposeComponentRoutineUPP (page 333)
: Disposes of the universal procedure pointer (UPP) to a component routine callback function.

NewComponentFunctionUPP (page 343)

DisposeComponentFunctionUPP (page 332)

NewComponentMPWorkFunctionUPP (page 344)

InvokeComponentMPWorkFunctionUPP (page 342)

DisposeComponentMPWorkFunctionUPP (page 332)

NewGetMissingComponentResourceUPP (page 344)

InvokeGetMissingComponentResourceUPP (page 343)

DisposeGetMissingComponentResourceUPP (page 333)

Registering Components

RegisterComponent (page 348)
Registers a component stored in memory.

RegisterComponentResource (page 352)
Registers a component stored in a resource file.

RegisterComponentResourceFile (page 352)
Registers all component resources in the given resource file.

UnregisterComponent (page 357)
Removes a component from the Component Manager's registration list.

RegisterComponentFileRef (page 351)

RegisterComponentFileRefEntries (page 351)

RegisterComponentFile (page 350) Deprecated in Mac OS X v10.5

RegisterComponentFileEntries (page 350) Deprecated in Mac OS X v10.5

Dispatching to Component Functions

CallComponentFunction (page 321)
Invokes the specified function of your component.

CallComponentFunctionWithStorage (page 322)
Invokes the specified function of your component.

CallComponentFunctionWithStorageProcInfo (page 323)

Managing Component Connections

CountComponentInstances (page 329)
Determines the number of open connections being managed by a specified component.

GetComponentInstanceStorage (page 337)
Allows your component to retrieve a handle to the memory associated with a connection.

SetComponentInstanceStorage (page 354)
Allows your component to associate memory with a connection.

`ComponentSetTarget` (page 328) Deprecated in Mac OS X v10.5
Calls a component's target request function and informs a component that it has been targeted by another component.

Setting Component Errors

`SetComponentInstanceError` (page 353)
Passes error information to the Component Manager which sets the current error value for the appropriate connection.

Working With Component Reference Constants

`GetComponentRefcon` (page 339)
Retrieves the value of the reference constant for your component.

`SetComponentRefcon` (page 355)
Sets the reference constant for your component.

Accessing a Component's Resource File

`OpenAComponentResFile` (page 345)

`OpenComponentResFile` (page 347)
Allows your component to gain access to its resource file.

`CloseComponentResFile` (page 327)
Closes the resource file that your component opened previously with the `OpenComponentResFile` function.

`GetComponentResource` (page 340)

`GetComponentIndString` (page 335)

Calling Other Components

`DelegateComponentCall` (page 331)
Allows your component to pass on a request to a specified component.

Capturing Components

`CaptureComponent` (page 326)
Allows your component to capture another component.

`UncaptureComponent` (page 356)
Allows your component to uncapture a previously captured component.

Changing the Default Search Order

`SetDefaultComponent` (page 356)
Changes the search order for registered components.

Functions

CallComponentCanDo

```
ComponentResult CallComponentCanDo (
   ComponentInstance ci,
   SInt16 ftnNumber
);
```

Parameters

ci

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentClose

```
ComponentResult CallComponentClose (
   ComponentInstance ci,
   ComponentInstance self
);
```

Parameters

ci

self

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentDispatch

```
ComponentResult CallComponentDispatch (
   ComponentParameters *cp
);
```

Parameters

cp

Return Value

See the description of the `ComponentResult` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

CallComponentFunction

Invokes the specified function of your component.

```
ComponentResult CallComponentFunction (
   ComponentParameters *params,
   ComponentFunctionUPP func
);
```

Parameters

params

A pointer to the `ComponentDescription` (page 361) structure that your component received from the Component Manager. These are the parameters originally provided by the application that called your component.

func

A universal procedure pointer to the component function that is to handle the request. The Component Manager calls the function referred to by the `func` parameter, using Pascal calling conventions, with the parameters that were originally provided by the application that called your component. The function referred to by this parameter must return a function result of type `ComponentResult` indicating the success or failure of the operation. See the `ComponentRoutineProcPtr` (page 358) callback for more information on component functions.

Return Value

The value that is returned by the function referred to by the `func` parameter. Your component should use this value to set the current error for this connection. You can use the `SetComponentInstanceError` (page 353) function to set the current error.

Discussion

When an application requests service from your component, your component receives a component parameters structure containing the parameters that the application provided when it called your component. Your component can use this structure to access the parameters directly. Alternatively, you can use either this function or `CallComponentFunctionWithStorage` (page 322) to extract those parameters and pass them to a subroutine of your component. By taking advantage of these functions, you can simplify the structure of your component code.

If your component subroutine does not need global data, your component should use this function. If your component subroutine requires memory in which to store global data for the component, your component must use `CallComponentFunctionWithStorage`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentFunctionWithStorage

Invokes the specified function of your component.

```
ComponentResult CallComponentFunctionWithStorage (
   Handle storage,
   ComponentParameters *params,
   ComponentFunctionUPP func
);
```

Parameters

storage

A handle to the memory associated with the current connection. The Component Manager provides this handle to your component along with the request.

params

A pointer to the `ComponentParameters` (page 365) structure that your component received from the Component Manager. These are the parameters originally provided by the application that called your component.

func

A universal procedure pointer to the component function that is to handle the request. The Component Manager calls the function referred to by the `func` parameter, using Pascal calling conventions, with the parameters that were originally provided by the application that called your component. These parameters are preceded by a handle to the memory associated with the current connection. The function referred to by the `func` parameter must return a function result of type `ComponentResult` indicating the success or failure of the operation. See the `ComponentRoutineProcPtr` (page 358) callback for more information on component functions.

Return Value
The value that is returned by the function referred to by the `func` parameter. Your component should use this value to set the current error for this connection. Use the `SetComponentInstanceError` (page 353) function to set the current error for a connection.

Discussion
When an application requests service from your component, your component receives a component parameters structure containing the parameters that the application provided when it called your component. Your component can use this structure to access the parameters directly. Alternatively, you can use either the `CallComponentFunction` (page 321) function or this function to extract those parameters and pass them to a subroutine of your component. By taking advantage of these functions, you can simplify the structure of your component code.

If your component subroutine requires a handle to the memory associated with the connection, you must use this function. You allocate the memory for a given connection each time your component is opened. You inform the Component Manager that a connection has memory associated with it by calling the `SetComponentInstanceError` (page 353) function.

Subroutines of a component that don't need global data should use `CallComponentFunction` instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentFunctionWithStorageProcInfo

```
ComponentResult CallComponentFunctionWithStorageProcInfo (
   Handle storage,
   ComponentParameters *params,
   ProcPtr func,
   ProcInfoType funcProcInfo
);
```

Parameters

storage

params

funcProcInfo

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentGetMPWorkFunction

```
ComponentResult CallComponentGetMPWorkFunction (
   ComponentInstance ci,
   ComponentMPWorkFunctionUPP *workFunction,
   void **refCon
);
```

Parameters

ci

workFunction

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentGetPublicResource

```
ComponentResult CallComponentGetPublicResource (
   ComponentInstance ci,
   OSType resourceType,
   SInt16 resourceID,
   Handle *resource
);
```

Parameters

ci

resourceType

resource

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentOpen

```
ComponentResult CallComponentOpen (
   ComponentInstance ci,
   ComponentInstance self
);
```

Parameters

ci

self

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentRegister

```
ComponentResult CallComponentRegister (
   ComponentInstance ci
);
```

Parameters

ci

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentTarget

```
ComponentResult CallComponentTarget (
   ComponentInstance ci,
   ComponentInstance target
);
```

Parameters

ci

target

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentUnregister

```
ComponentResult CallComponentUnregister (
   ComponentInstance ci
);
```

Parameters

ci

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CallComponentVersion

```
ComponentResult CallComponentVersion (
   ComponentInstance ci
);
```

Parameters

ci

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CaptureComponent

Allows your component to capture another component.

```
Component CaptureComponent (
   Component capturedComponent,
   Component capturingComponent
);
```

Parameters

capturedComponent

The component to be captured. Your component can obtain this identifier from the `FindNextComponent` (page 333) function or from the component registration functions. You can use a component instance here, but you must coerce the data type appropriately.

capturingComponent

Your component. Note that you can use the component instance (appropriately coerced) that your component received in its open request in this parameter.

Return Value
A new component identifier. Your component can use this new identifier to refer to the captured component. For example, your component can open the captured component by providing this identifier to the `OpenComponent` (page 346) structure. Your component must provide this identifier to the `UncaptureComponent` (page 356) function to specify the component to be restored to the search list. If the component you wish to capture is already captured, the component identifier is set to `NULL`. See the description of the `Component` data type.

Discussion
Typically, your component captures another component when you want to override all or some of the features provided by a component or to provide new features. For example, a component called NewMath might capture a component called OldMath. Suppose the NewMath component provides a new function, `DoExponent`. Whenever NewMath gets an exponent request, it can handle the request itself. For all other requests, NewMath might call the OldMath component to perform the request.

After capturing a component, your component might choose to target a particular instance of the captured component.

In response to this function, the Component Manager removes the specified component from the list of available components. As a result, applications cannot retrieve information about the captured component or gain access to it. Current clients of the captured component are not affected by this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CloseComponent

Terminates your application's connection to a component.

```
OSErr CloseComponent (
   ComponentInstance aComponentInstance
);
```

Parameters

aComponentInstance

The connection you wish to close. Your application obtains the component instance from the `OpenComponent` (page 346) function or the `OpenDefaultComponent` (page 348) function. You can use a component identifier here, but you must coerce the data type appropriately.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Discussion
This function closes only a single connection. If your application has several connections to a single component, you must call it once for each connection.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
WhackedTV

Declared In
`Components.h`

CloseComponentResFile

Closes the resource file that your component opened previously with the `OpenComponentResFile` function.

```
OSErr CloseComponentResFile (
   ResFileRefNum refnum
);
```

Parameters

refnum

The reference number that identifies the resource file to be closed. Your component obtains this value from the `OpenComponentResFile` (page 347) function. Your component must close any open resource files before returning to the calling application.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ComponentFunctionImplemented

Allows your application to determine whether a component supports a specified request. (Deprecated in Mac OS X v10.5.)

```
ComponentResult ComponentFunctionImplemented (
   ComponentInstance ci,
   SInt16 ftnNumber
);
```

Parameters

ci

The component instance of which you wish to make a request. Your application obtains the component instance from the `OpenDefaultComponent` (page 348) function or the `OpenComponent` (page 346) function. You can use a component identifier here, but you must coerce the data type appropriately.

ftnNumber

A request code value. See the documentation supplied with the component for request code values.

Return Value
Indicates whether the component supports the specified request. You can interpret this number as if it were a Boolean value. If the returned value is `TRUE`, the component supports the specified request. If the returned value is `FALSE`, the component does not support the request. Your application can use this function to determine a component's capabilities.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Components.h`

ComponentSetTarget

Calls a component's target request function and informs a component that it has been targeted by another component. (Deprecated in Mac OS X v10.5.)

```
ComponentResult ComponentSetTarget (
   ComponentInstance ci,
   ComponentInstance target
);
```

Parameters

ci

The component instance to which to send a target request (the component that has been targeted). You can use a component identifier here, but you must coerce the data type appropriately.

target

The component instance issuing the target request.

Return Value

The value that the targeted component instance returns in response to the target request, or `badComponentSelector` if the targeted component does not support the target request.

Discussion

Your component can target a component instance without capturing the component or your component can first capture the component and then target a specific instance of the component.

You should not target a component instance if the component does not support the target request. Before calling this function, you should issue a can do request to the component instance you want to target to verify that the component supports the target request. After receiving a target request, the targeted component instance should call the component instance that targeted it whenever the targeted component instance would normally call one of its defined functions.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Components.h`

CountComponentInstances

Determines the number of open connections being managed by a specified component.

```
long CountComponentInstances (
   Component aComponent
);
```

Parameters

aComponent

The component for which you want a count of open connections. You can use a component instance here, but you must coerce the data type appropriately.

Return Value

The number of open connections for the specified component.

Discussion

This function can be useful if you want to restrict the number of connections for your component or if your component needs to perform special processing based on the number of open connections.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
SoftVDigX

Declared In
`Components.h`

CountComponents

Returns the number of registered components that meet the selection criteria specified by your application.

```
long CountComponents (
   ComponentDescription *looking
);
```

Parameters

looking

A pointer to a `ComponentDescription` (page 361) structure. Your application specifies the criteria for the component search in the fields of this structure.

The Component Manager ignores fields in the component description structure that are set to 0. For example, if you set all the fields to 0, the Component Manager returns the number of components registered in the system. Similarly, if you set all fields to 0 except for the `componentManufacturer` field, the Component Manager returns the number of registered components supplied by the manufacturer you specify.

Return Value
The number of components that meet the specified search criteria.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

CSGetComponentsThreadMode

Indicates whether using thread-unsafe components is allowed in the current thread.

```
CSComponentsThreadMode CSGetComponentsThreadMode (
   void
);
```

Return Value
A flag that indicates whether using thread-unsafe components is allowed in the current thread.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Components.h`

CSSetComponentsThreadMode

Sets whether or not using thread-unsafe components is allowed in the current thread.

```
void CSSetComponentsThreadMode (
   CSComponentsThreadMode mode
);
```

Parameters

mode

A flag that determines whether the current thread is restricted to calling components that are thread-safe. You should set this flag to `kCSAcceptThreadSafeComponentsOnlyMode` whenever you want the current thread to call only components that are thread-safe.

Discussion

Core Services maintains a component thread-mode flag for each thread in the current process. The default value of this flag is `kCSAcceptAllComponentsMode`, which means the thread can call any component regardless of whether the component is thread-safe. Applications and other high-level code that call component-based APIs (such as QuickTime) from preemptive threads should call this function from their thread beforehand and pass in the value `kCSAcceptThreadSafeComponentsOnlyMode`.

A thread's component thread-mode flag can safely retain its default value only if the thread is the main thread or if it participates in cooperative locking, such as Carbon Thread Manager-style cooperative threads and application threads that perform their own private locking.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`Components.h`

DelegateComponentCall

Allows your component to pass on a request to a specified component.

```
ComponentResult DelegateComponentCall (
   ComponentParameters *originalParams,
   ComponentInstance ci
);
```

Parameters

originalParams

A pointer to the `ComponentParameters` (page 365) structure provided to your component by the Component Manager.

ci

The component instance that is to process the request. The Component Manager provides a component instance to your component when it opens a connection to another component with the `OpenComponent` (page 346) or `OpenDefaultComponent` (page 348) function. You must specify a component instance; this function does not accept a component identifier.

Return Value

The component result returned by the specified component.

Discussion
Your component may supplement its capabilities by using the services of another component to directly satisfy application requests using this function. For example, you might want to create two similar components that provide different levels of service to applications. Rather than completely implementing both components, you could design one to rely on the capabilities of the other. In this manner, you have to implement only that portion of the more capable component that provides additional services.

You may also invoke the services of another component using the standard mechanisms used by applications. The Component Manager then passes the requests to the appropriate component, and your component receives the results of those requests.

Your component must open a connection to the component to which the requests are to be passed. Your component must close that connection when it has finished using the services of the other component.

Your component should never use this function with open or close requests from the Component Manager—always use the `OpenComponent` and `CloseComponent` (page 327) functions to manage connections with other components.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

DisposeComponentFunctionUPP

```
void DisposeComponentFunctionUPP (
   ComponentFunctionUPP userUPP
);
```

Parameters
userUPP

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

DisposeComponentMPWorkFunctionUPP

```
void DisposeComponentMPWorkFunctionUPP (
   ComponentMPWorkFunctionUPP userUPP
);
```

Parameters
userUPP

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

DisposeComponentRoutineUPP

Disposes of the universal procedure pointer (UPP) to a component routine callback function.

```
void DisposeComponentRoutineUPP (
   ComponentRoutineUPP userUPP
);
```

Parameters

userUPP

Discussion

See the `ComponentRoutineProcPtr` (page 358) callback for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

DisposeGetMissingComponentResourceUPP

```
void DisposeGetMissingComponentResourceUPP (
   GetMissingComponentResourceUPP userUPP
);
```

Parameters

userUPP

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

FindNextComponent

Returns the component identifier for the next registered component that meets the selection criteria specified by your application.

```
Component FindNextComponent (
   Component aComponent,
   ComponentDescription *looking
);
```

Parameters

aComponent

The starting point for the search. Set this field to 0 to start the search at the beginning of the component list. If you are continuing a search, you can specify a component identifier previously returned by this function. The function then searches the remaining components.

looking

A pointer to a `ComponentDescription` (page 361) structure. Your application specifies the criteria for the component search in the fields of this structure.

The Component Manager ignores fields in the component description structure that are set to 0. For example, if you set all the fields to 0, all components meet the search criteria. In this case, your application can retrieve information about all of the components that are registered in the system by repeatedly calling `FindNextComponent` and `GetComponentInfo` (page 335) until the search is complete. Similarly, if you set all fields to 0 except for the `componentManufacturer` field, the Component Manager searches all registered components for a component supplied by the manufacturer you specify. Note that this function does not modify the contents of the component description structure you supply. To retrieve detailed information about a component, you need to use the `GetComponentInfo` (page 335) function to get the component description structure for each returned component.

Return Value

The component identifier of a component that meets the search criteria or 0 when there are no more matching components. Your application can use the component identifier returned by this function to get more information about the component, using `GetComponentInfo`, or to open the component, using either the `OpenDefaultComponent` (page 348) function or the `OpenComponent` (page 346) function. See the description of the `Component` data type.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

SoftVDigX

Declared In

`Components.h`

GetComponentIconSuite

Returns a handle to a component's icon suite to your application.

```
OSErr GetComponentIconSuite (
   Component aComponent,
   Handle *iconSuite
);
```

Parameters

aComponent

The component whose icon suite you wish to obtain. Your application obtains a component identifier from the `FindNextComponent` (page 333) function. If your application registers a component, it can also obtain a component identifier from the `RegisterComponent` (page 348) or `RegisterComponentResource` (page 352) function. You can use a component instance here, but you must coerce the data type appropriately.

iconSuite

On return, a pointer to a handle for the component's icon suite or, if the component has not provided an icon suite, `NULL`. A component provides the resource ID of its icon family to the Component Manager in the optional extensions to the component resource. Your application is responsible for disposing of the returned icon suite handle.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Components.h`

GetComponentIndString

```
OSErr GetComponentIndString (
   Component aComponent,
   Str255 theString,
   SInt16 strListID,
   SInt16 index
);
```

Parameters

aComponent

theString

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
SoftVDigX

Declared In
`Components.h`

GetComponentInfo

Returns to your application the registration information for a component.

```
OSErr GetComponentInfo (
   Component aComponent,
   ComponentDescription *cd,
   Handle componentName,
   Handle componentInfo,
   Handle componentIcon
);
```

Parameters

aComponent

The component about which you wish to obtain information. Your application obtains a component identifier from the `FindNextComponent` (page 333) function. If your application registers a component, it can also obtain a component identifier from the `RegisterComponent` (page 348) or `RegisterComponentResource` (page 352) function.

You may supply a component instance rather than a component identifier to this function, but you must coerce the data type appropriately. Your application can obtain a component instance from the `OpenComponent` (page 346) or `OpenDefaultComponent` (page 348) functions.

cd

A pointer to a `ComponentDescription` (page 361) structure. The function returns information about the specified component in this structure.

componentName

On return, a handle to the component's name. If the component does not have a name, an empty handle. Set this field to `NULL` if you do not want to receive the component's name.

componentInfo

On return, a handle to the component's information string. If the component does not have an information string, an empty handle. Set this field to `NULL` if you do not want to receive the component's information string.

componentIcon

On return, a handle to the component's icon. If the component does not have an icon, an empty handle. Set this field to `NULL` if you do not want to receive the component's icon. To get a handle to the component's icon suite, if it provides one, use the `GetComponentIconSuite` (page 334) function.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Discussion
For information on registering components, see "Registering Components".

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
WhackedTV

Declared In
`Components.h`

GetComponentInstanceError

Returns to your application the last error generated by a specific connection to a component.

```
OSErr GetComponentInstanceError (
   ComponentInstance aComponentInstance
);
```

Parameters

aComponentInstance

The component instance from which you want error information. Your application obtains the component instance from the `OpenDefaultComponent` (page 348) function or the `OpenComponent` (page 346) function. You can use a component identifier here, but you must coerce the data type appropriately.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Discussion
Some component functions return error information as their function result. Other component functions set an error code that your application can retrieve using this function. Refer to the documentation supplied with the component for information on how that particular component handles errors.

Once you have retrieved an error code, the Component Manager clears the error code for the connection. If you want to retain that error value, you should save it in your application's local storage.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

GetComponentInstanceStorage

Allows your component to retrieve a handle to the memory associated with a connection.

```
Handle GetComponentInstanceStorage (
   ComponentInstance aComponentInstance
);
```

Parameters

aComponentInstance

The connection for which to retrieve the associated memory. The Component Manager provides a component instance to your component when the connection is opened. You can use a component identifier here, but you must coerce the data type appropriately.

Return Value
A handle to the memory associated with the specified connection.

Discussion
Typically, your component does not need to use this function, because the Component Manager provides this handle to your component each time the client application requests service from this connection.

Your component tells the Component Manager about the memory associated with a connection by calling the `SetComponentInstanceStorage` (page 354) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

GetComponentListModSeed

Allows your application to determine if the list of registered components has changed.

```
SInt32 GetComponentListModSeed (
   void
);
```

Parameters

Return Value
The component registration seed number. Each time the Component Manager registers or unregisters a component it generates a new, unique seed number. By comparing the return value to values previously returned by this function, you can determine whether the list has changed. Your application may use this information to rebuild its internal component lists or to trigger other activity that is necessary whenever new components are available.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

GetComponentPublicIndString

```
OSErr GetComponentPublicIndString (
   Component aComponent,
   Str255 theString,
   SInt16 strListID,
   SInt16 index
);
```

Parameters
aComponent
theString

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

GetComponentPublicResource

```
OSErr GetComponentPublicResource (
   Component aComponent,
   OSType resourceType,
   SInt16 resourceID,
   Handle *theResource
);
```

Parameters

aComponent

resourceType

theResource

Return Value

A result code. See "Component Manager Result Codes" (page 380).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

GetComponentPublicResourceList

```
OSErr GetComponentPublicResourceList (
   OSType resourceType,
   SInt16 resourceID,
   SInt32 flags,
   ComponentDescription *cd,
   GetMissingComponentResourceUPP missingProc,
   void *refCon,
   void *atomContainerPtr
);
```

Parameters

resourceType

cd

missingProc

Return Value

A result code. See "Component Manager Result Codes" (page 380).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

GetComponentRefcon

Retrieves the value of the reference constant for your component.

```
long GetComponentRefcon (
   Component aComponent
);
```

Parameters

aComponent

The component whose reference constant you wish to get. You can use a component instance here, but you must coerce the data type appropriately.

Return Value
The reference constant for the specified component.

Discussion
There is one reference constant for each component, regardless of the number of connections to that component. When your component is registered, the Component Manager sets this reference constant to 0.

The reference constant is a 4-byte value that your component can use in any way you decide. For example, you might use the reference constant to store the address of a data structure that is shared by all connections maintained by your component. You should allocate shared structures in the system heap. Your component should deallocate the structure when its last connection is closed or when it is unregistered.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Components.h

GetComponentResource

```
OSErr GetComponentResource (
   Component aComponent,
   OSType resType,
   SInt16 resID,
   Handle *theResource
);
```

Parameters

aComponent

resType

theResource

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Components.h

GetComponentTypeModSeed

```
SInt32 GetComponentTypeModSeed (
   OSType componentType
);
```

Parameters

componentType

Availability

Available in Mac OS X v10.0 and later.

Declared In

Components.h

GetComponentVersion

Returns the version number of a component to your application. (Deprecated in Mac OS X v10.5.)

```
ComponentResult GetComponentVersion (
   ComponentInstance ci
);
```

Parameters

ci

The component instance from which you want to retrieve version information. Your application obtains the component instance from the `OpenDefaultComponent` (page 348) function or the `OpenComponent` (page 346) function.

Return Value

The version number of the component you specify. The high-order 16 bits represent the major version, and the low-order 16 bits represent the minor version. The major version specifies the component specification level the minor version specifies a particular implementation's version number.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

Components.h

InvokeComponentMPWorkFunctionUPP

```
ComponentResult InvokeComponentMPWorkFunctionUPP (
   void *globalRefCon,
   ComponentMPWorkFunctionHeaderRecordPtr header,
   ComponentMPWorkFunctionUPP userUPP
);
```

Parameters

header

userUPP

Return Value

See the description of the `ComponentResult` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

InvokeComponentRoutineUPP

Calls your component routine callback function

```
ComponentResult InvokeComponentRoutineUPP (
   ComponentParameters *cp,
   Handle componentStorage,
   ComponentRoutineUPP userUPP
);
```

Parameters

cp

componentStorage

userUPP

Return Value

See the description of the `ComponentResult` data type.

Discussion

See the `ComponentRoutineProcPtr` (page 358) callback for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

InvokeGetMissingComponentResourceUPP

```
OSErr InvokeGetMissingComponentResourceUPP (
   Component c,
   OSType resType,
   SInt16 resID,
   void *refCon,
   Handle *resource,
   GetMissingComponentResourceUPP userUPP
);
```

Parameters

c

resType

resource

userUPP

Return Value

A result code. See "Component Manager Result Codes" (page 380).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

NewComponentFunctionUPP

```
ComponentFunctionUPP NewComponentFunctionUPP (
   ProcPtr userRoutine,
   ProcInfoType procInfo
);
```

Parameters

procInfo

Return Value

See the description of the `ComponentFunctionUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

NewComponentMPWorkFunctionUPP

```
ComponentMPWorkFunctionUPP NewComponentMPWorkFunctionUPP (
   ComponentMPWorkFunctionProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `ComponentMPWorkFunctionUPP` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

NewComponentRoutineUPP

Creates a new universal procedure pointer (UPP) to a component routine callback function.

```
ComponentRoutineUPP NewComponentRoutineUPP (
   ComponentRoutineProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `ComponentRoutineUPP` data type.

Discussion
See the `ComponentRoutineProcPtr` (page 358) callback for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

NewGetMissingComponentResourceUPP

```
GetMissingComponentResourceUPP NewGetMissingComponentResourceUPP (
   GetMissingComponentResourceProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `GetMissingComponentResourceUPP` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

OpenAComponent

```
OSErr OpenAComponent (
   Component aComponent,
   ComponentInstance *ci
);
```

Parameters

aComponent

ci

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

OpenAComponentResFile

```
OSErr OpenAComponentResFile (
   Component aComponent,
   ResFileRefNum *resRef
);
```

Parameters

aComponent

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

OpenADefaultComponent

```
OSErr OpenADefaultComponent (
   OSType componentType,
   OSType componentSubType,
   ComponentInstance *ci
);
```

Parameters

componentType

componentSubType

ci

Return Value

A result code. See "Component Manager Result Codes" (page 380).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

WhackedTV

Declared In

`Components.h`

OpenComponent

Opens a connection to the component with the component identifier specified by your application.

```
ComponentInstance OpenComponent (
   Component aComponent
);
```

Parameters

aComponent

The component you wish to open. Your application obtains this identifier from the `FindNextComponent` (page 333) function. If your application registers a component, it can also obtain a component identifier from the `RegisterComponent` function or the `RegisterComponentResource` function.

Return Value

A component instance which identifies your application's connection to the component. You must supply this component instance whenever you call the functions provided by the component. When you close the component, you must also supply this component instance to the `CloseComponent` (page 327) function.

If it cannot open the specified component, the function returns `NULL`.

See the description of the `ComponentInstance` data type.

Discussion

Your application must open a component before it can call any component functions. To use this function, you must already have obtained a component identifier. Alternatively, you can use the `OpenDefaultComponent` (page 348) function to open a component without calling `FindNextComponent`.

Note that your application may maintain several connections to a single component, or it may have connections to several components at the same time.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
WhackedTV

Declared In
`Components.h`

OpenComponentResFile

Allows your component to gain access to its resource file.

```
ResFileRefNum OpenComponentResFile (
   Component aComponent
);
```

Parameters

aComponent

The component whose resource file you wish to open. Applications that register components may obtain this identifier from the `RegisterComponentResource` (page 352) function. You can use a component instance here, but you must coerce the data type appropriately.

Return Value
A reference number that your component can use to read data from the appropriate resource file. If the specified component does not have an associated resource file or if the Component Manager cannot open the resource file, the function returns 0 or a negative number.

Discussion
This function opens the resource file with read-only permission. The Component Manager adds the resource file to the current resource chain. Your component must close the resource file with the `CloseComponentResFile` (page 327) function before returning to the calling application. Note that there is only one resource file associated with a component.

Your component can use `FSpOpenResFile` or equivalent Resource Manager functions to open other resource files, but you must use this function to open your component's resource file.

If you store your component in a component resource but register the component with the `RegisterComponent` (page 348) function, rather than with the `RegisterComponentResource` or `RegisterComponentResourceFile` function, your component cannot access its resource file with this function.

Note that when working with resources, your component should always first save the current resource file, perform any resource operations, then restore the current resource file to its previous value before returning.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

OpenDefaultComponent

Opens a connection to a registered component of the component type and subtype specified by your application.

```
ComponentInstance OpenDefaultComponent (
   OSType componentType,
   OSType componentSubType
);
```

Parameters

componentType

The type of the component. All components of a particular type support a common set of interface functions. Use this parameter to search for components of a given type.

componentSubType

The subtype of the component. Different subtypes of a component type may support additional features or provide interfaces that extend beyond the standard functions for a given component type. For example, the subtype of an image compressor component indicates the compression algorithm employed by the compressor.

Your application can use the `componentSubType` parameter to perform a more specific lookup operation than is possible using only the `componentType` parameter. For example, you may want your application to use only components of a certain component type (`'draw'`) that also have a specific subtype (`'oval'`). Set this parameter to 0 to select a component with any subtype value.

Return Value

A component instance that identifies the connection opened to the component which matches your search criteria. You must supply this component instance whenever you call the functions provided by the component. When you close the component, you must also supply this component instance to the `CloseComponent` (page 327) function.

If more than one component in the list of registered components meets the search criteria, the function opens the first one that it finds in its list. If it cannot open the specified component, it returns `NULL`.

See the description of the `ComponentInstance` data type.

Discussion

Your application must open a component before it can call any component functions. This function searches for a component by type and subtype. You do not have to supply a component description structure or call the `FindNextComponent` (page 333) function to use this function. If you want to exert more control over the selection process, you can use the `FindNextComponent` and `OpenComponent` (page 346) functions.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

RegisterComponent

Registers a component stored in memory.

```
Component RegisterComponent (
   ComponentDescription *cd,
   ComponentRoutineUPP componentEntryPoint,
   SInt16 global,
   Handle componentName,
   Handle componentInfo,
   Handle componentIcon
);
```

Parameters

cd

A pointer to a `ComponentDescription` (page 361) structure that describes the component to be registered. You must correctly fill in the fields of this structure before calling this function. When applications search for components using the `FindNextComponent` (page 333) function, the Component Manager compares the attributes you specify here with those specified by the application. If the attributes match, the Component Manager returns the component identifier to the application.

componentEntryPoint

A universal procedure pointer (UPP) to your component's main entry point. The function referred to by this parameter receives all requests for the component. See the `ComponentRoutineProcPtr` (page 358) callback for more information on creating a component function.

global

A set of flags that control the scope of component registration. See Register Component Resource flags (page 377) for a description of the flags.

componentName

A handle to the component's name. Set this parameter to `NULL` if you do not want to assign a name to the component.

componentInfo

A handle to the component's information string. Set this parameter to `NULL` if you do not want to assign an information string to the component.

componentIcon

A handle to the component's icon (a 32-by-32 pixel black-and-white icon). Set this parameter to `NULL` if you do not want to supply an icon for this component. Note that this icon is not used by the Finder you supply an icon only so that other components or applications can display your component's icon if needed.

Return Value

The unique component identifier assigned to the component by the Component Manager or, if it cannot register the component, `NULL`. See the description of the `Component` data type.

Discussion

Before a component can be used by an application, the component must be registered with the Component Manager. Applications can then find and open the component using the standard Component Manager functions.

Components you register with the `RegisterComponent` function must be in memory when you call this function. If you want to register a component that is stored in the resource fork of a file, use the `RegisterComponentResource` (page 352) function. Use the `RegisterComponentResourceFile` (page 352) function to register all components in the resource fork of a file. The Component Manager automatically registers component resources stored in files with file types of `'thng'` that are stored in the Extensions folder. See "Resources" for more information on component resource files.

Note that a component residing in your application heap remains registered until your application unregisters it or quits. When an application quits, the Component Manager automatically closes any component connections to that application. In addition, if the application has registered components that reside in its heap space, the Component Manager automatically unregisters those components. A component residing in the system heap and registered by your application remains registered until your application unregisters it or until the computer is shut down.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

RegisterComponentFile

(Deprecated in Mac OS X v10.5.)

```
OSErr RegisterComponentFile (
   const FSSpec *spec,
   short global
);
```

Parameters

spec

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Components.h`

RegisterComponentFileEntries

(Deprecated in Mac OS X v10.5.)

```
OSErr RegisterComponentFileEntries (
   const FSSpec *spec,
   short global,
   const ComponentDescription *toRegister,
   UInt32 registerCount
);
```

Parameters

spec
toRegister
registerCount

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Components.h`

RegisterComponentFileRef

```
OSErr RegisterComponentFileRef (
   const FSRef *ref,
   SInt16 global
);
```

Parameters
ref

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

RegisterComponentFileRefEntries

```
OSErr RegisterComponentFileRefEntries (
   const FSRef *ref,
   SInt16 global,
   const ComponentDescription *toRegister,
   UInt32 registerCount
);
```

Parameters
ref
toRegister
registerCount

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

RegisterComponentResource

Registers a component stored in a resource file.

```
Component RegisterComponentResource (
   ComponentResourceHandle cr,
   SInt16 global
);
```

Parameters

cr

A handle to a component resource that describes the component to be registered. The component resource contains all the information required to register the component. Components you register with this function must be stored in a resource file as a component resource. The Component Manager automatically registers component resources stored in files with file types of `'thng'` that are stored in the Extensions folder. See "Resources" for more information on component resource files.

global

A set of flags that controls the scope of component registration. See Register Component Resource flags (page 377) for a description of the flags.

Return Value

The unique component identifier assigned to the component by the Component Manager, or `NULL` if the function could not register the component. See the description of the `Component` data type.

Discussion

Before a component can be used by an application, the component must be registered with the Component Manager. Applications can then find and open the component using the standard Component Manager functions.

If you want to register a component that is in memory, use the `RegisterComponent` (page 348) function.

This function does not actually load the code specified by the component resource into memory. Rather, the Component Manager loads the component code the first time an application opens the component. If the code is not in the same file as the component resource or if the Component Manager cannot find the file, the open request fails.

Note that a component registered locally by your application remains registered until your application unregisters it or quits. When an application quits, the Component Manager automatically closes any component connections to that application. In addition, if the application has registered components that reside in its heap space, the Component Manager automatically unregisters those components. A component registered globally by your application remains registered until your application unregisters it or until the computer is shut down.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

RegisterComponentResourceFile

Registers all component resources in the given resource file.

```
SInt32 RegisterComponentResourceFile (
   SInt16 resRefNum,
   SInt16 global
);
```

Parameters

resRefNum

The reference number of the resource file containing the components to register.

global

A set of flags that control the scope of the registration of the components in the resource file. See Register Component Resource flags (page 377) for a description of the flags.

Return Value

The number of components registered, if all components in the specified resource file are successfully registered. If one or more of the components in the resource file could not be registered, or if the specified file reference number is invalid, a negative function result.

Discussion

Before a component can be used by an application, the component must be registered with the Component Manager. The Component Manager automatically registers component resources stored in files with file types of `'thng'` that are stored in the Extensions folder. For a description of the format and content of component resources, see "Resources".

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

ResolveComponentAlias

```
Component ResolveComponentAlias (
   Component aComponent
);
```

Parameters

aComponent

Return Value

See the description of the `Component` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

SetComponentInstanceError

Passes error information to the Component Manager which sets the current error value for the appropriate connection.

```
void SetComponentInstanceError (
   ComponentInstance aComponentInstance,
   OSErr theError
);
```

Parameters

aComponentInstance

The connection for which to set the error. The Component Manager provides a component instance to your component when the connection is opened. The Component Manager also provides a component instance to your component as the first parameter in the `params` field of the parameters structure.

theError

The new value for the current error.

Discussion

In general, your component returns error information in its function result a nonzero function result indicates an error occurred, and a function result of 0 indicates the request was successful. However, some requests require that your component return other information as its function result. In these cases, your component can use this function to report its latest error state to the Component Manager. You can also use this function at any time during your component's execution to report an error.

Applications retrieve this error information by calling the `GetComponentInstanceError` (page 336) function. The documentation for your component should specify how the component indicates errors.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Components.h`

SetComponentInstanceStorage

Allows your component to associate memory with a connection.

```
void SetComponentInstanceStorage (
   ComponentInstance aComponentInstance,
   Handle theStorage
);
```

Parameters

aComponentInstance

The connection to associate with the allocated memory. The Component Manager provides a component instance to your component when the connection is opened. You can use a component identifier here, but you must coerce the data type appropriately.

theStorage

A handle to the memory that your component has allocated for the connection. Your component must allocate this memory in the current heap. The Component Manager saves this handle and provides it to your component, along with other parameters, in subsequent requests to this connection.

Discussion
When an application or component opens a connection to your component, the Component Manager sends your component an open request. In response to this open request, your component should set up an environment to service the connection. Typically, your component should allocate some memory for the connection. Your component can then use that memory to maintain state information appropriate to the connection.

Your component should dispose of any allocated memory for the connection only in response to the close request. Note that whenever an open request fails, the Component Manager always issues the close request. Furthermore, the value stored with this function is always passed to the close request, so it must be valid or `NULL`. If the open request tries to dispose of its allocated memory before returning, it should call this function again with a `NULL` handle to keep the Component Manager from passing an invalid handle to the close request.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
SoftVDigX

Declared In
`Components.h`

SetComponentRefcon

Sets the reference constant for your component.

```
void SetComponentRefcon (
   Component aComponent,
   long theRefcon
);
```

Parameters

aComponent
The component whose reference constant you wish to set. You can use a component instance here, but you must coerce the data type appropriately.

theRefcon
The reference constant value that you want to set for your component. Your component can retrieve the reference constant using the `GetComponentRefcon` (page 339) function.

Discussion
There is one reference constant for each component, regardless of the number of connections to that component. When your component is registered, the Component Manager sets this reference constant to 0.

The reference constant is a 4-byte value that your component can use in any way you decide. For example, you might use the reference constant to store the address of a data structure that is shared by all connections maintained by your component. You should allocate shared structures in the system heap. Your component should deallocate the structure when its last connection is closed or when it is unregistered.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

SetDefaultComponent

Changes the search order for registered components.

```
OSErr SetDefaultComponent (
   Component aComponent,
   SInt16 flags
);
```

Parameters

aComponent

The component which you wish moved to the front of the search chain. The order of the search chain influences which component the Component Manager selects in response to an application's use of the `OpenDefaultComponent` (page 348) and `FindNextComponent` (page 333) functions. You can use a component instance here, but you must coerce the data type appropriately.

flags

A value specifying the control information governing the operation. The value of this parameter controls which component description fields the Component Manager examines during the reorder operation. Set the appropriate flags to 1 to define the fields that are examined during the reorder operation. See Set Default Component Flags (page 379) for a description of the values you can use here.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Discussion
Note that this function changes the search order for all applications. As a result, you should use this function carefully.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

UncaptureComponent

Allows your component to uncapture a previously captured component.

```
OSErr UncaptureComponent (
   Component aComponent
);
```

Parameters

aComponent

The component to be uncaptured. Your component obtains this identifier from the `CaptureComponent` (page 326) function. You can use a component instance here, but you must coerce the data type appropriately.

Return Value
A result code. See "Component Manager Result Codes" (page 380).

Discussion
This function restores the specified component to the list of available components. Applications can then access the component and retrieve information about the component using Component Manager functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

UnregisterComponent

Removes a component from the Component Manager's registration list.

```
OSErr UnregisterComponent (
   Component aComponent
);
```

Parameters

aComponent

The component to be removed. Applications that register components may obtain this identifier from the `RegisterComponent` (page 348) or `RegisterComponentResource` (page 352) functions. The component must not be in use by any applications or components. You can use a component instance here, but you must coerce the data type appropriately.

Return Value
A result code. See "Component Manager Result Codes" (page 380). If there are open connections to the component, returns a `validInstancesExist` error.

Discussion
Most components are registered at startup and remain registered until the computer is shut down. However, you may want to provide some services temporarily. In that case you dispose of the component that provides the temporary service by using this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

Callbacks

ComponentMPWorkFunctionProcPtr

```
typedef ComponentResult (*ComponentMPWorkFunctionProcPtr) (
   void * globalRefCon,
   ComponentMPWorkFunctionHeaderRecordPtr header
);
```

If you name your function `MyComponentMPWorkFunctionProc`, you would declare it like this:

```
ComponentResult MyComponentMPWorkFunctionProc (
```

```
   void * globalRefCon,
   ComponentMPWorkFunctionHeaderRecordPtr header
);
```

Parameters

header

Return Value
See the description of the `ComponentResult` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ComponentRoutineProcPtr

Defines a pointer to your component callback function, which serves as the main entry point into your component and performs the component's services.

```
typedef ComponentResult (*ComponentRoutineProcPtr) (
   ComponentParameters * cp,
   Handle componentStorage
);
```

If you name your function `MyComponentRoutineProc`, you would declare it like this:

```
ComponentResult ComponentRoutineProcPtr (
   ComponentParameters * cp,
   Handle componentStorage
);
```

Parameters

cp

A `ComponentParameters` (page 365) structure. The `what` field of the component parameters structure indicates the action your component should perform. The parameters that the client invoked your function with are contained in the `params` field of the component parameters structure. Your component can use the `CallComponentFunction` (page 321) or `CallComponentFunctionWithStorage` (page 322) function to extract the parameters from this structure.

componentStorage

A handle to any memory that your component has associated with the connection. Typically, upon receiving an open request, your component allocates memory and uses the `SetComponentInstanceStorage` (page 354) function to associate the allocated memory with the component connection.

Return Value
Your component should return a value of type `ComponentResult`. If your component does not return error information as its function result, it should indicate errors using the `SetComponentInstanceError` (page 353) function. See the description of the `ComponentResult` data type.

Discussion
You pass a pointer to your component callback function to the Component Manager when you register your component. The Component Manager can then call your component when another application or component requests its services. When your component receives a request, it should perform the action specified in the `what` field of the component parameters structure.

The pointer which you pass to the Component Manager should be a universal procedure pointer (UPP). The definition of the UPP data type for your component function is as follows:

```
typedef (ComponentRoutineProcPtr) ComponentRoutineUPP;
```

Before using your component function, you must first create a UPP for your callback function, using the `NewComponentRoutineUPP` (page 344) function, as shown here:

```
ComponentRoutineUPP MyComponentRoutineUPP;
MyComponentRoutineUPP =
NewComponentRoutineUPP(&MyComponentRoutineProc)
```

You then pass `MyComponentRoutineUPP` to the Component Manager when you register your component. The Component Manager will call your function each time your component receives a request. If you wish to call your component function yourself, you can use the `InvokeComponentRoutineUPP` (page 342) function.

```
result = InvokeComponentRoutineUPP &myParams, myStorage,
MyComponentRoutineUPP)
```

When you are finished with your component callback function, you should dispose of the universal procedure pointer associated with it, using the `DisposeComponentRoutineUPP` (page 333) function.

```
DisposeComponentRoutineUPP(MyComponentRoutineUPP);
```

To provide a component, you define a component function and supply the appropriate registration information. You store your component function in a code resource and typically store your component's registration information as resources in a component file.

Availability
Available in Mac OS X v10.0 and later.

`Components.h`

GetMissingComponentResourceProcPtr

```
typedef OSErr (*GetMissingComponentResourceProcPtr) (
   Component c,
   OSType resType,
   short resID,
   void * refCon,
   Handle * resource
);
```

If you name your function `MyGetMissingComponentResourceProc`, you would declare it like this:

```
OSErr GetMissingComponentResourceProcPtr (
   Component c,
   OSType resType,
```

```
    short resID,
    void * refCon,
    Handle * resource
);
```

Parameters

c

resType

resource

Return Value
A result code. See "Component Manager Result Codes" (page 380).

`descArray`

ComponentDescription

```
struct ComponentDescription {
    OSType componentType;
    OSType componentSubType;
    OSType componentManufacturer;
    unsigned long componentFlags;
    unsigned long componentFlagsMask;
};
typedef struct ComponentDescription ComponentDescription;
```

Fields

`componentType`

A four-character code that identifies the type of component. All components of a particular type must support a common set of interface functions. For example, drawing components all have a component type of `'draw'`.

If you are developing an application which uses components, you can use this field to search for components of a given type by specifying the component type in this field of the component description structure you supply to the `FindNextComponent` (page 333) function or the `CountComponents` (page 330) function. A value of 0 operates as a wildcard.

If you are developing a component, it must support all of the standard functions for the component type specified by this field. Type codes with all lowercase characters are reserved for definition by Apple. You can define your own component type code as long as you register it with Apple's Component Registry Group.

`componentSubType`

A four-character code that identifies the subtype of the component. Different subtypes of a component type may support additional features or provide interfaces that extend beyond the standard functions for a given component type. For example, the subtype of drawing components indicates the type of object the component draws. Drawing components that draw ovals have a subtype of `'oval'`.

If you are developing an application which uses components, you can use the `componentSubType` field to perform a more specific lookup operation than is possible using only the `componentType` field. By specifying particular values for both fields in the component description structure that you supply to the `FindNextComponent` or `CountComponents` function, your application retrieves information about only those components that meet both of these search criteria. A value of 0 operates as a wildcard.

If you are developing a component, you may use this field to indicate more specific information about the capabilities of the component. There are no restrictions on the content you assign to this field. If no additional information is appropriate for your component type, you may set the `componentSubType` field to 0.

`componentManufacturer`

A four-character code that identifies the manufacturer of the component. This field allows for further differentiation between individual components. For example, components made by a specific manufacturer may support an extended feature set. Components provided by Apple use a manufacturer value of `'appl'`.

If you are developing an application which uses components, you can use this field to find components from a certain manufacturer. Specify the appropriate manufacturer code in this field of the component description structure you supply to the `FindNextComponent` or `CountComponents` function. A value of 0 operates as a wildcard.

If you are developing a component, you obtain your manufacturer code, which can be the same as your application signature, from Apple's Component Registry Group.

`componentFlags`

A 32-bit field that provides additional information about a particular component.

The high-order 8 bits are reserved for definition by the Component Manager. If you are developing an application, you should usually set these bits to 0.

The low-order 24 bits are specific to each component type. These flags can be used to indicate the presence of features or capabilities in a given component.

If you are developing an application which uses components, you can use these flags to further narrow the search criteria applied by the `FindNextComponent` or `CountComponents` function. If you use the `componentFlags` field in a component search, you use the `componentFlagsMask` field to indicate which flags are to be considered in the search.

If you are developing a component, you can use these flags to indicate any special capabilities or features of your component. You may use all 24 bits, as appropriate to its component type. You must set all unused bits to 0.

`componentFlagsMask`

A 32-bit field that indicates which flags in the `componentFlags` field are relevant to a particular component search operation.

If you are developing an application which uses components, your application should set each bit which corresponds to a flag in the `componentFlags` field that is to be considered as a search criterion by the `FindNextComponent` or `CountComponents` function to 1. The Component Manager considers only these flags during the search. You specify the desired flag value (either 0 or 1) in the `componentFlags` field.

For example, to look for a component with a specific control flag that is set to 0, set the appropriate bit in the `ComponentFlags` field to 0 and the same bit in the `ComponentFlagsMask` field to 1. To look for a component with a specific control flag that is set to 1, set the bit in the `ComponentFlags` field to 1 and the same bit in the `ComponentFlagsMask` field to 1. To ignore a flag, set the bit in the `ComponentFlagsMask` field to 0.

If you are developing a component, your component must set the `componentFlagsMask` field in its component description structure to 0.

Discussion

The ComponentDescription structure identifies the characteristics of a component, including the type of services offered by the component and its manufacturer.

Applications and components use component description structures in different ways. An application that uses components specifies the selection criteria for a component in a component description structure. The functions `FindNextComponent` (page 333) , `CountComponents` (page 330) , and `GetComponentInfo` (page 335) all use the component description structure to specify the criteria for their search.

A component uses the component description structure to specify its registration information and capabilities and identify itself to the Component Manager. If your component is stored in a component resource, the information in the component description structure must be part of that resource. See the description of the component 'thng' resource. If you have developed an application that registers your component, that application must supply a component description structure to the `RegisterComponent` (page 348) function. See "Registering Components" for information about registering components.

The `ComponentDescription` data type defines the component description structure. Note that the valid values of fields in the component description structure are determined by the component type specification. For example, all image compressor components must use the `componentSubType` field to specify the compression algorithm used by the compressor.

ComponentParameters

```
struct ComponentParameters {
    UInt8 flags;
    UInt8 paramSize;
    short what;
    long params[1];
};
typedef struct ComponentParameters ComponentParameters;
```

Fields

`flags`

Reserved for use by Apple.

`paramSize`

Specifies the number of bytes of parameter data for this request. The actual parameters are stored in the `params` field.

`what`

Specifies the type of request. Component designers define the meaning of positive values and assign them to requests that are supported by components of a given type. Negative values are reserved for definition by Apple. See "Result Codes" for Apple-defined request code values.

`params`

An array that contains the parameters specified by the application that called your component. You can use the `CallComponentRoutine` or `CallComponentRoutineWithStorage` function to convert this array into a Pascal-style invocation of a subroutine in your component.

Discussion

The Component Manager uses the component parameters structure to pass information to your component about a request from an application. Functions which use this data type are `CallComponentFunction` (page 321), `CallComponentFunctionWithStorage` (page 322), and `DelegateComponentCall` (page 331).The information in this structure completely defines the request. Your component services the request as appropriate.

The `ComponentParameters` data type defines the component parameters structure.

ComponentResource

```
struct ComponentResource {
    ComponentDescription cd;
    ResourceSpec component;
    ResourceSpec componentName;
    ResourceSpec componentInfo;
    ResourceSpec componentIcon;
};
typedef struct ComponentResource ComponentResource;
typedef ComponentResource * ComponentResourcePtr;
```

Fields
cd

A ComponentDescription (page 361) structure that specifies the characteristics of the component.

`component`
: A resource specification structure that specifies the type and ID of the component code resource. The `resType` field of the resource specification structure may contain any value. The component's main entry point must be at offset 0 in the resource.

`componentName`
: A resource specification structure that specifies the resource type and ID for the name of the component. This is a Pascal string. Typically, the name is stored in a resource of type `'STR '`.

`componentInfo`
: A resource specification structure that specifies the resource type and ID for the information string that describes the component. This is a Pascal string. Typically, the information string is stored in a resource of type `'STR '`. You might use the information stored in this resource in a Get Info dialog box.

`componentIcon`
: A resource specification structure that specifies the resource type and ID for the icon for a component. Component icons are stored as 32-by-32 bit maps. Typically, the icon is stored in a resource of type `'ICON'`. Note that this icon is not used by the Finder you supply an icon only so that other components or applications can display your component's icon in a dialog box if needed.

Discussion
The `ComponentResource` data type defines the structure of a component resource. You can also optionally append to the end of this structure the information defined by the `ComponentResourceExtension` (page 367) data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ComponentResourceExtension

```
struct ComponentResourceExtension {
    long componentVersion;
    long componentRegisterFlags;
    short componentIconFamily;
};
typedef struct ComponentResourceExtension ComponentResourceExtension;
```

Fields
`componentVersion`
: The version number of the component. If you specify the `componentDoAutoVersion` flag in `componentRegisterFlags`, the Component Manager must obtain the version number of your component when your component is registered. Either you can provide a version number in your component's resource, or you can specify a value of 0 for its version number. If you specify 0, the Component Manager sends your component a version request to get the version number of your component.

`componentRegisterFlags`
: A set of flags containing additional registration information. See Component Resource Extension Flags (page 372) for the flag values.

`componentIconFamily`
: The resource ID of an icon family. You can provide an icon family in addition to the icon provided in the `componentIcon` field. Note that members of this icon family are not used by the Finder you supply an icon family only so that other components or applications can display your component's icon in a dialog box if needed.

Discussion
You can optionally include in your component resource the information defined by the `ComponentResourceExtension` data type:

Discussion

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ComponentRoutineUPP

```
typedef ComponentRoutineProcPtr ComponentRoutineUPP;
```

Discussion
For more information, see the description of the ComponentRoutineUPP callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ExtComponentResource

```
struct ExtComponentResource {
    ComponentDescription cd;
    ResourceSpec component;
    ResourceSpec componentName;
    ResourceSpec componentInfo;
    ResourceSpec componentIcon;
    long componentVersion;
    long componentRegisterFlags;
    short componentIconFamily;
    long count;
    ComponentPlatformInfo platformArray[1];
};
typedef struct ExtComponentResource ExtComponentResource;
typedef ExtComponentResource * ExtComponentResourcePtr;
```

Fields

`cd`

`component`

`componentName`

`componentInfo`

`componentIcon`

`platformArray`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

GetMissingComponentResourceUPP

```
typedef GetMissingComponentResourceProcPtr GetMissingComponentResourceUPP;
```

Discussion
For more information, see the description of the GetMissingComponentResourceUPP callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

RegisteredComponentInstanceRecord

```
struct RegisteredComponentInstanceRecord {
    long data[1];
};
typedef struct RegisteredComponentInstanceRecord  RegisteredComponentInstanceRecord;
typedef RegisteredComponentInstanceRecord *  RegisteredComponentInstanceRecordPtr;
```

Fields
`data`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

RegisteredComponentRecord

```
struct RegisteredComponentRecord {
    long data[1];
};
typedef struct RegisteredComponentRecord RegisteredComponentRecord;
typedef RegisteredComponentRecord * RegisteredComponentRecordPtr;
```

Fields
`data`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

ResourceSpec

```
struct ResourceSpec {
    OSType resType;
    short resID;
};
typedef struct ResourceSpec ResourceSpec;
```

Fields
`resType`
The type of the resource.

`resID`
The ID of the resource.

Discussion
The `ComponentResource` (page 366) structure uses the resource specification structure, defined by the `ResourceSpec` data type, to describe the component's code, name, information string, or icon. The resources specified by the resource specification structures must reside in the same resource file as the component resource itself.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Components.h`

Constants

cmpAliasNoFlags

```
enum {
    cmpAliasNoFlags = 0,
    cmpAliasOnlyThisFile = 1
};
```

Constants
`cmpAliasNoFlags`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`cmpAliasOnlyThisFile`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

cmpIsMissing

```
enum {
    cmpThreadSafe = 1L << 28,
    cmpIsMissing = 1L << 29,
    cmpWantsRegisterMessage = 1L << 31
};
```

Constants
`cmpThreadSafe`
Available in Mac OS X v10.3 and later.
Declared in `Components.h`.

`cmpIsMissing`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`cmpWantsRegisterMessage`
The setting of the `cmpWantsRegisterMessage` bit determines whether the Component Manager calls this component during registration. Set this bit to 1 if your component should be called when it is registered; otherwise, set this bit to 0.
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

Discussion
These values are used by the `componentFlags` field of the `ComponentDescription` (page 361) structure to provide additional information about a component.

Component Resource Extension Flags

```
enum {
    componentDoAutoVersion = (1 << 0),
    componentWantsUnregister = (1 << 1),
    componentAutoVersionIncludeFlags = (1 << 2),
    componentHasMultiplePlatforms = (1 << 3),
    componentLoadResident = (1 << 4)
};
```

Constants

`componentDoAutoVersion`
Specify this flag if you want the Component Manager to resolve conflicts between different versions of the same component. If you specify this flag, the Component Manager registers your component only if there is no later version available. If an older version is already registered, the Component Manager unregisters it. If a newer version of the same component is registered after yours, the Component Manager automatically unregisters your component. You can use this automatic version control feature to make sure that the most recent version of your component is registered, regardless of the number of versions that are installed

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`componentWantsUnregister`
Specify this flag if you want your component to receive an unregister request when it is unregistered.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`componentAutoVersionIncludeFlags`
Specify this flag if you want the Component Manager to include the `componentFlags` field of the component description structure when it searches for identical components in the process of performing automatic version control for your component. If you do not specify this flag, the Component Manager searches only the `componentType`, `componentSubType`, and `componentManufacturer` fields.

Note that the setting of the `componentAutoVersionIncludeFlags` flag affects automatic version control only and does not affect the search operations performed by `FindNextComponent` and `CountComponents`.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`componentHasMultiplePlatforms`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`componentLoadResident`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

Discussion
These values are used in the `ComponentResourceExtension` (page 367) structure to specify additional information about component registration.

CSComponentsThreadMode

```
typedef UInt32 CSComponentsThreadMode;
enum {
    kCSAcceptAllComponentsMode = 0,
    kCSAcceptThreadSafeComponentsOnlyMode = 1
};
```

Constants

`kCSAcceptAllComponentsMode`
Available in Mac OS X v10.3 and later.
Declared in `Components.h`.

`kCSAcceptThreadSafeComponentsOnlyMode`
Available in Mac OS X v10.3 and later.
Declared in `Components.h`.

kAnyComponentType

```
enum {
    kAnyComponentType = 0,
    kAnyComponentSubType = 0,
    kAnyComponentManufacturer = 0,
    kAnyComponentFlagsMask = 0
};
```

Constants

`kAnyComponentType`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`kAnyComponentSubType`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`kAnyComponentManufacturer`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`kAnyComponentFlagsMask`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

kAppleManufacturer

```
enum {
    kAppleManufacturer = 'appl',
    kComponentResourceType = 'thng',
    kComponentAliasResourceType = 'thga'
};
```

Constants

`kAppleManufacturer`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`kComponentResourceType`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`kComponentAliasResourceType`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

mpWorkFlagDoWork

```
enum {
    mpWorkFlagDoWork = (1 << 0),
    mpWorkFlagDoCompletion = (1 << 1),
    mpWorkFlagCopyWorkBlock = (1 << 2),
    mpWorkFlagDontBlock = (1 << 3),
    mpWorkFlagGetProcessorCount = (1 << 4),
    mpWorkFlagGetIsRunning = (1 << 6)
};
```

Constants

`mpWorkFlagDoWork`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`mpWorkFlagDoCompletion`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`mpWorkFlagCopyWorkBlock`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`mpWorkFlagDontBlock`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`mpWorkFlagGetProcessorCount`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`mpWorkFlagGetIsRunning`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

platform68k

```
enum {
    platform68k = 1,
    platformPowerPC = 2,
    platformInterpreted = 3,
    platformWin32 = 4,
    platformPowerPCNativeEntryPoint = 5,
    platformIA32NativeEntryPoint = 6
};
```

Constants

`platform68k`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformPowerPC`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformInterpreted`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformWin32`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformPowerPCNativeEntryPoint`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformIA32NativeEntryPoint`
Available in Mac OS X v10.3 and later.
Declared in `Components.h`.

Discussion

platformIRIXmips

```
enum {
    platformIRIXmips = 1000,
    platformSunOSsparc = 1100,
    platformSunOSintel = 1101,
    platformLinuxppc = 1200,
    platformLinuxintel = 1201,
    platformAIXppc = 1300,
    platformNeXTIntel = 1400,
    platformNeXTppc = 1401,
    platformNeXTsparc = 1402,
    platformNeXT68k = 1403,
    platformMacOSx86 = 1500
};
```

Constants

`platformIRIXmips`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformSunOSsparc`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformSunOSintel`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformLinuxppc`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformLinuxintel`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformAIXppc`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformNeXTIntel`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformNeXTppc`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformNeXTsparc`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformNeXT68k`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`platformMacOSx86`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

Register Component Resource flags

```
enum {
    registerComponentGlobal = 1,
    registerComponentNoDuplicates = 2,
    registerComponentAfterExisting = 4,
    registerComponentAliasesOnly = 8
};
```

Constants

`registerComponentGlobal`
Specify this flag to indicate that this component should be made available to other applications and clients as well as the one performing the registration. If you do not specify this flag, the component is available for use only by the registering application or component (that is, the component is local to the A5 world of the registering program).
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`registerComponentNoDuplicates`
Specify this flag to indicate that if a component with identical characteristics to the one being registered already exists, then the new one should not be registered (`RegisterComponent` returns 0 in this situation). If you do not specify this flag, the component is registered even if a component with identical characteristics to the one being registered already exists.
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`registerComponentAfterExisting`
Specify this flag to indicate that this component should be registered after all other components with the same component type. Usually components are registered before others with identical descriptions; specifying this flag overrides that behavior.
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

`registerComponentAliasesOnly`
Available in Mac OS X v10.0 and later.
Declared in `Components.h`.

Discussion

The functions `RegisterComponent` (page 348) , `RegisterComponentResource` (page 352) , and `RegisterComponentResourceFile` (page 352) use these flags in the `global` parameter.

Request Codes

```
enum {
    kComponentOpenSelect = -1,
    kComponentCloseSelect = -2,
    kComponentCanDoSelect = -3,
    kComponentVersionSelect = -4,
    kComponentRegisterSelect = -5,
    kComponentTargetSelect = -6,
    kComponentUnregisterSelect = -7,
    kComponentGetMPWorkFunctionSelect = -8,
    kComponentExecuteWiredActionSelect = -9,
    kComponentGetPublicResourceSelect = -10
};
```

Constants

`kComponentOpenSelect`

A request to open a connection. Your component must respond to this request code.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentCloseSelect`

A request to close a connection. Your component must respond to this request code.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentCanDoSelect`

A request to determine whether your component supports a particular request. Your component must respond to this request code

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentVersionSelect`

A request to return your component's version number. Your component must respond to this request code.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentRegisterSelect`

A request to determine whether your component can operate in the current environment. Your component may or may not respond to this request code.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentTargetSelect`

A request to call another component whenever your component would call itself. Your component may or may not respond to this request code.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentUnregisterSelect`
A request to perform any operations necessary as a result of your component being unregistered. Your component may or may not respond to this request code

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentGetMPWorkFunctionSelect`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentExecuteWiredActionSelect`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`kComponentGetPublicResourceSelect`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

Discussion
These values are used in the `ComponentParameters` (page 365) structure to specify the type of a request to a component. Apple has defined these request codes:

Set Default Component Flags

```
enum {
    defaultComponentIdentical = 0,
    defaultComponentAnyFlags = 1,
    defaultComponentAnyManufacturer = 2,
    defaultComponentAnySubType = 4,
    defaultComponentAnyFlagsAnyManufacturer = (defaultComponentAnyFlags  +
defaultComponentAnyManufacturer),
    defaultComponentAnyFlagsAnyManufacturerAnySubType =  (defaultComponentAnyFlags
 + defaultComponentAnyManufacturer +  defaultComponentAnySubType)
};
```

Constants
`defaultComponentIdentical`
The Component Manager places the component specified in the call to `SetDefaultComponent` in front of all other components that have the same component description.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`defaultComponentAnyFlags`
The Component Manager ignores the value of the `componentFlags` field during the reorder operation.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`defaultComponentAnyManufacturer`
The Component Manager ignores the value of the `componentManufacturer` field during the reorder operation.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`defaultComponentAnySubType`
The Component Manager ignores the value of the `componentSubType` field during the reorder operation.

Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`defaultComponentAnyFlagsAnyManufacturer`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

`defaultComponentAnyFlagsAnyManufacturerAnySubType`
Available in Mac OS X v10.0 and later.

Declared in `Components.h`.

Discussion
The `SetDefaultComponent` (page 356) function uses these values in the `flags` parameter to control which component description fields the Component Manager examines during the reorder operation.

Result Codes

The result codes defined by the Component Manager are listed below.

Result Code	Value	Description
`invalidComponentID`	-3000	Invalid component ID. Available in Mac OS X v10.0 and later.
`validInstancesExist`	-3001	This component has open connections. Available in Mac OS X v10.0 and later.
`componentNotCaptured`	-3002	This component has not been captured. Available in Mac OS X v10.0 and later.
`componentDontRegister`	-3003	Available in Mac OS X v10.0 and later.
`unresolvedComponentDLLErr`	-3004	Available in Mac OS X v10.0 and later.
`retryComponentRegistrationErr`	-3005	Available in Mac OS X v10.0 and later.
`badComponentSelector`	0x80008002	Component does not support the specified request code. Available in Mac OS X v10.0 and later.
`badComponentInstance`	0x80008001	Invalid component passed to Component Manager. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Component Manager selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Date, Time, and Measurement Utilities Reference

Framework: CoreServices/CoreServices.h

Declared in DateTimeUtils.h
UTCUtils.h

Overview

You can use the Date, Time, and Measurement Utilities to manipulate the date-time information and geographic location data used by a Macintosh computer. A Macintosh computer contains a battery-operated clock chip that maintains information on the current date-time. In Mac OS 9, the date and time were retrieved from this clock chip. In Mac OS X, the date and time are retrieved through the BSD/CoreFoundation level.

You can use the routines provided by the Date, Time, and Measurement Utilities to

- get the current date and time
- set the current date and time, if necessary
- convert between internal date-time structures
- get and set the geographic location and time-zone information
- determine the number of elapsed microseconds since system startup

Please note, setting the time or geographical location requires authorization by using Authorization Services. See Authorization Concepts for more information.

To make the best use of the Date, Time, and Measurement Utilities, you should be familiar with the international resources, especially the numeric-format and long-date-format resources, and the Script Manager.

Carbon supports the majority of the Date, Time, and Measurement Utilities. However, obsolete functions that are prefixed with “iu” or “IU” (such as `IUDateString` and `IUTimeString`) are not supported.

Functions by Task

Converting Between Date-Time Formats

`DateToSeconds` (page 390) Deprecated in Mac OS X v10.3
Converts a date and time to a number of seconds elapsed since midnight, January 1, 1904. (Deprecated. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

SecondsToDate (page 397) Deprecated in Mac OS X v10.3
Converts a number of seconds elapsed since midnight, January 1, 1904 to a date and time. (Deprecated. Use the CFCalendarRef data type and the functions that operate on it instead.)

Converting Between Long Date-Time Format

LongDateToSeconds (page 395) Deprecated in Mac OS X v10.3
Converts a date and time to the number of seconds elapsed since midnight, January 1, 1904. (Deprecated. Use the CFCalendarRef data type and the functions that operate on it instead.)

LongSecondsToDate (page 395) Deprecated in Mac OS X v10.3
Converts the number of seconds elapsed since midnight, January 1, 1904 to a date and time. (Deprecated. Use the CFCalendarRef data type and the functions that operate on it instead.)

Converting Date and Time Strings Into Numeric Representations

InitDateCache (page 393) Deprecated in Mac OS X v10.3
Initializes the date cache structure, which is used to store data for use by the StringToDate and StringToTime functions. (Deprecated. There is no replacement.)

StringToDate (page 400) Deprecated in Mac OS X v10.3
Parses a string for a date and converts the date information into values in a date-time structure. (Deprecated. Use CFDateFormatterCreateDateFromString instead.)

StringToTime (page 401) Deprecated in Mac OS X v10.3
Parses a string for a time specification and converts the date information into values in a date-time structure. (Deprecated. Use CFDateFormatterCreateDateFromString instead.)

Converting Long Date and Time Values Into Strings

LongDateString (page 394) Deprecated in Mac OS X v10.3
Converts a date that is specified as a LongDateTime value into a Pascal string, making use of the date formatting information in the specified resource. (Deprecated. Use CFDateFormatterCreateStringWithDate instead.)

LongTimeString (page 396) Deprecated in Mac OS X v10.3
Converts a time that is specified as a LongDateTime value into a Pascal string, making use of the time formatting information in the specified resource. (Deprecated. Use CFDateFormatterCreateStringWithDate instead.)

Converting Numeric Representations Into Date and Time Strings

DateString (page 389) Deprecated in Mac OS X v10.3
Converts a date in the standard date-time representation into a Pascal string, making use of the date formatting information in the specified resource. (Deprecated. Use CFDateFormatterCreateStringWithDate instead.)

`TimeString` (page 402) Deprecated in Mac OS X v10.3
Converts a time in the standard date-time representation into a string, making use of the time formatting information in the specified resource. (Deprecated. Use `CFDateFormatterCreateStringWithDate` instead.)

Converting Between CF and Carbon Time Types

`UCConvertCFAbsoluteTimeToUTCDateTime` (page 406)
Converts a value of type `CFAbsoluteTime` to `UTCDateTime`.

`UCConvertCFAbsoluteTimeToSeconds` (page 405)
Converts a value of type `CFAbsoluteTime` to seconds.

`UCConvertCFAbsoluteTimeToLongDateTime` (page 405)
Converts a value of type `CFAbsoluteTime` to `LongDateTime`.

`UCConvertLongDateTimeToCFAbsoluteTime` (page 406)
Converts a value of type `LongDateTime` to `CFAbsoluteTime`.

`UCConvertSecondsToCFAbsoluteTime` (page 407)
Converts a value from the normal seconds time representation to `CFAbsoluteTime`.

`UCConvertUTCDateTimeToCFAbsoluteTime` (page 408)
Converts a value of type `UTCDateTime` time to `CFAbsoluteTime`.

Converting Between UTC and Local Time

`ConvertLocalTimeToUTC` (page 386) Deprecated in Mac OS X v10.4
Converts local time to UTC. (Deprecated. Use `CFTimeZoneGetSecondsFromGMT` instead.)

`ConvertLocalToUTCDateTime` (page 387) Deprecated in Mac OS X v10.4
Converts local date and time to UTC date and time. (Deprecated. Use `CFTimeZoneGetSecondsFromGMT` instead.)

`ConvertUTCToLocalDateTime` (page 388) Deprecated in Mac OS X v10.4
Converts UTC date and time to local date and time. (Deprecated. Use `CFTimeZoneGetSecondsFromGMT` instead.)

`ConvertUTCToLocalTime` (page 388) Deprecated in Mac OS X v10.4
Converts UTC time to local time. (Deprecated. Use `CFTimeZoneGetSecondsFromGMT` instead.)

Getting the Current Date and Time

`GetTime` (page 392)
Obtains the current date-time information, expressed as a date and time. (Deprecated. Use `CFAbsoluteTimeGetCurrent` instead.)

`GetDateTime` (page 390) Deprecated in Mac OS X v10.3
Obtains the current date-time information, expressed as the number of seconds elapsed since midnight, January 1, 1904. (Deprecated. Use `CFAbsoluteTimeGetCurrent` instead.)

`ReadDateTime` (page 397) Deprecated in Mac OS X v10.3
Reads time information from the system. (Deprecated. Use `CFAbsoluteTimeGetCurrent` instead.)

GetLocalDateTime (page 391) Deprecated in Mac OS X v10.4
Gets the local date and time. (Deprecated. Use CFAbsoluteTimeGetCurrent and CFTimeZoneGetSecondsFromGMT instead.)

GetUTCDateTime (page 392) Deprecated in Mac OS X v10.4
Gets the UTC date and time. (Deprecated. Use CFAbsoluteTimeGetCurrent instead.)

Modifying and Verifying Long Date-Time Records

ToggleDate (page 403) Deprecated in Mac OS X v10.3
Modifies a date and time, by modifying one specific component of a date and time (day, hour, minute, seconds, day of week, and so on). (Deprecated. Use the CFCalendarRef data type and the functions that operate on it instead.)

ValidDate (page 408) Deprecated in Mac OS X v10.3
Verifies specific date and time values in a long date-time structure. (Deprecated. Use the CFCalendarRef data type and the functions that operate on it instead.)

Setting the Current Date and Time

SetDateTime (page 398) Deprecated in Mac OS X v10.3
Changes the date-time information stored by the system to the specified value, expressed as the number of seconds elapsed since midnight, January 1, 1904. (Deprecated. There is no replacement.)

SetTime (page 399) Deprecated in Mac OS X v10.3
Changes the date-time information in the system to the specified value, expressed as a date and time. (Deprecated. There is no replacement.)

SetLocalDateTime (page 398) Deprecated in Mac OS X v10.4
Sets the local date and time. (Deprecated. There is no replacement.)

SetUTCDateTime (page 400) Deprecated in Mac OS X v10.4
Sets the UTC date and time. (Deprecated. Use settimeofday(2) instead.)

Functions

ConvertLocalTimeToUTC

Converts local time to UTC. (Deprecated in Mac OS X v10.4. Use CFTimeZoneGetSecondsFromGMT instead.)

```
OSStatus ConvertLocalTimeToUTC (
   UInt32 localSeconds,
   UInt32 *utcSeconds
);
```

Parameters

localSeconds
A value of type UInt32 containing the local time.

utcSeconds
A pointer to a value of type `UInt32`. On return, this points to the UTC value corresponding to the given time in `localSeconds`.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Given a local time in `localSeconds`, the function will place the corresponding UTC value in `utcSeconds`. This function returns `noErr` if the conversion is successful. Otherwise, it may return `kUTCUnderflowErr` or `kUTCOverflowErr`.

Special Considerations

For information on using `CFTimeZoneGetSecondsFromGMT`, see *Dates and Times Programming Guide for Core Foundation* and*CFTimeZone Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`UTCUtils.h`

ConvertLocalToUTCDateTime

Converts local date and time to UTC date and time. (Deprecated in Mac OS X v10.4. Use `CFTimeZoneGetSecondsFromGMT` instead.)

```
OSStatus ConvertLocalToUTCDateTime (
   const LocalDateTime *localDateTime,
   UTCDateTime *utcDateTime
);
```

Parameters

localDateTime
A value of type `LocalDateTime` containing the local date and time.

utcDateTime
A pointer to a value of type `UTCDateTime`. On return, this points to the UTC value corresponding to the given date and time in `localDateTime`.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Given a local date and time in the `localDateTime` parameter, this function places the corresponding UTC value in `utcDateTime`. This function returns `noErr` if the conversion is successful. Otherwise, it may return `kUTCUnderflowErr`, `kUTCOverflowErr`, or `paramErr` if `utcDateTime` is `NULL`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`UTCUtils.h`

ConvertUTCToLocalDateTime

Converts UTC date and time to local date and time. (Deprecated in Mac OS X v10.4. Use `CFTimeZoneGetSecondsFromGMT` instead.)

```
OSStatus ConvertUTCToLocalDateTime (
   const UTCDateTime *utcDateTime,
   LocalDateTime *localDateTime
);
```

Parameters

`utcDateTime`
A value of type `UTCDateTime` specifying the UTC date and time.

`localDateTime`
A pointer to a value of type `LocalDateTime`. On return, this points to the local value corresponding to the given date and time in `utcDateTime`.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Given a UTC date and time in `utcDateTime`, this function places the corresponding local value in `localDateTime`. This function returns `noErr` if the conversion is successful. Otherwise, it may return `kUTCUnderflowErr`, `kUTCOverflowErr`, or `paramErr` if `localDateTime` is `NULL`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`UTCUtils.h`

ConvertUTCToLocalTime

Converts UTC time to local time. (Deprecated in Mac OS X v10.4. Use `CFTimeZoneGetSecondsFromGMT` instead.)

```
OSStatus ConvertUTCToLocalTime (
   UInt32 utcSeconds,
   UInt32 *localSeconds
);
```

Parameters

`utcSeconds`
A value of type `UInt32` specifying UTC time in seconds.

`localSeconds`
A pointer to a value of type `UInt32`. On return, this points to the local time corresponding to the UTC time specified in `utcSeconds`.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Given a UTC time in `utcSeconds` this function places the corresponding local value in `localSeconds`. This function returns `noErr` if the conversion is successful. Otherwise, it may return `kUTCUnderflowErr` or `kUTCOverflowErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`UTCUtils.h`

DateString

Converts a date in the standard date-time representation into a Pascal string, making use of the date formatting information in the specified resource. (Deprecated in Mac OS X v10.3. Use `CFDateFormatterCreateStringWithDate` instead.)

```
void DateString (
   SInt32 dateTime,
   DateForm longFlag,
   Str255 result,
   Handle intlHandle
);
```

Parameters

`dateTime`

The date-time value in the representation returned by the `GetDateTime` function. The numeric representation used in these functions is the standard date-time representation: a 32-bit integer value that is returned by the `GetDateTime` function. This is a long integer value that represents the number of seconds between midnight, January 1, 1904, and the time at which `GetDateTime` was called.

`longFlag`

A flag that indicates the desired format for the date string. This is one of the three values defined as the `DateForm` type.

The string produced by `DateString` is in one of three standard date formats used on the Macintosh, depending on which of the three `DateForm` values that you specify for the `longFlag` parameter: `shortDate`, `abbrevDate`, or `longDate`. The information in the supplied resource defines how month and day names are written and provides for calendars with more than 7 days and more than 12 months.

For the Roman script system's resource, the date January 31, 1992, produces the following three strings: "1/31/92", "Fri, Jan 31, 1992", and "Friday, January 31, 1992"(for `DateForm` values `shortDate`, `abbrevDate`, and `longDate`, respectively).

`result`

On output, contains the string representation of the date in the format indicated by the `longFlag` parameter.

intlHandle

A handle to a numeric-format or a long-date-format resource that specifies date formatting information for use in the conversion. If you specify `NULL` as the value of the resource handle parameter, `DateString` uses information from the current script. The numeric-format (`'itl0'`) resource specifies the short date formats and the long-date-format (`'itl1'`) resource specifies the long date formats.

`DateString` formats its data according to the information in the specified numeric-format resource (for short date formats) or long-date-format resource (for long date formats). If you specify `shortDate`, the `intlHandle` value should be the handle to a numeric-format resource; if you specify `abbrevDate` or `longDate`, it should be the handle to a long-date-format resource.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

DateToSeconds

Converts a date and time to a number of seconds elapsed since midnight, January 1, 1904. (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
void DateToSeconds (
   const DateTimeRec *d,
   unsigned long *secs
);
```

Parameters

d

The date-time structure containing the date and time to convert.

secs

On return, the number of seconds elapsed between midnight, January 1, 1904, and the time specified in the `d` parameter. For example, specifying a date and time of 11:33 A.M. on January 1, 1904 results in 41580 being returned in this parameter.

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

GetDateTime

Obtains the current date-time information, expressed as the number of seconds elapsed since midnight, January 1, 1904. (Deprecated in Mac OS X v10.3. Use `CFAbsoluteTimeGetCurrent` instead.)

```
void GetDateTime (
   unsigned long *secs
);
```

Parameters

secs

On return, the number of seconds elapsed since midnight, January 1, 1904.

Discussion

The low-memory copy of the date and time information is also accessible through the global variable `Time`.

If an application disables interrupts for longer than a second, the date-time information returned by the `GetDateTime` function might not be exact. The `GetDateTime` function is intended to provide fairly accurate time information, but not scientifically precise data.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

GetLocalDateTime

Gets the local date and time. (Deprecated in Mac OS X v10.4. Use `CFAbsoluteTimeGetCurrent` and `CFTimeZoneGetSecondsFromGMT` instead.)

```
OSStatus GetLocalDateTime (
   LocalDateTime *localDateTime,
   OptionBits options
);
```

Parameters

localDateTime

A pointer to a value of type `LocalDateTime`. On return, the value this parameter points to is the current local date and time.

options

A value of type `OptionBits`. Pass `kUTCDefaultOptions` for the default behavior.

Return Value

A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion

This API returns the current date and time in `localTime`. Otherwise, it is set to 0. Use `kUTCDefaultOptions` in the options parameter for default behavior. Different behavior may be specified through this parameter in the future. If the operation is successful `noErr` is returned. If a `NULL` pointer is passed in the `localDateTime` parameter, `paramErr` is returned.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
UTCUtils.h

GetTime

Obtains the current date-time information, expressed as a date and time. (**Deprecated.** Use `CFAbsoluteTimeGetCurrent` instead.)

```
void GetTime (
   DateTimeRec *d
);
```

Parameters

d

On return, the fields of the date-time structure contain the current date and time.

Discussion
The `GetTime` function first calls the `GetDateTime` function to obtain the number of seconds elapsed since midnight, January 1, 1904. It then calls the `SecondsToDate` function to convert the number of seconds into a date and time.

As an alternative to using the `GetTime` procedure, you can pass the value of the global variable `Time` to the `SecondsToDate` (page 397) function; a `SecondsToDate(Time)` function call is identical to a `GetTime(d)` function call.

If an application disables interrupts for longer than a second, the date-time information returned by the `GetTime` function might not be exact. The `GetTime` function is intended to provide fairly accurate time information, but not scientifically precise data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
QuickTimeComponents.k.h

GetUTCDateTime

Gets the UTC date and time. (Deprecated in Mac OS X v10.4. Use `CFAbsoluteTimeGetCurrent` instead.)

```
OSStatus GetUTCDateTime (
   UTCDateTime *utcDateTime,
   OptionBits options
);
```

Parameters

utcDateTime

A pointer to a value of type `UTCDateTime`. On return, the value this parameter points to is the current UTC date and time.

options

A value of type `OptionBits`. Pass `kUTCDefaultOptions` for the default behavior.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
This API returns the current date and time as UTC in `utcDateTime`. Otherwise, it is set to 0. Use `kUTCDefaultOptions` in the options for default behavior. Different behavior may be specified through this parameter in the future. If the operation is successful `noErr` is returned. If a `NULL` pointer is passed in `utcDateTime`, `paramErr` is returned.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`UTCUtils.h`

InitDateCache

Initializes the date cache structure, which is used to store data for use by the `StringToDate` and `StringToTime` functions. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
OSErr InitDateCache (
   DateCachePtr theCache
);
```

Parameters

theCache
A pointer to a date cache structure. This parameter can be a local variable, a pointer, or a locked handle.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
You must call `InitDateCache` to initialize the date cache structure before using either the `StringToDate` (page 400) or `StringToTime` (page 401) functions. You must pass a pointer to a date cache structure. You have to declare the structure as a variable or allocate it in the heap.

If you are writing an application that allows the use of global variables, you can make your date cache structure a global variable and initialize it once, when you perform other global initialization.

`InitDateCache` calls the `GetResource` and `LoadResource` functions and it can also return the error codes they produce.

Special Considerations
You no longer need to initialize the data cache in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

LongDateString

Converts a date that is specified as a `LongDateTime` value into a Pascal string, making use of the date formatting information in the specified resource. (Deprecated in Mac OS X v10.3. Use `CFDateFormatterCreateStringWithDate` instead.)

```
void LongDateString (
   const LongDateTime *dateTime,
   DateForm longFlag,
   Str255 result,
   Handle intlHandle
);
```

Parameters

dateTime

A pointer to a 64-bit, signed representation of the number of seconds since Jan. 1, 1904. This allows coverage of a much longer span of time (plus or minus approximately 30,000 years) than the standard, 32-bit representation.

longFlag

A flag that indicates the desired format for the date string. This is one of the three values defined as the `DateForm` type.

The string produced by `LongDateString` is in one of three standard date formats used on the Macintosh, depending on which of the three `DateForm` values that you specify for the `longFlag` parameter: `shortDate`, `abbrevDate`, or `longDate`. The information in the supplied resource defines how month and day names are written and provides for calendars with more than 7 days and more than 12 months.

For the U.S. resource, the date January 31, 1992, produces the following three strings: "1/31/92", "Fri, Jan 31, 1992", and "Friday, January 31, 1992"(for `DateForm` values `shortDate`, `abbrevDate`, and `longDate`, respectively).

result

On output, contains the string representation of the date in the format indicated by the `longFlag` parameter.

intlHandle

A handle to a numeric-format or long-date-format resource that specifies date formatting information for use in the conversion. If you specify `NULL` as the value of the resource handle parameter, `LongDateString` uses information from the current script. The numeric-format (`'itl0'`) resource specifies the short date formats and the long-date-format (`'itl1'`) resource specifies the long date formats.

If you specify `shortDate` in the `longFlag` parameter, the `intlHandle` value should be the handle to a numeric-format resource; if you specify `abbrevDate` or `longDate`, it should be the handle to a long-date-format resource.

Discussion

You can use the `LongSecondsToDate` and `LongDateToSeconds` functions to convert between the `LongDateRec` (as produced by the `StringToDate` function) and `LongDateTime` data types.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

LongDateToSeconds

Converts a date and time to the number of seconds elapsed since midnight, January 1, 1904. (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
void LongDateToSeconds (
   const LongDateRec *lDate,
   LongDateTime *lSecs
);
```

Parameters

lDate

The long date-time structure containing the date and time to convert.

lSecs

On return, the number of seconds elapsed since midnight, January 1, 1904, and the time specified in the `lDate` parameter. The number of seconds are returned as a long date-time value.

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

LongSecondsToDate

Converts the number of seconds elapsed since midnight, January 1, 1904 to a date and time. (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
void LongSecondsToDate (
   const LongDateTime *lSecs,
   LongDateRec *lDate
);
```

Parameters

lSecs

The number of seconds elapsed since midnight, January 1, 1904.

lDate

On return, the fields of the long date-time structure that contain the date and time corresponding to the value indicated in the `lSecs` parameter. For example, specifying the number of seconds 41580 results in the date and time 11:33 A.M. on January 1, 1904 being returned in this parameter.

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
DateTimeUtils.h

LongTimeString

Converts a time that is specified as a LongDateTime value into a Pascal string, making use of the time formatting information in the specified resource. (Deprecated in Mac OS X v10.3. Use CFDateFormatterCreateStringWithDate instead.)

```
void LongTimeString (
   const LongDateTime *dateTime,
   Boolean wantSeconds,
   Str255 result,
   Handle intlHandle
);
```

Parameters

dateTime

A pointer to a 64-bit, signed representation of the number of seconds since Jan. 1, 1904. This allows coverage of a much longer span of time (plus or minus approximately 30,000 years) than the standard, 32-bit representation.

wantSeconds

A flag that indicates whether the seconds are to be included in the resulting string. LongTimeString produces a string that includes the seconds if you set this parameter to TRUE.

result

On output, contains the string representation of the time.

intlHandle

A handle to a numeric-format ('itl0') resource that specifies time formatting information for use in the conversion. If you specify NULL as the value of the resource handle parameter, LongTimeString uses information from the current script.

The numeric-format resource specifies whether or not to use leading zeros for the time values, whether to use a 12- or 24-hour time cycle, and how to specify morning or evening if a 12-hour time cycle is used.

Discussion
You can use the LongSecondsToDate and LongDateToSeconds functions to convert between the LongDateRec (as produced by the StringToTime (page 401) function) and LongDateTime data types.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
DateTimeUtils.h

ReadDateTime

Reads time information from the system. (Deprecated in Mac OS X v10.3. Use `CFAbsoluteTimeGetCurrent` instead.)

```
OSErr ReadDateTime (
   unsigned long *time
);
```

Parameters

time

On return, the current time expressed as the number of seconds elapsed since midnight, January 1, 1904.

Return Value

A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421). If the clock chip cannot be read, `ReadDateTime` returns the `clkRdErr` result code. The operation might fail if the clock chip is damaged. Otherwise, the function returns the `noErr` result code.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

SecondsToDate

Converts a number of seconds elapsed since midnight, January 1, 1904 to a date and time. (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
void SecondsToDate (
   unsigned long secs,
   DateTimeRec *d
);
```

Parameters

secs

The number of seconds elapsed since midnight, January 1, 1904.

d

On return, the fields of the date-time structure that contain the date and time corresponding to the value indicated in the `s` parameter.

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

SetDateTime

Changes the date-time information stored by the system to the specified value, expressed as the number of seconds elapsed since midnight, January 1, 1904. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
OSErr SetDateTime (
   unsigned long time
);
```

Parameters

time

The number of seconds elapsed since midnight, January 1, 1904; this value is written to the system.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421). The `SetDateTime` function attempts to verify the value written by reading it back in and comparing it to the value in the low-memory copy. If a problem occurs, the `SetDateTime` function returns either the `clkRdErr` result code, because the clock chip could not be read, or the `clkWrErr` result code, because the time written to the clock chip could not be verified. Otherwise, the function returns the `noErr` result code.

Special Considerations

Only the root user can set the time in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

SetLocalDateTime

Sets the local date and time. (Deprecated in Mac OS X v10.4. There is no replacement.)

```
OSStatus SetLocalDateTime (
   const LocalDateTime *localDateTime,
   OptionBits options
);
```

Parameters

localDateTime

A pointer to a value of type `LocalDateTime` specifying the current local date and time.

options

A value of type `OptionBits`. Pass `kUTCDefaultOptions` for the default behavior.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use this call to set the clock to the date and time passed in the `localDateTime` parameter. Use `kUTCDefaultOptions` in the options for default behavior. Different behavior may be specified through this parameter in the future. If successful `noErr` is returned. Other errors include `kIllegalClockValueErr`, `paramErr` if `localDateTime` is `NULL`, or `clkWrErr` due to a failed attempt to write the value to the system.

Special Considerations

Only the root user can set the time in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`UTCUtils.h`

SetTime

Changes the date-time information in the system to the specified value, expressed as a date and time. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
void SetTime (
   const DateTimeRec *d
);
```

Parameters

d

The date and time to which to set in the system.

Discussion
The `SetTime` function first converts the date and time to the number of seconds elapsed since midnight, January 1, 1904 by calling the `DateToSeconds` function. It then writes these seconds to the system and to the system global variable `Time` by calling the `SetDateTime` function.

The `SetTime` function does not return a result code. If you need to know whether an attempt to change the date and time information in the system is successful, you must use the `SetDateTime` function.

As an alternative to using the `SetTime` procedure, you can use the `DateToSeconds` (page 390) and `SetDateTime` (page 398) functions.

Special Considerations

Only the root user can set the time in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

SetUTCDateTime

Sets the UTC date and time. (Deprecated in Mac OS X v10.4. Use settimeofday(2) instead.)

```
OSStatus SetUTCDateTime (
   const UTCDateTime *utcDateTime,
   OptionBits options
);
```

Parameters

utcDateTime

A pointer to a value of type `UTCDateTime` specifying the current UTC date and time.

options

A value of type `OptionBits`. Pass `kUTCDefaultOptions` for the default behavior.

Return Value

A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion

Use this call to set the clock to the date and time passed in the `utcDateTime` parameter. Use `kUTCDefaultOptions` in the options for default behavior. Different behavior may be specified through this parameter in the future. If successful `noErr` is returned. Other errors include `kIllegalClockValueErr`, `kUTCUnderflowErr`, `kUTCOverflowErr`, and `paramErr` if `NULL` is passed for `utcDateTime`. It may also return `clkWrErr` due to a failed attempt to write the value to the system.

Special Considerations

Only the root user can set the time in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`UTCUtils.h`

StringToDate

Parses a string for a date and converts the date information into values in a date-time structure. (Deprecated in Mac OS X v10.3. Use `CFDateFormatterCreateDateFromString` instead.)

```
StringToDateStatus StringToDate (
   Ptr textPtr,
   SInt32 textLen,
   DateCachePtr theCache,
   SInt32 *lengthUsed,
   LongDateRec *dateTime
);
```

Parameters

textPtr

A pointer to the text string to be parsed. `StringToDate` expects a date specification, in a format defined by the current script, at the beginning of the string.

textLen

The number of bytes in the text string.

theCache

A pointer to the date cache structure initialized by the `InitDateCache` (page 393) function with data that is used during the conversion process.

lengthUsed

On output, contains a pointer to the number of bytes of the string that were parsed for the date. Use this value to compute the starting location of the text that you can pass to `StringToTime` (page 401). Alternatively, you can use them in reverse order.

dateTime

On output, a pointer to the `LongDateRec` structure, which contains the year, month, day, and day of the week parsed for the date.

Return Value

A set of bit values that indicate confidence levels, with higher numbers indicating low confidence in how closely the input string matched what the function expected. For example, specifying a date with nonstandard separators may work, but it returns a message indicating that the separator was not standard. See the description of the `StringToDateStatus` data type.

Discussion

`StringToDate` parses the text string until it has finished finding all date information or until it has examined the number of bytes specified by `textLen`.

Note that `StringToDate` fills in only the year, month, day, and day of the week; `StringToTime` fills in the hour, minute, and second. You can use these two functions sequentially to fill in all of the values in a `LongDateRec` structure.

When one of the date components is missing, such as the year, the current date value is used as a default.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

StringToTime

Parses a string for a time specification and converts the date information into values in a date-time structure. (Deprecated in Mac OS X v10.3. Use `CFDateFormatterCreateDateFromString` instead.)

```
StringToDateStatus StringToTime (
   Ptr textPtr,
   SInt32 textLen,
   DateCachePtr theCache,
   SInt32 *lengthUsed,
   LongDateRec *dateTime
);
```

Parameters

textPtr

A pointer to the text string to be parsed. At the beginning of the string, `StringToTime` expects a time specification in a format defined by the current script.

textLen

The number of bytes in the text string.

theCache

A pointer to the date cache structure initialized by the `InitDateCache` function with data that is used during the conversion process.

lengthUsed

On output, contains a pointer to the length, in bytes, of the string that was parsed for the time.

dateTime

On output, a pointer to the `LongDateRec` structure, which contains the hour, minute, and second values that were parsed for the time.

Return Value

`StringToTime` returns a status value that indicates the confidence level for the success of the conversion. This is the same status value indicator type as does `StringToDate`: a set of bit values that indicate confidence levels, with higher numbers indicating low confidence in how closely the input string matched what the function expected. See the description of the `StringToDateStatus` data type.

Discussion

`StringToTime` parses the string until it has finished finding all time information or until it has examined the number of bytes specified by `textLen`.

Note that `StringToTime` fills in only the hour, minute, and second; `StringToDate` (page 400) fills in the year, month, day, and day of the week. You can use these two functions sequentially to fill in all of the values in a `LongDateRec` structure.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

TimeString

Converts a time in the standard date-time representation into a string, making use of the time formatting information in the specified resource. (Deprecated in Mac OS X v10.3. Use `CFDateFormatterCreateStringWithDate` instead.)

```
void TimeString (
   SInt32 dateTime,
   Boolean wantSeconds,
   Str255 result,
   Handle intlHandle
);
```

Parameters

dateTime

The date-time value in the representation returned by the Operating System function `GetDateTime`. The numeric representation used in these functions is the standard date-time representation: a 32-bit integer value that is returned by the `GetDateTime` function. This is a long integer value that represents the number of seconds between midnight, January 1, 1904, and the time at which `GetDateTime` was called.

wantSeconds

A flag that indicates whether the seconds are to be included in the resulting string.

result

On output, contains the string representation of the time.

intlHandle

A handle to a numeric-format (`'itl0'`) resource that specifies time formatting information for use in the conversion. If you specify `NULL` as the value of the resource handle parameter, `TimeString` uses information from the current script.

The numeric-format resource specifies whether or not to use leading zeros for the time values, whether to use a 12- or 24-hour time cycle, and how to specify morning or evening if a 12-hour time cycle is used.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`DateTimeUtils.h`

ToggleDate

Modifies a date and time, by modifying one specific component of a date and time (day, hour, minute, seconds, day of week, and so on). (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
ToggleResults ToggleDate (
   LongDateTime *lSecs,
   LongDateField field,
   DateDelta delta,
   short ch,
   const TogglePB *params
);
```

Parameters

lSecs

The date-time information to modify, expressed as the number of seconds elapsed since midnight, January 1, 1904.

field
The name of the field in the date-time structure you want modify. Use one of the Long Date Mask Constants (page 418) for the value of this parameter.

delta
A signed byte specifying the action you want to perform on the value specified in the `field` parameter. Set `delta` to 1, to increase the value in the field by 1. Set `delta` to -1, to decrease the value of the field by 1. Set `delta` to 0. If you want to set the value of the field explicitly; pass the new value through the `ch` field.

ch
If the value in the `delta` field is 0, the value of the field in the date-time structure (specified by the `field` parameter) is set to the value in the `ch` parameter. If the value in the `delta` field is not equal to 0, the value in the `ch` parameter is ignored.

params
The user-defined settings of the toggle parameter block settings.

Return Value
See the description of the `ToggleResults` data type.

Discussion
The relevant fields of the toggle parameter block are:

- `togFlags` A value of type `SInt32`. On input, the fields to be checked by the `ValidDate` function.
- `amChars` A value of type `ResType`. On input, A.M. characters from `'itl0'` resource.
- `pmChars` A value of type `ResType`. On input, P.M. characters from `'itl0'` resource.
- `reserved` An array of `SInt32` values. Reserved; on input, set each element to 0.

You must supply values for all input parameters.

The `ToggleDate` function first converts the number of seconds and makes each component of the date and time available through a long date-time structure. The `ToggleDate` function then modifies the value of the field, specified by the `field` parameter. If the value in the `delta` field is greater than 0, the value of the field increases by 1; if the value in the `delta` field is less than 0, the value of the field decreases by 1; and if the value of `delta` is 0, the value of the field is explicitly set to the value specified in the `ch` field. After the `ToggleDate` function modifies the field, it calls the `ValidDate` function. The `ValidDate` function checks the long date-time structure for correctness. If any of the structure fields are invalid, the `ValidDate` function returns a `LongDateField` value corresponding to the field in error. Otherwise, it returns the result code for `validDateFields`. Note that `ValidDate` reports only the least significant erroneous field.

After the `ToggleDate` function checks the validity of the modified field, it converts the modified date and time back into a number of seconds and returns these seconds in the `lSecs` parameter.

The `ToggleDate` function was previously available with the Script Manager.

For more information on the `LongDateRec` structure, see `LongDateRec` (page 413). The toggle parameter block structure is described in `TogglePB` (page 415).

For more information about the `GetIntlResource` function, see the Script Manager. For details on the `UppercaseText` function, see Text Utilities.

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

UCConvertCFAbsoluteTimeToLongDateTime

Converts a value of type `CFAbsoluteTime` to `LongDateTime`.

```
OSStatus UCConvertCFAbsoluteTimeToLongDateTime (
   CFAbsoluteTime iCFTime,
   LongDateTime *oLongDate
);
```

Parameters

`iCFTime`
A CFAbsoluteTime value that represents the time from which you wish to convert.

`oLongDate`
A pointer to a value of type `LongDateTime`. On successful return, this will contain the converted time from the `CFAbsoluteTime` input.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertCFAbsoluteTimeToLongDateTime` to convert from a `CFAbsoluteTime` to a `LongDateTime`. Remember that the epoch for `LongDateTime` is January 1, 1904 while the epoch for `CFAbsoluteTime` is January 1, 2001.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

UCConvertCFAbsoluteTimeToSeconds

Converts a value of type `CFAbsoluteTime` to seconds.

```
OSStatus UCConvertCFAbsoluteTimeToSeconds (
   CFAbsoluteTime iCFTime,
   UInt32 *oSeconds
);
```

Parameters

`iCFTime`
A `CFAbsoluteTime` value that represents the time from which you wish to convert.

oSeconds
A pointer to a value of type `UInt32`. On successful return, this contains the converted time from the `CFAbsoluteTime` input.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertCFAbsoluteTimeToSeconds` to convert from a `CFAbsoluteTime` to a *`UInt32`* representation of seconds. Remember that the epoch for seconds is January 1, 1904 while the epoch for CFAbsoluteTime is January 1, 2001.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

UCConvertCFAbsoluteTimeToUTCDateTime

Converts a value of type `CFAbsoluteTime` to `UTCDateTime`.

```
OSStatus UCConvertCFAbsoluteTimeToUTCDateTime (
   CFAbsoluteTime iCFTime,
   UTCDateTime *oUTCDate
);
```

Parameters
`iCFTime`
A `CFAbsoluteTime` value that represents the time from which you wish to convert.

`oUTCDate`
A pointer to a `UTCDateTime`. On successful return, this will contain the converted time from the `CFAbsoluteTime` input.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertCFAbsoluteTimeToUTCDateTime` to convert from a `CFAbsoluteTime` to a `UTCDateTime`. Remember that the epoch for `UTCDateTime` is January 1, 1904 while the epoch for `CFAbsoluteTime` is January 1, 2001.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

UCConvertLongDateTimeToCFAbsoluteTime

Converts a value of type `LongDateTime` to `CFAbsoluteTime`.

```
OSStatus UCConvertLongDateTimeToCFAbsoluteTime (
   LongDateTime iLongTime,
   CFAbsoluteTime *oCFTime
);
```

Parameters

iLongTime

A `LongDateTime` value that represents the time from which you wish to convert.

oCFTime

A pointer to a `CFAbsoluteTime`. On successful return, this will contain the converted time from the input time type.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertLongDateTimeToCFAbsoluteTime` to convert from a `LongDateTime` to a `CFAbsoluteTime`. Remember that the epoch for LongDateTime is January 1, 1904 while the epoch for `CFAbsoluteTime` is January 1, 2001.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

UCConvertSecondsToCFAbsoluteTime

Converts a value from the normal seconds time representation to `CFAbsoluteTime`.

```
OSStatus UCConvertSecondsToCFAbsoluteTime (
   UInt32 iSeconds,
   CFAbsoluteTime *oCFTime
);
```

Parameters

iSeconds

A `UInt32` value that represents the time from which you wish to convert.

oCFTime

A pointer to a `CFAbsoluteTime`. On successful return, this will contain the converted time from the input time type.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertSecondsToCFAbsoluteTime` to convert from the normal seconds representation of time to a `CFAbsoluteTime`. Remember that the epoch for seconds is January 1, 1904 while the epoch for `CFAbsoluteTime` is January 1, 2001.

Keep in mind that this function converts local time (that is, the time in the local time zone) to GMT/UTC.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

UCConvertUTCDateTimeToCFAbsoluteTime

Converts a value of type `UTCDateTime` time to `CFAbsoluteTime`.

```
OSStatus UCConvertUTCDateTimeToCFAbsoluteTime (
   const UTCDateTime *iUTCDate,
   CFAbsoluteTime *oCFTime
);
```

Parameters

iUTCDate
A pointer to a `UTCDateTime` structure that represents the time from which you wish to convert.

oCFTime
A pointer to a `CFAbsoluteTime`. On successful return, this contains the converted time from the input time type.

Return Value
A result code. See "Date, Time, and Measurement Utilities Result Codes" (page 421).

Discussion
Use `UCConvertUTCDateTimeToCFAbsoluteTime` to convert from a `UTCDDateTime` to a `CFAbsoluteTime`. Remember that the epoch for `UTCDateTime` is January 1, 1904 while the epoch for `CFAbsoluteTime` is January 1, 2001.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`DateTimeUtils.h`

ValidDate

Verifies specific date and time values in a long date-time structure. (Deprecated in Mac OS X v10.3. Use the `CFCalendarRef` data type and the functions that operate on it instead.)

```
short ValidDate (
   const LongDateRec *vDate,
   long flags,
   LongDateTime *newSecs
);
```

Parameters

vDate
The long date-time structure whose fields you want to verify.

flags
The fields that you want to verify in the long date-time structure. For a description of the values you can use in this parameter, see Long Date Mask Constants (page 418).

newSecs
The date-time information, passed by the `ToggleDate` function, that you want to verify.

Return Value
If any of the specified fields contain invalid values, the `ValidDate` function returns a `LongDateField` value indicating the field in error. Otherwise, it returns the constant `validDateFields`. `ValidDate` reports only the least significant erroneous field.

Discussion
For more information on the `LongDateRec` structure, see `LongDateRec` (page 413). The toggle parameter block structure is described in `TogglePB` (page 415).

Special Considerations

For information on using the `CFCalendarRef` data type, see *Data Formatting Guide for Core Foundation* and *CFCalendar Reference*.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`DateTimeUtils.h`

Data Types

DateCacheRecord

```
struct DateCacheRecord {
    short hidden[256];
};
typedef struct DateCacheRecord DateCacheRecord;
typedef DateCacheRecord * DateCachePtr;
```

Fields
`hidden`
The storage used for converting dates and times.

Discussion
The `StringToDate` and `StringToTime` functions use the date cache, defined by the `DateCacheStructure` data type, as an area to store date conversion data that is used by the date conversion functions. This structure must be initialized by a call to the `InitDateCache` (page 393) function. The data in this structure is private—you should not attempt to access it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`DateTimeUtils.h`

DateDelta

```
typedef SInt8 DateDelta;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`DateTimeUtils.h`

DateTimeRec

```
struct DateTimeRec {
    short year;
    short month;
    short day;
    short hour;
    short minute;
    short second;
    short dayOfWeek;
};
typedef struct DateTimeRec DateTimeRec;
```

Fields

`year`

The year, ranging from 1904 to 2040. Note that to indicate the year 1984, this field would store the integer 1984, not just 84. This field accepts input of 0 or negative values, but these values produce unpredictable results in the `year`, `month`, and `day` fields when you use the `SecondsToDate` and `DateToSeconds` functions. In addition, using `SecondsToDate` and `DateToSeconds` with year values greater than 2040 causes a wraparound to 1904 plus the number of years over 2040. For example, setting the year to 2045 returns a value of 1909, and the other fields in this record return unpredictable results.

`month`

The month of the year, where 1 represents January, and 12 represents December. Values greater than 12 cause a wraparound to a future year and month. This field accepts input of 0 or negative values, but these values produce unpredictable results in the `year`, `month`, and `day` fields when you use the `SecondsToDate` and `DateToSeconds` functions.

`day`

The day of the month, ranging from 1 to 31. Values greater than the number of days in a given month cause a wraparound to a future month and day. This feature is useful for working with leap years. For example, the 366th day of January in 1992 (1992 was a leap year) evaluates as December 31, 1992, and the 367th day of that year evaluates as January 1, 1993.

This field accepts 0 or negative values, but when you use the `SecondsToDate` and `DateToSeconds` procedures, a value of 0 in this field returns the last day of the previous month. For example, a month value of 2 and a day value of 0 return 1 and 31, respectively.

Using `SecondsToDate` and `DateToSeconds` with a negative number in this field subtracts that number of days from the last day in the previous month. For example, a month value of 5 and a day value of –1 return 4 for the month and 29 for the day a month value of 2 and a day value of –15 return 1 and 16, respectively.

`hour`

The hour of the day, ranging from 0 to 23, where 0 represents midnight and 23 represents 11:00 P.M. Values greater than 23 cause a wraparound to a future day and hour. This field accepts input of negative values, but these values produce unpredictable results in the `month`, `day`, `hour`, and `minute` fields you use the `SecondsToDate` and `DateToSeconds` procedures.

`minute`

The minute of the hour, ranging from 0 to 59. Values greater than 59 cause a wraparound to a future hour and minute. When you use the `SecondsToDate` and `DateToSeconds` procedures, a negative value in this field has the effect of subtracting that number from the beginning of the given hour. For example, an `hour` value of 1 and a `minute` value of –10 return 0 hours and 50 minutes. However, if the negative value causes the `hour` value to be less than 0, for example `hour` = 0, `minute` = –61, unpredictable results occur.

`second`

The second of the minute, ranging from 0 to 59. Values greater than 59 cause a wraparound to a future minute and second. When you use the `SecondsToDate` and `DateToSeconds` procedures, a negative value in this field has the effect of subtracting that number from the beginning of the given minute. For example, a `minute` value of 1 and a `second` value of –10 returns 0 minutes and 50 seconds. However, if the negative value causes the `hour` value to be less than 0, for example `hour` = 0, `minute` = 0, and `second` = –61, unpredictable results occur.

`dayOfWeek`

The day of the week, where 1 indicates Sunday and 7 indicates Saturday. This field accepts 0, negative values, or values greater than 7. When you use the `SecondsToDate` and `DateToSeconds` procedures, you get correct values because this field is automatically calculated from the values in the `year`, `month`, and `day` fields.

Discussion

The date-time record describes the date-time information as a date and time. The Date, Time, and Measurement Utilities use a date-time record to read and write date-time information to and from the system.

The date-time record can be used to hold date and time values only for a Gregorian calendar. The long date-time record, `LongDateRec` (page 413), can be used for a Gregorian calendar as well as other calendar systems.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`DateTimeUtils.h`

LocalDateTime

```
struct LocalDateTime {
     UInt16 highSeconds;
     UInt32 lowSeconds;
     UInt16 fraction;
};
typedef struct LocalDateTime LocalDateTime;
typedef LocalDateTime * LocalDateTimePtr;
typedef LocalDateTimePtr * LocalDateTimeHandle;
```

Discussion
`UTCDateTime` and `LocalDateTime` are both 64 bits wide. The first 48 bits represent the number of seconds since 1904. The remaining 16 bits are used to indicate a fractional seconds value, which has no inherent precision. Each unit of this 16-bit value represents 1/65535 of a second. Developers may apply the appropriate arithmetic to derive milliseconds or microseconds.

Note that the decision to have the `lowSeconds` field divided between the high and low 32 bits of the 64 bit structure was intentional. The structure above is perfect for performing 64 bit math and logical comparisons. Having the `lowSeconds` field in the low or high 32 bits would have been easier for the compilers to handle and probably execute faster, however it would have rendered the structure unusable for 64 bit math and logical comparisons.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UTCUtils.h`

LongDateCvt

```
union LongDateCvt {
     SInt64 c
     struct {
         UInt32 lHigh;
         UInt32 lLow;
     } hl;
};
typedef union LongDateCvt LongDateCvt;
```

Fields

`c`
: The date and time, specified in seconds relative to midnight, January 1, 1904, as a signed, 64-bit integer in SANE `comp` format. The high-order bit of this field represents the sign of the 64-bit integer. Negative values allow you to indicate dates and times prior to midnight, January 1, 1904.

`hl`
: The high-order 32 bits when converting from a standard date-time value. Set this field to 0.

Discussion
The Date, Time, and Measurement Utilities provide the `LongDateCvt` structure to help in setting up `LongDateTime` values.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`DateTimeUtils.h`

LongDateRec

```
union LongDateRec {
     struct {
         short era;
         short year;
         short month;
         short day;
         short hour;
         short minute;
         short second;
         short dayOfWeek;
         short dayOfYear;
         short weekOfYear;
         short pm;
         short res1;
         short res2;
         short res3;
     } ld;
     short list[14]
     struct {
         short eraAlt;
         DateTimeRec oldDate;
     } od;
};
typedef union LongDateRec LongDateRec;
```

Fields

`era`
The value `0` represents A.D. and `-1` represents B.C

`year`
The year, from 30081 B.C. to 29940 A.D.

`month`
The month (1 = January and 12 = December).

`day`
The day of the month, from 1 to 31.

`hour`
The hour, from 0 to 23.

`minute`
The minute, from 0 to 59.

`second`
The second., from 0 to 59

`dayOfWeek`
The day of the week (1 through 7).

`dayOfYear`
The day of the year, from 1 to 365.

`weekOfYear`
The week of the year. from 1 through 52.

`pm`
The value `0` represents AM and the value `1` represents PM.

`res1`
Reserved.

`res2`
Reserved.

`res3`
Reserved.

`list`
An array `[0 . . 13]` whose values indicate which of the fields in a long date-time record need to be verified.

`eraAlt`
Indicates the era, used only for conversion from a date-time record to a long date-time record.

`oldDate`
Used only for conversion from a date-time record to a long date-time record.

Discussion
In addition to the date-time record, system software provides the long date-time record, which extends the date-time record format by adding several more fields. This format lets you use dates and times with a much longer span (30,000 B.C. to 30,000 A.D.). In addition, the long date-time record allows conversions to different calendar systems, such as a lunar calendar.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`DateTimeUtils.h`

LongDateTime

```
typedef SInt64 LongDateTime;
```

Discussion
The long date-time value specifies the date and time as seconds relative to midnight, January 1, 1904. But where the standard date-time value is an unsigned, 32-bit long integer, the long date-time value is a signed, 64-bit integer in SANE `comp` format. This format lets you use dates and times with a much longer span—roughly 500 billion years. You can use this value to represent dates and times prior to midnight, January 1, 1904. The `LongDateTime` data type defines the long date-time value.

When storing a long date-time value in files, you can use a 5-byte or 6-byte format for a range of roughly 35,000 years. You should sign extend this value to restore it to a `comp` format. Use the `LongDateCvt` (page 412) structure to help you in setting up a `LongDateTime` value.

TogglePB

```
struct TogglePB {
     long togFlags;
     ResType amChars;
     ResType pmChars;
     long reserved[4];
};
typedef struct TogglePB TogglePB;
```

Fields

`togFlags`
: The high-order word of this field contains flags that specify special conditions for the `ToggleDate` function.

  The low-order word of this field contains masks representing fields to be checked by the `ValidDate` function. Each mask corresponds to a value in the enumerated type `LongDateField`. See Long Date Mask Constants (page 418) for a description of the values which you can use in this field. You can set this field to check the `era` through `second` fields by using the predeclared constant `dateStdMask`.

`amChars`
: The trailing string to display for morning (for example, A.M.). This string is read from the numeric-format resource (resource type `'itl0'`) of the current script system.

`pmChars`
: The trailing to display for evening (for example, P.M.). This string is read from the numeric-format resource (resource type `'itl0'`) of the current script system.

`reserved`
: Reserved. Set each of the three elements of this field to 0.

Discussion
The `ToggleDate` function exchanges information with your application using the toggle parameter block, defined by the `TogglePB` data type.

Availability
Available in Mac OS X v10.0 and later.

`DateTimeUtils.h`

UTCDateTime

```
struct UTCDateTime {
     UInt16 highSeconds;
     UInt32 lowSeconds;
     UInt16 fraction;
};
typedef struct UTCDateTime UTCDateTime;
typedef UTCDateTime * UTCDateTimePtr;
typedef UTCDateTimePtr * UTCDateTimeHandle;
```

Discussion
`UTCDateTime` and `LocalDateTime` are both 64 bits wide. The first 48 bits represent the number of seconds since 1904. The remaining 16 bits are used to indicate a fractional seconds value, which has no inherent precision. Each unit of this 16-bit value represents 1/65535 of a second. Developers may apply the appropriate arithmetic to derive milliseconds or microseconds.

Note that the decision to divide the `lowSeconds` field between the high and low 32 bits of the 64 bit structure was intentional. You can use the structure to perform 64 bit math and logical comparisons. Having the `lowSeconds` field in the low or high 32 bits would have been easier for the compilers to handle and probably execute faster, however it would have rendered the structure unusable for 64 bit math and logical comparisons.

Important: You cannot access this structure as a `UInt64` data type. Doing so on systems that use little-endian byte odering may produce the wrong result.

Declared in `DateTimeUtils.h`.

`pmMask`
Verify the evening (P.M.).

Available in Mac OS X v10.0 and later.

Declared in `DateTimeUtils.h`.

`dateStdMask`
Verify the era through the second.

Available in Mac OS X v10.0 and later.

Declared in `DateTimeUtils.h`.

Discussion
These constants are used in the `field` parameter of the `ToggleDate` (page 403) function to specify the `LongDateRec` fields for the `ValidDate` function to check.

Flags

```
enum {
     smallDateBit = 31,
     togChar12HourBit = 30,
     togCharZCycleBit = 29,
     togDelta12HourBit = 28,
     genCdevRangeBit = 27,
     validDateFields = -1,
     maxDateField = 10
};
```

Constants
`smallDateBit`
If this bit is set, the valid date and time are restricted to the range of the system global variable `Time`—that is, between midnight on January 1, 1904 and 6:28:15 A.M. on February 6, 2040.

Available in Mac OS X v10.0 and later.

Declared in `DateTimeUtils.h`.

`togChar12HourBit`
If this bit is set, modifying the hour by character is limited to the 12-hour range defined by `togCharZCycleBit`, mapped to the appropriate half of the 24-hour range, as determined by the `pm` field. This bit works with system software version 6.0.4 and later.

Available in Mac OS X v10.0 and later.

Declared in `DateTimeUtils.h`.

`togCharZCycleBit`
If this bit is set, the input character is treated as if it modifies an hour whose value is in the range 0–11. If this bit is not set, the input character is treated as if it modifies an hour whose value is in the range 12, 1–11. This bit works with system software version 6.0.4 and later.

Available in Mac OS X v10.0 and later.

Declared in `DateTimeUtils.h`.

`togDelta12HourBit`
: If this bit is set, modifying the hour up or down is limited to a 12-hour range. For example, increasing by one from 11 produces 0, increasing by one from 23 produces 12, and so on. This bit works with system software version 6.0.4 and later.

  Available in Mac OS X v10.0 and later.

  Declared in `DateTimeUtils.h`.

`genCdevRangeBit`
: If this bit is set in addition to `smallDateBit`, then the date range is restricted to that used by the General Controls control panel—January 1, 1920 to December 31, 2019 in the Gregorian calendar (the routine works correctly for other calendars as well). For dates outside this range but within the range specified by the system global variable `Time`—January 1, 1904 to February 6, 2040 in the Gregorian calendar—`ToggleDate` adds or subtracts 100 years to bring the dates into the range of the General Controls control panel if these bits are set. The `ToggleDate` function returns an error if the `smallDateBit` is set and the date is outside the range specified by the system global variable `Time`. This bit works with system software version 6.0.4 and later.

  Available in Mac OS X v10.0 and later.

  Declared in `DateTimeUtils.h`.

`validDateFields`
: Available in Mac OS X v10.0 and later.

  Declared in `DateTimeUtils.h`.

`maxDateField`
: Available in Mac OS X v10.0 and later.

  Declared in `DateTimeUtils.h`.

Toggle Results

```
typedef SInt16 ToggleResults;
enum {
     toggleUndefined = 0,
     toggleOK = 1,
     toggleBadField = 2,
     toggleBadDelta = 3,
     toggleBadChar = 4,
     toggleUnknown = 5,
     toggleBadNum = 6,
     toggleOutOfRange = 7,
     toggleErr3 = 7,
     toggleErr4 = 8,
     toggleErr5 = 9
};
```

Result Codes

The most common result codes returned by Date, Time, and Measurement Utilities are listed below.

Result Code	Value	Description
clkRdErr	-85	Unable to read the same clock value twice. Available in Mac OS X v10.0 and later.
clkWrErr	-86	The time written did not verify. Available in Mac OS X v10.0 and later.
kUTCUnderflowErr	-8850	An underflow error occurred. Available in Mac OS X v10.0 and later.
kUTCOverflowErr	-8851	An overflow error occurred. Available in Mac OS X v10.0 and later.
kIllegalClockValueErr	-8852	An illegal clock value was encountered. Available in Mac OS X v10.0 and later.

Debugger Services Reference

Framework: CoreServices/CoreServices.h
Declared in Debugging.h

Overview

Debugger Services is a Carbon API that provides standard exception handling and assertion functions to assist you in debugging Mac OS applications.

Functions by Task

Using Debugger Services

`NewDebugComponent` (page 429)
Registers a component with Debugger Services.

`NewDebugOption` (page 429)
Registers a new debug option with Debugger Services.

`GetDebugComponentInfo` (page 426)
Returns the signature and name of a registered component.

`GetDebugOptionInfo` (page 426)
Returns information about the debug option of a registered component.

`SetDebugOptionValue` (page 430)
Modifies the setting of a registered debug option.

`DisposeDebugComponent` (page 425)
Removes a component registration and all related debug options.

`DebugAssert` (page 424)
Displays an assertion messsage using the current output handler.

`InstallDebugAssertOutputHandler` (page 427)
Installs an output handler for `DebugAssert` to call in place of `DebugStr`, the default handler.

`TaskLevel` (page 431)
Provides information about the task interrupt level, if the task is running at interrupt-time.

Managing Callback UPPs

NewDebugAssertOutputHandlerUPP (page 428)

InvokeDebugAssertOutputHandlerUPP (page 428)

DisposeDebugAssertOutputHandlerUPP (page 425)

NewDebugComponentCallbackUPP (page 429)

InvokeDebugComponentCallbackUPP (page 428)

DisposeDebugComponentCallbackUPP (page 426)

Functions

DebugAssert

Displays an assertion messsage using the current output handler.

```
void DebugAssert (
   OSType componentSignature,
   UInt32 options,
   const char *assertionString,
   const char *exceptionLabelString,
   const char *errorString,
   const char *fileName,
   long lineNumber,
   void *value
);
```

Parameters

componentSignature
The unique signature of the component causing the assertion.

options
Reserved for use by Apple.

assertionString
A pointer to a string containing the assertion, or NULL.

exceptionLabelString
A pointer to a string containing the exceptionLabel, or NULL.

errorString
A pointer to the error string, or NULL.

fileName
A pointer to the file name or path name generated by the preprocessor __FILE__ identifier, or NULL.

lineNumber
The line number in the file (generated by the preprocessor __LINE__ identifier), or 0 (zero).

value
A value associated with the assertion, or NULL.

Discussion
The DEBUGASSERTMSG macro calls this function (by default) to display assertion messages. To redirect the output from this function, use InstallDebugAssertOutputHandler (page 427) to install a custom output handler.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
Debugging.h

DisposeDebugAssertOutputHandlerUPP

```
void DisposeDebugAssertOutputHandlerUPP (
   DebugAssertOutputHandlerUPP userUPP
);
```

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
Debugging.h

DisposeDebugComponent

Removes a component registration and all related debug options.

```
OSStatus DisposeDebugComponent (
   OSType componentSignature
);
```

Parameters

componentSignature
The unique signature of a component.

Return Value
A result code. If the result is non-zero, the Notification Manager cannot remove the debug options.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Debugging.h

DisposeDebugComponentCallbackUPP

```
void DisposeDebugComponentCallbackUPP (
   DebugComponentCallbackUPP userUPP
);
```

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

GetDebugComponentInfo

Returns the signature and name of a registered component.

```
OSStatus GetDebugComponentInfo (
   UInt32 index,
   OSType *componentSignature,
   Str255 componentName
);
```

Parameters

index
An index into a list of registered components (one-based).

componentSignature
A pointer to an `OSType`, provided by the caller to receive the unique signature of the specified component.

componentName
A string buffer, provided by the caller to receive the component name.

Return Value
A result code. If `index` is not valid, the result code is `debuggingNoMatchErr`.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

GetDebugOptionInfo

Returns information about the debug option of a registered component.

```
OSStatus GetDebugOptionInfo (
   UInt32 index,
   OSType componentSignature,
   SInt32 *optionSelectorNum,
   Str255 optionName,
   Boolean *optionSetting
);
```

Parameters

index

An index into a list of registered debug options (zero-based). You should use the constant `kComponentDebugOption` (page 435).

componentSignature

The unique signature of your registered component.

optionSelectorNum

A pointer to an integer, provided by the caller to receive the option selector number.

optionName

A string buffer, provided by the caller to receive the option name.

optionSetting

A pointer to a `Boolean`, provided by the caller to receive the current option setting.

Return Value

A result code. Debugger Services returns `debuggingNoMatchErr` if the index is not valid, `debuggingInvalidSignatureErr` if the component is not registered, or `noErr`.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`Debugging.h`

InstallDebugAssertOutputHandler

Installs an output handler for `DebugAssert` to call in place of `DebugStr`, the default handler.

```
void InstallDebugAssertOutputHandler (
   DebugAssertOutputHandlerUPP handler
);
```

Parameters

handler

The custom output handler to install, or NULL to switch back to `DebugStr`.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`Debugging.h`

InvokeDebugAssertOutputHandlerUPP

```
void InvokeDebugAssertOutputHandlerUPP (
   OSType componentSignature,
   UInt32 options,
   const char *assertionString,
   const char *exceptionLabelString,
   const char *errorString,
   const char *fileName,
   long lineNumber,
   void *value,
   ConstStr255Param outputMsg,
   DebugAssertOutputHandlerUPP userUPP
);
```

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

InvokeDebugComponentCallbackUPP

```
void InvokeDebugComponentCallbackUPP (
   SInt32 optionSelectorNum,
   UInt32 command,
   Boolean *optionSetting,
   DebugComponentCallbackUPP userUPP
);
```

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

NewDebugAssertOutputHandlerUPP

```
DebugAssertOutputHandlerUPP NewDebugAssertOutputHandlerUPP (
   DebugAssertOutputHandlerProcPtr userRoutine
);
```

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

NewDebugComponent

Registers a component with Debugger Services.

```
OSStatus NewDebugComponent (
   OSType componentSignature,
   ConstStr255Param componentName,
   DebugComponentCallbackUPP componentCallback
);
```

Parameters

componentSignature

The unique signature of a new component.

componentName

A displayable string that names the new component.

componentCallback

A universal procedure pointer (UPP) to a debug component callback function, provided by the caller for working with options.

Return Value

A result code. See Debugger Services Result Codes (page 436).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

Debugging.h

NewDebugComponentCallbackUPP

```
DebugComponentCallbackUPP NewDebugComponentCallbackUPP (
   DebugComponentCallbackProcPtr userRoutine
);
```

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

Debugging.h

NewDebugOption

Registers a new debug option with Debugger Services.

```
OSStatus NewDebugOption (
   OSType componentSignature,
   SInt32 optionSelectorNum,
   ConstStr255Param optionName
);
```

Parameters

componentSignature

The unique signature of a registered component.

optionSelectorNum

The selector number of the new debug option.

optionName

A displayable string that names this debug option.

Return Value

A result code. See `Debugger Services Result Codes` (page 436).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`Debugging.h`

SetDebugOptionValue

Modifies the setting of a registered debug option.

```
OSStatus SetDebugOptionValue (
   OSType componentSignature,
   SInt32 optionSelectorNum,
   Boolean newOptionSetting
);
```

Parameters

componentSignature

The unique signature of a registered component.

optionSelectorNum

The selector number of a registered debug option.

newOptionSetting

The new setting for the option.

Return Value

A result code. Debugger Services returns `debuggingInvalidOptionErr` if the selector number is not valid, `debuggingInvalidSignatureErr` if the component is not registered, or `noErr`.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`Debugging.h`

TaskLevel

Provides information about the task interrupt level, if the task is running at interrupt-time.

```
UInt32 TaskLevel (
   void
);
```

Return Value
The current task interrupt level. If the return value is 0, the task is (probably) running at non-interrupt time. Otherwise, one of the `TaskLevel` masks can be used to learn more.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`Debugging.h`

Callbacks

DebugAssertOutputHandlerProcPtr

Defines a pointer to a function that handles the output from `DebugAssert` (page 424).

```
typedef void (*DebugAssertOutputHandlerProcPtr)
(
    OSType componentSignature,
    UInt32 options,
    const char * assertionString,
    const char * exceptionLabelString,
    const char * errorString,
    const char * fileName,
    long lineNumber,
    void * value,
    ConstStr255Param outputMsg
);
```

If you name your function `MyDebugAssertOutputHandler`, you would declare it like this:

```
void MyDebugAssertOutputHandler (
    OSType componentSignature,
    UInt32 options,
    const char * assertionString,
    const char * exceptionLabelString,
    const char * errorString,
    const char * fileName,
    long lineNumber,
    void * value,
    ConstStr255Param outputMsg
);
```

Parameters

componentSignature
The unique signature of the component causing the assertion.

options
Reserved for use by Apple.

assertionString
The name of the assertion, or NULL.

exceptionLabelString
The exception label, or NULL.

errorString
The description of an error condition, or NULL.

fileName
The file or path name (generated by the preprocessor __FILE__ identifier), or NULL.

fileName
The file or path name (generated by the preprocessor __FILE__ identifier), or NULL.

lineNumber
The line number in the file (generated by the preprocessor __LINE__ identifier), or 0 (zero).

value
A value associated with the assertion, or NULL.

outputMsg
The string that the caller (DebugAssert) normally passes to DebugStr when a custom output handler isn't installed.

Discussion
The parameters (excluding outputMsg) are the raw values passed to DebugAssert when an exception occurs. A custom output handler can safely ignore these parameters and simply redirect the output message (for example, to a log file).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Debugging.h

DebugComponentCallbackProcPtr

Defines a pointer to a function that Debugger Services calls to read or modify the debug option settings defined by a component.

```
typedef void (*DebugComponentCallbackProcPtr)
(
    SInt32 optionSelectorNum,
    UInt32 command,
    Boolean * optionSetting
);
```

If you name your function MyDebugComponentCallback, you would declare it like this:

```
void MyDebugComponentCallback (
    SInt32 optionSelectorNum,
```

```
    UInt32 command,
    Boolean * optionSetting
);
```

Parameters

optionSelectorNum

A component debug option, previously defined by calling `NewDebugOption` (page 429).

command

Specifies the operation to be performed—`kGetDebugOption` to get current setting, or `kSetDebugOption` to modify the setting.

optionSetting

A pointer to a `Boolean` that Debugger Services uses to

- pass in the new setting, if `command` is `kSetDebugOption`
- receive the result of the operation, if `command` is `kGetDebugOption`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Debugging.h`

Data Types

DebugAssertOutputHandlerUPP

Defines a universal procedure pointer (UPP) type for a custom assertion output handler.

```
typedef DebugAssertOutputHandlerProcPtr DebugAssertOutputHandlerUPP;
```

Discussion
For information about custom assertion output handlers, see `DebugAssertOutputHandlerProcPtr` (page 431).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Debugging.h`

DebugComponentCallbackUPP

Defines a universal procedure pointer (UPP) type for a custom component debug option callback.

```
typedef DebugComponentCallbackProcPtr DebugComponentCallbackUPP;
```

Discussion
For information about custom component debug option callbacks, see `DebugComponentCallbackProcPtr` (page 432).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Debugging.h`

Constants

Interrupt Level Masks

Masks to determine what kind of tasks are executing at interrupt time.

```
enum {
    k68kInterruptLevelMask = 0x00000007,
    kInVBLTaskMask = 0x00000010,
    kInDeferredTaskMask = 0x00000020,
    kInSecondaryIntHandlerMask = 0x00000040,
    kInNestedInterruptMask = 0x00000080
};
```

Constants

`k68kInterruptLevelMask`
68K interrupt levels 0 through 7.
Available in Mac OS X v10.0 and later.
Declared in `Debugging.h`.

`kInVBLTaskMask`
VBLs are executing.
Available in Mac OS X v10.0 and later.
Declared in `Debugging.h`.

`kInDeferredTaskMask`
Deferred tasks are executing.
Available in Mac OS X v10.0 and later.
Declared in `Debugging.h`.

`kInSecondaryIntHandlerMask`
Secondary interrupt handlers are executing.
Available in Mac OS X v10.0 and later.
Declared in `Debugging.h`.

`kInNestedInterruptMask`
The operating system is handling an interrupt.
Available in Mac OS X v10.0 and later.
Declared in `Debugging.h`.

Discussion
For more information, see `TaskLevel` (page 431).

Unmapped Addresses

Addresses not mapped in Mac OS 8 or 9.

```
enum {
    kBlessedBusErrorBait = 0x68F168F1
};
```

Constants

`kBlessedBusErrorBait`

An address that will never be mapped in Mac OS 8 or 9.

Available in Mac OS X v10.0 and later.

Declared in `Debugging.h`.

Discussion

An exception occurs when an application tries to access the address `kBlessedBusErrorBait` in Mac OS 8 or 9, which makes it a good value to use when initializing pointers.

In Mac OS X, you should use 0x00000000 for this purpose.

Debug Option Types

Defines the debug option types supported by Debugger Services.

```
enum {
    kComponentDebugOption = 0
};
```

Constants

`kComponentDebugOption`

Specifies the component debug option type.

Available in Mac OS X v10.0 and later.

Declared in `Debugging.h`.

Discussion

For information about how this constant is used, see `GetDebugOptionInfo` (page 426).

Commands for Debug Option Callbacks

Defines the commands (or operations) that a debug option callback needs to implement.

```
enum {
    kGetDebugOption = 1,
    kSetDebugOption = 2
};
```

Constants

`kGetDebugOption`

The callback should return the current `Boolean` value of the specified debug option.

Available in Mac OS X v10.0 and later.

Declared in `Debugging.h`.

`kSetDebugOption`

The callback should modify the `Boolean` value of the specified debug option.

Available in Mac OS X v10.0 and later.

Declared in `Debugging.h`.

Result Codes

The most common result codes returned by Debugger Services are listed in the table below.

Result Code	Value	Description
`debuggingExecutionContextErr`	-13880	routine cannot be called at this time Available in Mac OS X v10.0 and later.
`debuggingDuplicateSignatureErr`	-13881	componentSignature already registered Available in Mac OS X v10.0 and later.
`debuggingDuplicateOptionErr`	-13882	optionSelectorNum already registered Available in Mac OS X v10.0 and later.
`debuggingInvalidSignatureErr`	-13883	componentSignature not registered Available in Mac OS X v10.0 and later.
`debuggingInvalidOptionErr`	-13884	optionSelectorNum is not registered Available in Mac OS X v10.0 and later.
`debuggingInvalidNameErr`	-13885	componentName or optionName is invalid (NULL) Available in Mac OS X v10.0 and later.
`debuggingNoCallbackErr`	-13886	debugging component has no callback Available in Mac OS X v10.0 and later.
`debuggingNoMatchErr`	-13887	debugging component or option not found at this index Available in Mac OS X v10.0 and later.

File Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Files.h

Overview

The File Manager is a core service in Mac OS X that manages the organization, reading, and writing of data located on physical data storage devices such as disk drives. The File Manager provides an abstraction layer that hides lower-level implementation details such as different file systems and volume formats. If you want your application to have the same view of the file system seen in the Mac OS X user interface, the File Manager is an appropriate tool. For example, the File Manager is often used in application frameworks such as Carbon and Cocoa to implement file-related operations.

The File Manager API provides a large number of functions for performing various operations on files, directories, and volumes. The requirements of your application will dictate which of these functions you need to use. Many applications simply need to open files, read and write the data in those files, and then close the files. Other applications might provide more capabilities, such as the ability to copy or move a file to another directory. A few programs, such as the Mac OS X Finder, perform more extensive file operations and hence need to use some of the advanced functions provided by the File Manager.

A number of deprecated functions in the File Manager were inherited from earlier versions of Mac OS and have been carried along to facilitate porting legacy applications to Mac OS X. You should avoid using these deprecated functions. In particular, you should avoid any function or data structure that uses the `FSSpec` data type. This reference document clearly marks every deprecated function and, in most cases, provides a recommended replacement.

Functions by Task

Accessing Information About Files and Directories

`FSGetCatalogInfo` (page 494)
Returns catalog information about a file or directory. You can use this function to map an `FSRef` to an `FSSpec`.

`PBGetCatalogInfoSync` (page 647)
Returns catalog information about a file or directory. You can use this function to map from an `FSRef` to an `FSSpec`.

`PBGetCatalogInfoAsync` (page 643)
Returns catalog information about a file or directory. You can use this function to map from an `FSRef` to an `FSSpec`.

FSSetCatalogInfo (page 540)
Sets catalog information about a file or directory.

PBSetCatalogInfoSync (page 753)
Sets the catalog information about a file or directory.

PBSetCatalogInfoAsync (page 751)
Sets the catalog information about a file or directory.

FSpGetFInfo (page 530) Deprecated in Mac OS X v10.4
Obtains the Finder information for a file. (Deprecated. Use FSGetCatalogInfo (page 494) instead.)

FSpSetFInfo (page 535) Deprecated in Mac OS X v10.4
Sets the Finder information about a file. (Deprecated. Use FSSetCatalogInfo (page 540) instead.)

HGetFInfo (page 551) Deprecated in Mac OS X v10.4
Obtains the Finder information for a file. (Deprecated. Use FSGetCatalogInfo (page 494) instead.)

HSetFInfo (page 557) Deprecated in Mac OS X v10.4
Sets the Finder information for a file. (Deprecated. Use FSSetCatalogInfo (page 540) instead.)

PBGetCatInfoAsync (page 648) Deprecated in Mac OS X v10.4
Returns catalog information about a file or directory. (Deprecated. Use PBGetCatalogInfoAsync (page 643) instead.)

PBGetCatInfoSync (page 651) Deprecated in Mac OS X v10.4
Returns catalog information about a file or directory. (Deprecated. Use PBGetCatalogInfoSync (page 647) instead.)

PBHGetFInfoAsync (page 682) Deprecated in Mac OS X v10.4
Obtains information about a file. (Deprecated. Use PBGetCatalogInfoAsync (page 643) instead.)

PBHGetFInfoSync (page 683) Deprecated in Mac OS X v10.4
Obtains information about a file. (Deprecated. Use PBGetCatalogInfoSync (page 647) instead.)

PBHSetFInfoAsync (page 721) Deprecated in Mac OS X v10.4
Sets information for a file. (Deprecated. Use PBSetCatalogInfoAsync (page 751) instead.)

PBHSetFInfoSync (page 722) Deprecated in Mac OS X v10.4
Sets information for a file. (Deprecated. Use PBSetCatalogInfoSync (page 753) instead.)

PBSetCatInfoAsync (page 754) Deprecated in Mac OS X v10.4
Modifies catalog information for a file or directory. (Deprecated. Use PBSetCatalogInfoAsync (page 751) instead.)

PBSetCatInfoSync (page 755) Deprecated in Mac OS X v10.4
Modifies catalog information for a file or directory. (Deprecated. Use PBSetCatalogInfoSync (page 753) instead.)

Accessing the Desktop Database

PBDTAddAPPLAsync (page 602) Deprecated in Mac OS X v10.4
Adds an application to the desktop database. (Deprecated. There is no replacement function.)

PBDTAddAPPLSync (page 603) Deprecated in Mac OS X v10.4
Adds an application to the desktop database. (Deprecated. There is no replacement function.)

PBDTAddIconAsync (page 604) Deprecated in Mac OS X v10.4
Adds an icon definition to the desktop database. (Deprecated. There is no replacement function.)

PBDTAddIconSync (page 605) Deprecated in Mac OS X v10.4
Adds an icon definition to the desktop database. (Deprecated. There is no replacement function.)

PBDTCloseDown (page 606) Deprecated in Mac OS X v10.4
Closes the desktop database, though your application should never do this itself. (Deprecated. There is no replacement function.)

PBDTDeleteAsync (page 607) Deprecated in Mac OS X v10.4
Removes the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated. There is no replacement function.)

PBDTDeleteSync (page 608) Deprecated in Mac OS X v10.4
Removes the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated. There is no replacement function.)

PBDTFlushAsync (page 609) Deprecated in Mac OS X v10.4
Saves your changes to the desktop database. (Deprecated. There is no replacement function.)

PBDTFlushSync (page 610) Deprecated in Mac OS X v10.4
Saves your changes to the desktop database. (Deprecated. There is no replacement function.)

PBDTGetAPPLAsync (page 611) Deprecated in Mac OS X v10.4
Identifies the application that can open a file with a given creator. (Deprecated. There is no replacement function.)

PBDTGetAPPLSync (page 612) Deprecated in Mac OS X v10.4
Identifies the application that can open a file with a given creator. (Deprecated. There is no replacement function.)

PBDTGetCommentAsync (page 613) Deprecated in Mac OS X v10.4
Retrieves the user comments for a file or directory. (Deprecated. There is no replacement function.)

PBDTGetCommentSync (page 614) Deprecated in Mac OS X v10.4
Retrieves the user comments for a file or directory. (Deprecated. There is no replacement function.)

PBDTGetIconAsync (page 615) Deprecated in Mac OS X v10.4
Retrieves an icon definition. (Deprecated. There is no replacement function.)

PBDTGetIconInfoAsync (page 616) Deprecated in Mac OS X v10.4
Retrieves an icon type and the associated file type supported by a given creator in the desktop database. (Deprecated. There is no replacement function.)

PBDTGetIconInfoSync (page 618) Deprecated in Mac OS X v10.4
Retrieves an icon type and the associated file type supported by a given creator in the desktop database. (Deprecated. There is no replacement function.)

PBDTGetIconSync (page 619) Deprecated in Mac OS X v10.4
Retrieves an icon definition. (Deprecated. There is no replacement function.)

PBDTGetInfoAsync (page 620) Deprecated in Mac OS X v10.4
Determines information about the location and size of the desktop database on a particular volume. (Deprecated. There is no replacement function.)

PBDTGetInfoSync (page 621) Deprecated in Mac OS X v10.4
Determines information about the location and size of the desktop database on a particular volume. (Deprecated. There is no replacement function.)

PBDTGetPath (page 622) Deprecated in Mac OS X v10.4
Gets the reference number of the specified desktop database. (Deprecated. There is no replacement function.)

PBDTOpenInform (page 623) Deprecated in Mac OS X v10.4
Gets the reference number of the specified desktop database, reporting whether the desktop database was empty when it was opened. (Deprecated. There is no replacement function.)

PBDTRemoveAPPLAsync (page 624) Deprecated in Mac OS X v10.4
Removes an application from the desktop database. (Deprecated. There is no replacement function.)

PBDTRemoveAPPLSync (page 625) Deprecated in Mac OS X v10.4
Removes an application from the desktop database. (Deprecated. There is no replacement function.)

PBDTRemoveCommentAsync (page 626) Deprecated in Mac OS X v10.4
Removes a user comment associated with a file or directory from the desktop database. (Deprecated. There is no replacement function.)

PBDTRemoveCommentSync (page 627) Deprecated in Mac OS X v10.4
Removes a user comment associated with a file or directory from the desktop database. (Deprecated. There is no replacement function.)

PBDTResetAsync (page 627) Deprecated in Mac OS X v10.4
Removes information from the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated. There is no replacement function.)

PBDTResetSync (page 628) Deprecated in Mac OS X v10.4
Removes information from the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated. There is no replacement function.)

PBDTSetCommentAsync (page 629) Deprecated in Mac OS X v10.4
Adds a user comment for a file or a directory to the desktop database. (Deprecated. There is no replacement function.)

PBDTSetCommentSync (page 630) Deprecated in Mac OS X v10.4
Adds a user comment for a file or a directory to the desktop database. (Deprecated. There is no replacement function.)

Allocating Storage for Files

FSAllocateFork (page 470)
Allocates space on a volume to an open fork.

PBAllocateForkSync (page 567)
Allocates space on a volume to an open fork.

PBAllocateForkAsync (page 565)
Allocates space on a volume to an open fork.

Allocate (page 459) Deprecated in Mac OS X v10.4
Allocates additional space on a volume to an open file. (Deprecated. Use FSAllocateFork (page 470) instead.)

AllocContig (page 461) Deprecated in Mac OS X v10.4
Allocates additional contiguous space on a volume to an open file. (Deprecated. Use FSAllocateFork (page 470) instead.)

PBAllocateAsync (page 564) Deprecated in Mac OS X v10.4
Allocates additional space on a volume to an open file. (Deprecated. Use PBAllocateForkAsync (page 565) instead.)

`PBAllocateSync` (page 568) Deprecated in Mac OS X v10.4
: Allocates additional space on a volume to an open file. (Deprecated. Use `PBAllocateForkSync` (page 567) instead.)

`PBAllocContigAsync` (page 569) Deprecated in Mac OS X v10.4
: Allocates additional contiguous space on a volume to an open file. (Deprecated. Use `PBAllocateForkAsync` (page 565) instead.)

`PBAllocContigSync` (page 570) Deprecated in Mac OS X v10.4
: Allocates additional contiguous space on a volume to an open file. (Deprecated. Use `PBAllocateForkSync` (page 567) instead.)

Closing Files

`FSCloseFork` (page 475)
: Closes an open fork.

`PBCloseForkSync` (page 583)
: Closes an open fork.

`PBCloseForkAsync` (page 582)
: Closes an open fork.

`FSClose` (page 474)
: Closes an open file. (Deprecated. Use `FSCloseFork` (page 475) instead.)

`PBCloseAsync` (page 582) Deprecated in Mac OS X v10.5
: Closes an open file. (Deprecated. Use `PBCloseForkAsync` (page 582) instead.)

`PBCloseSync` (page 585) Deprecated in Mac OS X v10.5
: Closes an open file. (Deprecated. Use `PBCloseForkSync` (page 583) instead.)

Comparing File System References

`FSCompareFSRefs` (page 476)
: Determines whether two `FSRef` structures refer to the same file or directory.

`PBCompareFSRefsSync` (page 586)
: Determines whether two `FSRef` structures refer to the same file or directory.

`PBCompareFSRefsAsync` (page 586)
: Determines whether two `FSRef` structures refer to the same file or directory.

Controlling Directory Access

`PBHGetDirAccessAsync` (page 680) Deprecated in Mac OS X v10.5
: Returns the access control information for a directory or file. (Deprecated. Use `FSGetCatalogInfo` (page 494) instead.)

`PBHGetDirAccessSync` (page 681) Deprecated in Mac OS X v10.5
: Returns the access control information for a directory or file. (Deprecated. Use `FSGetCatalogInfo` (page 494) instead.)

PBHSetDirAccessAsync (page 719) Deprecated in Mac OS X v10.5
Changes the access control information for a directory. (Deprecated. Use FSSetCatalogInfo (page 540) instead.)

PBHSetDirAccessSync (page 720) Deprecated in Mac OS X v10.5
Changes the access control information for a directory. (Deprecated. Use FSSetCatalogInfo (page 540) instead.)

Controlling Login Access

PBHMapIDAsync (page 696) Deprecated in Mac OS X v10.5
Determines the name of a user or group given the user or group ID. (Deprecated. There is no replacement function.)

PBHMapIDSync (page 698) Deprecated in Mac OS X v10.5
Determines the name of a user or group given the user or group ID. (Deprecated. There is no replacement function.)

PBHMapNameAsync (page 698) Deprecated in Mac OS X v10.5
Determines the user ID or group ID from a user or group name. (Deprecated. There is no replacement function.)

PBHMapNameSync (page 700) Deprecated in Mac OS X v10.5
Determines the user ID or group ID from a user or group name. (Deprecated. There is no replacement function.)

PBHGetLogInInfoAsync (page 685) Deprecated in Mac OS X v10.4
Determines the login method used to log on to a particular shared volume. (Deprecated. There is no replacement function.)

Converting Between Paths and FSRef Structures

FSRefMakePath (page 539)
Converts an FSRef structure into a POSIX-style pathname.

FSPathMakeRef (page 519)
Converts a POSIX-style pathname into an FSRef structure.

FSPathMakeRefWithOptions (page 520)
Converts a POSIX-style pathname into an FSRef structure with options.

Copying and Moving Files

PBFSCopyFileSync (page 643)
Duplicates a file and optionally renames it.

PBFSCopyFileAsync (page 643)
Duplicates a file and optionally renames it.

PBHCopyFileAsync (page 673) Deprecated in Mac OS X v10.5
Duplicates a file and optionally renames it. (Deprecated. Use PBFSCopyFileAsync (page 643) instead.)

PBHCopyFileSync (page 675) Deprecated in Mac OS X v10.5
Duplicates a file and optionally renames it. (Deprecated. Use PBFSCopyFileSync (page 643) instead.)

PBHMoveRenameAsync (page 701) Deprecated in Mac OS X v10.4
Moves a file or directory and optionally renames it. (Deprecated. Use FSMoveObjectAsync (page 511) instead.)

PBHMoveRenameSync (page 702) Deprecated in Mac OS X v10.4
Moves a file or directory and optionally renames it. (Deprecated. Use FSMoveObjectSync (page 512) instead.)

Copying and Moving Objects Using Asynchronous High-Level File Operations

FSFileOperationCreate (page 488)
Creates an object that represents an asynchronous file operation.

FSFileOperationCancel (page 487)
Cancels an asynchronous file operation.

FSFileOperationGetTypeID (page 489)
Returns the Core Foundation type identifier for the FSFileOperation opaque type.

FSFileOperationScheduleWithRunLoop (page 489)
Schedules an asynchronous file operation with the specified run loop and mode.

FSFileOperationUnscheduleFromRunLoop (page 490)
Unschedules an asynchronous file operation from the specified run loop and mode.

FSCopyObjectAsync (page 477)
Starts an asynchronous file operation to copy a source object to a destination directory.

FSMoveObjectAsync (page 511)
Starts an asynchronous file operation to move a source object to a destination directory.

FSMoveObjectToTrashAsync (page 513)
Starts an asynchronous file operation to move a source object to the Trash.

FSPathCopyObjectAsync (page 517)
Starts an asynchronous file operation to copy a source object to a destination directory using pathnames.

FSPathMoveObjectAsync (page 521)
Starts an asynchronous file operation to move a source object to a destination directory using pathnames.

FSPathMoveObjectToTrashAsync (page 523)
Starts an asynchronous file operation to move a source object, specified using a pathname, to the Trash.

FSFileOperationCopyStatus (page 487)
Gets a copy of the current status information for an asynchronous file operation.

FSPathFileOperationCopyStatus (page 518)
Gets a copy of the current status information for an asynchronous file operation that uses pathnames.

Copying and Moving Objects Using Synchronous High-Level File Operations

FSCopyObjectSync (page 478)
Copies a source object to a destination directory.

FSMoveObjectSync (page 512)
Moves a source object to a destination directory.

FSMoveObjectToTrashSync (page 514)
Moves a source object to the Trash.

FSPathCopyObjectSync (page 518)
Copies a source object to a destination directory using pathnames.

FSPathMoveObjectSync (page 522)
Moves a source object to a destination directory using pathnames.

FSPathMoveObjectToTrashSync (page 524)
Moves a source object, specified using a pathname, to the Trash.

Creating a File System Reference (FSRef)

FSMakeFSRefUnicode (page 504)
Constructs an FSRef for a file or directory, given a parent directory and a Unicode name.

PBMakeFSRefUnicodeSync (page 733)
Constructs an FSRef for a file or directory, given a parent directory and a Unicode name.

PBMakeFSRefUnicodeAsync (page 733)
Constructs an FSRef for a file or directory, given a parent directory and a Unicode name.

FSpMakeFSRef (page 531) Deprecated in Mac OS X v10.5
Creates an FSRef for a file or directory, given an FSSpec. (Deprecated. There is no replacement function.)

PBMakeFSRefAsync (page 731) Deprecated in Mac OS X v10.5
Creates an FSRef for a file or directory, given an FSSpec. (Deprecated. Use PBMakeFSRefUnicodeAsync (page 733) instead.)

PBMakeFSRefSync (page 732) Deprecated in Mac OS X v10.5
Creates an FSRef for a file or directory, given an FSSpec. (Deprecated. Use PBMakeFSRefUnicodeSync (page 733) instead.)

Creating and Deleting File ID References

PBCreateFileIDRefAsync (page 590) Deprecated in Mac OS X v10.5
Establishes a file ID reference for a file. (Deprecated. Use FSGetCatalogInfo (page 494) instead.)

PBCreateFileIDRefSync (page 591) Deprecated in Mac OS X v10.5
Establishes a file ID reference for a file. (Deprecated. Use FSGetCatalogInfo (page 494) instead.)

PBDeleteFileIDRefAsync (page 596) Deprecated in Mac OS X v10.5
Deletes a file ID reference. (Deprecated. There is no replacement function.)

PBDeleteFileIDRefSync (page 597) Deprecated in Mac OS X v10.5
Deletes a file ID reference. (Deprecated. There is no replacement function.)

Creating and Deleting Named Forks

`FSCreateFork` (page 482)
Creates a named fork for a file or directory.

`PBCreateForkSync` (page 595)
Creates a named fork for a file or directory.

`PBCreateForkAsync` (page 594)
Creates a named fork for a file or directory.

`FSDeleteFork` (page 483)
Deletes a named fork from a file or directory.

`PBDeleteForkSync` (page 598)
Deletes a named fork from a file or directory.

`PBDeleteForkAsync` (page 597)
Deletes a named fork of a file or directory.

Creating Directories

`FSCreateDirectoryUnicode` (page 479)
Creates a new directory (folder) with a Unicode name.

`PBCreateDirectoryUnicodeSync` (page 589)
Creates a new directory (folder) with a Unicode name.

`PBCreateDirectoryUnicodeAsync` (page 587)
Creates a new directory (folder) with a Unicode name.

`DirCreate` (page 463) Deprecated in Mac OS X v10.4
Creates a new directory. (Deprecated. Use `FSCreateDirectoryUnicode` (page 479) instead.)

`FSpDirCreate` (page 527) Deprecated in Mac OS X v10.4
Creates a new directory. (Deprecated. Use `FSCreateDirectoryUnicode` (page 479) instead.)

`PBDirCreateAsync` (page 600) Deprecated in Mac OS X v10.4
Creates a new directory. (Deprecated. Use `PBCreateDirectoryUnicodeAsync` (page 587) instead.)

`PBDirCreateSync` (page 601) Deprecated in Mac OS X v10.4
Creates a new directory. (Deprecated. Use `PBCreateDirectoryUnicodeSync` (page 589) instead.)

Creating File System Specifications

`FSMakeFSSpec` (page 505) Deprecated in Mac OS X v10.4
Creates an `FSSpec` structure describing a file or directory. (Deprecated. Use `FSMakeFSRefUnicode` (page 504) instead.)

`PBMakeFSSpecAsync` (page 734) Deprecated in Mac OS X v10.4
Creates an `FSSpec` structure for a file or directory. (Deprecated. Use `PBMakeFSRefUnicodeAsync` (page 733) instead.)

`PBMakeFSSpecSync` (page 736) Deprecated in Mac OS X v10.4
Creates an `FSSpec` structure for a file or directory. (Deprecated. Use `PBMakeFSRefUnicodeSync` (page 733) instead.)

Creating Files

`FSCreateFileUnicode` (page 481)
Creates a new file with a Unicode name.

`PBCreateFileUnicodeSync` (page 593)
Creates a new file with a Unicode name.

`PBCreateFileUnicodeAsync` (page 591)
Creates a new file with a Unicode name.

`FSpCreate` (page 525) Deprecated in Mac OS X v10.4
Creates a new file. (Deprecated. Use `FSCreateFileUnicode` (page 481) instead.)

`HCreate` (page 550) Deprecated in Mac OS X v10.4
Creates a new file. (Deprecated. Use `FSCreateFileUnicode` (page 481) instead.)

`PBHCreateAsync` (page 676) Deprecated in Mac OS X v10.4
Creates a new file. (Deprecated. Use `PBCreateFileUnicodeAsync` (page 591) instead.)

`PBHCreateSync` (page 677) Deprecated in Mac OS X v10.4
Creates a new file. (Deprecated. Use `PBCreateFileUnicodeSync` (page 593) instead.)

Creating, Calling, and Deleting Universal Procedure Pointers

`NewIOCompletionUPP` (page 563)
Creates a new universal procedure pointer (UPP) to your I/O completion callback function.

`NewFNSubscriptionUPP` (page 562)
Creates a new universal procedure pointer (UPP) to your directory change callback function.

`NewFSVolumeEjectUPP` (page 562)
Creates a new universal procedure pointer (UPP) to your volume ejection callback function.

`NewFSVolumeMountUPP` (page 563)
Creates a new universal procedure pointer (UPP) to your volume mount callback function.

`NewFSVolumeUnmountUPP` (page 563)
Creates a new universal procedure pointer (UPP) to your volume unmount callback function.

`InvokeIOCompletionUPP` (page 561)
Calls your I/O completion callback function.

`InvokeFNSubscriptionUPP` (page 559)
Calls your directory change callback function.

`InvokeFSVolumeEjectUPP` (page 560)
Calls your volume ejection callback function.

`InvokeFSVolumeMountUPP` (page 560)
Calls your volume mount callback function.

`InvokeFSVolumeUnmountUPP` (page 561)
Calls your volume unmount callback function.

`DisposeIOCompletionUPP` (page 465)
Deletes a universal procedure pointer (UPP) to your I/O completion callback function.

`DisposeFNSubscriptionUPP` (page 464)
Deletes a universal procedure pointer (UPP) to your directory change callback function.

DisposeFSVolumeEjectUPP (page 464)
Deletes a universal procedure pointer (UPP) to your volume ejection callback function.

DisposeFSVolumeMountUPP (page 465)
Deletes a universal procedure pointer (UPP) to your volume mount callback function.

DisposeFSVolumeUnmountUPP (page 465)
Deletes a universal procedure pointer (UPP) to your volume unmount callback function.

Deleting Files and Directories

FSDeleteObject (page 484)
Deletes a file or an empty directory.

PBDeleteObjectSync (page 600)
Deletes a file or an empty directory.

PBDeleteObjectAsync (page 599)
Deletes a file or an empty directory.

FSpDelete (page 527) Deprecated in Mac OS X v10.4
Deletes a file or directory. (Deprecated. Use FSDeleteObject (page 484) instead.)

HDelete (page 551) Deprecated in Mac OS X v10.4
Deletes a file or directory. (Deprecated. Use FSDeleteObject (page 484) instead.)

PBHDeleteAsync (page 678) Deprecated in Mac OS X v10.4
Deletes a file or directory. (Deprecated. Use PBDeleteObjectAsync (page 599) instead.)

PBHDeleteSync (page 679) Deprecated in Mac OS X v10.4
Deletes a file or directory. (Deprecated. Use PBDeleteObjectSync (page 600) instead.)

Determining the Unicode Names of the Data and Resource Forks

FSGetDataForkName (page 497)
Returns a Unicode string constant for the name of the data fork.

FSGetResourceForkName (page 500)
Returns a Unicode string constant for the name of the resource fork.

Exchanging the Contents of Two Files

FSExchangeObjects (page 486)
Swaps the contents of two files.

PBExchangeObjectsSync (page 636)
Swaps the contents of two files.

PBExchangeObjectsAsync (page 635)
Swaps the contents of two files.

FSpExchangeFiles (page 528) Deprecated in Mac OS X v10.4
Exchanges the data stored in two files on the same volume. (Deprecated. Use FSExchangeObjects (page 486) instead.)

PBExchangeFilesAsync (page 631) Deprecated in Mac OS X v10.4
Exchanges the data stored in two files on the same volume. (Deprecated. Use PBExchangeObjectsAsync (page 635) instead.)

PBExchangeFilesSync (page 633) Deprecated in Mac OS X v10.4
Exchanges the data stored in two files on the same volume. (Deprecated. Use PBExchangeObjectsSync (page 636) instead.)

Getting and Setting Volume Information

FSGetVolumeInfo (page 500)
Returns information about a volume.

PBGetVolumeInfoSync (page 671)
Returns information about a volume.

PBGetVolumeInfoAsync (page 670)
Returns information about a volume.

FSSetVolumeInfo (page 543)
Sets information about a volume.

PBSetVolumeInfoSync (page 768)
Sets information about a volume.

PBSetVolumeInfoAsync (page 767)
Sets information about a volume.

FSCopyDiskIDForVolume (page 476)
Returns a copy of the disk ID for a volume.

FSCopyURLForVolume (page 479)
Returns a copy of the URL for a volume.

GetVRefNum (page 549) Deprecated in Mac OS X v10.4
Gets a volume reference number from a file reference number. (Deprecated. Use FSGetCatalogInfo (page 494) instead.)

PBHGetVInfoAsync (page 686) Deprecated in Mac OS X v10.4
Gets detailed information about a volume. (Deprecated. Use PBGetVolumeInfoAsync (page 670) instead.)

PBHGetVInfoSync (page 690) Deprecated in Mac OS X v10.4
Gets detailed information about a volume. (Deprecated. Use PBGetVolumeInfoSync (page 671) instead.)

PBSetVInfoAsync (page 765) Deprecated in Mac OS X v10.4
Changes information about a volume. (Deprecated. Use PBSetVolumeInfoAsync (page 767) instead.)

PBSetVInfoSync (page 766) Deprecated in Mac OS X v10.4
Changes information about a volume. (Deprecated. Use PBSetVolumeInfoSync (page 768) instead.)

PBXGetVolInfoAsync (page 779) Deprecated in Mac OS X v10.4
Returns information about a volume, including size information for volumes up to 2 terabytes. (Deprecated. Use FSGetVolumeInfo (page 500) instead.)

PBXGetVolInfoSync (page 782) Deprecated in Mac OS X v10.4
Returns information about a volume, including size information for volumes up to 2 terabytes. (Deprecated. Use FSGetVolumeInfo (page 500) instead.)

Getting Volume Attributes

`FSGetVolumeParms` (page 503)
Retrieves information about the characteristics of a volume.

`PBHGetVolParmsAsync` (page 694) Deprecated in Mac OS X v10.5
Returns information about the characteristics of a volume. (Deprecated. Use `FSGetVolumeParms` (page 503) instead.)

`PBHGetVolParmsSync` (page 695) Deprecated in Mac OS X v10.5
Returns information about the characteristics of a volume. (Deprecated. Use `FSGetVolumeParms` (page 503) instead.)

Iterating Over Named Forks

`FSIterateForks` (page 503)
Determines the name and size of every named fork belonging to a file or directory.

`PBIterateForksSync` (page 727)
Determines the name and size of every named fork belonging to a file or directory.

`PBIterateForksAsync` (page 726)
Determines the name and size of every named fork belonging to a file or directory.

Locking and Unlocking File Ranges

`FSLockRange` (page 504)
Locks a range of bytes of the specified fork.

`PBXLockRangeSync` (page 785)
Locks a range of bytes of the specified fork.

`PBXLockRangeAsync` (page 785)
Locks a range of bytes of the specified fork.

`FSUnlockRange` (page 543)
Unlocks a range of bytes of the specified fork.

`PBXUnlockRangeSync` (page 786)
Unlocks a range of bytes of the specified fork.

`PBXUnlockRangeAsync` (page 785)
Unlocks a range of bytes of the specified fork.

`PBLockRangeAsync` (page 728) Deprecated in Mac OS X v10.4
Locks a portion of a file. (Deprecated. Use `PBXLockRangeAsync` (page 785) instead.)

`PBLockRangeSync` (page 730) Deprecated in Mac OS X v10.4
Locks a portion of a file. (Deprecated. Use `PBXLockRangeSync` (page 785) or `FSLockRange` (page 504) instead.)

`PBUnlockRangeAsync` (page 770) Deprecated in Mac OS X v10.4
Unlocks a portion of a file. (Deprecated. Use `PBXUnlockRangeAsync` (page 785) instead.)

`PBUnlockRangeSync` (page 771) Deprecated in Mac OS X v10.4
Unlocks a portion of a file. (Deprecated. Use `PBXUnlockRangeSync` (page 786) or `FSUnlockRange` (page 543) instead.)

Locking and Unlocking Files and Directories

`FSpRstFLock` (page 534) Deprecated in Mac OS X v10.4
Unlocks a file or directory. (Deprecated. Use `FSSetCatalogInfo` (page 540) instead.)

`FSpSetFLock` (page 535) Deprecated in Mac OS X v10.4
Locks a file or directory. (Deprecated. Use `FSSetCatalogInfo` (page 540) instead.)

`HRstFLock` (page 556) Deprecated in Mac OS X v10.4
Unlocks a file or directory. (Deprecated. Use `FSSetCatalogInfo` (page 540) instead.)

`HSetFLock` (page 558) Deprecated in Mac OS X v10.4
Locks a file or directory. (Deprecated. Use `FSSetCatalogInfo` (page 540) instead.)

`PBHRstFLockAsync` (page 717) Deprecated in Mac OS X v10.4
Unlocks a file or directory. (Deprecated. Use `PBSetCatalogInfoAsync` (page 751) instead.)

`PBHRstFLockSync` (page 718) Deprecated in Mac OS X v10.4
Unlocks a file or directory. (Deprecated. Use `PBSetCatalogInfoSync` (page 753) instead.)

`PBHSetFLockAsync` (page 723) Deprecated in Mac OS X v10.4
Locks a file or directory. (Deprecated. Use `PBSetCatalogInfoAsync` (page 751) instead.)

`PBHSetFLockSync` (page 724) Deprecated in Mac OS X v10.4
Locks a file or directory. (Deprecated. Use `PBSetCatalogInfoSync` (page 753) instead.)

Manipulating File and Fork Size

`FSGetForkSize` (page 499)
Returns the size of an open fork.

`PBGetForkSizeSync` (page 665)
Returns the size of an open fork.

`PBGetForkSizeAsync` (page 664)
Returns the size of an open fork.

`FSSetForkSize` (page 542)
Changes the size of an open fork.

`PBSetForkSizeSync` (page 762)
Changes the size of an open fork.

`PBSetForkSizeAsync` (page 761)
Changes the size of an open fork.

`GetEOF` (page 548) Deprecated in Mac OS X v10.4
Determines the current logical size of an open file. (Deprecated. Use `FSGetForkSize` (page 499) instead.)

`PBGetEOFAsync` (page 654) Deprecated in Mac OS X v10.4
Determines the current logical size of an open file. (Deprecated. Use `PBGetForkSizeAsync` (page 664) instead.)

`PBGetEOFSync` (page 655) Deprecated in Mac OS X v10.4
Determines the current logical size of an open file. (Deprecated. Use `PBGetForkSizeSync` (page 665) instead.)

`PBSetEOFAsync` (page 757) Deprecated in Mac OS X v10.4
Sets the logical size of an open file. (Deprecated. Use `PBSetForkSizeAsync` (page 761) instead.)

PBSetEOFSync (page 758) Deprecated in Mac OS X v10.4
Sets the logical size of an open file. (Deprecated. Use PBSetForkSizeSync (page 762) instead.)

SetEOF (page 786) Deprecated in Mac OS X v10.4
Sets the logical size of an open file. (Deprecated. Use FSSetForkSize (page 542) instead.)

Manipulating File Position

FSGetForkPosition (page 499)
Returns the current position of an open fork.

PBGetForkPositionSync (page 663)
Returns the current position of an open fork.

PBGetForkPositionAsync (page 663)
Returns the current position of an open fork.

FSSetForkPosition (page 541)
Sets the current position of an open fork.

PBSetForkPositionSync (page 760)
Sets the current position of an open fork.

PBSetForkPositionAsync (page 759)
Sets the current position of an open fork.

GetFPos (page 548) Deprecated in Mac OS X v10.4
Returns the current position of the file mark. (Deprecated. Use FSGetForkPosition (page 499) instead.)

PBGetFPosAsync (page 666) Deprecated in Mac OS X v10.4
Returns the current position of the file mark. (Deprecated. Use PBGetForkPositionAsync (page 663) instead.)

PBGetFPosSync (page 666) Deprecated in Mac OS X v10.4
Returns the current position of the file mark. (Deprecated. Use PBGetForkPositionSync (page 663) instead.)

PBSetFPosAsync (page 763) Deprecated in Mac OS X v10.4
Sets the position of the file mark. (Deprecated. Use PBSetForkPositionAsync (page 759) instead.)

PBSetFPosSync (page 764) Deprecated in Mac OS X v10.4
Sets the position of the file mark. (Deprecated. Use PBSetForkPositionSync (page 760) instead.)

SetFPos (page 787) Deprecated in Mac OS X v10.4
Sets the position of the file mark. (Deprecated. Use FSSetForkPosition (page 541) instead.)

Manipulating the Default Volume

HGetVol (page 552) Deprecated in Mac OS X v10.4
Determines the current default volume and default directory. (Deprecated. There is no replacement function.)

HSetVol (page 559) Deprecated in Mac OS X v10.4
Sets the default volume and the default directory. (Deprecated. There is no replacement function.)

PBHGetVolAsync (page 693) Deprecated in Mac OS X v10.4
Determines the default volume and default directory. (Deprecated. There is no replacement function.)

PBHGetVolSync (page 695) Deprecated in Mac OS X v10.4
Determines the default volume and default directory. (Deprecated. There is no replacement function.)

PBHSetVolAsync (page 725) Deprecated in Mac OS X v10.4
Sets the default volume and the default directory. (Deprecated. There is no replacement function.)

PBHSetVolSync (page 726) Deprecated in Mac OS X v10.4
Sets the default volume and the default directory. (Deprecated. There is no replacement function.)

Mounting and Unmounting Volumes

FSMountLocalVolumeSync (page 507)
Mounts a volume.

FSMountServerVolumeSync (page 509)
Mounts a server volume.

FSUnmountVolumeSync (page 545)
Unmounts a volume.

FSEjectVolumeSync (page 486)
Ejects a volume.

FSCreateVolumeOperation (page 483)
Returns an FSVolumeOperation which can be used for an asynchronous volume operation.

FSCancelVolumeOperation (page 471)
Cancels an outstanding asynchronous volume mounting operation.

FSDisposeVolumeOperation (page 484)
Releases the memory associated with a volume operation.

FSMountLocalVolumeAsync (page 506)
Mounts a volume asynchronously.

FSMountServerVolumeAsync (page 508)
Mounts a server volume asynchronously.

FSUnmountVolumeAsync (page 544)
Unmounts a volume asynchronously.

FSEjectVolumeAsync (page 485)
Asynchronously ejects a volume.

FSGetAsyncMountStatus (page 492)
Returns the current status of an asynchronous mount operation.

FSGetAsyncUnmountStatus (page 493)
Returns the current status of an asynchronous unmount operation.

FSGetAsyncEjectStatus (page 491)
Returns the current status of an asynchronous eject operation.

PBUnmountVol (page 772) Deprecated in Mac OS X v10.4
Unmounts a volume. (Deprecated. Use FSEjectVolumeSync (page 486) or FSUnmountVolumeSync (page 545) instead.)

UnmountVol (page 787) Deprecated in Mac OS X v10.4
Unmounts a volume that isn't currently being used. (Deprecated. Use FSUnmountVolumeSync (page 545) instead.)

Mounting Remote Volumes

`FSGetVolumeMountInfoSize` (page 502)
Determines the size of the mounting information associated with the specified volume.

`FSGetVolumeMountInfo` (page 502)
Retrieves the mounting information associated with the specified volume.

`FSVolumeMount` (page 545)
Mounts a volume using the specified mounting information.

`PBGetVolMountInfo` (page 668) Deprecated in Mac OS X v10.5
Retrieves a record containing all the information needed to mount a volume, except for passwords. (Deprecated. Use `FSVolumeMount` (page 545) instead.)

`PBGetVolMountInfoSize` (page 669) Deprecated in Mac OS X v10.5
Determines how much space to allocate for a volume mounting information structure. (Deprecated. Use `FSVolumeMount` (page 545) instead.)

`PBVolumeMount` (page 773) Deprecated in Mac OS X v10.5
Mounts a volume. (Deprecated. Use `FSVolumeMount` (page 545) instead.)

Moving and Renaming Files or Directories

`FSMoveObject` (page 510)
Moves a file or directory into a different directory.

`PBMoveObjectSync` (page 738)
Moves a file or directory into a different directory.

`PBMoveObjectAsync` (page 737)
Moves a file or directory into a different directory.

`FSRenameUnicode` (page 539)
Renames a file or folder.

`PBRenameUnicodeSync` (page 748)
Renames a file or folder.

`PBRenameUnicodeAsync` (page 748)
Renames a file or folder.

`CatMove` (page 462) Deprecated in Mac OS X v10.4
Moves files or directories from one directory to another on the same volume. (Deprecated. Use `FSMoveObject` (page 510) instead.)

`FSpCatMove` (page 524) Deprecated in Mac OS X v10.4
Moves a file or directory from one location to another on the same volume. (Deprecated. Use `FSMoveObject` (page 510) instead.)

`FSpRename` (page 533) Deprecated in Mac OS X v10.4
Renames a file or directory. (Deprecated. Use `FSRenameUnicode` (page 539) instead.)

`HRename` (page 555) Deprecated in Mac OS X v10.4
Renames a file, directory, or volume. (Deprecated. Use `FSRenameUnicode` (page 539) instead.)

`PBCatMoveAsync` (page 575) Deprecated in Mac OS X v10.4
Moves files or directories from one directory to another on the same volume. (Deprecated. Use `PBMoveObjectAsync` (page 737) instead.)

`PBCatMoveSync` (page 576) Deprecated in Mac OS X v10.4
Moves files or directories from one directory to another on the same volume. (Deprecated. Use `PBMoveObjectSync` (page 738) instead.)

`PBHRenameAsync` (page 715) Deprecated in Mac OS X v10.4
Renames a file, directory, or volume. (Deprecated. Use `PBRenameUnicodeAsync` (page 748) instead.)

`PBHRenameSync` (page 716) Deprecated in Mac OS X v10.4
Renames a file, directory, or volume. (Deprecated. Use `PBRenameUnicodeSync` (page 748) instead.)

Obtaining File and Directory Information Using a Catalog Iterator on HFS Plus Volumes

`FSGetCatalogInfoBulk` (page 495)
Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

`PBGetCatalogInfoBulkSync` (page 646)
Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

`PBGetCatalogInfoBulkAsync` (page 644)
Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

Obtaining File Control Block Information

`PBGetFCBInfoAsync` (page 656) Deprecated in Mac OS X v10.4
Gets information about an open file from the file control block. (Deprecated. Use `PBGetForkCBInfoAsync` (page 660) instead.)

`PBGetFCBInfoSync` (page 658) Deprecated in Mac OS X v10.4
Gets information about an open file from the file control block. (Deprecated. Use `PBGetForkCBInfoSync` (page 661) instead.)

Obtaining Fork Control Block Information

`FSGetForkCBInfo` (page 497)
Returns information about a specified open fork, or about all open forks.

`PBGetForkCBInfoSync` (page 661)
Returns information about a specified open fork, or about all open forks.

`PBGetForkCBInfoAsync` (page 660)
Returns information about a specified open fork, or about all open forks.

Opening Files

`FSOpenFork` (page 514)
Opens any fork of a file or directory for streaming access.

PBOpenForkSync (page 740)
Opens any fork of a file or directory for streaming access.

PBOpenForkAsync (page 739)
Opens any fork of a file or directory for streaming access.

FSpOpenDF (page 531) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use FSOpenFork (page 514) instead.)

FSpOpenRF (page 532) Deprecated in Mac OS X v10.4
Opens the resource fork of a file. (Deprecated. Use FSOpenFork (page 514) instead.)

HOpen (page 553) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use FSOpenFork (page 514) instead.)

HOpenDF (page 554) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use FSOpenFork (page 514) instead.)

HOpenRF (page 554) Deprecated in Mac OS X v10.4
Opens the resource fork of a file. (Deprecated. Use FSOpenFork (page 514) instead.)

PBHOpenAsync (page 703) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use PBOpenForkAsync (page 739) instead.)

PBHOpenDFAsync (page 706) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use PBOpenForkAsync (page 739) instead.)

PBHOpenDFSync (page 708) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use PBOpenForkSync (page 740) instead.)

PBHOpenRFAsync (page 709) Deprecated in Mac OS X v10.4
Opens the resource fork of a file. (Deprecated. Use PBOpenForkAsync (page 739) instead.)

PBHOpenRFSync (page 713) Deprecated in Mac OS X v10.4
Opens the resource fork of a file. (Deprecated. Use PBOpenForkSync (page 740) instead.)

PBHOpenSync (page 714) Deprecated in Mac OS X v10.4
Opens the data fork of a file. (Deprecated. Use PBOpenForkSync (page 740) instead.)

Opening Files While Denying Access

PBHOpenDenyAsync (page 704) Deprecated in Mac OS X v10.5
Opens a file's data fork using the access deny modes. (Deprecated. Use PBOpenForkAsync (page 739) with deny modes in the permissions field.)

PBHOpenDenySync (page 705) Deprecated in Mac OS X v10.5
Opens a file's data fork using the access deny modes. (Deprecated. Use PBOpenForkSync (page 740) with deny modes in the permissions field.)

PBHOpenRFDenyAsync (page 710) Deprecated in Mac OS X v10.5
Opens a file's resource fork using the access deny modes. (Deprecated. Use PBOpenForkAsync (page 739) with deny modes in the permissions field.)

PBHOpenRFDenySync (page 711) Deprecated in Mac OS X v10.5
Opens a file's resource fork using the access deny modes. (Deprecated. Use PBOpenForkSync (page 740) with deny modes in the permissions field.)

Reading and Writing Files

`FSReadFork` (page 537)
Reads data from an open fork.

`PBReadForkSync` (page 745)
Reads data from an open fork.

`PBReadForkAsync` (page 744)
Reads data from an open fork.

`FSWriteFork` (page 546)
Writes data to an open fork.

`PBWriteForkSync` (page 777)
Writes data to an open fork.

`PBWriteForkAsync` (page 776)
Writes data to an open fork.

`PBReadAsync` (page 743) Deprecated in Mac OS X v10.5
Reads any number of bytes from an open file. (Deprecated. Use `PBReadForkAsync` (page 744) instead.)

`PBReadSync` (page 746) Deprecated in Mac OS X v10.5
Reads any number of bytes from an open file. (Deprecated. Use `PBReadForkSync` (page 745) instead.)

`PBWriteAsync` (page 775) Deprecated in Mac OS X v10.5
Writes any number of bytes to an open file. (Deprecated. Use `PBWriteForkAsync` (page 776) instead.)

`PBWriteSync` (page 779) Deprecated in Mac OS X v10.5
Writes any number of bytes to an open file. (Deprecated. Use `PBWriteForkSync` (page 777) instead.)

`FSRead` (page 536) Deprecated in Mac OS X v10.4
Reads any number of bytes from an open file. (Deprecated. Use `FSReadFork` (page 537) instead.)

`FSWrite` (page 546) Deprecated in Mac OS X v10.4
Writes any number of bytes to an open file. (Deprecated. Use `FSWriteFork` (page 546) instead.)

Resolving File ID References

`PBResolveFileIDRefAsync` (page 749) Deprecated in Mac OS X v10.5
Retrieves the filename and parent directory ID of a file given its file ID. (Deprecated. Use `FSGetCatalogInfo` (page 494) instead.)

`PBResolveFileIDRefSync` (page 750) Deprecated in Mac OS X v10.5
Retrieves the filename and parent directory ID of a file given its file ID. (Deprecated. Use `FSGetCatalogInfo` (page 494) instead.)

Searching a Volume

`PBCatSearchAsync` (page 577) Deprecated in Mac OS X v10.4
Searches a volume's catalog file using a set of search criteria that you specify. (Deprecated. Use `PBCatalogSearchAsync` (page 572) instead.)

`PBCatSearchSync` (page 580) Deprecated in Mac OS X v10.4
Searches a volume's catalog file using a set of search criteria that you specify. (Deprecated. Use `PBCatalogSearchSync` (page 573) instead.)

Searching a Volume Using a Catalog Iterator

`FSOpenIterator` (page 515)
Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

`PBOpenIteratorSync` (page 742)
Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

`PBOpenIteratorAsync` (page 741)
Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

`FSCatalogSearch` (page 472)
Searches for objects traversed by a catalog iterator that match a given set of criteria.

`PBCatalogSearchSync` (page 573)
Searches for objects traversed by a catalog iterator that match a given set of criteria.

`PBCatalogSearchAsync` (page 572)
Searches for objects traversed by a catalog iterator that match a given set of criteria.

`FSCloseIterator` (page 475)
Closes a catalog iterator.

`PBCloseIteratorSync` (page 584)
Closes a catalog iterator.

`PBCloseIteratorAsync` (page 584)
Closes a catalog iterator.

Updating Files

`FSFlushFork` (page 490)
Causes all data written to an open fork to be written to disk.

`PBFlushForkSync` (page 639)
Causes all data written to an open fork to be written to disk.

`PBFlushForkAsync` (page 638)
Causes all data written to an open fork to be written to disk.

`PBFlushFileAsync` (page 636) Deprecated in Mac OS X v10.4
Writes the contents of a file's access path buffer to the disk. (Deprecated. Use `PBFlushForkAsync` (page 638) instead.)

`PBFlushFileSync` (page 637) Deprecated in Mac OS X v10.4
Writes the contents of a file's access path buffer to the disk. (Deprecated. Use `PBFlushForkSync` (page 639) instead.)

Updating Volumes

`FSFlushVolume` (page 491)
For the specified volume, writes all open and modified files in the current process to permanent storage.

`PBFlushVolumeSync` (page 642)
For the specified volume, writes all open and modified files in the current process to permanent storage.

`PBFlushVolumeAsync` (page 642)
For the specified volume, writes all open and modified files in the current process to permanent storage.

`FlushVol` (page 466) Deprecated in Mac OS X v10.5
Writes the contents of the volume buffer and updates information about the volume. (Deprecated. Use `FSFlushVolume` (page 491) instead.)

`PBFlushVolAsync` (page 640) Deprecated in Mac OS X v10.5
Writes the contents of the volume buffer and updates information about the volume. (Deprecated. Use `PBFlushVolumeAsync` (page 642) instead.)

`PBFlushVolSync` (page 641) Deprecated in Mac OS X v10.5
Writes the contents of the volume buffer and updates information about the volume. (Deprecated. Use `PBFlushVolumeSync` (page 642) instead.)

Using Change Notifications

`FNNotify` (page 467)
Broadcasts notification of changes to the specified directory.

`FNNotifyAll` (page 468)
Broadcasts notification of changes to the filesystem.

`FNNotifyByPath` (page 468)
Broadcasts notification of changes to the specified directory.

`FNSubscribe` (page 469)
Subscribes to change notifications for the specified directory.

`FNSubscribeByPath` (page 469)
Subscribes to change notifications for the specified directory.

`FNUnsubscribe` (page 470)
Releases a subscription which is no longer needed.

`FNGetDirectoryForSubscription` (page 466)
Fetches the directory for which this subscription was originally entered.

Not Recommended

This section lists functions that are not recommended and you should no longer use.

`PBWaitIOComplete` (page 775) Deprecated in Mac OS X v10.5
Keeps the system idle until either an interrupt occurs or the specified timeout value is reached. (Deprecated. There is no replacement function.)

`PBGetForeignPrivsAsync` (page 659) Deprecated in Mac OS X v10.4
Determines the native access-control information for a file or directory stored on a volume managed by a foreign file system. (Deprecated. There is no replacement function.)

`PBGetForeignPrivsSync` (page 660) Deprecated in Mac OS X v10.4
Determines the native access-control information for a file or directory stored on a volume managed by a foreign file system. (Deprecated. There is no replacement function.)

`PBGetUGEntryAsync` (page 667) Deprecated in Mac OS X v10.4
Gets a user or group entry from the list of User and Group names and IDs on the local file server. (Deprecated. There is no replacement function.)

PBGetUGEntrySync (page 668) Deprecated in Mac OS X v10.4
: Gets a user or group entry from the list of User and Group names and IDs on a local file server. (Deprecated. There is no replacement function.)

PBGetXCatInfoAsync (page 672) Deprecated in Mac OS X v10.4
: Returns the short name (MS-DOS format name) and the ProDOS information for a file or directory. (Deprecated. There is no replacement function.)

PBGetXCatInfoSync (page 673) Deprecated in Mac OS X v10.4
: Returns the short name (MS-DOS format name) and the ProDOS information for a file or directory. (Deprecated. There is no replacement function.)

PBHGetLogInInfoSync (page 686) Deprecated in Mac OS X v10.4
: Determines the login method used to log on to a particular shared volume. (Deprecated. There is no replacement function.)

PBSetForeignPrivsAsync (page 759) Deprecated in Mac OS X v10.4
: Changes the native access-control information for a file or directory stored on a volume managed by a foreign file system. (Deprecated. There is no replacement function.)

PBSetForeignPrivsSync (page 759) Deprecated in Mac OS X v10.4
: Changes the native access-control information for a file or directory stored on a volume managed by a foreign file system. (Deprecated. There is no replacement function.)

PBShareAsync (page 769) Deprecated in Mac OS X v10.4
: Establishes a local volume or directory as a share point. (Deprecated. There is no replacement function.)

PBShareSync (page 769) Deprecated in Mac OS X v10.4
: Establishes a local volume or directory as a share point. (Deprecated. There is no replacement function.)

PBUnshareAsync (page 773) Deprecated in Mac OS X v10.4
: Makes a share point unavailable on the network. (Deprecated. There is no replacement function.)

PBUnshareSync (page 773) Deprecated in Mac OS X v10.4
: Makes a share point unavailable on the network. (Deprecated. There is no replacement function.)

Functions

Allocate

Allocates additional space on a volume to an open file. (Deprecated in Mac OS X v10.4. Use FSAllocateFork (page 470) instead.)

```
OSErr Allocate (
   FSIORefNum refNum,
   SInt32 *count
);
```

Parameters

refNum
: The file reference number of the open file.

count
: On input, a pointer to the number of additional bytes to allocate to the file. On return, a pointer to the number of bytes actually allocated, rounded up to the nearest multiple of the allocation block size.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `Allocate` function adds the specified number of bytes to the file and sets the physical end-of-file to 1 byte beyond the last block allocated. If there isn't enough empty space on the volume to satisfy the allocation request, `Allocate` allocates the rest of the space on the volume and returns `dskFulErr` as its function result.

The `Allocate` function always attempts to allocate contiguous blocks. If the total number of requested bytes is unavailable, `Allocate` allocates whatever space, contiguous or not, is available. To force the allocation of the entire requested space as a contiguous piece, call `AllocContig` (page 461) instead.

The File Manager automatically allocates file blocks if you move the logical end-of-file past the physical end-of-file, and it automatically deallocates unneeded blocks from a file if you move the logical end-of-file to a position more than one allocation block before the current physical end-of-file. Consequently, you do not in general need to be concerned with allocating or deallocating file blocks. However, you can improve file block contiguity if you use the `Allocate` or `AllocContig` function to preallocate file blocks. This is most useful if you know in advance how big a file is likely to become.

When the File Manager allocates (or deallocates) file blocks automatically, it always adds (or removes) blocks in clumps. The `Allocate` function allows you to add blocks in allocation blocks, which may be smaller than clumps.

The space allocated with this function is not permanently assigned to the file until the file's logical end-of-file is changed to include the allocated space. When a file (or volume) is closed, the space beyond the file's logical EOF is made available for other purposes, even if previously allocated to the file with a call to this function. You can change the end-of-file by setting it with the `SetEOF` (page 786) function, or by writing data to the file with the `FSWrite` (page 546) function.

This function is not supported by all file systems; for example, volumes mounted by the AppleShare file system do not support this function. To allocate space for a file on any volume, use the `SetEOF` (page 786) function, or one of the related parameter block calls, `PBSetEOFSync` (page 758) and `PBSetEOFAsync` (page 757).

To allocate space for a file beyond 2 GB, use the `FSAllocateFork` (page 470) function, or one of the corresponding parameter block functions, `PBAllocateForkSync` (page 567) and `PBAllocateForkAsync` (page 565).

Special Considerations

In Mac OS 7.5.5 through Mac OS 8.5, if there is not enough space left on the volume to allocate the requested number of bytes, the `Allocate` function does not return the number of bytes actually allocated. Your application should not rely on the value returned in the `count` parameter.

To determine the remaining space on a volume before calling `Allocate`, use the functions `PBXGetVolInfoSync` or `PBXGetVolInfoAsync`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

AllocContig

Allocates additional contiguous space on a volume to an open file. (Deprecated in Mac OS X v10.4. Use FSAllocateFork (page 470) instead.)

```
OSErr AllocContig (
   FSVolumeRefNum refNum,
   SInt32 *count
);
```

Parameters

refNum

The file reference number of an open file.

count

On input, a pointer to the number of additional bytes to allocate to the file; on return, a pointer to the number of bytes allocated, rounded up to the nearest multiple of the allocation block size.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The AllocContig function is identical to the Allocate (page 459) function except that if there isn't enough contiguous empty space on the volume to satisfy the allocation request, AllocContig does nothing and returns dskFulErr as its function result. If you want to allocate whatever space is available, even when the entire request cannot be filled by the allocation of a contiguous piece, call Allocate (page 459) instead.

The File Manager automatically allocates file blocks if you move the logical end-of-file past the physical end-of-file, and it automatically deallocates unneeded blocks from a file if you move the logical end-of-file to a position more than one allocation block before the current physical end-of-file. Consequently, you do not in general need to be concerned with allocating or deallocating file blocks. However, you can improve file block contiguity if you use the AllocContig function to preallocate file blocks. This is most useful if you know in advance how big a file is likely to become.

When the File Manager allocates (or deallocates) file blocks automatically, it always adds (or removes) blocks in clumps. The AllocContig function allows you to add blocks in allocation blocks, which may be smaller than clumps.

The space allocated with this function is not permanently assigned to the file until the file's logical end-of-file is changed to include the allocated space. When a file (or volume) is closed, the space beyond the file's logical EOF is made available for other purposes, even if previously allocated to the file with a call to this function. You can change the end-of-file by setting it with the SetEOF (page 786) function, or by writing data to the file with the FSWrite (page 546) function.

This function is not supported by all file systems; for example, volumes mounted by the AppleShare file system do not support this function. To allocate space for a file on any volume, use the SetEOF (page 786) function, or one of the related parameter block calls, PBSetEOFSync (page 758) and PBSetEOFAsync (page 757).

To allocate space for a file beyond 2 GB, use the FSAllocateFork (page 470) function, or one of the corresponding parameter block functions, PBAllocateForkSync (page 567) and PBAllocateForkAsync (page 565).

Special Considerations

In Mac OS 7.5.5 through Mac OS 8.5, when there is not enough space to allocate the requested number of bytes, `AllocContig` does not return 0 in the `count` parameter, so your application cannot rely upon this value.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

CatMove

Moves files or directories from one directory to another on the same volume. (Deprecated in Mac OS X v10.4. Use `FSMoveObject` (page 510) instead.)

```
OSErr CatMove (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param oldName,
   SInt32 newDirID,
   ConstStr255Param newName
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The parent directory ID of the file or directory to move.

oldName

The existing name of the file or directory to move.

newDirID

If the `newName` parameter is empty, the directory ID of the destination directory; otherwise, the parent directory ID of the destination directory.

newName

The name of the destination directory. If a valid directory name is provided in this parameter, the destination directory's parent directory is specified in the `newDirID` parameter. However, you can specify an empty name for `newName`, in which case `newDirID` should be set to the directory ID of the destination directory.

It is usually simplest to specify the destination directory by passing its directory ID in the `newDirID` parameter and by setting `newName` to an empty name. To specify an empty name, set `newName` to `':'`.

Return Value

A result code. See "File Manager Result Codes" (page 943). This function returns `permErr` if called on a locked file.

Discussion
`CatMove` is strictly a file catalog operation; it does not actually change the location of the file or directory on the disk.

The `CatMove` function cannot move a file or directory to another volume (that is, the `vRefNum` parameter is used in specifying both the source and the destination). Also, you cannot use it to rename files or directories; to rename a file or directory, use `HRename` (page 555).

If you need to move files or directories with named forks other than the data and resource forks, with long Unicode names, or files larger than 2GB, you should use the `FSMoveObject` (page 510) function, or one of the corresponding parameter block calls, `PBMoveObjectSync` (page 738) and `PBMoveObjectAsync` (page 737).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

DirCreate

Creates a new directory. (Deprecated in Mac OS X v10.4. Use `FSCreateDirectoryUnicode` (page 479) instead.)

```
OSErr DirCreate (
   FSVolumeRefNum vRefNum,
   SInt32 parentDirID,
   ConstStr255Param directoryName,
   SInt32 *createdDirID
);
```

Parameters

vRefNum
A volume reference number, drive number, or 0 for the default volume.

parentDirID
The directory ID of the parent directory. If the parent directory ID is 0 and the volume specified in the `vRefNum` parameter is the default volume, the new directory is placed in the default directory of the volume. If the parent directory ID is 0 and the volume specified in the `vRefNum` parameter is a volume other than the default volume, the new directory is placed in the root directory of the volume. To create a directory at the root of a volume, regardless of whether that volume is the current default volume, pass the constant `fsRtDirID`(2) in this parameter.

directoryName
The name of the new directory.

createdDirID
On return, a pointer to the directory ID of the new directory. Note that a directory ID, unlike a volume reference number, is a long integer.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The date and time of the new directory's creation and last modification are set to the current date and time.

To create a directory with a Unicode name, use the function `FSCreateDirectoryUnicode` (page 479) , or one of the corresponding parameter block calls, `PBCreateDirectoryUnicodeSync` (page 589) and `PBCreateDirectoryUnicodeAsync` (page 587).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

DisposeFNSubscriptionUPP

Deletes a universal procedure pointer (UPP) to your directory change callback function.

```
void DisposeFNSubscriptionUPP (
   FNSubscriptionUPP userUPP
);
```

Parameters
userUPP
The UPP to delete.

Discussion
You should use this function to delete the UPP after the File Manager is finished calling your directory change callback function.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

DisposeFSVolumeEjectUPP

Deletes a universal procedure pointer (UPP) to your volume ejection callback function.

```
void DisposeFSVolumeEjectUPP (
   FSVolumeEjectUPP userUPP
);
```

Parameters
userUPP
The UPP to delete.

Discussion
You should use this function to delete the UPP after the File Manager is finished calling your volume ejection callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

DisposeFSVolumeMountUPP

Deletes a universal procedure pointer (UPP) to your volume mount callback function.

```
void DisposeFSVolumeMountUPP (
   FSVolumeMountUPP userUPP
);
```

Parameters

userUPP

The UPP to delete.

Discussion
You should use this function to delete the UPP after the File Manager is finished calling your volume mount callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

DisposeFSVolumeUnmountUPP

Deletes a universal procedure pointer (UPP) to your volume unmount callback function.

```
void DisposeFSVolumeUnmountUPP (
   FSVolumeUnmountUPP userUPP
);
```

Parameters

userUPP

The UPP to delete.

Discussion
You should use this function to delete the UPP after the File Manager is finished calling your volume unmount callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

DisposeIOCompletionUPP

Deletes a universal procedure pointer (UPP) to your I/O completion callback function.

```
void DisposeIOCompletionUPP (
   IOCompletionUPP userUPP
);
```

Parameters

userUPP

The UPP to delete.

Discussion
You should use this function to delete the UPP after the File Manager is finished calling your I/O completion callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FlushVol

Writes the contents of the volume buffer and updates information about the volume. (Deprecated in Mac OS X v10.5. Use `FSFlushVolume` (page 491) instead.)

```
OSErr FlushVol (
   ConstStr63Param volName,
   FSVolumeRefNum vRefNum
);
```

Parameters

volName

The name of the mounted volume to flush.

vRefNum

The volume reference number, drive number, or 0 for the default volume.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
For the specified volume, the `FlushVol` function writes the contents of the associated volume buffer and descriptive information about the volume. Information which has changed since the last time `FlushVol` was called is written to the volume.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

FNGetDirectoryForSubscription

Fetches the directory for which this subscription was originally entered.

```
OSStatus FNGetDirectoryForSubscription (
   FNSubscriptionRef subscription,
   FSRef *ref
);
```

Parameters

subscription

The subscription previously returned from the functions `FNSubscribe` or `FNSubscribeByPath`.

ref

On return, a file system reference to the directory for which this subscription was created.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

There is no path variant because paths are fragile, and the path may have changed. If the caller does not care about this subtlety, she can call `FSRefMakePath` to get a path from the returned reference.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Files.h`

FNNotify

Broadcasts notification of changes to the specified directory.

```
OSStatus FNNotify (
   const FSRef *ref,
   FNMessage message,
   OptionBits flags
);
```

Parameters

ref

A file system reference describing the directory for which to broadcast the notification.

message

An indication of what happened to the target directory.

flags

Options regarding the delivery of the notification. Specify `kNilOptions` for the default behavior.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FNNotifyAll

Broadcasts notification of changes to the filesystem.

```
OSStatus FNNotifyAll (
   FNMessage message,
   OptionBits flags
);
```

Parameters

message

An indication of what happened.

flags

Options regarding the delivery of the notification. Specify `kNilOptions` for the default behavior.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

This function should only be used by installers or programs which make lots of changes and only send one broadcast.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FNNotifyByPath

Broadcasts notification of changes to the specified directory.

```
OSStatus FNNotifyByPath (
   const UInt8 *path,
   FNMessage message,
   OptionBits flags
);
```

Parameters

path

The path to the directory for which to broadcast the notification.

message

An indication of what happened to the target directory.

flags

Options regarding the delivery of the notification. Specify `kNilOptions` for the default behavior.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FNSubscribe

Subscribes to change notifications for the specified directory.

```
OSStatus FNSubscribe (
   const FSRef *directoryRef,
   FNSubscriptionUPP callback,
   void *refcon,
   OptionBits flags,
   FNSubscriptionRef *subscription
);
```

Parameters

directoryRef

A file system reference describing the directory for which the caller wants notifications.

callback

A pointer to the function to call when a notification arrives.

refcon

A pointer to user state carried with the subscription.

flags

Specify `kNilOptions`, or one of the options described in "Notification Subscription Options" (page 925).

subscription

A subscription token for subsequent query or unsubscription.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Files.h`

FNSubscribeByPath

Subscribes to change notifications for the specified directory.

```
OSStatus FNSubscribeByPath (
   const UInt8 *directoryPath,
   FNSubscriptionUPP callback,
   void *refcon,
   OptionBits flags,
   FNSubscriptionRef *subscription
);
```

Parameters

directoryPath

A path to the directory for which the caller wants notifications.

callback

The function to call when a notification arrives.

refcon

A pointer to the user state carried with the subscription.

flags

Specify `kNilOptions`, or one of the options described in "Notification Subscription Options" (page 925).

subscription

A subscription token for subsequent query or unsubscription.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

FNUnsubscribe

Releases a subscription which is no longer needed.

```
OSStatus FNUnsubscribe (
   FNSubscriptionRef subscription
);
```

Parameters

subscription

A subscription previously returned from the `FNSubscribe` or`FNSubscribeByPath` functions.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

FSAllocateFork

Allocates space on a volume to an open fork.

```
OSErr FSAllocateFork (
   FSIORefNum forkRefNum,
   FSAllocationFlags flags,
   UInt16 positionMode,
   SInt64 positionOffset,
   UInt64 requestCount,
   UInt64 *actualCount
);
```

Parameters

forkRefNum

The reference number of the open fork. You can obtain a fork reference number with the `FSOpenFork` (page 514) function, or with one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

flags

A constant indicating how the new space should be allocated. See "Allocation Flags" (page 887) for a description of the constants which you can use in this parameter.

positionMode

A constant specifying the base location for the start of the allocation. See "Position Mode Constants" (page 928) for more information on the constants which you can use to specify the base location.

positionOffset

The offset from the base location of the start of the allocation.

requestCount

The number of bytes to allocate.

actualCount

On return, a pointer to the number of bytes actually allocated to the file. The value returned in here may be smaller than the number specified in the `requestCount` parameter if some of the space was already allocated. The value pointed to by the `actualCount` parameter does not reflect any additional bytes that may have been allocated because space is allocated in terms of fixed units such as allocation blocks, or the use of a clump size to reduce fragmentation.

The `actualCount` output is optional if you don't want the number of allocated bytes returned, set `actualCount` to `NULL`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSAllocateFork` function attempts to allocate `requestCount` bytes of physical storage starting at the offset specified by the `positionMode` and `positionOffset` parameters. For volume formats that support preallocated space, you can later write to this range of bytes (including extending the size of the fork) without requiring an implicit allocation.

Any extra space allocated but not used will be deallocated when the fork is closed, using `FSCloseFork` (page 475) , `PBCloseForkSync` (page 583) , or `PBCloseForkAsync` (page 582) ; or when the fork is flushed, using `FSFlushFork` (page 490) , `PBFlushForkSync` (page 639) , or `PBFlushForkAsync` (page 638).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCancelVolumeOperation

Cancels an outstanding asynchronous volume mounting operation.

```
OSStatus FSCancelVolumeOperation (
   FSVolumeOperation volumeOp
);
```

Parameters

volumeOp

The asynchronous volume operation to cancel.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Special Considerations

This function currently is only supported for server mounts.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Files.h`

FSCatalogSearch

Searches for objects traversed by a catalog iterator that match a given set of criteria.

```
OSErr FSCatalogSearch (
   FSIterator iterator,
   const FSSearchParams *searchCriteria,
   ItemCount maximumObjects,
   ItemCount *actualObjects,
   Boolean *containerChanged,
   FSCatalogInfoBitmap whichInfo,
   FSCatalogInfo *catalogInfos,
   FSRef *refs,
   FSSpecPtr specs,
   HFSUniStr255 *names
);
```

Parameters

iterator

The iterator to use. Objects traversed by this iterator are matched against the criteria specified by the `searchCriteria` parameter. You can obtain a catalog iterator with the function `FSOpenIterator` (page 515), or with one of the related parameter block calls, `PBOpenIteratorSync` (page 742) and `PBOpenIteratorAsync` (page 741). Currently, this iterator must be created with the `kFSIterateSubtree` option and the container must be the root directory of a volume. See `FSIterator` (page 835) for more information on the `FSIterator` data type.

searchCriteria

A pointer to a structure containing the search criteria.

You can match against the object's name in Unicode and by the fields in an `FSCatalogInfo` (page 826) structure. You may use the same search bits as passed in the `ioSearchBits` field to the `PBCatSearchSync` (page 580) and `PBCatSearchAsync` (page 577) functions; they control the corresponding `FSCatalogInfo` fields. See "Catalog Search Masks" (page 900) for a description of the search bits.

There are a few new search criteria supported by `FSCatalogSearch` but not by `PBCatSearchSync` and `PBCatSearchAsync`. These new search criteria are indicated by the constants described in "Catalog Search Constants" (page 899).

If the `searchTime` field of this structure is non-zero, it is interpreted as a Time Manager duration; the search may terminate after this duration even if `maximumObjects` objects have not been returned and the entire catalog has not been scanned. If `searchTime` is zero, there is no time limit for the search.

If you are searching by any criteria other than name, you must set the `searchInfo1` and `searchInfo2` fields of the structure in this parameter to point to `FSCatalogInfo` structures containing the values to match against.

See `FSSearchParams` (page 839) for a description of the `FSSearchParams` data type.

maximumObjects

The maximum number of items to return for this call.

actualObjects

On return, a pointer to the actual number of items found for this call.

containerChanged

On return, a pointer to a Boolean value indicating whether the container's contents have changed. If `true`, the container's contents changed since the previous `FSCatalogSearch` call. Objects may still be returned even though the container changed. Note that if the container has changed, then the total set of items returned may be incorrect; some items may be returned multiple times, and some items may not be returned at all.

This parameter is optional if you don't want this information, pass a `NULL` pointer.

whichInfo

A bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant `kFSCatInfoNone` in this parameter. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this parameter.

catalogInfos

A pointer to an array of catalog information structures; one for each found item. On input, the `catalogInfos` parameter should point to an array of `maximumObjects` catalog information structures.

This parameter is optional; if you do not wish any catalog information returned, pass `NULL` here.

See `FSCatalogInfo` (page 826) for a description of the `FSCatalogInfo` data type.

refs

A pointer to an array of `FSRef` structures; one for each returned item. If you want an `FSRef` for each item found, set this parameter to point to an array of `maximumObjectsFSRef` structures. Otherwise, set it to `NULL`. See `FSRef` (page 837) for a description of the `FSRef` data type.

specs
names

A pointer to an array of filenames; one for each returned item. If you want the Unicode filename for each item found, set this parameter to point to an array of `maximumObjectsHFSUniStr255` structures. Otherwise, set it to `NULL`. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). When the entire volume has been searched, `errFSNoMoreItems` is returned.

Discussion
A single search may span more than one call to `FSCatalogSearch`. The call may complete with no error before scanning the entire volume. This typically happens because the time limit (`searchTime`) has been reached or `maximumObjects` items have been returned. If the search is not completed, you can continue the search by making another call to `FSCatalogSearch` and passing the updated iterator returned by the previous call in the `iterator` parameter.

Before calling this function, you should determine that it is present, by calling the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSClose

Closes an open file. (Deprecated in Mac OS X v10.4. Use `FSCloseFork` (page 475) instead.)

```
OSErr FSClose (
    FSIORefNum refNum
);
```

Parameters

refNum

The file reference number of the open file.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSClose` function removes the access path for the specified file and writes the contents of the volume buffer to the volume.

The `FSClose` function calls the `PBFlushFileSync` function internally to write the file's bytes onto the volume. To ensure that the file's catalog entry is updated, you should call `FlushVol` (page 466) after you call `FSClose`.

Special Considerations

Make sure that you do not call `FSClose` with a file reference number of a file that has already been closed. Attempting to close the same file twice may result in loss of data on a volume.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSCloseFork

Closes an open fork.

```
OSErr FSCloseFork (
    FSIORefNum forkRefNum
);
```

Parameters

forkRefNum

The reference number of the fork to close. After the call to this function, the reference number in this parameter is invalid.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSCloseFork` function causes all data written to the fork to be written to disk, in the same manner as the `FSFlushFork` (page 490) function, before it closes the fork.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCloseIterator

Closes a catalog iterator.

```
OSErr FSCloseIterator (
   FSIterator iterator
);
```

Parameters

iterator

The catalog iterator to be closed. `FSCloseIterator` releases memory and other system resources used by the iterator, making the iterator invalid. See `FSIterator` (page 835) for a description of the `FSIterator` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function releases memory and other system resources used by the iterator. The iterator becomes invalid.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`Files.h`

FSCompareFSRefs

Determines whether two `FSRef` structures refer to the same file or directory.

```
OSErr FSCompareFSRefs (
   const FSRef *ref1,
   const FSRef *ref2
);
```

Parameters

ref1

A pointer to the first `FSRef` to compare. For a description of the `FSRef` data type, see `FSRef` (page 837).

ref2

A pointer to the second `FSRef` to compare.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the two `FSRef` structures refer to the same file or directory, then `noErr` is returned. If they refer to objects on different volumes, then `diffVolErr` is returned. If they refer to different files or directories on the same volume, then `errFSRefsDifferent` is returned. This function may return other errors, including `nsvErr`, `fnfErr`, `dirNFErr`, and `volOffLinErr`.

Discussion
You must use `FSCompareFSRefs`, or one of the corresponding parameter block functions, `PBCompareFSRefsSync` (page 586) and `PBCompareFSRefsAsync` (page 586) , to compare `FSRef` structures. It is not possible to compare the `FSRef` structures directly since some bytes may be uninitialized, case-insensitive text, or contain hint information.

Some volume formats may be able to tell that two `FSRef` structures would refer to two different files or directories, without having to actually find those objects. In this case, the volume format may return `errFSRefsDifferent` even if one or both objects no longer exist. Similarly, if the `FSRef` structures are for objects on different volumes, the File Manager will return `diffVolErr` even if one or both volumes are no longer mounted.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCopyDiskIDForVolume

Returns a copy of the disk ID for a volume.

```
OSStatus FSCopyDiskIDForVolume (
    FSVolumeRefNum vRefNum,
    CFStringRef *diskID
);
```

Parameters

vRefNum

The volume reference number of the target volume.

diskID

A pointer to a Core Foundation string. On return, the string contains the disk ID associated with the target volume. The caller is responsible for releasing the string.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSCopyObjectAsync

Starts an asynchronous file operation to copy a source object to a destination directory.

```
OSStatus FSCopyObjectAsync (
   FSFileOperationRef fileOp,
   const FSRef *source,
   const FSRef *destDir,
   CFStringRef destName,
   OptionBits flags,
   FSFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

fileOp

The file operation object you created for this copy operation.

source

A pointer to the source object to copy. The object can be a file or a directory.

destDir

A pointer to the destination directory.

destName

The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

flags

One or more file operation option flags. See "File Operation Options" (page 917).

callback

A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

statusChangeInterval
The minimum time in seconds between callbacks within a single stage of an operation.

clientContext
User-defined data to associate with this operation. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you specify a status callback function, status callbacks will occur in one of the run loop and mode combinations with which you scheduled the file operation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSCopyObjectSync

Copies a source object to a destination directory.

```
OSStatus FSCopyObjectSync (
   const FSRef *source,
   const FSRef *destDir,
   CFStringRef destName,
   FSRef *target,
   OptionBits options
);
```

Parameters

source
A pointer to the source object to copy. The object can be a file or a directory.

destDir
A pointer to the destination directory.

destName
The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

target
A pointer to an `FSRef` variable that, on output, refers to the new object in the destination directory. This parameter is optional; pass `NULL` if you don't need to refer to the new object.

options
One or more file operation option flags. See "File Operation Options" (page 917).

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function could take a significant amount of time to execute. To avoid blocking your user interface, you should either call this function in a thread other than the main thread or use `FSCopyObjectAsync` (page 477) instead.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSCopyURLForVolume

Returns a copy of the URL for a volume.

```
OSStatus FSCopyURLForVolume (
    FSVolumeRefNum vRefNum,
    CFURLRef *url
);
```

Parameters

vRefNum

The volume reference number of the target volume.

url

A pointer to a `CFURLRef` variable allocated by the caller. On return, a Core Foundation URL that specifies the location of the target volume. The caller is responsible for releasing the URL.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Files.h`

FSCreateDirectoryUnicode

Creates a new directory (folder) with a Unicode name.

```
OSErr FSCreateDirectoryUnicode (
   const FSRef *parentRef,
   UniCharCount nameLength,
   const UniChar *name,
   FSCatalogInfoBitmap whichInfo,
   const FSCatalogInfo *catalogInfo,
   FSRef *newRef,
   FSSpecPtr newSpec,
   UInt32 *newDirID
);
```

Parameters

parentRef

A pointer to an `FSRef` specifying the parent directory where the new directory is to be created. See `FSRef` (page 837) for a description of the `FSRef` data type.

nameLength

The length of the new directory's Unicode name.

name

A pointer to the Unicode name of the new directory.

whichInfo

A bitmap specifying which catalog information fields to set for the new directory. Specify the values for these fields in the `catalogInfo` parameter.

If you do not wish to set catalog information for the new directory, specify the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this parameter.

catalogInfo

A pointer to the `FSCatalogInfo` structure which specifies the values for the catalog information fields for the new directory. Specify which fields to set in the `whichInfo` parameter.

This parameter is optional; specify `NULL` if you do not wish to set catalog information for the new directory.

See `FSCatalogInfo` (page 826) for a description of the `FSCatalogInfo` data type.

newRef

On return, a pointer to the `FSRef` for the new directory. This parameter is optional; specify `NULL` if you do not want the `FSRef` returned.

newSpec

On return, a pointer to the `FSSpec` for the new directory. This parameter is optional; specify `NULL` if you do not want the `FSSpec` returned. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

newDirID

On return, a pointer to the directory ID of the directory. This parameter is optional; specify `NULL` if you do not want the directory ID returned.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
You may optionally set catalog information for the new directory using the `whichInfo` and `catalogInfo` parameters; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the directory.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catalogInfo` parameter. This will be used by the volume format when converting the Unicode filename to other encodings.

Special Considerations

If the `FSCreateDirectoryUnicode` function is present, but is not implemented by a particular volume, the File Manager will emulate this function by making the appropriate call to `PBDirCreateSync` (page 601). However, if the function is not directly supported by the volume, you will not be able to use the long Unicode directory names, or other features added with HFS Plus.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest

Declared In
`Files.h`

FSCreateFileUnicode

Creates a new file with a Unicode name.

```
OSErr FSCreateFileUnicode (
   const FSRef *parentRef,
   UniCharCount nameLength,
   const UniChar *name,
   FSCatalogInfoBitmap whichInfo,
   const FSCatalogInfo *catalogInfo,
   FSRef *newRef,
   FSSpecPtr newSpec
);
```

Parameters

parentRef
A pointer to an `FSRef` for the directory where the file is to be created. See `FSRef` (page 837) for a description of the `FSRef` data type.

nameLength
The length of the file's name.

name
A pointer to the Unicode name for the new file.

whichInfo
A bitmap specifying which catalog information fields to set for the new file. You specify the values for these fields in the `catalogInfo` parameter. If you do not wish to set catalog information for the new file, pass the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this parameter.

catalogInfo
A pointer to the `FSCatalogInfo` structure which specifies the values of the new file's catalog information. Specify which fields to set in the `whichInfo` parameter.

This parameter is optional; specify `NULL` if you do not wish to set catalog information for the new file.

newRef
On return, a pointer to the `FSRef` for the new file. If you do not want the `FSRef` returned, specify `NULL`.

newSpec
On return, a pointer to the `FSSpec` for the new file. If you do not want the `FSSpec` returned, specify `NULL`. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
You may optionally set catalog information for the new file using the `whichInfo` and `catalogInfo` parameters; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the file.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catalogInfo` parameter. This will be used by the volume format when converting the Unicode filename to other encodings.

Special Considerations

If the `FSCreateFileUnicode` function is present, but is not implemented by a particular volume, the File Manager will emulate this function by making the appropriate call to `PBHCreateSync` (page 677). However, if the function is not directly supported by the volume, you will not be able to use the long Unicode filenames, or other features added with HFS Plus.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
CarbonSketch
QTCarbonShell

Declared In
`Files.h`

FSCreateFork

Creates a named fork for a file or directory.

```
OSErr FSCreateFork (
   const FSRef *ref,
   UniCharCount forkNameLength,
   const UniChar *forkName
);
```

Parameters

ref
A pointer to an `FSRef` specifying the file or directory. See `FSRef` (page 837) for a description of the `FSRef` data type.

forkNameLength
The length of the name of the new fork.

forkName
A pointer to the Unicode name of the fork.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the named fork already exists, the function returns `errFSForkExists`. If the fork name is syntactically invalid or otherwise unsupported for the given volume, `FSCreateFork` returns `errFSBadForkName` or `errFSNameTooLong`.

Discussion
A newly created fork has zero length (that is, its logical end-of-file is zero). The data and resource forks of a file are automatically created and deleted as needed. This is done for compatibility with older APIs, and because data and resource forks are often handled specially. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), an attempt to create that fork when a zero-length fork already exists should return `noErr`; if a non-empty fork already exists then `errFSForkExists` should be returned.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCreateVolumeOperation

Returns an `FSVolumeOperation` which can be used for an asynchronous volume operation.

```
OSStatus FSCreateVolumeOperation (
   FSVolumeOperation *volumeOp
);
```

Parameters

`volumeOp`
The new `FSVolumeOperation`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
When the operation is completed the `FSVolumeOperation` should be disposed of to free the memory associated with the operation using `FSDisposeVolumeOperation`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSDeleteFork

Deletes a named fork from a file or directory.

```
OSErr FSDeleteFork (
   const FSRef *ref,
   UniCharCount forkNameLength,
   const UniChar *forkName
);
```

Parameters

`ref`
A pointer to an `FSRef` for the file or directory from which to delete the fork. See `FSRef` (page 837) for a description of the `FSRef` data type.

`forkNameLength`
The length of the Unicode name of the fork name.

`forkName`
A pointer to the Unicode name of the fork to delete.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the named fork does not exist, the function returns `errFSForkNotFound`.

Discussion
Any storage allocated to the fork is released. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), this is equivalent to setting the logical size of the fork to zero.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSDeleteObject

Deletes a file or an empty directory.

```
OSErr FSDeleteObject (
   const FSRef *ref
);
```

Parameters

ref

A pointer to an `FSRef` specifying the file or directory to be deleted. If the object to be deleted is a directory, it must be empty (it must contain no files or folders). See `FSRef` (page 837) for a description of the `FSRef` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If you attempt to delete a folder for which there is an open catalog iterator, this function succeeds and returns `noErr`. Iteration, however, will continue to work until the iterator is closed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
CarbonSketch
QTCarbonShell

Declared In
`Files.h`

FSDisposeVolumeOperation

Releases the memory associated with a volume operation.

```
OSStatus FSDisposeVolumeOperation (
   FSVolumeOperation volumeOp
);
```

Parameters

volumeOp

The `FSVolumeOperation` to release.

Return Value
A result code. See "File Manager Result Codes" (page 943). This function will return `paramErr` if the `FSVolumeOperation` is in use.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSEjectVolumeAsync

Asynchronously ejects a volume.

```
OSStatus FSEjectVolumeAsync (
   FSVolumeRefNum vRefNum,
   OptionBits flags,
   FSVolumeOperation volumeOp,
   void *clientData,
   FSVolumeEjectUPP callback,
   CFRunLoopRef runloop,
   CFStringRef runloopMode
);
```

Parameters

vRefNum
The volume reference number of the volume to eject.

flags
Options for future use.

volumeOp
An `FSVolumeOperation` returned by `FSCreateVolumeOperation`.

clientData
A pointer to client data associated with the operation. This parameter can be `NULL`.

callback
The function to call when eject is complete.

runloop
The runloop to run on.

runloopMode
The mode for the runloop.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function starts the process of ejecting the volume specified by the *vRefNum* parameter. If a callback function is provided, that function will be called when the eject operation is complete. Once this function returns `noErr` the status of the operation can be found using `FSGetAsyncEjectStatus`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
Files.h

FSEjectVolumeSync

Ejects a volume.

```
OSStatus FSEjectVolumeSync (
   FSVolumeRefNum vRefNum,
   OptionBits flags,
   pid_t *dissenter
);
```

Parameters

vRefNum
The volume reference number of the volume to eject.

flags
Options for future use.

dissenter
On return, a pointer to the pid of the process which denied the unmount if the eject is denied.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function ejects the volume specified by the *vRefNum* parameter. If the volume cannot be ejected the pid of the process which denied the unmount will be returned in the *dissenter* parameter. This function returns after the eject is complete. Ejecting a volume will result in the unmounting of other volumes on the same device.

Availability
Available in Mac OS X v10.2 and later.

Declared In
Files.h

FSExchangeObjects

Swaps the contents of two files.

```
OSErr FSExchangeObjects (
   const FSRef *ref,
   const FSRef *destRef
);
```

Parameters

ref
A pointer to an FSRef for the first file. See FSRef (page 837) for a description of the FSRef data type.

destRef
A pointer to an FSRef for the second file.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSExchangeObjects` function allows programs to implement a "safe save" operation by creating and writing a complete new file and swapping the contents. An alias, `FSSpec`, or `FSRef` that refers to the old file will now access the new data. The corresponding information in in-memory data structures are also exchanged.

Either or both files may have open access paths. After the exchange, the access path will refer to the opposite file's data (that is, to the same data it originally referred, which is now part of the other file).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSFileOperationCancel

Cancels an asynchronous file operation.

```
OSStatus FSFileOperationCancel (
   FSFileOperationRef fileOp
);
```

Parameters

`fileOp`
The file operation to cancel.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function makes the specified file operation ineligible to run on any run loop. You may call this function at any time during the operation. Typically, you would use this function if the user cancels the operation. Note that to release your file operation object, you still need to call `CFRelease`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFileOperationCopyStatus

Gets a copy of the current status information for an asynchronous file operation.

```
OSStatus FSFileOperationCopyStatus (
   FSFileOperationRef fileOp,
   FSRef *currentItem,
   FSFileOperationStage *stage,
   OSStatus *error,
   CFDictionaryRef *statusDictionary,
   void **info
);
```

Parameters

fileOp

The file operation to access.

currentItem

A pointer to an `FSRef` variable. On output, the variable contains the object currently being moved or copied. If the operation is complete, this parameter refers to the target (the new object corresponding to the source object in the destination directory).

stage

A pointer to a file operation stage variable. On output, the variable contains the current stage of the file operation.

error

A pointer to an error status variable. On output, the variable contains the current error status of the file operation.

statusDictionary

A pointer to a dictionary variable. On output, the variable contains a dictionary with more detailed status information. For information about the contents of the dictionary, see "`File Operation Status Dictionary Keys`" (page 919). You should release the dictionary when you are finished using it.

info

A pointer to a generic pointer. On output, the generic pointer refers to user-defined data associated with this file operation.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`Files.h`

FSFileOperationCreate

Creates an object that represents an asynchronous file operation.

```
FSFileOperationRef FSFileOperationCreate (
   CFAllocatorRef alloc
);
```

Parameters

alloc

The allocator to use. Pass `NULL` for the default allocator.

Return Value
A new FSFileOperation object, or `NULL` if the object could not be created. When you no longer need the object, you should release it by calling `CFRelease`.

Discussion
Before passing a file operation object to a function that starts an asynchronous copy or move operation, you should schedule the file operation using the function `FSFileOperationScheduleWithRunLoop` (page 489).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFileOperationGetTypeID

Returns the Core Foundation type identifier for the FSFileOperation opaque type.

```
CFTypeID FSFileOperationGetTypeID (
   void
);
```

Return Value
The type identifier for the FSFileOperation opaque type. For information about this type, see `FSFileOperationRef` (page 830).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFileOperationScheduleWithRunLoop

Schedules an asynchronous file operation with the specified run loop and mode.

```
OSStatus FSFileOperationScheduleWithRunLoop (
   FSFileOperationRef fileOp,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

fileOp
The file operation to schedule.

runLoop
The run loop in which to schedule the operation. For information about Core Foundation run loops, see *Run Loops*.

runLoopMode
The run loop mode in which to schedule the operation. In most cases, you may specify `kCFRunLoopCommonModes`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
To run, a file operation must be scheduled with at least one run loop. A file operation can be scheduled with multiple run loop and mode combinations.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFileOperationUnscheduleFromRunLoop

Unschedules an asynchronous file operation from the specified run loop and mode.

```
OSStatus FSFileOperationUnscheduleFromRunLoop (
   FSFileOperationRef fileOp,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode
);
```

Parameters

fileOp
The file operation to unschedule.

runLoop
The run loop on which to unschedule the operation.

runLoopMode
The run loop mode in which to unschedule the operation.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFlushFork

Causes all data written to an open fork to be written to disk.

```
OSErr FSFlushFork (
   FSIORefNum forkRefNum
);
```

Parameters

forkRefNum
The reference number of the fork to flush.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSFlushFork` function causes the actual fork contents to be written to disk, as well as any other volume structures needed to access the fork. On HFS and HFS Plus, this includes the catalog, extents, and attribute B-trees; the volume bitmap; and the volume header and alternate volume header (the MDB and alternate MDB on HFS volumes), as needed.

On volumes that do not support `FSFlushFork` directly, the entire volume is flushed to be sure all volume structures associated with the fork are written to disk.

You do not, need to use `FSFlushFork` to flush a file fork before it is closed; the file is automatically flushed when it is closed and all cache blocks associated with it are removed from the cache.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSFlushVolume

For the specified volume, writes all open and modified files in the current process to permanent storage.

```
OSStatus FSFlushVolume (
    FSVolumeRefNum vRefNum
);
```

Parameters

vRefNum
The volume reference number of the volume to flush.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSGetAsyncEjectStatus

Returns the current status of an asynchronous eject operation.

```
OSStatus FSGetAsyncEjectStatus (
   FSVolumeOperation volumeOp,
   FSEjectStatus *status,
   OSStatus *volumeOpStatus,
   FSVolumeRefNum *volumeRefNum,
   pid_t *dissenter,
   void **clientData
);
```

Parameters

volumeOp

The asynchronous volume operation to get status about.

status

On return, a pointer to the status of the operation.

volumeOpStatus

If the *status* parameter is `kAsyncEjectComplete` then this contains the result code (`OSStatus`) for the operation on return.

volumeRefNum

On return, the volume reference number of the volume being ejected.

dissenter

On return, a pointer to the pid of the process which denied the unmount if the eject is denied.

clientData

On return, a pointer to client data associated with the original `FSMountServerVolumeAsync` operation.

Return Value

A result code. See "File Manager Result Codes" (page 943). A return value of `noErr` signifies that the `status` parameter has been filled with valid information.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Files.h`

FSGetAsyncMountStatus

Returns the current status of an asynchronous mount operation.

```
OSStatus FSGetAsyncMountStatus (
   FSVolumeOperation volumeOp,
   FSMountStatus *status,
   OSStatus *volumeOpStatus,
   FSVolumeRefNum *mountedVolumeRefNum,
   void **clientData
);
```

Parameters

volumeOp

The asynchronous volume operation to get status about.

status

On return, a pointer to the status of the operation.

volumeOpStatus
If the status is kAsyncMountComplete then this parameter contains the result code for the operation on return.

mountedVolumeRefNum
If the status is kAsyncMountComplete and the *volumeOpStatus* parameter is noErr then this is the volume reference number for the newly mounted volume, on return.

clientData
On return, a pointer to client data associated with the original FSMountServerVolumeAsync operation.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
A return value of noErr signifies that the *status* parameter has been filled with valid information. If the status is kAsyncMountComplete then the rest of data returned is valid. If the status is anything else then the *volumeOpStatus* and *mountedVolumeRefNum* parameters are invalid, but the *clientData* parameter is valid.

Availability
Available in Mac OS X v10.2 and later.

Declared In
Files.h

FSGetAsyncUnmountStatus

Returns the current status of an asynchronous unmount operation.

```
OSStatus FSGetAsyncUnmountStatus (
   FSVolumeOperation volumeOp,
   FSUnmountStatus *status,
   OSStatus *volumeOpStatus,
   FSVolumeRefNum *volumeRefNum,
   pid_t *dissenter,
   void **clientData
);
```

Parameters

volumeOp
The asynchronous volume operation to get status about.

status
On return, a pointer to the status of the operation.

volumeOpStatus
If the status is kAsyncUnmountComplete then this parameter contains a pointer to the result code (OSStatus) for the operation on return.

volumeRefNum
On return, a pointer to the volume reference number of the volume being unmounted.

dissenter
On return, a pointer to the pid of the process which denied the unmount if the unmount is denied.

clientData
On return, a pointer to client data associated with the original `FSMountServerVolumeAsync` operation.

Return Value
A result code. See "File Manager Result Codes" (page 943). A return value of `noErr` signifies that the *status* parameter has been filled with valid information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSGetCatalogInfo

Returns catalog information about a file or directory. You can use this function to map an `FSRef` to an `FSSpec`.

```
OSErr FSGetCatalogInfo (
   const FSRef *ref,
   FSCatalogInfoBitmap whichInfo,
   FSCatalogInfo *catalogInfo,
   HFSUniStr255 *outName,
   FSSpecPtr fsSpec,
   FSRef *parentRef
);
```

Parameters

ref
A pointer to an `FSRef` specifying the file or directory for which to retrieve information. See `FSRef` (page 837) for a description of the `FSRef` data type.

whichInfo
A bitmap specifying the catalog information fields to return. If you don't want any catalog information, set `whichInfo` to the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this parameter.

catalogInfo
On return, a pointer to a catalog information structure containing the information about the file or directory. Only the information specified in the `whichInfo` parameter is returned. If you don't want any catalog information, pass `NULL` here. See `FSCatalogInfo` (page 826) for a description of the `FSCatalogInfo` data type.

outName
On return, a pointer to the Unicode name of the file or directory is returned here. This parameter is optional; if you do not wish the name returned, pass `NULL` here. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

fsSpec
On return, a pointer to the `FSSpec` for the file or directory. This parameter is optional; if you do not wish the `FSSpec` returned, pass `NULL` here. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

parentRef

On return, a pointer to the `FSRef` for the object's parent directory. This parameter is optional; if you do not wish the parent directory returned, pass `NULL` here.

If the object specified in the `ref` parameter is a volume's root directory, then the `FSRef` returned here will not be a valid `FSRef`, since the root directory has no parent object.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
QTCarbonShell

Declared In
`Files.h`

FSGetCatalogInfoBulk

Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

```
OSErr FSGetCatalogInfoBulk (
   FSIterator iterator,
   ItemCount maximumObjects,
   ItemCount *actualObjects,
   Boolean *containerChanged,
   FSCatalogInfoBitmap whichInfo,
   FSCatalogInfo *catalogInfos,
   FSRef *refs,
   FSSpecPtr specs,
   HFSUniStr255 *names
);
```

Parameters

iterator

The iterator to use. You can obtain a catalog iterator with the function `FSOpenIterator` (page 515), or with one of the related parameter block calls, `PBOpenIteratorSync` (page 742) and `PBOpenIteratorAsync` (page 741). Currently, the iterator must be created with the `kFSIterateFlat` option. See `FSIterator` (page 835) for a description of the `FSIterator` data type.

maximumObjects

The maximum number of items to return for this call.

actualObjects

On return, a pointer to the actual number of items found for this call.

containerChanged

On return, a pointer to a value indicating whether or not the container's contents have changed since the previous `FSGetCatalogInfoBulk` call. If `true`, the contents have changed. Objects may still be returned, even though the container has changed. If so, note that if the container has changed, then the total set of items returned may be incorrect: some items may be returned multiple times, and some items may not be returned at all.

This parameter is optional if you don't want this information returned, pass a `NULL` pointer.

In Mac OS X version 10.2 and later, this parameter is always set to `false`. To find out whether the container has changed since the last call to `FSGetCatalogInfoBulk`, check the modification date of the container.

whichInfo

A bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant `kFSCatInfoNone` in this parameter. For a description of the bits in this parameter, see "Catalog Information Bitmap Constants" (page 891).

catalogInfos

A pointer to an array of catalog information structures; one for each returned item. On input, the `catalogInfos` parameter should point to an array of `maximumObjects` catalog information structures.

This parameter is optional; if you do not wish any catalog information returned, pass `NULL` here.

refs

A pointer to an array of `FSRef` structures; one for each returned item. On input, this parameter should to point to an array of `maximumObjectsFSRef` structures.

This parameter is optional; if you do not wish any `FSRef` structures returned, pass `NULL` here.

specs

A pointer to an array of `FSSpec` structures; one for each returned item. On input, this parameter should to point to an array of `maximumObjectsFSSpec` structures.

This parameter is optional; if you do not wish any `FSSpec` structures returned, pass `NULL` here.

names

A pointer to an array of names; one for each returned item. If you want the Unicode name for each item found, set this parameter to point to an array of `maximumObjectsHFSUniStr255` structures. Otherwise, set it to `NULL`.

Return Value
A result code. See "File Manager Result Codes" (page 943). When all of the iterator's objects have been returned, the call will return `errFSNoMoreItems`.

Discussion
The `FSGetCatalogInfoBulk` call may complete and return `noErr` with fewer than `maximumObjects` items returned. This may be due to various reasons related to the internal implementation. In this case, you may continue to make `FSGetCatalogInfoBulk` calls using the same iterator.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`Files.h`

FSGetDataForkName

Returns a Unicode string constant for the name of the data fork.

```
OSErr FSGetDataForkName (
   HFSUniStr255 *dataForkName
);
```

Parameters

dataForkName

On input, a pointer to an `HFSUniStr255` structure. On return, this structure contains the Unicode name of the data fork. Currently, this is the empty string. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

There is no parameter block-based form of this call since it is not dispatched to individual volume formats, and does not require any I/O.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSGetForkCBInfo

Returns information about a specified open fork, or about all open forks.

```
OSErr FSGetForkCBInfo (
   FSIORefNum desiredRefNum,
   FSVolumeRefNum volume,
   short *iterator,
   FSIORefNum *actualRefNum,
   FSForkInfo *forkInfo,
   FSRef *ref,
   HFSUniStr255 *outForkName
);
```

Parameters

desiredRefNum

If you want information on a specific fork, set this parameter to that fork's reference number, and pass `NULL` in the `iterator` parameter. If you pass a non-zero value in this parameter, the function attempts to get information on the fork specified by that reference number.

Pass zero in this parameter to iterate over all open forks. You can limit this iteration to a specific volume with the `volume` parameter.

volume

The volume to search, when iterating over multiple forks. To iterate over all open forks on a single volume, specify the volume reference number in this parameter. To iterate over all open forks on all volumes, set this parameter to the constant `kFSInvalidVolumeRefNum`.

This parameter is ignored if you specify a fork reference number in the `desiredRefNum` parameter. Set `desiredRefNum` to zero if you wish to iterate over multiple forks.

See `FSVolumeRefNum` (page 847) for a description of the `FSVolumeRefNum` data type.

iterator

A pointer to an iterator. If the `desiredRefNum` parameter is 0, the iterator maintains state between calls to `FSGetForkCBInfo`. Set the `iterator` parameter to 0 before you begin iterating, on the first call to `FSGetForkCBInfo`. On return, the iterator will be updated; pass this updated iterator in the `iterator` parameter of the next call to `FSIterateForks` to continue iterating.

actualRefNum

On return, a pointer to the reference number of the open fork. This parameter is optional if you do not wish to retrieve the fork's reference number, pass `NULL`.

forkInfo

On return, a pointer to an `FSForkInfo` structure containing information about the open fork. This parameter is optional; if you do not wish this information returned, set `forkInfo` to `NULL`. See `FSForkInfo` (page 832) for a description of the `FSForkInfo` data type.

On OS X, the value returned by `FSGetForkCBInfo` in the `physicalEOF` field of the `FSForkInfo` structure may differ from the physical file length reported by `FSGetCatalogInfo`, `PBGetCatInfo`, and related functions. When a write causes a file to grow in size, the physical length reported by `FSGetCatalogInfo` and similar calls increases by the clump size, which is a multiple of the allocation block size. However, the physical length returned by `FSGetForkCBInfo` changes according to the allocation block size and the file lengths returned by the respective functions get out of sync.

ref

On return, a pointer to the `FSRef` for the file or directory that contains the fork. This parameter is optional; if you do not wish to retrieve the `FSRef`, set `ref` to `NULL`. See `FSRef` (page 837) for a description of the `FSRef` data type.

outForkName

On return, a pointer to the name of the fork. This parameter is optional; if you do not wish the name returned, set `outForkName` to `NULL`. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you are iterating over multiple forks, the function returns `errFSNoMoreItems` if there are no more open forks to return.

Discussion

Carbon applications are no longer guaranteed access to the FCB table. Instead, applications should use `FSGetForkCBInfo`, or one of the related parameter block functions, `PBGetForkCBInfoSync` (page 661) and `PBGetForkCBInfoAsync` (page 660) , to access information about a fork control block.

Special Considerations

Returning the fork information in the `forkInfo` parameter generally does not require a disk access; returning the information in the `ref` or `forkName` parameters may cause disk access for some volume formats.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSGetForkPosition

Returns the current position of an open fork.

```
OSErr FSGetForkPosition (
   FSIORefNum forkRefNum,
   SInt64 *position
);
```

Parameters

forkRefNum

The reference number of a fork previously opened by the `FSOpenFork` (page 514) function or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

position

On return, a pointer to the current position of the fork. The returned fork position is relative to the start of the fork (that is, it is an absolute offset in bytes).

Return Value
A result code. See "File Manager Result Codes" (page 943).

Special Considerations

Before calling the `FSGetForkPosition` function, call the `Gestalt` function with the `gestaltFSAttr` selector to determine if `FSGetForkPosition` is available. If the function is available, but is not directly supported by a volume, the File Manager will automatically call `PBGetFPosSync` (page 666); however, you will not be able to determine the fork position of a named fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSGetForkSize

Returns the size of an open fork.

```
OSErr FSGetForkSize (
   FSIORefNum forkRefNum,
   SInt64 *forkSize
);
```

Parameters

forkRefNum

The reference number of the open fork. You can obtain this fork reference number with the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

forkSize

On return, a pointer to the logical size (the logical end-of-file) of the fork, in bytes. The size returned is the total number of bytes that can be read from the fork; the amount of space actually allocated on the volume (the physical size) will probably be larger.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Special Considerations

To determine whether the `FSGetForkSize` function is present, call the `Gestalt` function. If `FSGetForkSize` is present, but is not directly supported by a volume, the File Manager will call `PBGetEOFSync` (page 655); however, you will not be able to determine the size of a fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSGetResourceForkName

Returns a Unicode string constant for the name of the resource fork.

```
OSErr FSGetResourceForkName (
   HFSUniStr255 *resourceForkName
);
```

Parameters

resourceForkName

On input, a pointer to an `HFSUniStr255` structure. On return, this structure contains the Unicode name of the resource fork. Currently, this is "RESOURCE_FORK". See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
There is no parameter block-based form of this call since it is not dispatched to individual volume formats, and does not require any I/O.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSGetVolumeInfo

Returns information about a volume.

```
OSErr FSGetVolumeInfo (
   FSVolumeRefNum volume,
   ItemCount volumeIndex,
   FSVolumeRefNum *actualVolume,
   FSVolumeInfoBitmap whichInfo,
   FSVolumeInfo *info,
   HFSUniStr255 *volumeName,
   FSRef *rootDirectory
);
```

Parameters

volume

If you wish to obtain information on a particular volume, pass that volume's reference number here. If you wish to index through the list of mounted volumes, pass the constant `kFSInvalidVolumeRefNum` in this parameter. See `FSVolumeRefNum` (page 847) for a description of the `FSVolumeRefNum` data type.

volumeIndex

The index of the desired volume, or 0 to use the volume reference number in the `volume` parameter.

actualVolume

On return, a pointer to the volume reference number of the volume. This is useful when indexing over all mounted volumes. If you don't want this information (if, for instance, you supplied a particular volume reference number in the `volume`) parameter, set `actualVolume` to `NULL`.

whichInfo

A bitmap specifying which volume information fields to get and return in the `info` parameter. If you don't want information about the volume returned in the `info` parameter, set `whichInfo` to `kFSVolInfoNone`. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this parameter.

info

On return, a pointer to the volume information. If you don't want this output, set this parameter to `NULL`. See `FSVolumeInfo` (page 842) for a description of the `FSVolumeInfo` data type.

volumeName

On return, a pointer to the Unicode name of the volume. If you do not wish the name returned, pass `NULL`. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

rootDirectory

On return, a pointer to the `FSRef` for the volume's root directory. If you do not wish the root directory returned, pass `NULL`. See `FSRef` (page 837) for a description of the `FSRef` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

You can specify a particular volume or index through the list of mounted volumes. To get information on a particular volume, pass the volume reference number of the desired volume in the `volume` parameter and set the `volumeIndex` parameter to zero. To index through the list of mounted volumes, pass `kFSInvalidVolumeRefNum` in the volume parameter and set `volumeIndex` to the index, starting at 1 with the first call to `FSGetVolumeInfo`.

When indexing through the list of mounted volumes, you may encounter an error with a particular volume. The terminating error code for full traversal of this list is `nsvErr`. In order to completely traverse the entire list, you may have to bump the index count when encountering other errors (for example, `ioErr`).

To get information about the root directory of a volume, use the `FSGetCatalogInfo` (page 494) function, or one of the corresponding parameter block calls, `PBGetCatalogInfoSync` (page 647) and `PBGetCatalogInfoAsync` (page 643).

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `FSGetVolumeInfo` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSGetVolumeMountInfo

Retrieves the mounting information associated with the specified volume.

```
OSStatus FSGetVolumeMountInfo (
   FSVolumeRefNum volume,
   BytePtr buffer,
   ByteCount bufferSize,
   ByteCount *actualSize
);
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSGetVolumeMountInfoSize

Determines the size of the mounting information associated with the specified volume.

```
OSStatus FSGetVolumeMountInfoSize (
   FSVolumeRefNum volume,
   ByteCount *size
);
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSGetVolumeParms

Retrieves information about the characteristics of a volume.

```
OSStatus FSGetVolumeParms (
   FSVolumeRefNum volume,
   GetVolParmsInfoBuffer *buffer,
   ByteCount bufferSize
);
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSIterateForks

Determines the name and size of every named fork belonging to a file or directory.

```
OSErr FSIterateForks (
   const FSRef *ref,
   CatPositionRec *forkIterator,
   HFSUniStr255 *forkName,
   SInt64 *forkSize,
   UInt64 *forkPhysicalSize
);
```

Parameters

ref

A pointer to an `FSRef` specifying the file or directory to iterate. See `FSRef` (page 837) for a description of the `FSRef` data type.

forkIterator

A pointer to a structure which maintains state between calls to `FSIterateForks`. Before the first call, set the `initialize` field of the structure to 0. The fork iterator will be updated after the call completes; the updated iterator should be passed into the next call. See `CatPositionRec` (page 801) for a description of the `CatPositionRec` data type.

forkName

On return, a pointer to the Unicode name of the fork. This parameter is optional; if you do not wish the name returned, pass a `NULL` pointer. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

forkSize

On return, a pointer to the logical size of the fork, in bytes. This parameter is optional; if you do not wish to retrieve the logical fork size, pass a `NULL` pointer.

forkPhysicalSize

On return, a pointer to the physical size of the fork (that is, to the amount of space allocated on disk), in bytes. This parameter is optional; if you do not wish to retrieve the physical fork size, pass a `NULL` pointer.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Since information is returned about one fork at a time, several calls may be required to iterate through all the forks. There is no guarantee about the order in which forks are returned; the order may vary between iterations.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSLockRange

Locks a range of bytes of the specified fork.

```
OSStatus FSLockRange (
    FSIORefNum forkRefNum,
    UInt16 positionMode,
    SInt64 positionOffset,
    UInt64 requestCount,
    UInt64 *rangeStart
);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSMakeFSRefUnicode

Constructs an `FSRef` for a file or directory, given a parent directory and a Unicode name.

```
OSErr FSMakeFSRefUnicode (
   const FSRef *parentRef,
   UniCharCount nameLength,
   const UniChar *name,
   TextEncoding textEncodingHint,
   FSRef *newRef
);
```

Parameters

parentRef

A pointer to the `FSRef` of the parent directory of the file or directory for which to create a new `FSRef`. See `FSRef` (page 837) for a description of the `FSRef` data type.

nameLength

The length of the file or directory name.

name

A pointer to the Unicode name for the file or directory. The name must be a leaf name; partial or full pathnames are not allowed. If you have a partial or full pathname in Unicode, you will have to parse it yourself and make multiple calls to `FSMakeFSRefUnicode`.

textEncodingHint

The suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant `kTextEncodingUnknown`, the File Manager will use a default value.

newRef

On return, if the function returns a result of `noErr`, a pointer to the new `FSRef`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
CarbonSketch
QTCarbonShell

Declared In
`Files.h`

FSMakeFSSpec

Creates an `FSSpec` structure describing a file or directory. (Deprecated in Mac OS X v10.4. Use `FSMakeFSRefUnicode` (page 504) instead.)

```
OSErr FSMakeFSSpec (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   FSSpec *spec
);
```

Parameters

vRefNum

A volume specification for the volume containing the file or directory. This parameter can contain a volume reference number, a drive number, or 0 to specify the default volume.

dirID

The parent directory ID of the target object. If the directory is sufficiently specified in the `fileName` parameter, the `dirID` parameter can be set to 0. If the `fileName` parameter contains an empty string, `FSMakeFSSpec` creates an `FSSpec` structure for the directory specified by the `dirID` parameter.

fileName

A full or partial pathname. If the `fileName` parameter specifies a full pathname, `FSMakeFSSpec` ignores both the `vRefNum` and `dirID` parameters. A partial pathname might identify only the final target, or it might include one or more parent directory names. If `fileName` specifies a partial pathname, then `vRefNum`, `dirID`, or both must be valid.

spec

A pointer to a file system specification to be filled in by `FSMakeFSSpec`. The `FSMakeFSSpec` function fills in the fields of the file system specification using the information contained in the other three parameters. If your application receives any result code other than `noErr` or `fnfErr`, all fields of the resulting `FSSpec` structure are set to 0.

The file system specification structure that you pass in this parameter should not share storage space with the input pathname; the `name` field may be initialized to the empty string before the pathname has been processed. For example, `fileName` should not refer to the `name` field of the output file system specification.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
You should call `FSMakeFSSpec`, or one of the corresponding parameter block functions, `PBMakeFSSpecSync` (page 736) and `PBMakeFSSpecAsync` (page 734) , whenever you want to create an `FSSpec` structure. You should not create an `FSSpec` by filling in the fields of the structure yourself.

If the specified volume is mounted and the specified parent directory exists, but the target file or directory doesn't exist in that location, `FSMakeFSSpec` fills in the structure and then returns `fnfErr` instead of `noErr`. The structure is valid, but it describes a target that doesn't exist. You can use the structure for other operations, such as creating a file with the `FSpCreate` (page 525) function.

Carbon Porting Notes

Non-Carbon applications can also specify a working directory reference number in the `vRefNum` parameter. However, because working directories are not supported in Carbon, you cannot specify a working directory reference number if you wish your application to be Carbon-compatible.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code
QTMetaData

Simple DrawSprocket

Declared In
`Files.h`

FSMountLocalVolumeAsync

Mounts a volume asynchronously.

```
OSStatus FSMountLocalVolumeAsync (
   CFStringRef diskID,
   CFURLRef mountDir,
   FSVolumeOperation volumeOp,
   void *clientData,
   OptionBits flags,
   FSVolumeMountUPP callback,
   CFRunLoopRef runloop,
   CFStringRef runloopMode
);
```

Parameters

diskID

The disk to mount.

mountDir

Pass in `NULL` ; currently only `NULL` is supported.

volumeOp

An `FSVolumeOperation` returned by `FSCreateVolumeOperation`

clientData

A pointer to client data associated with the operation. This parameter can be `NULL`.

flags

Options for future use.

callback

The function to call when mount is complete. This parameter can be `NULL`.

runloop

The runloop to run on.

runloopMode

The mode for the runloop.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

This function starts the process to mount the disk specified by the *diskID* parameter at the location specified by the *mountDir* parameter. If *mountDir* is `NULL`, the default location is used. If a callback function is provided, that function will be called when the mount operation is complete. Once this function returns `noErr` the status of the operation can be found using the `FSGetAsyncMountStatus` function.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Files.h`

FSMountLocalVolumeSync

Mounts a volume.

```
OSStatus FSMountLocalVolumeSync (
   CFStringRef diskID,
   CFURLRef mountDir,
   FSVolumeRefNum *mountedVolumeRefNum,
   OptionBits flags
);
```

Parameters

diskID

The disk to mount.

mountDir

Pass in `NULL`; currently only `NULL` is supported.

mountedVolumeRefNum

On return, a pointer to the volume reference number of the newly mounted volume.

flags

Options for future use.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

This function mounts the disk specified by the *diskID* parameter at the location specified by the *mountDir* parameter. If *mountDir* is `NULL`, the default location is used. This function returns after the mount is complete.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Files.h`

FSMountServerVolumeAsync

Mounts a server volume asynchronously.

```
OSStatus FSMountServerVolumeAsync (
   CFURLRef url,
   CFURLRef mountDir,
   CFStringRef user,
   CFStringRef password,
   FSVolumeOperation volumeOp,
   void *clientData,
   OptionBits flags,
   FSVolumeMountUPP callback,
   CFRunLoopRef runloop,
   CFStringRef runloopMode
);
```

Parameters

url

The server to mount.

mountDir

The directory to mount the server to. If this parameter is `NULL`, the default location is used.

user
A string to pass as the user for authentication. This parameter can be NULL.

password
A string to pass as the password for authenticated log in. This parameter can be NULL.

volumeOp
An FSVolumeOperation returned by the FSCreateVolumeOperation function.

clientData
A pointer to client data associated with the operation. This parameter can be NULL.

flags
Options for future use.

callback
A function to call when the mount is complete. This parameter can be NULL.

runloop
The runloop to run on.

runloopMode
The mode for the runloop.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function will start the process to mount the server specified by the *url* parameter at the location specified by the *mountDir* parameter. If *mountDir* is NULL, the default location is used. An optional user and password can be passed in for authentication. If no user or password is provided then the underlying file system will handle authentication if required. If a callback function is provided, that function will be called when the mount operation is complete. Once this function returns noErr the status of the operation can be found using the FSGetAsyncMountStatus function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
Files.h

FSMountServerVolumeSync

Mounts a server volume.

```
OSStatus FSMountServerVolumeSync (
   CFURLRef url,
   CFURLRef mountDir,
   CFStringRef user,
   CFStringRef password,
   FSVolumeRefNum *mountedVolumeRefNum,
   OptionBits flags
);
```

Parameters

url
The server to mount.

mountDir
The directory to mount the server to. If this parameter is NULL, the default location is used.

user
A string to pass as the user for authentication.

password
A string to pass as the password for authenticated log in.

mountedVolumeRefNum
On return, a pointer to the volume reference number of the newly mounted volume.

flags
Options for future use.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function will mount the server specified by the *url* parameter at the location specified by the *mountDir* parameter. If *mountDir* is NULL, the default location is used. An optional user and password can be passed in for authentication. If no user or password is provided then the underlying file system will handle authentication if required. This function returns after the mount is complete.

Availability
Available in Mac OS X v10.2 and later.

Declared In
Files.h

FSMoveObject

Moves a file or directory into a different directory.

```
OSErr FSMoveObject (
   const FSRef *ref,
   const FSRef *destDirectory,
   FSRef *newRef
);
```

Parameters

ref
A pointer to an FSRef specifying the file or directory to move. See FSRef (page 837) for a description of the FSRef data type.

destDirectory
A pointer to an FSRef specifying the directory into which the file or directory indicated by the ref parameter will be moved.

newRef
On return, a pointer to the new FSRef for the file or directory in its new location. This parameter is optional; if you do not wish the FSRef returned, pass NULL.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the destDirectory parameter specifies a non-existent object, dirNFErr is returned; if it refers to a file, errFSNotAFolder is returned. If the directory specified in the destDirectory parameter is on a different volume than the file or directory indicated in the ref parameter, diffVolErr is returned.

Discussion
Moving an object may change its `FSRef`. If you want to continue to refer to the object, you should pass a non- `NULL` pointer in the `newRef` parameter and use the `FSRef` returned there to refer to the object after the move. The original `FSRef` passed in the `ref` parameter may or may not be usable after the move. The `newRef` parameter may point to the same storage as the `destDirectory` or `ref` parameters.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSMoveObjectAsync

Starts an asynchronous file operation to move a source object to a destination directory.

```
OSStatus FSMoveObjectAsync (
   FSFileOperationRef fileOp,
   const FSRef *source,
   const FSRef *destDir,
   CFStringRef destName,
   OptionBits flags,
   FSFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

`fileOp`
The file operation object you created for this move operation.

`source`
A pointer to the source object to move. The object can be a file or a directory.

`destDir`
A pointer to the destination directory. If the destination directory is not on the same volume as the source object, the source object is copied and then deleted.

`destName`
The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

`flags`
One or more file operation option flags. See "File Operation Options" (page 917). If you specify the `kFSFileOperationDoNotMoveAcrossVolumes` flag and the destination directory is not on the same volume as the source object, this function does nothing and returns an error.

`callback`
A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

`statusChangeInterval`
The minimum time in seconds between callbacks within a single stage of an operation.

clientContext

User-defined data to associate with this operation. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you specify a status callback function, status callbacks will occur in one of the run loop and mode combinations with which you scheduled the file operation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSMoveObjectSync

Moves a source object to a destination directory.

```
OSStatus FSMoveObjectSync (
   const FSRef *source,
   const FSRef *destDir,
   CFStringRef destName,
   FSRef *target,
   OptionBits options
);
```

Parameters

source

A pointer to the source object to move. The object can be a file or a directory. On output, the source object is no longer valid; if you want to refer to the moved object, you should use the `FSRef` variable passed back in the `target` parameter.

destDir

A pointer to the destination directory. If the destination directory is not on the same volume as the source object, the source object is copied and then deleted.

destName

The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

target

A pointer to an `FSRef` variable that, on output, refers to the new object in the destination directory. This parameter is optional; pass `NULL` if you don't need to refer to the new object.

options

One or more file operation option flags. See "File Operation Options" (page 917). If you specify the `kFSFileOperationDoNotMoveAcrossVolumes` flag and the destination directory is not on the same volume as the source object, this function does nothing and returns an error.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If the destination directory is on the same volume as the source object, this is a fast operation. If the move is across volumes, this function could take a significant amount of time to execute; you should either call it in a thread other than the main thread or use `FSMoveObjectAsync` (page 511) instead.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSMoveObjectToTrashAsync

Starts an asynchronous file operation to move a source object to the Trash.

```
OSStatus FSMoveObjectToTrashAsync (
   FSFileOperationRef fileOp,
   const FSRef *source,
   OptionBits flags,
   FSFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

fileOp
The file operation object you created for this move operation. For more information, see the function `FSFileOperationCreate` (page 488).

source
A pointer to the source object to move. The object can be a file or a directory.

flags
One or more file operation option flags. See "File Operation Options" (page 917).

callback
A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

statusChangeInterval
The minimum time in seconds between callbacks within a single stage of an operation.

clientContext
User-defined data to associate with this operation. This data is passed to the function you specify in the *callback* parameter. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function starts an asynchronous file operation to move the object specified by the *source* parameter to the Trash. If the source volume does not support a trash folder, the operation will fail and return an error to the status callback specified in the *callback* parameter. (This is the same circumstance that triggers the delete immediately behavior in the Finder.)

Status callbacks occur on one of the runloop and mode combinations on which the operation was scheduled. Upon successful completion of the operation, the last *currentItem* parameter (passed to the last status callback or retrieved by calling `FSFileOperationCopyStatus` (page 487)) is the object in the Trash.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSMoveObjectToTrashSync

Moves a source object to the Trash.

```
OSStatus FSMoveObjectToTrashSync (
   const FSRef *source,
   FSRef *target,
   OptionBits options
);
```

Parameters

source
: A pointer to the source object to move. The object can be a file or a directory. On output, the source object is no longer valid; if you want to refer to the moved object, you should use the value passed back in the *target* parameter.

target
: A pointer to the target object that, on output, resides in a trash folder. This parameter is optional; pass `NULL` if you don't need to refer to this object.

options
: One or more file operation option flags. See "File Operation Options" (page 917).

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function moves a file or directory to the Trash, adjusting the object's name if necessary. The appropriate trash folder is chosen based on the source volume and the current user. If the source volume does not support a trash folder, this function does nothing and returns an error. (This is the same circumstance that triggers the delete immediately behavior in the Finder.)

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSOpenFork

Opens any fork of a file or directory for streaming access.

```
OSErr FSOpenFork (
   const FSRef *ref,
   UniCharCount forkNameLength,
   const UniChar *forkName,
   SInt8 permissions,
   FSIORefNum *forkRefNum
);
```

Parameters

ref

A pointer to an `FSRef` specifying the file or directory owning the fork to open. See `FSRef` (page 837) for a description of the `FSRef` data type.

forkNameLength

The length of the fork name in Unicode characters.

forkName

A pointer to the Unicode name of the fork to open. You can obtain the string constants for the data fork and resource fork names using the `FSGetDataForkName` (page 497) and `FSGetResourceForkName` (page 500) functions. All volume formats should support data and resource forks; other named forks may be supported by some volume formats.

permissions

A constant indicating the type of access which you wish to have to the fork via the returned fork reference. This parameter is the same as the `permission` parameter passed to the `FSpOpenDF` and `FSpOpenRF` functions. For a description of the types of access which you can request, see "File Access Permission Constants" (page 908).

forkRefNum

On return, a pointer to the fork reference number for accessing the open fork.

Return Value

A result code. See "File Manager Result Codes" (page 943). On some file systems, `FSOpenFork` will return the error `eofErr` if you try to open the resource fork of a file for which no resource fork exists with read-only access.

Discussion

When you use this function to open a file on a local volume and pass in a permissions value of `fsCurPerm`, `fsWrPerm`, or `fsRdWrPerm`, Mac OS X does not guarantee exclusive file access. Before making any assumptions about the underlying file access, you should always check to see whether the Supports Exclusive Locks feature is available. If this feature is not available, your application cannot know whether another application has access to the same file. For more information, see ADC Technical Note TN2037.

To access named forks or forks larger than 2GB, you must use the `FSOpenFork` function or one of the corresponding parameter block calls: `PBOpenForkSync` and `PBOpenForkAsync`. To determine if the `FSOpenFork` function is present, call the `Gestalt` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSOpenIterator

Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

```
OSErr FSOpenIterator (
   const FSRef *container,
   FSIteratorFlags iteratorFlags,
   FSIterator *iterator
);
```

Parameters

container

A pointer to an FSRef for the directory to iterate. The set of items to iterate over can either be the objects directly contained in the directory, or all items directly or indirectly contained in the directory (in which case, the specified directory is the root of the subtree to iterate). See FSRef (page 837) for a description of the FSRef data type.

iteratorFlags

A set of flags which controls whether the iterator iterates over subtrees or just the immediate children of the container. See "Iterator Flags" (page 924) for a description of the flags defined for this parameter.

Iteration over subtrees which do not originate at the root directory of a volume are not currently supported, and passing the kFSIterateSubtree flag in this parameter returns errFSBadIteratorFlags. To determine whether subtree iterators are supported, check that the bSupportsSubtreeIterators bit returned by PBHGetVolParmsSync (page 695) or PBHGetVolParmsAsync (page 694) is set.

iterator

On return, a pointer to the new FSIterator. You can pass this iterator to the FSGetCatalogInfoBulk (page 495) or FSCatalogSearch (page 472) functions and their parameter block-based counterparts.

The iterator is automatically initialized so that the next use of the iterator returns the first item. The order that items are returned in is volume format dependent and may be different for two different iterators created with the same container and flags.

See FSIterator (page 835) for a description of the FSIterator data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Catalog iterators must be closed when you are done using them, whether or not you have iterated over all the items. Iterators are automatically closed upon process termination, just like open files. However, you should use the FSCloseIterator (page 475) function, or one of the related parameter block functions, PBCloseIteratorSync (page 584) and PBCloseIteratorAsync (page 584) , to close an iterator to free up any system resources allocated to the iterator.

Before calling this function, you should check that it is present, by calling the Gestalt function.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code

Files.h

FSPathCopyObjectAsync

Starts an asynchronous file operation to copy a source object to a destination directory using pathnames.

```
OSStatus FSPathCopyObjectAsync (
   FSFileOperationRef fileOp,
   const char *sourcePath,
   const char *destDirPath,
   CFStringRef destName,
   OptionBits flags,
   FSPathFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

fileOp
: The file operation object you created for this copy operation.

sourcePath
: The UTF-8 pathname of the source object to copy. The object can be a file or a directory.

destDirPath
: The UTF-8 pathname of the destination directory.

destName
: The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

flags
: One or more file operation option flags. See "File Operation Options" (page 917).

callback
: A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

statusChangeInterval
: The minimum time in seconds between callbacks within a single stage of an operation.

clientContext
: User-defined data to associate with this operation. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

If you specify a status callback function, status callbacks will occur in one of the run loop and mode combinations with which you scheduled the file operation.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`Files.h`

FSPathCopyObjectSync

Copies a source object to a destination directory using pathnames.

```
OSStatus FSPathCopyObjectSync (
   const char *sourcePath,
   const char *destDirPath,
   CFStringRef destName,
   char **targetPath,
   OptionBits options
);
```

Parameters

sourcePath

The UTF-8 pathname of the source object to copy. The object can be a file or a directory.

destDirPath

The UTF-8 pathname of the destination directory.

destName

The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

targetPath

A pointer to a char* variable that, on output, refers to the UTF-8 pathname of the new object in the destination directory. If the operation fails, the pathname is set to `NULL`. When you no longer need the pathname, you should free it. This parameter is optional; pass `NULL` if you don't need the pathname.

options

One or more file operation option flags. See "File Operation Options" (page 917).

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

This function could take a significant amount of time to execute. To avoid blocking your user interface, you should either call this function in a thread other than the main thread or use `FSPathCopyObjectAsync` (page 517) instead.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`Files.h`

FSPathFileOperationCopyStatus

Gets a copy of the current status information for an asynchronous file operation that uses pathnames.

```
OSStatus FSPathFileOperationCopyStatus (
   FSFileOperationRef fileOp,
   char **currentItem,
   FSFileOperationStage *stage,
   OSStatus *error,
   CFDictionaryRef *statusDictionary,
   void **info
);
```

Parameters

fileOp

The file operation to access.

currentItem

A pointer to a char* variable. On output, the variable refers to the UTF-8 pathname of the object currently being moved or copied. If the operation is complete, this parameter refers to the target (the new object corresponding to the source object in the destination directory). You should free the pathname when you are finished using it.

stage

A pointer to a file operation stage variable. On output, the variable contains the current stage of the file operation.

error

A pointer to an error status variable. On output, the variable contains the current error status of the file operation.

statusDictionary

A pointer to a dictionary variable. On output, the variable contains a dictionary with more detailed status information. For information about the contents of the dictionary, see "File Operation Status Dictionary Keys" (page 919). You should release the dictionary when you are finished using it.

info

A pointer to a generic pointer. On output, the generic pointer refers to user-defined data associated with this file operation.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.4 and later.

Declared In

Files.h

FSPathMakeRef

Converts a POSIX-style pathname into an `FSRef` structure.

```
OSStatus FSPathMakeRef (
    const UInt8 *path,
    FSRef *ref,
    Boolean *isDirectory
);
```

Parameters

path

A UTF-8 C string that contains the pathname to convert.

ref

A pointer to an `FSRef` structure allocated by the caller. On output, the `FSRef` structure refers to the object whose location is specified by the *path* parameter.

isDirectory

A pointer to a Boolean variable allocated by the caller. On output, `true` indicates the object is a directory. This parameter is optional and may be `NULL`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CocoaDVDPlayer

Declared In
`Files.h`

FSPathMakeRefWithOptions

Converts a POSIX-style pathname into an `FSRef` structure with options.

```
OSStatus FSPathMakeRefWithOptions (
   const UInt8 *path,
   OptionBits options,
   FSRef *ref,
   Boolean *isDirectory
);
```

Parameters

path

A UTF-8 C string that contains the pathname to convert.

options

One or more conversion flags. See "Path Conversion Options" (page 928).

ref

A pointer to an `FSRef` structure allocated by the caller. On output, the `FSRef` structure refers to the object whose location is specified by the *path* parameter. If the object is a symbolic link, the *options* parameter determines whether the `FSRef` structure refers to the link itself or to the linked object.

isDirectory

A pointer to a Boolean variable allocated by the caller. On output, `true` indicates the object is a directory. This parameter is optional and may be `NULL`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSPathMoveObjectAsync

Starts an asynchronous file operation to move a source object to a destination directory using pathnames.

```
OSStatus FSPathMoveObjectAsync (
   FSFileOperationRef fileOp,
   const char *sourcePath,
   const char *destDirPath,
   CFStringRef destName,
   OptionBits flags,
   FSPathFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

fileOp
The file operation object you created for this move operation.

sourcePath
The UTF-8 pathname of the source object to move. The object can be a file or a directory.

destDirPath
The UTF-8 pathname of the destination directory. If the destination directory is not on the same volume as the source object, the source object is copied and then deleted.

destName
The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

flags
One or more file operation option flags. See "File Operation Options" (page 917). If you specify the `kFSFileOperationDoNotMoveAcrossVolumes` flag and the destination directory is not on the same volume as the source object, this function does nothing and returns an error.

callback
A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

statusChangeInterval
The minimum time in seconds between callbacks within a single stage of an operation.

clientContext
User-defined data to associate with this operation. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you specify a status callback function, status callbacks will occur in one of the run loop and mode combinations with which you scheduled the file operation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSPathMoveObjectSync

Moves a source object to a destination directory using pathnames.

```
OSStatus FSPathMoveObjectSync (
   const char *sourcePath,
   const char *destDirPath,
   CFStringRef destName,
   char **targetPath,
   OptionBits options
);
```

Parameters

sourcePath
The UTF-8 pathname of the source object to move. The object can be a file or a directory.

destDirPath
The UTF-8 pathname of the destination directory. If the destination directory is not on the same volume as the source object, the source object is copied and then deleted.

destName
The name for the new object in the destination directory. Pass `NULL` to use the name of the source object.

targetPath
A pointer to a char* variable that, on output, refers to the UTF-8 pathname of the new object in the destination directory. When you no longer need the pathname, you should free it. If the operation fails, the pathname is set to `NULL`. This parameter is optional; pass `NULL` if you don't need the pathname.

options
One or more file operation option flags. See "File Operation Options" (page 917). If you specify the `kFSFileOperationDoNotMoveAcrossVolumes` flag and the destination directory is not on the same volume as the source object, this function does nothing and returns an error.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If the destination directory is on the same volume as the source object, this is a fast operation. If the move is across volumes, this function could take a significant amount of time to execute; you should call it in a thread other than the main thread or use `FSPathMoveObjectAsync` (page 521) instead.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSPathMoveObjectToTrashAsync

Starts an asynchronous file operation to move a source object, specified using a pathname, to the Trash.

```
OSStatus FSPathMoveObjectToTrashAsync (
   FSFileOperationRef fileOp,
   const char *sourcePath,
   OptionBits flags,
   FSPathFileOperationStatusProcPtr callback,
   CFTimeInterval statusChangeInterval,
   FSFileOperationClientContext *clientContext
);
```

Parameters

fileOp
The file operation object you created for this move operation. For more information, see the function `FSFileOperationCreate` (page 488).

sourcePath
The UTF-8 pathname of the source object to move. The object can be a file or a directory.

flags
One or more file operation option flags. See "File Operation Options" (page 917).

callback
A callback function to receive status updates as the file operation proceeds. For more information, see "File Operation Callbacks" (page 788). This parameter is optional; pass `NULL` if you don't need to supply a status callback.

statusChangeInterval
The minimum time in seconds between callbacks within a single stage of an operation.

clientContext
User-defined data to associate with this operation. This data is passed to the function you specify in the *callback* parameter. For more information, see `FSFileOperationClientContext` (page 829). This parameter is optional; pass `NULL` if you don't need to supply a client context.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function starts an asynchronous file operation to move the object specified by the *sourcePath* parameter to the Trash. If the source volume does not support a trash folder, the operation will fail and return an error to the status callback specified in the *callback* parameter. (This is the same circumstance that triggers the delete immediately behavior in the Finder.)

Status callbacks occur on one of the runloop and mode combinations on which the operation was scheduled. Upon successful completion of the operation, the last *currentItem* parameter (passed to the last status callback or retrieved by calling `FSFileOperationCopyStatus` (page 487)) is the object in the Trash.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSPathMoveObjectToTrashSync

Moves a source object, specified using a pathname, to the Trash.

```
OSStatus FSPathMoveObjectToTrashSync (
   const char *sourcePath,
   char **targetPath,
   OptionBits options
);
```

Parameters

sourcePath
The UTF-8 pathname of the source object to move. The object can be a file or a directory.

targetPath
A pointer to a char* variable that, on output, refers to the UTF-8 pathname of the target object in the Trash. When you no longer need the pathname, you should free it. If the operation fails, the pathname is set to `NULL`. This parameter is optional; pass `NULL` if you don't need the pathname.

options
One or more file operation option flags. See "File Operation Options" (page 917).

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function moves a file or directory to the Trash, adjusting the object's name if necessary. The appropriate trash folder is chosen based on the source volume and the current user. If the source volume does not support a trash folder, this function does nothing and returns an error. (This is the same circumstance that triggers the delete immediately behavior in the Finder.)

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSpCatMove

Moves a file or directory from one location to another on the same volume. (Deprecated in Mac OS X v10.4. Use `FSMoveObject` (page 510) instead.)

```
OSErr FSpCatMove (
   const FSSpec *source,
   const FSSpec *dest
);
```

Parameters

source

A pointer to an `FSSpec` structure specifying the name and location of the file or directory to move. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

dest

A pointer to an `FSSpec` structure specifying the name and location of the directory into which the source file or directory is to be moved. The directory ID specified in the `parID` field of this `FSSpec` is the directory ID of the parent of the directory into which you want to move the source file or directory. The `name` field of this `FSSpec` specifies the name of the directory into which you want to move the source file or directory.

If you don't already know the parent directory ID of the destination directory, it might be easier to use the `PBCatMoveSync` or `PBCatMoveAsync` function, which allow you to specify only the directory ID of the destination directory.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSpCatMove` function is strictly a file catalog operation; it does not actually change the location of the file or directory on the disk. You cannot use `FSpCatMove` to move a file or directory to another volume (that is, the `vRefNum` field in both `FSSpec` structures in the `source` and `dest` parameters must be the same). Also, you cannot use `FSpCatMove` to rename files or directories; to rename a file or directory, use `FSpRename` (page 533).

If you need to move files or directories with named forks other than the data and resource forks, with long Unicode names, or files larger than 2GB, you should use the `FSMoveObject` (page 510) function, or one of the corresponding parameter block calls, `PBMoveObjectSync` (page 738) and `PBMoveObjectAsync` (page 737).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSpCreate

Creates a new file. (Deprecated in Mac OS X v10.4. Use `FSCreateFileUnicode` (page 481) instead.)

```
OSErr FSpCreate (
   const FSSpec *spec,
   OSType creator,
   OSType fileType,
   ScriptCode scriptTag
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file to be created. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

creator

The creator of the new file. See the documentation for the Finder Interface for more information on file creators.

fileType

The file type of the new file. See the documentation for the Finder Interface for more information on file types.

scriptTag

The code of the script system in which the filename is to be displayed. If you have established the name and location of the new file using either the `NavAskSaveChanges` or `NavCustomAskSaveChanges` function, specify the script code returned in the reply structure. Otherwise, specify the system script by setting the `scriptTag` parameter to the value `smSystemScript`.

For more information about the functions `NavAskSaveChanges` and `NavCustomAskSaveChanges`, see *Programming With Navigation Services*. See the *Script Manager Reference* for a description of the `smSystemScript` constant.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `FSpCreate` function creates a new file (both data and resource forks) with the specified type, creator, and script code. The new file is unlocked and empty. The date and time of creation and last modification are set to the current date and time.

Files created using `FSpCreate` are not automatically opened. If you want to write data to the new file, you must first open the file using one of the file access functions, `FSpOpenDF` (page 531) , `HOpenDF` (page 554) , `PBHOpenDFSync` (page 708) or `PBHOpenDFAsync` (page 706).

The resource fork of the new file exists but is empty. You'll need to call one of the Resource Manager functions `HCreateResFile` or `FSpCreateResFile` to create a resource map in the file before you can open it by calling one of the Resource Manager functions `HOpenResFile` or `FSpOpenResFile`).

Before calling this function, you should call the `Gestalt` function to check that the function is available. If `FSpCreate` is not available, you can use the function `HCreate` (page 550) instead. To create a file with a Unicode filename, use the function `FSCreateFileUnicode` (page 481) , or one of the corresponding parameter block calls, `PBCreateFileUnicodeSync` (page 593) and `PBCreateFileUnicodeAsync` (page 591).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

FSpDelete

Deletes a file or directory. (Deprecated in Mac OS X v10.4. Use `FSDeleteObject` (page 484) instead.)

```
OSErr FSpDelete (
   const FSSpec *spec
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file or directory to delete. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If you attempt to delete an open file or a non-empty directory, `FSpDelete` returns the result code `fBsyErr`. `FSpDelete` also returns the result code `fBsyErr` if the directory has an open working directory associated with it.

Discussion
If the specified target is a file, both forks of the file are deleted. The file ID reference, if any, is removed. A file must be closed before you can delete it. Similarly, a directory must be empty before you can delete it.

Before calling this function, you should call the `Gestalt` function to check that the function is available. If `FSpDelete` is not available, you can use the function `HDelete` (page 551) instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Files.h`

FSpDirCreate

Creates a new directory. (Deprecated in Mac OS X v10.4. Use `FSCreateDirectoryUnicode` (page 479) instead.)

```
OSErr FSpDirCreate (
   const FSSpec *spec,
   ScriptCode scriptTag,
   SInt32 *createdDirID
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the directory to be created.

Note that if the parent directory ID for the directory described by this `FSSpec` is 0 and the volume specified in this `FSSpec` is the default volume, the new directory is placed in the default directory of the volume. If the parent directory ID is 0 and the specified volume is a volume other than the default volume, the new directory is placed in the root directory of the volume. To create a directory at the root of a volume, regardless of whether that volume is the current default volume, set the parent directory ID to the constant `fsRtDirID`(2).

scriptTag

The code of the script system in which the directory name is to be displayed. If you have established the name and location of the new directory using either the `NavAskSaveChanges` or `NavCustomAskSaveChanges` function, specify the script code returned in the reply structure. Otherwise, specify the system script by setting the `scriptTag` parameter to the value `smSystemScript`.

For more information on the functions `NavAskSaveChanges` and `NavCustomAskSaveChanges`, see *Programming With Navigation Services*. For a description of the `smSystemScript` constant, see the *Script Manager Reference*.

createdDirID

On return, a pointer to the directory ID of the directory that was created.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSpDirCreate` function sets the date and time of creation and last modification to the current date and time.

Before calling this function, you should call the `Gestalt` function to check that the function is available. If `FSpDirCreate` is not available, you can use the function `DirCreate` (page 463) instead. To create a directory with a Unicode name, use the function `FSCreateDirectoryUnicode` (page 479) , or one of the corresponding parameter block calls, `PBCreateDirectoryUnicodeSync` (page 589) and `PBCreateDirectoryUnicodeAsync` (page 587).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSpExchangeFiles

Exchanges the data stored in two files on the same volume. (Deprecated in Mac OS X v10.4. Use `FSExchangeObjects` (page 486) instead.)

```
OSErr FSpExchangeFiles (
   const FSSpec *source,
   const FSSpec *dest
);
```

Parameters

source

A pointer to an `FSSpec` for the first file to swap. The contents of this file and its file information are placed in the file specified in the `dest` parameter. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

dest

A pointer to an `FSSpec` for the second file to swap. The contents of this file and its file information are placed in the file specified in the `source` parameter.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `FSpExchangeFiles` function swaps the data in two files by changing the information in the volume's catalog and, if either of the files are open, in the file control blocks. The following fields in the catalog entries for the files are exchanged:

- `ioFlStBlk`
- `ioFlLgLen`
- `ioFlPyLen`
- `ioFlRStBlk`
- `ioFlRLgLen`
- `ioFlRPyLen`
- `ioFlMdDat`

In the file control blocks, the `fcbFlNum`, `fcbDirID`, and `fcbCName` fields are exchanged.

You should use `FSpExchangeFiles` when updating an existing file, so that the file ID remains valid in case the file is being tracked through its file ID. The `FSpExchangeFiles` function changes the fields in the catalog entries that record the location of the data and the modification dates. It swaps both the data forks and the resource forks.

The `FSpExchangeFiles` function works on both open and closed files. If either file is open, `FSpExchangeFiles` updates any file control blocks associated with the file. Exchanging the contents of two files requires essentially the same access permissions as opening both files for writing.

The files whose data is to be exchanged must both reside on the same volume. If they do not, `FSpExchangeFiles` returns the result code `diffVolErr`.

To exchange the contents of files with named forks other than the data and resource forks, or of files larger than 2 GB, use the `FSExchangeObjects` (page 486) , `PBExchangeObjectsSync` (page 636) , or `PBExchangeObjectsAsync` (page 635) function.

Special Considerations

The "compatibility code," by which `FSpExchangeFiles` attempted to perform the file exchange itself if it suspected that the underlying filesystem did not have Exchange capability, has been removed in Mac OS 9 and X.

Because other programs may have access paths open to one or both of the files exchanged, your application should have exclusive read/write access permission (`fsRdWrPerm`) to both files before calling `FSpExchangeFiles`. Exclusive read/write access to both files will ensure that `FSpExchangeFiles` doesn't affect another application because it prevents other applications from obtaining write access to one or both of the files exchanged.

`FSpExchangeFiles` does not respect the file-locked attribute; it will perform the exchange even if one or both of the files are locked. Obtaining exclusive read/write access to both files before calling `FSpExchangeFiles` ensures that the files are unlocked because locked files cannot be opened with write access.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

FSpGetFInfo

Obtains the Finder information for a file. (Deprecated in Mac OS X v10.4. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr FSpGetFInfo (
   const FSSpec *spec,
   FInfo *fndrInfo
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

fndrInfo

On return, a pointer to information used by the Finder. The `FSpGetFInfo` function returns the Finder information from the volume catalog entry for the specified file. The function provides only the original Finder information—the information in the `FInfo` or `DInfo` structures, not the information in the `FXInfo` or `DXInfo` structures. For a description of the `FInfo` structure, see the *Finder Interface Reference*.

Return Value

A result code. If the specified object is a folder, this function returns `fnfErr`. For other possible return values, see "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Files.h`

FSpMakeFSRef

Creates an `FSRef` for a file or directory, given an `FSSpec`. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr FSpMakeFSRef (
   const FSSpec *source,
   FSRef *newRef
);
```

Parameters

source

A pointer to the `FSSpec` for the file or directory. This parameter must point to a valid `FSSpec` for an existing file or directory; if it does not, the call will return `fnfErr`. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

newRef

On input, a pointer to an `FSRef` structure. On return, a pointer to the `FSRef` for the file or directory specified in the `FSSpec` pointed to in the `source` parameter.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
To obtain an `FSSpec` from an `FSRef`, use the `FSGetCatalogInfo` (page 494) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Files.h`

FSpOpenDF

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `FSOpenFork` (page 514) instead.)

```
OSErr FSpOpenDF (
   const FSSpec *spec,
   SInt8 permission,
   FSIORefNum *refNum
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file whose data fork is to be opened. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

permission

A constant indicating the type of access with which to open the file's data fork. In most cases, you can simply set the `permission` parameter to `fsCurPerm`. Some applications request `fsRdWrPerm`, to ensure that they can both read from and write to a file. For a description of the types of access that you can request, see "File Access Permission Constants" (page 908).

refNum

On return, a pointer to the file reference number for accessing the open data fork.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

Before calling this function, you should call the `Gestalt` function to check that the function is available. If `FSpOpenDF` is not available, you can use the function `HOpenDF` (page 554) instead.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `FSpOpenDF` function, you will receive an error message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

FSpOpenRF

Opens the resource fork of a file. (Deprecated in Mac OS X v10.4. Use `FSOpenFork` (page 514) instead.)

```
OSErr FSpOpenRF (
   const FSSpec *spec,
   SInt8 permission,
   FSIORefNum *refNum
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file whose resource fork is to be opened. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

permission

A constant indicating the type of access with which to open the file's resource fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908).

refNum

On return, a pointer to the file reference number for accessing the open resource fork.

Return Value

A result code. See "File Manager Result Codes" (page 943). On some file systems, `FSpOpenRF` will return the error `eofErr` if you try to open the resource fork of a file for which no resource fork exists with read-only access.

Discussion

Before calling this function, you should call the `Gestalt` function to check that the function is available. If `FSpOpenRF` is not available, you can use the function `HOpenRF` (page 554) instead.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `FSpOpenRF` function, you will receive an error message.

Special Considerations

Generally, your application should use Resource Manager functions rather than File Manager functions to access a file's resource fork. The `FSpOpenRF` function does not read the resource map into memory and is generally useful only for applications (such as utilities that copy files) that need block-level access to a resource fork.

You should not use the resource fork of a file to hold non-resource data. Many parts of the system software assume that a resource fork always contains resource data.

Because there is no support for locking and unlocking file ranges on local disks in Mac OS X, regardless of whether File Sharing is enabled, you cannot open more than one path to a resource fork with read/write permission. If you try to open a more than one path to a file's resource fork with `fsRdWrShPerm` permission, only the first attempt will succeed. Subsequent attempts will return an invalid reference number and the `ResError` function will return the error `opWrErr`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

FSpRename

Renames a file or directory. (Deprecated in Mac OS X v10.4. Use `FSRenameUnicode` (page 539) instead.)

```
OSErr FSpRename (
   const FSSpec *spec,
   ConstStr255Param newName
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file or directory to rename. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

newName

The new name of the file or directory.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If a file ID reference for the specified file exists, it remains with the renamed file.

If you want to change the name of a new copy of an existing file, you should use the `FSpExchangeFiles` (page 528) function instead. To rename a file or directory using a long Unicode name, use the `FSRenameUnicode` (page 539) function or one of the corresponding parameter block calls, `PBRenameUnicodeSync` (page 748) and `PBRenameUnicodeAsync` (page 748).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSpRstFLock

Unlocks a file or directory. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr FSpRstFLock (
   const FSSpec *spec
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file to unlock. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function indicates that the volume supports folder locking (that is, the `bHasFolderLock` bit of the `vMAttrib` field is set), you can use `FSpRstFLock` to unlock a directory. Otherwise, you can only use this function to unlock a file.

You can lock a file or directory with the `FSpSetFLock` (page 535) , `HSetFLock` (page 558) , `PBHSetFLockSync` (page 724) , and `PBHSetFLockAsync` (page 723) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSpSetFInfo

Sets the Finder information about a file. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr FSpSetFInfo (
   const FSSpec *spec,
   const FInfo *fndrInfo
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file for which to set the Finder information. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

fndrInfo

A pointer to the new Finder information. For a description of the `FInfo` data type, see the *Finder Interface Reference*.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `FSpSetFInfo` function changes the Finder information in the volume catalog entry for the specified file. `FSpSetFInfo` allows you to set only the original Finder information—the information in the `FInfo` or `DInfo` structures, not the information in the `FXInfo` or `DXInfo` structures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Files.h`

FSpSetFLock

Locks a file or directory. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr FSpSetFLock (
   const FSSpec *spec
);
```

Parameters

spec

A pointer to an `FSSpec` structure specifying the file or directory to lock. See `FSSpec` (page 840) for a description of the `FSSpec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) functions indicate that the volume supports folder locking (that is, the `bHasFolderLock` bit of the `vMAttrib` field is set), you can use `FSpSetFLock` to lock a directory. Otherwise, you can only use this function to lock a file.

After you lock a file, all new access paths to that file are read-only. This function has no effect on existing access paths.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSRead

Reads any number of bytes from an open file. (Deprecated in Mac OS X v10.4. Use `FSReadFork` (page 537) instead.)

```
OSErr FSRead (
    FSIORefNum refNum,
    SInt32 *count,
    void *buffPtr
);
```

Parameters

refNum

The file reference number of the open file from which to read.

count

On input, a pointer to the number of bytes to read; on output, a pointer to the number of bytes actually read.

buffPtr

A pointer to the data buffer into which the data will be read. This buffer is allocated by your application and must be at least as large as the `count` parameter.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Because the read operation begins at the current mark, you might want to set the mark first by calling the `SetFPos` (page 787) function. If you try to read past the logical end-of-file, `FSRead` reads in all the data up to the end-of-file, moves the mark to the end-of-file, and returns `eofErr` as its function result. Otherwise, `FSRead` moves the file mark to the byte following the last byte read and returns `noErr`.

The low-level functions `PBReadSync` and `PBReadAsync` let you set the mark without having to call `SetFPos`. Furthermore, if you want to read data in newline mode, you must use `PBReadSync` or `PBReadAsync` instead of `FSRead`.

If you wish to read from named forks other than the data or resource forks, or from files larger than 2GB, you must use the `FSReadFork` (page 537) function, or one of its corresponding parameter block calls, `PBReadForkSync` (page 745) and `PBReadForkAsync` (page 744). If you attempt to use `FSRead` to read from a file larger than 2GB, you will receive an error message.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

FSReadFork

Reads data from an open fork.

```
OSErr FSReadFork (
    FSIORefNum forkRefNum,
    UInt16 positionMode,
    SInt64 positionOffset,
    ByteCount requestCount,
    void *buffer,
    ByteCount *actualCount
);
```

Parameters

forkRefNum
The reference number of the fork to read from. You should have previously opened this fork using the `FSOpenFork` (page 514) call, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

positionMode

A constant specifying the base location within the fork for the start of the read. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location.

The caller can also use this parameter to hint to the File Manager whether the data being read should or should not be cached. Caching reads appropriately can be important in ensuring that your program access files efficiently.

If you add the `forceReadMask` constant to the value you pass in this parameter, this tells the File Manager to force the data to be read directly from the disk. This is different from adding the `noCacheMask` constant since `forceReadMask` tells the File Manager to flush the appropriate part of the cache first, then ignore any data already in the cache. However, data that is read may be placed in the cache for future reads. The `forceReadMask` constant is also passed to the device driver, indicating that the driver should avoid reading from any device caches.

See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching the read.

positionOffset

The offset from the base location for the start of the read.

requestCount

The number of bytes to read.

buffer

A pointer to the buffer where the data will be returned.

actualCount

On return, a pointer to the number of bytes actually read. The value pointed to by the `actualCount` parameter should be equal to the value in the `requestCount` parameter unless there was an error during the read operation.

This parameter is optional; if you don't want this information returned, set `actualCount` to `NULL`.

Return Value

A result code. See "File Manager Result Codes" (page 943). If there are fewer than `requestCount` bytes from the specified position to the logical end-of-file, then all of those bytes are read, and `eofErr` is returned.

Discussion

`FSReadFork` reads data starting at the position specified by the `positionMode` and `positionOffset` parameters. The function reads up to `requestCount` bytes into the buffer pointed to by the `buffer` parameter and sets the fork's current position to the byte immediately after the last byte read (that is, the initial position plus `actualCount`).

To verify that data previously written has been correctly transferred to disk, read it back in using the `forceReadMask` constant in the `positionMode` parameter and compare it with the data you previously wrote.

When reading data from a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your read requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSRefMakePath

Converts an `FSRef` structure into a POSIX-style pathname.

```
OSStatus FSRefMakePath (
   const FSRef *ref,
   UInt8 *path,
   UInt32 maxPathSize
);
```

Parameters

ref

A pointer to the `FSRef` structure to convert.

path

A pointer to a character buffer allocated by the caller. On output, the buffer contains a UTF-8 C string that specifies the absolute path to the object referred to by the *ref* parameter. The File Manager uses the *maxPathSize* parameter to make sure it does not overrun the buffer.

maxPathSize

The maximum number of bytes to copy into the buffer.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

BSDLLCTest

Declared In

`Files.h`

FSRenameUnicode

Renames a file or folder.

```
OSErr FSRenameUnicode (
   const FSRef *ref,
   UniCharCount nameLength,
   const UniChar *name,
   TextEncoding textEncodingHint,
   FSRef *newRef
);
```

Parameters

ref

A pointer to an `FSRef` for the file or directory to rename. See `FSRef` (page 837) for a description of the `FSRef` data type.

nameLength

The length of the new name in Unicode characters.

name

A pointer to the new Unicode name of the file or directory.

textEncodingHint

The suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant `kTextEncodingUnknown`, the File Manager will use a default value.

newRef

On return, a pointer to the new `FSRef` for the file or directory. This parameter is optional; if you do not wish the `FSRef` returned, pass `NULL`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Because renaming an object may change its `FSRef`, you should pass a non- `NULL` pointer in the `newRef` parameter and use the `FSRef` returned there to access the object after the renaming, if you wish to continue to refer to the object. The `FSRef` passed in the `ref` parameter may or may not be usable after the object is renamed. The `FSRef` returned in the `newRef` parameter may point to the same storage as the `FSRef` passed in `ref`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSSetCatalogInfo

Sets catalog information about a file or directory.

```
OSErr FSSetCatalogInfo (
   const FSRef *ref,
   FSCatalogInfoBitmap whichInfo,
   const FSCatalogInfo *catalogInfo
);
```

Parameters

ref

A pointer to an `FSRef` specifying the file or directory whose information is to be changed. See `FSRef` (page 837) for a description of the `FSRef` data type.

whichInfo

A bitmap specifying which catalog information fields to set. Only some of the catalog information fields may be set. These fields are given by the constant `kFSCatInfoSettableInfo`; no other bits may be set in the `whichInfo` parameter. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this parameter.

To set the user ID (UID) and group ID (GID), specify the `kFSCatInfoSetOwnership` flag in this parameter. The File Manager attempts to set the user and group ID to the values specified in the `permissions` field of the catalog information structure. If `FSSetCatalogInfo` cannot set the user and group IDs, it returns an error.

catalogInfo

A pointer to the structure containing the new catalog information. Only some of the catalog information fields may be set. The fields which may be set are:

- createDate
- contentModDate
- attributeModDate
- accessDate
- backupDate
- permissions
- finderInfo
- extFinderInfo
- textEncodingHint

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest

Declared In
Files.h

FSSetForkPosition

Sets the current position of an open fork.

```
OSErr FSSetForkPosition (
   FSIORefNum forkRefNum,
   UInt16 positionMode,
   SInt64 positionOffset
);
```

Parameters

forkRefNum

The reference number of a fork previously opened by the FSOpenFork (page 514), PBOpenForkSync (page 740), or PBOpenForkAsync (page 739) function.

positionMode

A constant specifying the base location within the fork for the new position. If this parameter is equal to fsAtMark, then the positionOffset parameter is ignored. See "Position Mode Constants" (page 928) for a description of the constants you can use to specify the base location.

positionOffset

The offset of the new position from the base location specified in the positionMode parameter.

Return Value
A result code. See "File Manager Result Codes" (page 943). This function returns the result code posErr if you attempt to set the current position of the fork to an offset before the start of the file.

Special Considerations

To determine if the `FSSetForkPosition` function is present, call the `Gestalt` function with the `gestaltFSAttr` selector. If the `FSSetForkPosition` function is present, but the volume does not directly support it, the File Manager will automatically call the `PBSetFPosSync` (page 764) function. However, if the volume does not directly support the `FSSetForkPosition` function, you can only set the file position for the data and resource forks, and you cannot grow these files beyond 2GB.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSSetForkSize

Changes the size of an open fork.

```
OSErr FSSetForkSize (
   FSIORefNum forkRefNum,
   UInt16 positionMode,
   SInt64 positionOffset
);
```

Parameters

forkRefNum

The reference number of the open fork. You can obtain this fork reference number with the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

positionMode

A constant indicating the base location within the fork for the new size. See "Position Mode Constants" (page 928) for more information about the constants you can use to specify the base location.

positionOffset

The offset of the new size from the base location specified in the `positionMode` parameter.

Return Value

A result code. See "File Manager Result Codes" (page 943). If there is not enough space on the volume to extend the fork, then `dskFulErr` is returned and the fork's size is unchanged.

Discussion

The `FSSetForkSize` function sets the logical end-of-file to the position indicated by the `positionMode` and `positionOffset` parameters. The fork's new size may be less than, equal to, or greater than the fork's current size. If the fork's new size is greater than the fork's current size, then the additional bytes, between the old and new size, will have an undetermined value.

If the fork's current position is larger than the fork's new size, then the current position will be set to the new fork size the current position will be equal to the logical end-of-file.

Special Considerations

You do not need to check that the volume supports the `FSSetForkSize` function. If a volume does not support the `FSSetForkSize` function, but the `FSSetForkSize` function is present, the File Manager automatically calls the `PBSetEOFSync` (page 758) function and translates between the calls appropriately.

Note, however, that if the volume does not support the `FSSetForkSize` function, you can only access the data and resource forks, and you cannot grow the fork beyond 2GB. To check that the `FSSetForkSize` function is present, call the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSSetVolumeInfo

Sets information about a volume.

```
OSErr FSSetVolumeInfo (
   FSVolumeRefNum volume,
   FSVolumeInfoBitmap whichInfo,
   const FSVolumeInfo *info
);
```

Parameters

`volume`

The volume reference number of the volume whose information is to be changed. See `FSVolumeRefNum` (page 847) for a description of the `FSVolumeRefNum` data type.

`whichInfo`

A bitmap specifying which information to set. Only some of the volume information fields may be set. The settable fields are given by the constant `kFSVolInfoSettableInfo`; no other bits may be set in `whichInfo`. The fields which may be set are the backupDate, finderInfo, and `flags` fields. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this parameter.

`info`

A pointer to the new volume information. See `FSVolumeInfo` (page 842) for a description of the `FSVolumeInfo` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
To set information about the root directory of a volume, use the `FSSetCatalogInfo` (page 540) function, or one of the corresponding parameter block calls, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSUnlockRange

Unlocks a range of bytes of the specified fork.

```
OSStatus FSUnlockRange (
    FSIORefNum forkRefNum,
    UInt16 positionMode,
    SInt64 positionOffset,
    UInt64 requestCount,
    UInt64 *rangeStart
);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSUnmountVolumeAsync

Unmounts a volume asynchronously.

```
OSStatus FSUnmountVolumeAsync (
   FSVolumeRefNum vRefNum,
   OptionBits flags,
   FSVolumeOperation volumeOp,
   void *clientData,
   FSVolumeUnmountUPP callback,
   CFRunLoopRef runloop,
   CFStringRef runloopMode
);
```

Parameters

vRefNum
The volume reference number of the volume to unmount.

flags
Options for future use.

volumeOp
An `FSVolumeOperation` returned by the `FSCreateVolumeOperation` function.

clientData
A pointer to client data associated with the operation.

callback
The function to call when the unmount is complete.

runloop
The runloop to run on.

runloopMode
The mode for the runloop.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function starts the process of unmounting the volume specified by the *vRefNum* parameter. If a callback function is provided, that function will be called when the unmount operation is complete. Once this function returns `noErr` the status of the operation can be found using the `FSGetAsyncUnmountStatus` function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSUnmountVolumeSync

Unmounts a volume.

```
OSStatus FSUnmountVolumeSync (
   FSVolumeRefNum vRefNum,
   OptionBits flags,
   pid_t *dissenter
);
```

Parameters

vRefNum
The volume reference number of the volume to unmount.

flags
Options for future use.

dissenter
On return, a pointer to the pid of the process which denied the unmount if the unmount is denied.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
This function unmounts the volume specified by the *vRefNum* parameter. If the volume cannot be unmounted the pid of the process which denied the unmount will be returned in the *dissenter* parameter. This function returns after the unmount is complete.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeMount

Mounts a volume using the specified mounting information.

```
OSStatus FSVolumeMount (
   BytePtr buffer,
   FSVolumeRefNum *mountedVolume
);
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Files.h`

FSWrite

Writes any number of bytes to an open file. (Deprecated in Mac OS X v10.4. Use `FSWriteFork` (page 546) instead.)

```
OSErr FSWrite (
    FSIORefNum refNum,
    SInt32 *count,
    const void *buffPtr
);
```

Parameters

refNum

The file reference number of the open file to which to write.

count

On input, a pointer to the number of bytes to write to the file. Passing 0 in this parameter will return a `paramErr` error.

On output, a pointer to the number of bytes actually written.

buffPtr

A pointer to the data buffer containing the data to write.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `FSWrite` function takes the specified number of bytes from the data buffer and attempts to write them to the file. Because the write operation begins at the current mark, you might want to set the mark first by calling the `SetFPos` (page 787) function.

If the write operation completes successfully, `FSWrite` moves the file mark to the byte following the last byte written and returns `noErr`. If you try to write past the logical end-of-file, `FSWrite` moves the logical end-of-file. If you try to write past the physical end-of-file, `FSWrite` adds one or more clumps to the file and moves the physical end-of-file accordingly.

The low-level functions `PBWriteSync` and `PBWriteAsync` let you set the mark without having to call `SetFPos`.

If you wish to write to named forks other than the data or resource forks, or grow files larger than 2GB, you must use the `FSWriteFork` (page 546) function, or one of its corresponding parameter block calls, `PBWriteForkSync` (page 777) and `PBWriteForkAsync` (page 776). If you attempt to use `FSWrite` to write to a file larger than 2GB, you will receive an error message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

FSWriteFork

Writes data to an open fork.

```
OSErr FSWriteFork (
    FSIORefNum forkRefNum,
    UInt16 positionMode,
    SInt64 positionOffset,
    ByteCount requestCount,
    const void *buffer,
    ByteCount *actualCount
);
```

Parameters

forkRefNum

The reference number of the fork to which to write. You should have previously opened the fork using the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

positionMode

A constant specifying the base location within the fork for the start of the write. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location.

The caller can also use this parameter to hint to the File Manager whether the data being written should or should not be cached. See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching.

positionOffset

The offset from the base location for the start of the write.

requestCount

The number of bytes to write.

buffer

A pointer to a buffer containing the data to write.

actualCount

On return, a pointer to the number of bytes actually written. The value pointed to by the `actualCount` parameter will be equal to the value in the `requestCount` parameter unless there was an error during the write operation.

This parameter is optional; if you don't want this information, set `actualCount` to `NULL`.

Return Value

A result code. See "File Manager Result Codes" (page 943). If there is not enough space on the volume to write `requestCount` bytes, then `dskFulErr` is returned.

Discussion

`FSWriteFork` writes data starting at the position specified by the `positionMode` and `positionOffset` parameters. The function attempts to write `requestCount` bytes from the buffer pointed at by the `buffer` parameter and sets the fork's current position to the byte immediately after the last byte written (that is, the initial position plus `actualCount`).

When writing data to a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your write requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

GetEOF

Determines the current logical size of an open file. (Deprecated in Mac OS X v10.4. Use `FSGetForkSize` (page 499) instead.)

```
OSErr GetEOF (
   FSIORefNum refNum,
   SInt32 *logEOF
);
```

Parameters

refNum

The file reference number of an open file.

logEOF

On return, a pointer to the logical size (the logical end-of-file) of the given file.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

To determine the size of a named fork other than the data or resource forks, or of a fork larger than 2 GB, use the `FSGetForkSize` (page 499) function, or one of the corresponding parameter block functions, `PBGetForkSizeSync` (page 665) and `PBGetForkSizeAsync` (page 664).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

GetFPos

Returns the current position of the file mark. (Deprecated in Mac OS X v10.4. Use `FSGetForkPosition` (page 499) instead.)

```
OSErr GetFPos (
   FSIORefNum refNum,
   SInt32 *filePos
);
```

Parameters

refNum

The file reference number of an open file.

filePos

On return, a pointer to the current position of the mark. The position value is zero-based; that is, the value of `filePos` is 0 if the file mark is positioned at the beginning of the file.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion
Because the read and write operations performed by the functions `FSRead` (page 536) and `FSWrite` (page 546) begin at the current mark, you should call `GetFPos`, or one of the parameter block functions, `PBGetFPosSync` (page 666) and `PBGetFPosAsync` (page 666) , to determine the current position of the file mark before reading from or writing to the file.

To determine the current position of a named fork, or of a fork larger than 2GB, use the `FSGetForkPosition` (page 499) function, or one of the corresponding parameter block calls, `PBGetForkPositionSync` (page 663) and `PBGetForkPositionAsync` (page 663).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

GetVRefNum

Gets a volume reference number from a file reference number. (Deprecated in Mac OS X v10.4. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr GetVRefNum (
   FSIORefNum fileRefNum,
   FSVolumeRefNum *vRefNum
);
```

Parameters

`fileRefNum`
The file reference number of an open file.

`vRefNum`
On return, a pointer to the volume reference number of the volume containing the file specified in the `refNum` parameter.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you also want to determine the directory ID of the specified file's parent directory, call the `PBGetFCBInfoSync` (page 658) or `PBGetFCBInfoAsync` (page 656) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

HCreate

Creates a new file. (Deprecated in Mac OS X v10.4. Use `FSCreateFileUnicode` (page 481) instead.)

```
OSErr HCreate (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   OSType creator,
   OSType fileType
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The directory ID of the directory in which to create the new file.

fileName

The name of the new file. This can be a full or partial pathname.

You should not allow users to give files names that begin with a period (.). This ensures that files can be successfully opened by applications calling `HOpen` (page 553) instead of `HOpenDF` (page 554).

creator

The creator of the new file. For more information on a file's creator, see the Finder Interface documentation.

fileType

The file type of the new file. For more information on a file's type, see the Finder Interface documentation.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `HCreate` function creates a new file (both data and resource forks) with the specified name, creator, and file type. The new file is unlocked and empty. The date and time of its creation and last modification are set to the current date and time.

Files created using `HCreate` are not automatically opened. If you want to write data to the new file, you must first open the file using a file access function.

The resource fork of the new file exists but is empty. You'll need to call one of the Resource Manager functions `HCreateResFile` or `FSpCreateResFile` to create a resource map in the file before you can open it (by calling one of the Resource Manager functions `HOpenResFile` or `FSpOpenResFile`).

To create a file with a Unicode filename, use the function `FSCreateFileUnicode` (page 481) , or one of the corresponding parameter block calls, `PBCreateFileUnicodeSync` (page 593) and `PBCreateFileUnicodeAsync` (page 591).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HDelete

Deletes a file or directory. (Deprecated in Mac OS X v10.4. Use `FSDeleteObject` (page 484) instead.)

```
OSErr HDelete (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The directory ID of the parent directory of the file or directory to delete.

fileName

The name of the file or directory to delete. This can be a full or partial pathname.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you attempt to delete an open file or a non-empty directory, `HDelete` returns the result code `fBsyErr`. `HDelete` also returns the result code `fBsyErr` if the directory has an open working directory associated with it.

Discussion

If the specified target is a file, both the data and the resource fork of the file are deleted. In addition, if a file ID reference for the specified file exists, that reference is removed. A file must be closed before you can delete it. Similarly, you cannot delete a directory unless it's empty.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HGetFInfo

Obtains the Finder information for a file. (Deprecated in Mac OS X v10.4. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr HGetFInfo (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   FInfo *fndrInfo
);
```

Parameters

vRefNum

The volume reference number, drive number, or 0 for the default volume.

dirID

The parent directory ID of the file.

fileName
The name of the file.

fndrInfo
On return, a pointer to the Finder information stored in the specified volume's catalog. The function returns only the original Finder information—that contained in an `FInfo` structure, not that in an `FXInfo` structure.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

HGetVol

Determines the current default volume and default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr HGetVol (
   StringPtr volName,
   FSVolumeRefNum *vRefNum,
   SInt32 *dirID
);
```

Parameters
volName
On return, a pointer to the name of the default volume. If you do not want the name of the default volume returned, set this parameter to `NULL`.

vRefNum
On return, a pointer to the volume reference number of the default volume.

dirID
On return, a pointer to the directory ID of the default directory.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Version Notes
When CarbonLib is not present, the `HGetVol` function returns a working directory reference number in the `vRefNum` parameter if the previous call to `HSetVol` (page 559) (or one of the corresponding parameter block calls) passed in a working directory reference number.

Carbon Porting Notes

Carbon applications should use `HGetVol` and `HSetVol` to get and set the default directory. the functions `GetVol` and `SetVol`, as well as working directories, are no longer supported.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
Files.h

HOpen

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use FSOpenFork (page 514) instead.)

```
OSErr HOpen (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   SInt8 permission,
   FSIORefNum *refNum
);
```

Parameters

vRefNum
A volume reference number, drive number, or 0 for the default volume.

dirID
The directory ID of the file's parent directory.

fileName
The name of the file.

permission
A constant specifying the type of access with which to open the file's data fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908).

refNum
On return, a pointer to the file reference number for accessing the open fork.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you use HOpen to try to open a file whose name begins with a period, you might mistakenly open a driver instead; subsequent attempts to write data might corrupt data on the target device. To avoid these problems, you should always use HOpenDF instead of HOpen.

Special Considerations

If you use HOpen to try to open a file whose name begins with a period, you might mistakenly open a driver instead; subsequent attempts to write data might corrupt data on the target device. To avoid these problems, you should always use HOpenDF (page 554) instead of HOpen.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

HOpenDF

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `FSOpenFork` (page 514) instead.)

```
OSErr HOpenDF (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   SInt8 permission,
   FSIORefNum *refNum
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The directory ID of the file's parent directory.

fileName

The name of the file.

permission

A constant specifying the type of access with which to open the file's data fork. For a description of the types of access which you can request, see "File Access Permission Constants" (page 908).

refNum

On return, a pointer to the file reference number for accessing the open data fork.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `HOpenDF` function, you will receive an error message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HOpenRF

Opens the resource fork of a file. (Deprecated in Mac OS X v10.4. Use `FSOpenFork` (page 514) instead.)

```
OSErr HOpenRF (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   SInt8 permission,
   FSIORefNum *refNum
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The directory ID for the file's parent directory.

fileName

The name of the file.

permission

A constant specifying the type of access with which to open the file's resource fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908).

refNum

On return, a pointer to the file reference number for accessing the open resource fork.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you try to open the resource fork of a file for which no resource fork exists with read-only access, `HOpenRF` returns the error `eofErr`.

Discussion

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `HOpenRF` function, you will receive an error message.

Special Considerations

Generally, your application should use Resource Manager functions rather than File Manager functions to access a file's resource fork. The `HOpenRF` function does not read the resource map into memory and is generally useful only for applications (such as utilities that copy files) that need block-level access to a resource fork.

You should not use the resource fork of a file to hold non-resource data. Many parts of the system software assume that a resource fork always contains resource data.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HRename

Renames a file, directory, or volume. (Deprecated in Mac OS X v10.4. Use `FSRenameUnicode` (page 539) instead.)

```
OSErr HRename (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param oldName,
   ConstStr255Param newName
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

A directory ID.

oldName

An existing filename, directory name, or volume name.

newName

The new filename, directory name, or volume name.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

Given the name of a file or directory in the `oldName` parameter, `HRename` changes it to the name in the `newName` parameter. Given a volume name in the `oldName` parameter or a volume reference number in the `vRefNum` parameter, `HRename` changes the name of the volume to the name in `newName`. Access paths currently in use aren't affected by this function.

If a file ID reference exists for a file you are renaming, the file ID remains with the renamed file.

To rename a file or directory using a long Unicode name, use the `FSRenameUnicode` (page 539) function or one of the corresponding parameter block calls, `PBRenameUnicodeSync` (page 748) and `PBRenameUnicodeAsync` (page 748).

Special Considerations

You cannot use `HRename` to change the directory in which a file resides. To move a file or directory, use the `FSpCatMove` (page 524), `PBCatMoveSync` (page 576), or `PBCatMoveAsync` (page 575) functions.

If you're renaming a volume, make sure that both names end with a colon.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HRstFLock

Unlocks a file or directory. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr HRstFLock (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The parent directory ID of the file or directory to unlock.

fileName

The name of the file or directory.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

If the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function indicates that the volume supports folder locking (that is, the `bHasFolderLock` bit of the `vMAttrib` field is set), you can use `HRstFLock` to unlock a directory. Otherwise, you can only use this function to unlock a file.

You can lock a file or directory with the `FSpSetFLock` (page 535) , `HSetFLock` (page 558) , `PBHSetFLockSync` (page 724) , and `PBHSetFLockAsync` (page 723) functions.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

HSetFInfo

Sets the Finder information for a file. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr HSetFInfo (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName,
   const FInfo *fndrInfo
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The parent directory ID of the file.

fileName

The name of the file.

fndrInfo

A pointer to the new Finder information. The function changes the Finder information stored in the volume's catalog. `HSetFInfo` changes only the original Finder information—that contained in an `FInfo` structure, not that contained in an `FXInfo` structure. For a description of the `FInfo` data type, see the *Finder Interface Reference*.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

HSetFLock

Locks a file or directory. (Deprecated in Mac OS X v10.4. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr HSetFLock (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   ConstStr255Param fileName
);
```

Parameters

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

The parent directory ID of the file or directory to lock.

fileName

The name of the file or directory.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function indicates that the volume supports folder locking (that is, the `bHasFolderLock` bit of the `vMAttrib` field is set), you can use `HSetFLock` to lock a directory. Otherwise, you can only use this function to lock a file.

After you lock a file, all new access paths to that file are read-only. This function has no effect on existing access paths.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

HSetVol

Sets the default volume and the default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr HSetVol (
   ConstStr63Param volName,
   FSVolumeRefNum vRefNum,
   SInt32 dirID
);
```

Parameters

volName

The name of a mounted volume or the partial pathname of a directory. This parameter can be `NULL`.

vRefNum

A volume reference number, drive number, or 0 for the default volume.

dirID

A directory ID.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `HSetVol` function lets you specify the default directory by volume reference number or by directory ID.

Both the default volume and the default directory are used in calls made with no volume name, a volume reference number of 0, and a directory ID of 0.

Special Considerations

Use of the `HSetVol` function is discouraged if your application may execute in system software versions prior to version 7.0. Because the specified directory might not itself be a working directory, `HSetVol` records the default volume and directory separately, using the volume reference number of the volume and the actual directory ID of the specified directory. Subsequent calls to `GetVol` (or `PBGetVolSync` or `PBGetVolAsync`) return only the volume reference number, which will cause that volume's root directory (rather than the default directory, as expected) to be accessed.

Carbon Porting Notes

Carbon applications should use `HGetVol` and `HSetVol` to get and set the default directory. the functions `GetVol` and `SetVol`, as well as working directories, are no longer supported.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

InvokeFNSubscriptionUPP

Calls your directory change callback function.

```
void InvokeFNSubscriptionUPP (
   FNMessage message,
   OptionBits flags,
   void *refcon,
   FNSubscriptionRef subscription,
   FNSubscriptionUPP userUPP
);
```

Discussion
The File Manager calls this function to invoke the directory change function which you have provided for use after an asynchronous call has been completed. You should not need to use this function yourself. For more information on directory change functions, see `FNSubscriptionProcPtr` (page 789).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

InvokeFSVolumeEjectUPP

Calls your volume ejection callback function.

```
void InvokeFSVolumeEjectUPP (
   FSVolumeOperation volumeOp,
   void *clientData,
   OSStatus err,
   FSVolumeRefNum volumeRefNum,
   pid_t dissenter,
   FSVolumeEjectUPP userUPP
);
```

Discussion
The File Manager calls this function to invoke the volume ejection function which you have provided for use after an asynchronous call has been completed. You should not need to use this function yourself. For more information on change notification functions, see `FSVolumeEjectProcPtr` (page 792).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

InvokeFSVolumeMountUPP

Calls your volume mount callback function.

```
void InvokeFSVolumeMountUPP (
   FSVolumeOperation volumeOp,
   void *clientData,
   OSStatus err,
   FSVolumeRefNum mountedVolumeRefNum,
   FSVolumeMountUPP userUPP
);
```

Discussion
The File Manager calls this function to invoke the volume mount function which you have provided for use after an asynchronous call has been completed. You should not need to use this function yourself. For more information on change notification functions, see `FSVolumeMountProcPtr` (page 792).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

InvokeFSVolumeUnmountUPP

Calls your volume unmount callback function.

```
void InvokeFSVolumeUnmountUPP (
   FSVolumeOperation volumeOp,
   void *clientData,
   OSStatus err,
   FSVolumeRefNum volumeRefNum,
   pid_t dissenter,
   FSVolumeUnmountUPP userUPP
);
```

Discussion
The File Manager calls this function to invoke the volume unmount function which you have provided for use after an asynchronous call has been completed. You should not need to use this function yourself. For more information on change notification functions, see `FSVolumeUnmountProcPtr` (page 793).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

InvokeIOCompletionUPP

Calls your I/O completion callback function.

```
void InvokeIOCompletionUPP (
   ParmBlkPtr paramBlock,
   IOCompletionUPP userUPP
);
```

Discussion
The File Manager calls this function to invoke the I/O completion function which you have provided for use after an asynchronous call has been completed. You should not need to use this function yourself. For more information on I/O completion functions, see `IOCompletionProcPtr` (page 794).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

NewFNSubscriptionUPP

Creates a new universal procedure pointer (UPP) to your directory change callback function.

```
FNSubscriptionUPP NewFNSubscriptionUPP (
   FNSubscriptionProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to a directory change callback function. For more information, see `FNSubscriptionProcPtr` (page 789).

Return Value
A UPP to your directory change callback function.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

NewFSVolumeEjectUPP

Creates a new universal procedure pointer (UPP) to your volume ejection callback function.

```
FSVolumeEjectUPP NewFSVolumeEjectUPP (
   FSVolumeEjectProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to a volume ejection callback function. For more information, see `FSVolumeEjectProcPtr` (page 792).

Return Value
A UPP to your volume ejection callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

NewFSVolumeMountUPP

Creates a new universal procedure pointer (UPP) to your volume mount callback function.

```
FSVolumeMountUPP NewFSVolumeMountUPP (
   FSVolumeMountProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to a volume mount callback function. For more information, see `FSVolumeEjectProcPtr` (page 792).

Return Value
A UPP to your volume mount callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

NewFSVolumeUnmountUPP

Creates a new universal procedure pointer (UPP) to your volume unmount callback function.

```
FSVolumeUnmountUPP NewFSVolumeUnmountUPP (
   FSVolumeUnmountProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to a volume unmount callback function. For more information, see `FSVolumeUnmountProcPtr` (page 793).

Return Value
A UPP to your volume unmount callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

NewIOCompletionUPP

Creates a new universal procedure pointer (UPP) to your I/O completion callback function.

```
IOCompletionUPP NewIOCompletionUPP (
   IOCompletionProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your I/O completion callback function. For more information, see `IOCompletionProcPtr` (page 794).

Return Value

A UPP to your I/O completion callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBAllocateAsync

Allocates additional space on a volume to an open file. (Deprecated in Mac OS X v10.4. Use `PBAllocateForkAsync` (page 565) instead.)

```
OSErr PBAllocateAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioRefNum`

On input, a file reference number for the file to which to allocate additional blocks.

`ioReqCount`

On input, the number of bytes to allocate.

`ioActCount`

On output, the number of bytes actually allocated, rounded up to the nearest multiple of the allocation block size.

The PBAllocateAsync function adds ioReqCount bytes to the specified file and sets the physical end-of-file to 1 byte beyond the last block allocated. If there isn't enough empty space on the volume to satisfy the allocation request, PBAllocateAsync allocates the rest of the space on the volume and returns dskFulErr as its function result.

If the total number of requested bytes is unavailable, PBAllocateAsync allocates whatever space, contiguous or not, is available. To force the allocation of the entire requested space as a contiguous piece, call PBAllocContigAsync (page 569) instead.

The File Manager automatically allocates file blocks if you move the logical end-of-file past the physical end-of-file, and it automatically deallocates unneeded blocks from a file if you move the logical end-of-file to a position more than one allocation block before the current physical end-of-file. Consequently, you do not in general need to be concerned with allocating or deallocating file blocks. However, you can improve file block contiguity if you use the PBAllocateAsync function to preallocate file blocks. This is most useful if you know in advance how big a file is likely to become.

The space allocated with this function is not permanently assigned to the file until the file's logical end-of-file is changed to include the allocated space. When a file (or volume) is closed, the space beyond the file's logical EOF is made available for other purposes, even if previously allocated to the file with a call to this function. You can change the end-of-file by setting it with the SetEOF (page 786) function, or by writing data to the file with the FSWrite (page 546) function.

This function is not supported by all file systems; for example, volumes mounted by the AppleShare file system do not support this function. To allocate space for a file on any volume, use the SetEOF (page 786) function, or one of the related parameter block calls, PBSetEOFSync (page 758) and PBSetEOFAsync (page 757).

To allocate space for a file beyond 2 GB, use the FSAllocateFork (page 470) function, or one of the corresponding parameter block functions, PBAllocateForkSync (page 567) and PBAllocateForkAsync (page 565).

Special Considerations

In Mac OS 7.5.5 through Mac OS 8.5, if there is not enough space left on the volume to allocate the requested number of bytes, the PBAllocateAsync function does not return the number of bytes actually allocated in the ioActCount field.

To determine the remaining space on a volume before calling PBAllocateAsync, use the functions PBXGetVolInfoSync or PBXGetVolInfoAsync.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Files.h

PBAllocateForkAsync

Allocates space on a volume to an open fork.

```
void PBAllocateForkAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See FSForkIOParam (page 833) for a description of the FSForkIOParam data type.

Discussion

The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function.

forkRefNum

On input, the reference number of the open fork. You can obtain a fork reference number with the FSOpenFork (page 514) function, or with one of the corresponding parameter block calls, PBOpenForkSync (page 740) and PBOpenForkAsync (page 739).

allocationFlags

On input, a constant indicating how the new space should be allocated. See "Allocation Flags" (page 887) for a description of the constants which you can use in this field.

positionMode

On input, a constant specifying the base location within the fork for the start of the allocation. See "Position Mode Constants" (page 928) for more information on the constants which you can use to specify the base location.

positionOffset

On input, the offset from the base location of the start of the allocation.

allocationAmount

On input, the number of bytes to allocate. On output, the number of bytes actually allocated to the file. The number of bytes allocated may be smaller than the requested amount if some of the space was already allocated. The value returned in this field does not reflect any additional bytes that may have been allocated because space is allocated in terms of fixed units such as allocation blocks, or the use of a clump size to reduce fragmentation.

The PBAllocateForkAsync function attempts to allocate the number of requested bytes of physical storage starting at the offset specified by the positionMode and positionOffset fields. For volume formats that support preallocated space, you can later write to this range of bytes (including extending the size of the fork) without requiring an implicit allocation.

Any extra space allocated but not used will be deallocated when the fork is closed, using FSCloseFork (page 475) , PBCloseForkSync (page 583) , or PBCloseForkAsync (page 582) ; or when flushed, using FSFlushFork (page 490) , PBFlushForkSync (page 639) , or PBFlushForkAsync (page 638).

Availability

Available in Mac OS X v10.0 and later.

Declared In

Files.h

PBAllocateForkSync

Allocates space on a volume to an open fork.

```
OSErr PBAllocateForkSync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`forkRefNum`

On input, the reference number of the open fork. You can obtain a fork reference number with the `FSOpenFork` (page 514) function, or with one of the corresponding parameter block functions, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`allocationFlags`

On input, a constant indicating how the new space should be allocated. See "Allocation Flags" (page 887) for a description of the constants you can use in this field.

`positionMode`

On input, a constant specifying the base location within the fork for the start of the allocation. See "Position Mode Constants" (page 928) for more information on the constants which you can use to specify the base location.

`positionOffset`

On input, the offset from the base location of the start of the allocation.

`allocationAmount`

On input, the number of bytes to allocate. On output, the number of bytes actually allocated to the file. The number of bytes allocated may be smaller than the requested amount if some of the space was already allocated. The value returned in this field does not reflect any additional bytes that may have been allocated because space is allocated in terms of fixed units such as allocation blocks, or the use of a clump size to reduce fragmentation.

The `PBAllocateForkSync` function attempts to allocate the number of requested bytes of physical storage starting at the offset specified by the `positionMode` and `positionOffset` fields. For volume formats that support preallocated space, you can later write to this range of bytes (including extending the size of the fork) without requiring an implicit allocation.

Any extra space allocated but not used will be deallocated when the fork is closed, using `FSCloseFork` (page 475) , `PBCloseForkSync` (page 583) , or `PBCloseForkAsync` (page 582) ; or when flushed, using `FSFlushFork` (page 490) , `PBFlushForkSync` (page 639) , or `PBFlushForkAsync` (page 638).

Availability

Available in Mac OS X v10.0 and later.

Declared In

PBAllocateSync

Allocates additional space on a volume to an open file. (Deprecated in Mac OS X v10.4. Use PBAllocateForkSync (page 567) instead.)

```
OSErr PBAllocateSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioRefNum
: On input, a file reference number for the file to which to allocate additional blocks.

ioReqCount
: On input, the number of bytes to allocate.

ioActCount
: On output, the number of bytes actually allocated, rounded up to the nearest multiple of the allocation block size.

The PBAllocateSync function adds ioReqCount bytes to the specified file and sets the physical end-of-file to 1 byte beyond the last block allocated. If there isn't enough empty space on the volume to satisfy the allocation request, PBAllocateSync allocates the rest of the space on the volume and returns dskFulErr as its function result.

If the total number of requested bytes is unavailable, PBAllocateSync allocates whatever space, contiguous or not, is available. To force the allocation of the entire requested space as a contiguous piece, call PBAllocContigSync (page 570) instead.

The File Manager automatically allocates file blocks if you move the logical end-of-file past the physical end-of-file, and it automatically deallocates unneeded blocks from a file if you move the logical end-of-file to a position more than one allocation block before the current physical end-of-file. Consequently, you do not in general need to be concerned with allocating or deallocating file blocks. However, you can improve file block contiguity if you use the PBAllocateSync function to preallocate file blocks. This is most useful if you know in advance how big a file is likely to become.

The space allocated with this function is not permanently assigned to the file until the file's logical end-of-file is changed to include the allocated space. When a file (or volume) is closed, the space beyond the file's logical EOF is made available for other purposes, even if previously allocated to the file with a call to this function. You can change the end-of-file by setting it with the SetEOF (page 786) function, or by writing data to the file with the FSWrite (page 546) function.

This function is not supported by all file systems; for example, volumes mounted by the AppleShare file system do not support this function. To allocate space for a file on any volume, use the SetEOF (page 786) function, or one of the related parameter block calls, PBSetEOFSync (page 758) and PBSetEOFAsync (page 757).

To allocate space for a file beyond 2 GB, use the `FSAllocateFork` (page 470) function, or one of the corresponding parameter block functions, `PBAllocateForkSync` (page 567) and `PBAllocateForkAsync` (page 565).

Special Considerations

In Mac OS 7.5.5 through Mac OS 8.5, if there is not enough space left on the volume to allocate the requested number of bytes, the `PBAllocateSync` function does not return the number of bytes actually allocated in the `ioActCount` field.

To determine the remaining space on a volume before calling `PBAllocateSync`, use the functions `PBXGetVolInfoSync` or `PBXGetVolInfoAsync`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBAllocContigAsync

Allocates additional contiguous space on a volume to an open file. (Deprecated in Mac OS X v10.4. Use `PBAllocateForkAsync` (page 565) instead.)

```
OSErr PBAllocContigAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioRefNum`

On input, a file reference number for the open file.

`ioReqCount`

On input, the number of bytes to allocate.

`ioActCount`

On output, the number of bytes actually allocated, rounded up to the nearest multiple of the allocation block size.

The PBAllocContigAsync function is identical to the PBAllocateAsync (page 564) function except that if there isn't enough contiguous empty space on the volume to satisfy the allocation request, PBAllocContigAsync does nothing and returns dskFulErr as its function result. If you want to allocate whatever space is available, even when the entire request cannot be filled by the allocation of a contiguous piece, call PBAllocateAsync (page 564) instead.

The File Manager automatically allocates file blocks if you move the logical end-of-file past the physical end-of-file, and it automatically deallocates unneeded blocks from a file if you move the logical end-of-file to a position more than one allocation block before the current physical end-of-file. Consequently, you do not in general need to be concerned with allocating or deallocating file blocks. However, you can improve file block contiguity if you use the PBAllocContigAsync function to preallocate file blocks. This is most useful if you know in advance how big a file is likely to become.

The space allocated with this function is not permanently assigned to the file until the file's logical end-of-file is changed to include the allocated space. When a file (or volume) is closed, the space beyond the file's logical EOF is made available for other purposes, even if previously allocated to the file with a call to this function. You can change the end-of-file by setting it with the SetEOF (page 786) function, or by writing data to the file with the FSWrite (page 546) function.

This function is not supported by all file systems; for example, volumes mounted by the AppleShare file system do not support this function. To allocate space for a file on any volume, use the SetEOF (page 786) function, or one of the related parameter block calls, PBSetEOFSync (page 758) and PBSetEOFAsync (page 757).

To allocate space for a file beyond 2 GB, use the FSAllocateFork (page 470) function, or one of the corresponding parameter block functions, PBAllocateForkSync (page 567) and PBAllocateForkAsync (page 565).

Special Considerations

In Mac OS 7.5.5 through Mac OS 8.5, when there is not enough space to allocate the requested number of bytes, PBAllocContigAsync does not return 0 in the ioActCount field, so your application cannot rely upon this value.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`Files.h`

PBCatalogSearchAsync

Searches for objects traversed by a catalog iterator that match a given set of criteria.

```
void PBCatalogSearchAsync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Discussion

The relevant fields of this parameter are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. When the entire volume has been searched, `errFSNoMoreItems` is returned.

`iterator`

On input, the iterator to use. Objects traversed by this iterator are matched against the criteria specified by the `searchParams` field. You can obtain a catalog iterator with the function `FSOpenIterator` (page 515) , or with one of the related parameter block calls, `PBOpenIteratorSync` (page 742) and `PBOpenIteratorAsync` (page 741). Currently, this iterator must be created with the `kFSIterateSubtree` option and the container must be the root directory of a volume. See `FSIterator` (page 835) for more information on the `FSIterator` data type.

`searchParams`

On input, a pointer to an `FSSearchParams` (page 839) structure containing the search criteria. You can match against the object's name in Unicode and by the fields in an `FSCatalogInfo` (page 826) structure. You may use the same search bits as passed in the `ioSearchBits` field to the `PBCatSearchSync` (page 580) and `PBCatSearchAsync` (page 577) functions; they control the corresponding `FSCatalogInfo` fields. See "Catalog Search Masks" (page 900) for a description of the search bits. There are a few new search criteria supported by `PBCatalogSearchAsync` but not by `PBCatSearchSync` and `PBCatSearchAsync`. These new search criteria are indicated by the constants described in "Catalog Search Constants" (page 899).If the `searchTime` field of this structure is non-zero,

it is interpreted as a Time Manager duration; the search may terminate after this duration even if `maximumItems` objects have not been returned and the entire catalog has not been scanned. If `searchTime` is zero, there is no time limit for the search. If you are searching by any criteria other than name, you must set the `searchInfo1` and `searchInfo2` fields of the structure in this field to point to `FSCatalogInfo` structures containing the values to match against.

`maximumItems`
On input, the maximum number of items to return for this call.

`actualItems`
On output, the actual number of items returned for this call.

`containerChanged`
On output, a Boolean value indicating whether the container's contents have changed. If `true`, the container's contents changed since the previous `PBCatalogSearchAsync` call. Objects may still be returned even though the container changed. Note that if the container has changed, then the total set of items returned may be incorrect; some items may be returned multiple times, and some items may not be returned at all.

`whichInfo`
On input, a bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant `kFSCatInfoNone` in this field. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

`catalogInfo`
On output, a pointer to an array of `FSCatalogInfo` (page 826) structures; one for each found item. On input, the `catalogInfo` field should point to an array of `maximumItems` catalog information structures. This field is optional; if you do not wish any catalog information returned, pass `NULL` here.

`refs`
On output, a pointer to an array of `FSRef` (page 837) structures; one for each returned item. On input, if you want an `FSRef` for each item found, pass a pointer to an array of `maximumItems FSRef` structures. Otherwise, pass `NULL`.

`names`
On output, a pointer to an array of filenames; one for each returned item. On input, if you want the Unicode filename for each item found, pass a pointer to an array of `maximumItems HFSUniStr255` (page 855) structures. Otherwise, pass `NULL`.

A single search may span more than one call to `PBCatalogSearchAsync`. The call may complete with no error before scanning the entire volume. This typically happens because the time limit (`searchTime`) has been reached or `maximumItems` items have been returned. If the search is not completed, you can continue the search by making another call to `PBCatalogSearchAsync` and passing the updated iterator returned by the previous call in the `iterator` field.

Before calling this function, you should determine that it is present, by calling the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCatalogSearchSync

Searches for objects traversed by a catalog iterator that match a given set of criteria.

```
OSErr PBCatalogSearchSync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). When the entire volume has been searched, `errFSNoMoreItems` is returned.

Discussion

The relevant fields of this parameter are:

`iterator`

On input, the iterator to use. Objects traversed by this iterator are matched against the criteria specified by the `searchParams` field. You can obtain a catalog iterator with the function `FSOpenIterator` (page 515) , or with one of the related parameter block calls, `PBOpenIteratorSync` (page 742) and `PBOpenIteratorAsync` (page 741). Currently, this iterator must be created with the `kFSIterateSubtree` option and the container must be the root directory of a volume. See `FSIterator` (page 835) for more information on the `FSIterator` data type.

`searchParams`

On input, a pointer to an `FSSearchParams` (page 839) structure containing the search criteria. You can match against the object's name in Unicode and by the fields in an `FSCatalogInfo` (page 826) structure. You may use the same search bits as passed in the `ioSearchBits` field to the `PBCatSearchSync` (page 580) and `PBCatSearchAsync` (page 577) functions; they control the corresponding `FSCatalogInfo` fields. See "Catalog Search Masks" (page 900) for a description of the search bits. There are a few new search criteria supported by `PBCatalogSearchSync` but not by `PBCatSearchSync` and `PBCatSearchAsync`. These new search criteria are indicated by the constants described in "Catalog Search Constants" (page 899).If the `searchTime` field of this structure is non-zero, it is interpreted as a Time Manager duration; the search may terminate after this duration even if `maximumItems` objects have not been returned and the entire catalog has not been scanned. If `searchTime` is zero, there is no time limit for the search. If you are searching by any criteria other than name, you must set the `searchInfo1` and `searchInfo2` fields of the structure in this field to point to `FSCatalogInfo` structures containing the values to match against.

`maximumItems`

On input, the maximum number of items to return for this call.

`actualItems`

On output, the actual number of items returned for this call.

`containerChanged`

On output, a Boolean value indicating whether the container's contents have changed. If `true`, the container's contents changed since the previous `PBCatalogSearchSync` call. Objects may still be returned even though the container changed. Note that if the container has changed, then the total set of items returned may be incorrect; some items may be returned multiple times, and some items may not be returned at all.

`whichInfo`

On input, a bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant `kFSCatInfoNone` in this field. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

catalogInfo
: On output, a pointer to an array of FSCatalogInfo (page 826) structures; one for each found item. On input, the catalogInfo field should point to an array of maximumItems catalog information structures. This field is optional; if you do not wish any catalog information returned, pass NULL here.

refs
: On output, a pointer to an array of FSRef (page 837) structures; one for each returned item. On input, if you want an FSRef for each item found, pass a pointer to an array of maximumItems FSRef structures. Otherwise, pass NULL.

names
: On output, a pointer to an array of filenames; one for each returned item. On input, if you want the Unicode filename for each item found, pass a pointer to an array of maximumItems HFSUniStr255 (page 855) structures. Otherwise, pass NULL.

A single search may span more than one call to PBCatalogSearchSync. The call may complete with no error before scanning the entire volume. This typically happens because the time limit (searchTime) has been reached or maximumItems items have been returned. If the search is not completed, you can continue the search by making another call to PBCatalogSearchSync and passing the updated iterator returned by the previous call in the iterator field.

Before calling this function, you should determine that it is present, by calling the Gestalt function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBCatMoveAsync

Moves files or directories from one directory to another on the same volume. (Deprecated in Mac OS X v10.4. Use PBMoveObjectAsync (page 737) instead.)

```
OSErr PBCatMoveAsync (
   CMovePBPtr paramBlock
);
```

Parameters

paramBlock
: A pointer to a catalog move parameter block. See CMovePBRec (page 802) for a description of the CMovePBRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). This function returns permErr if called on a locked file.

Discussion
The relevant fields of the parameter block are:

ioCompletion
: On input, a pointer to a completion function. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
: On output, the result code of the function.

`ioNamePtr`
: On input, a pointer to the name of the file or directory to move.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioNewName`
: On input, a pointer to the name of the destination directory. Pass `NULL` in this field if you wish to specify the destination directory by its directory ID.

`ioNewDirID`
: On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, this is the parent directory ID of the directory into which the file or directory is to be moved. It is usually simplest to specify the destination directory by passing its directory ID in the `ioNewDirID` field and by setting `ioNewName` to `NULL`.

`ioDirID`
: On input, the parent directory ID of the file or directory to move.

`PBCatMoveAsync` is strictly a file catalog operation; it does not actually change the location of the file or directory on the disk. If a file ID reference exists for the file, the file ID reference remains with the moved file.

The `PBCatMoveAsync` function cannot move a file or directory to another volume (that is, the value in the `ioVRefNum` field is used in specifying both the source and the destination). Also, you cannot use it to rename files or directories; to rename a file or directory, use `FSpRename` (page 533) , `PBHRenameSync` (page 716) , or `PBHRenameAsync` (page 715) .

If you need to move files or directories with named forks other than the data and resource forks, with long Unicode names, or files larger than 2GB, you should use the `FSMoveObject` (page 510) function, or one of the corresponding parameter block calls, `PBMoveObjectSync` (page 738) and `PBMoveObjectAsync` (page 737).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBCatMoveSync

Moves files or directories from one directory to another on the same volume. (Deprecated in Mac OS X v10.4. Use `PBMoveObjectSync` (page 738) instead.)

```
OSErr PBCatMoveSync (
   CMovePBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a catalog move parameter block. See `CMovePBRec` (page 802) for a description of the `CMovePBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). This function returns `permErr` if called on a locked file.

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name of the file or directory to move.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioNewName`
On input, a pointer to the name of the destination directory. Pass `NULL` in this field if you wish to specify the destination directory by its directory ID.

`ioNewDirID`
On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, this is the parent directory ID of the destination directory. It is usually simplest to specify the destination directory by passing its directory ID in the `ioNewDirID` field and by setting `ioNewName` to `NULL`.

`ioDirID`
On input, the parent directory ID of the file or directory to move.

`PBCatMoveSync` is strictly a file catalog operation; it does not actually change the location of the file or directory on the disk. If a file ID reference exists for the file, the file ID reference remains with the moved file.

The `PBCatMoveSync` function cannot move a file or directory to another volume (that is, the value in the `ioVRefNum` field is used in specifying both the source and the destination). Also, you cannot use it to rename files or directories; to rename a file or directory, use `FSpRename` (page 533) , `PBHRenameSync` (page 716) , or `PBHRenameAsync` (page 715).

If you need to move files or directories with named forks other than the data and resource forks, with long Unicode names, or files larger than 2GB, you should use the `FSMoveObject` (page 510) function, or one of the corresponding parameter block calls, `PBMoveObjectSync` (page 738) and `PBMoveObjectAsync` (page 737).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBCatSearchAsync

Searches a volume's catalog file using a set of search criteria that you specify. (Deprecated in Mac OS X v10.4. Use `PBCatalogSearchAsync` (page 572) instead.)

```
OSErr PBCatSearchAsync (
   CSParamPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a `CSParam` (page 807) variant of an HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. When `PBCatSearchAsync` has searched the entire volume, it returns `eofErr`. If it exits because it either spends the maximum time allowed in the `ioSearchTime` field or finds the maximum number of matches allowed in the `ioReqMatchCount` field, it returns `noErr`.

`ioNamePtr`

On input, a pointer to the name of the volume to search.

`ioVRefNum`

On input, a volume reference number or drive number for the volume to search; or 0 for the default volume.

`ioMatchPtr`

On input, a pointer to an array of `FSSpec` (page 840) structure to hold the matches found by this function. On return, the `FSSpec` structures in this array identify the files and directories that match the criteria.

`ioReqMatchCount`

On input, the maximum number of matches to return.

`ioActMatchCount`

On output, the actual number of matches returned.

`ioSearchBits`

On input, a bitmap specifying the fields in the criteria structures to match against. See "Catalog Search Masks" (page 900) for a description of the bits in this field.

`ioSearchInfo1`

On input, a pointer to a `CInfoPBRec` (page 802) union containing search information. For values that match by mask and value (Finder information, for example), set the bits in the structure passed in `ioSearchInfo2`, and set the matching value in this structure. For values that match against a range (such as dates), set the lower bounds for the range in this structure.

`ioSearchInfo2`

On input, a pointer to a `CInfoPBRec` (page 802) union containing search information. For values that match by mask and value (Finder information, for example), set the bits in this structure, and set the matching value in the structure passed in the `ioSearchInfo1` field. For values that match against a range (such as dates), set the upper bounds for the range in this structure.

`ioSearchTime`
: On input, the maximum allowed search time. If you pass 0 in this field, no time limit is set.

`ioCatPosition`
: The current catalog position, specified as a `CatPositionRec` (page 801) structure. You can use this field, along with the `ioSearchTime` field, to search a volume in segments. To search a volume in segments, set a time limit for the search in the `ioSearchTime` field and set the `initialize` field of the `CatPositionRec` structure to the location for the start of the search (0 if you wish to start searching at the beginning of the volume). On return, the catalog position will be updated. You can then pass this updated `CatPositionRec` structure to the next call to `PBCatSearchSync` to continue searching at the place where you left off.

`ioOptBuffer`
: On input, a pointer to an optional read buffer.

`ioOptBufSize`
: On input, the length of the optional read buffer.

If the catalog file changes between two timed calls to `PBCatSearchAsync` (that is, when you are using `ioSearchTime` and `ioCatPosition` to search a volume in segments and the catalog file changes between searches), `PBCatSearchAsync` returns a result code of `catChangedErr` and no matches. Depending on what has changed on the volume, `ioCatPosition` might be invalid, most likely by a few entries in one direction or another. You can continue the search, but you risk either skipping some entries or reading some twice.

Special Considerations

Not all volumes support the `PBCatSearchAsync` function. Before you call `PBCatSearchAsync` to search a particular volume, you should call the `PBHGetVolParmsAsync` (page 694) function to determine whether that volume supports `PBCatSearchAsync`. If the `bHasCatSearch` bit is set in the `vMAttrib` field, then the volume supports `PBCatSearchAsync`.

Even though AFP volumes support `PBCatSearchSync`, they do not support all of its features that are available on local volumes. These restrictions apply to AFP volumes:

- AFP volumes do not use the `ioSearchTime` field. Current versions of the AppleShare server software search for 1 second or until 4 matches are found. The AppleShare workstation software keeps requesting the appropriate number of matches until the server returns either the number specified in the `ioReqMatchCount` field or an error.
- AFP volumes do not support both logical and physical fork lengths. If you request a search using the length of a fork, the actual minimum length used is the smallest of the values in the logical and physical fields of the `ioSearchInfo1` structure and the actual maximum length used is the largest of the values in the logical and physical fields of the `ioSearchInfo2` structure.
- The `fsSBNegate` bit of the `ioSearchBits` field is ignored during searches of remote volumes that support AFP version 2.1.
- If the AFP server returns `afpCatalogChanged`, the catalog position structure returned to your application (in the `ioCatPosition` field) is the same one you passed to `PBCatSearchAsync`. You should clear the `initialize` field of that structure to restart the search from the beginning.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBCatSearchSync

Searches a volume's catalog file using a set of search criteria that you specify. (Deprecated in Mac OS X v10.4. Use `PBCatalogSearchSync` (page 573) instead.)

```
OSErr PBCatSearchSync (
   CSParamPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a `CSParam` (page 807) variant of an HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). When `PBCatSearchSync` has searched the entire volume, it returns `eofErr`. If it exits because it either spends the maximum time allowed in the `ioSearchTime` field or finds the maximum number of matches allowed in the `ioReqMatchCount` field, it returns `noErr`.

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to the name of the volume to search.

`ioVRefNum`

On input, a volume reference number or drive number for the volume to search; or 0 for the default volume.

`ioMatchPtr`

On input, a pointer to an array of `FSSpec` (page 840) structure to hold the matches found by this function. On return, the `FSSpec` structures in this array identify the files and directories that match the criteria.

`ioReqMatchCount`

On input, the maximum number of matches to return.

`ioActMatchCount`

On output, the actual number of matches returned.

`ioSearchBits`

On input, a bitmap specifying the fields in the criteria structures to match against. See "Catalog Search Masks" (page 900) for a description of the bits in this field.

`ioSearchInfo1`

On input, a pointer to a `CInfoPBRec` (page 802) union containing search information. For values that match by mask and value (Finder information, for example), set the bits in the structure passed in `ioSearchInfo2`, and set the matching value in this structure. For values that match against a range (such as dates), set the lower bounds for the range in this structure.

`ioSearchInfo2`

On input, a pointer to a `CInfoPBRec` (page 802) union containing search information. For values that match by mask and value (Finder information, for example), set the bits in this structure, and set the

matching value in the structure passed in the `ioSearchInfo1` field. For values that match against a range (such as dates), set the upper bounds for the range in this structure.

`ioSearchTime`
On input, the maximum allowed search time. If you pass 0 in this field, no time limit is set.

`ioCatPosition`
The current catalog position, specified as a `CatPositionRec` (page 801) structure. You can use this field, along with the `ioSearchTime` field, to search a volume in segments. To search a volume in segments, set a time limit for the search in the `ioSearchTime` field and set the `initialize` field of the `CatPositionRec` structure to the location for the start of the search (0 if you wish to start searching at the beginning of the volume). On return, the catalog position will be updated. You can then pass this updated `CatPositionRec` structure to the next call to `PBCatSearchSync` to continue searching at the place where you left off.

`ioOptBuffer`
On input, a pointer to an optional read buffer.

`ioOptBufSize`
On input, the length of the optional read buffer.

If the catalog file changes between two timed calls to `PBCatSearchSync` (that is, when you are using `ioSearchTime` and `ioCatPosition` to search a volume in segments and the catalog file changes between searches), `PBCatSearchSync` returns a result code of `catChangedErr` and no matches. Depending on what has changed on the volume, `ioCatPosition` might be invalid, most likely by a few entries in one direction or another. You can continue the search, but you risk either skipping some entries or reading some twice.

Special Considerations

Not all volumes support the `PBCatSearchSync` function. Before you call `PBCatSearchSync` to search a particular volume, you should call the `PBHGetVolParmsSync` (page 695) function to determine whether that volume supports `PBCatSearchSync`.If the `bHasCatSearch` bit is set in the `vMAttrib` field, then the volume supports `PBCatSearchSync`.

Even though AFP volumes support `PBCatSearchSync`, they do not support all of its features that are available on local volumes. These restrictions apply to AFP volumes:

- AFP volumes do not use the `ioSearchTime` field. Current versions of the AppleShare server software search for 1 second or until 4 matches are found. The AppleShare workstation software keeps requesting the appropriate number of matches until the server returns either the number specified in the `ioReqMatchCount` field or an error.
- AFP volumes do not support both logical and physical fork lengths. If you request a search using the length of a fork, the actual minimum length used is the smallest of the values in the logical and physical fields of the `ioSearchInfo1` structure and the actual maximum length used is the largest of the values in the logical and physical fields of the `ioSearchInfo2` structure.
- The `fsSBNegate` bit of the `ioSearchBits` field is ignored during searches of remote volumes that support AFP version 2.1.
- If the AFP server returns `afpCatalogChanged`, the catalog position structure returned to your application (in the `ioCatPosition` field) is the same one you passed to `PBCatSearchSync`. You should clear the `initialize` field of that structure to restart the search from the beginning.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBCloseAsync

Closes an open file. (Deprecated in Mac OS X v10.5. Use `PBCloseForkAsync` (page 582) instead.)

```
OSErr PBCloseAsync (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a basic File Manager parameter block.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine.

`ioResult`
On output, the result code of the function.

`ioRefNum`
On input, a file reference number to the file to close.

The `PBCloseAsync` function writes the contents of the access path buffer specified by the `ioRefNum` field to the volume and removes the access path.

Special Considerations

Some information stored on the volume won't be updated until `PBFlushVolAsync` is called.

Do not call `PBCloseAsync` with a file reference number of a file that has already been closed. Attempting to close the same file twice may result in loss of data on a volume.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBCloseForkAsync

Closes an open fork.

```
void PBCloseForkAsync (
    FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam`.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`forkRefNum`

On input, the reference number of the fork to close. After the call to this function, the reference number in this parameter is invalid.

The `PBCloseForkAsync` function causes all data written to the fork to be written to disk, in the same manner as the `PBFlushForkAsync` (page 638) function, before it closes the fork.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCloseForkSync

Closes an open fork.

```
OSErr PBCloseForkSync (
    FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam`.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant field of the parameter block is:

`forkRefNum`

On input, the reference number of the fork to close. After the call to this function, the reference number in this parameter is invalid.

The `PBCloseForkSync` function causes all data written to the fork to be written to disk, in the same manner as the `PBFlushForkSync` (page 639) function, before it closes the fork.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCloseIteratorAsync

Closes a catalog iterator.

```
void PBCloseIteratorAsync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`iterator`

On input, the catalog iterator to close. `PBCloseIteratorAsync` releases memory and other system resources used by the iterator, making the iterator invalid. See `FSIterator` (page 835) for a description of the `FSIterator` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCloseIteratorSync

Closes a catalog iterator.

```
OSErr PBCloseIteratorSync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant field of the parameter block is:

`iterator`
On input, the catalog iterator to close. `PBCloseIteratorSync` releases memory and other system resources used by the iterator, making the iterator invalid. See `FSIterator` (page 835) for a description of the `FSIterator` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCloseSync

Closes an open file. (Deprecated in Mac OS X v10.5. Use `PBCloseForkSync` (page 583) instead.)

```
OSErr PBCloseSync (
    ParmBlkPtr paramBlock
);
```

Parameters
paramBlock
A pointer to a basic File Manager parameter block.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant field of the parameter block is:

`ioRefNum`
On input, a file reference number to the file to close.

The `PBCloseSync` function writes the contents of the access path buffer specified by the `ioRefNum` field to the volume and removes the access path.

Special Considerations

Some information stored on the volume won't be updated until `PBFlushVolSync` is called.

Do not call `PBCloseSync` with a file reference number of a file that has already been closed. Attempting to close the same file twice may result in loss of data on a volume.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBCompareFSRefsAsync

Determines whether two FSRef structures refer to the same file or directory.

```
void PBCompareFSRefsAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Discussion

The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information about completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function. If the two FSRef structures refer to the same file or directory, then noErr is returned. If they refer to objects on different volumes, then diffVolErr is returned. If they refer to different files or directories on the same volume, then errFSRefsDifferent is returned. This call may return other errors, including nsvErr, fnfErr, dirNFErr, and volOffLinErr. See "File Manager Result Codes".

ref

On input, a pointer to the first FSRef to compare. See FSRef (page 837) for a description of the FSRef data type.

parentRef

On input, a pointer to the second FSRef to compare.

You must use FSCompareFSRefs (page 476) , or one of the corresponding parameter block functions, PBCompareFSRefsSync (page 586) and PBCompareFSRefsAsync, to compare FSRef structures. It is not possible to compare the FSRef structures directly since some bytes may be uninitialized, case-insensitive text, or contain hint information.

Some volume formats may be able to tell that two FSRef structures would refer to two different files or directories, without having to actually find those objects. In this case, the volume format may return errFSRefsDifferent even if one or both objects no longer exist. Similarly, if the FSRef structures are for objects on different volumes, the File Manager will return diffVolErr even if one or both volumes are no longer mounted.

Availability

Available in Mac OS X v10.0 and later.

Declared In

Files.h

PBCompareFSRefsSync

Determines whether two FSRef structures refer to the same file or directory.

```
OSErr PBCompareFSRefsSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). If the two `FSRef` structures refer to the same file or directory, then `noErr` is returned. If they refer to objects on different volumes, then `diffVolErr` is returned. If they refer to different files or directories on the same volume, then `errFSRefsDifferent` is returned. This function may return other errors, including `nsvErr`, `fnfErr`, `dirNFErr`, and `volOffLinErr`.

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to the first `FSRef` to compare. See `FSRef` (page 837) for a description of the `FSRef` data type.

`parentRef`

On input, a pointer to the second `FSRef` to compare.

You must use `FSCompareFSRefs` (page 476) , or one of the corresponding parameter block functions, `PBCompareFSRefsSync` and `PBCompareFSRefsAsync` (page 586) , to compare `FSRef` structures. It is not possible to compare the `FSRef` structures directly since some bytes may be uninitialized, case-insensitive text, or contain hint information.

Some volume formats may be able to tell that two `FSRef` structures would refer to two different files or directories, without having to actually find those objects. In this case, the volume format may return `errFSRefsDifferent` even if one or both objects no longer exist. Similarly, if the `FSRef` structures are for objects on different volumes, the File Manager will return `diffVolErr` even if one or both volumes are no longer mounted.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBCreateDirectoryUnicodeAsync

Creates a new directory (folder) with a Unicode name.

```
void PBCreateDirectoryUnicodeAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information about completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. See "File Manager Result Codes".

`ref`
: On input, a pointer to an `FSRef` (page 837) for the parent directory where the new directory is to be created.

`nameLength`
: On input, the number of Unicode characters in the new directory's name.

`name`
: On input, a pointer to the Unicode name of the new directory.

`whichInfo`
: On input, a bitmap specifying which catalog information fields to set for the new directory. Specify the values for these fields in the `catInfo` field. If you do not wish to set catalog information for the new directory, specify the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this field.

`catInfo`
: On input, a pointer to the `FSCatalogInfo` (page 826) structure which specifies the values of the new directory's catalog information fields. Specify which fields to set in the `whichInfo` field. Specify `NULL` if you do not wish to set catalog information for the new directory.

`newRef`
: On output, a pointer to the `FSRef` for the new directory. If you do not want the `FSRef` returned, pass `NULL` on input.

`spec`
: On output, a pointer to the `FSSpec` (page 840) for the new directory. If you do not want the `FSSpec` returned, pass `NULL` on input.

`ioDirID`
: On output, the directory ID of the new directory.

You may optionally set catalog information for the new directory using the `whichInfo` and `catInfo` fields; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the directory.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catInfo` field. This will be used by the volume format when converting the Unicode filename to other encodings.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCreateDirectoryUnicodeSync

Creates a new directory (folder) with a Unicode name.

```
OSErr PBCreateDirectoryUnicodeSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) for the parent directory where the new directory is to be created.

`nameLength`

On input, the number of Unicode characters in the new directory's name.

`name`

On input, a pointer to the Unicode name of the new directory.

`whichInfo`

On input, a bitmap specifying which catalog information fields to set for the new directory. Specify the values for these fields in the `catInfo` field. If you do not wish to set catalog information for the new directory, specify the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this field.

`catInfo`

On input, a pointer to the `FSCatalogInfo` (page 826) structure which specifies the values of the new directory's catalog information fields. Specify which fields to set in the `whichInfo` field. Specify `NULL` if you do not wish to set catalog information for the new directory.

`newRef`

On output, a pointer to the `FSRef` for the new directory. If you do not want the `FSRef` returned, pass `NULL` on input.

`spec`

On output, a pointer to the `FSSpec` (page 840) for the new directory. If you do not want the `FSSpec` returned, pass `NULL` on input.

`ioDirID`

On output, the directory ID of the new directory.

You may optionally set catalog information for the new directory using the `whichInfo` and `catInfo` fields; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the directory.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catInfo` field. This will be used by the volume format when converting the Unicode filename to other encodings.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCreateFileIDRefAsync

Establishes a file ID reference for a file. (Deprecated in Mac OS X v10.5. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr PBCreateFileIDRefAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `FIDParam` (page 818) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDs internally as part of its search algorithms for finding the target of an alias record.

Given a volume reference number, filename, and parent directory ID, the `PBCreateFileIDRefAsync` function creates a structure to hold the name and parent directory ID of the specified file. The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. `PBCreateFileIDRefAsync` returns the result code `fidExists` if a file ID reference already exists for the file.

`ioNamePtr`
On input, a pointer to the file's name.

`ioVRefNum`
On input, a volume reference number for the volume containing the file.

`ioSrcDirID`
On input, the file's parent directory ID.

`ioFileID`
On output, a file ID. If a file ID reference already exists for the file, `PBCreateFileIDRefAsync` supplies the file ID but returns the result code `fidExists`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Files.h

PBCreateFileIDRefSync

Establishes a file ID reference for a file. (Deprecated in Mac OS X v10.5. Use FSGetCatalogInfo (page 494) instead.)

```
OSErr PBCreateFileIDRefSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the FIDParam (page 818) variant of the HFS parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).PBCreateFileIDRefSync returns the result code fidExists if a file ID reference already exists for the file.

Discussion
Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDs internally as part of its search algorithms for finding the target of an alias record.

Given a volume reference number, filename, and parent directory ID, the PBCreateFileIDRefSync function creates a structure to hold the name and parent directory ID of the specified file. The relevant fields of the parameter block are:

ioNamePtr
On input, a pointer to the file's name.

ioVRefNum
On input, a volume reference number for the volume containing the file.

ioSrcDirID
On input, the file's parent directory ID.

ioFileID
On output, a file ID. If a file ID reference already exists for the file, PBCreateFileIDRefSync supplies the file ID but returns the result code fidExists.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Files.h

PBCreateFileUnicodeAsync

Creates a new file with a Unicode name.

```
void PBCreateFileUnicodeAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. See "File Manager Result Codes".

`ref`

On input, a pointer to an `FSRef` (page 837) for the directory where the file is to be created.

`nameLength`

On input, the number of Unicode characters in the file's name.

`name`

On input, a pointer to the Unicode name of the new file.

`whichInfo`

On input, a bitmap specifying which catalog information fields to set for the new file. Specify the values for these fields in the `catInfo` field. If you do not wish to set catalog information for the new file, pass the constant `kFSCatInfoNone` here. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this field.

`catInfo`

On input, a pointer to the `FSCatalogInfo` (page 826) structure which specifies the values of the new file's catalog information fields. Specify which fields to set in the `whichInfo` field. This field is optional; specify `NULL` if you do not wish to set catalog information for the new file.

`newRef`

On output, a pointer to the `FSRef` for the new file. If you do not want the `FSRef` returned, pass `NULL` on input.

`spec`

On output, a pointer to the `FSSpec` for the new file. If you do not want the `FSSpec` (page 840) returned, pass `NULL` on input.

You may optionally set catalog information for the file using the `whichInfo` and `catInfo` fields; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the file.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catInfo` field. This will be used by the volume format when converting the Unicode filename to other encodings.

Special Considerations

If the `PBCreateFileUnicodeAsync` function is present, but is not implemented by a particular volume, the File Manager will emulate this function by making the appropriate call to `PBHCreateAsync` (page 676). However, if the function is not directly supported by the volume, you will not be able to use the long Unicode filenames, or other features added with HFS Plus.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBCreateFileUnicodeSync

Creates a new file with a Unicode name.

```
OSErr PBCreateFileUnicodeSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) for the directory where the file is to be created.

`nameLength`

On input, the number of Unicode characters in the file's name.

`name`

On input, a pointer to the Unicode name of the new file.

`whichInfo`

On input, a bitmap specifying which catalog information fields to set for the new file. Specify the values for these fields in the `catInfo` field. If you do not wish to set catalog information for the new file, pass the constant `kFSCatInfoNone` here. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits defined for this field.

`catInfo`

On input, a pointer to the `FSCatalogInfo` (page 826) structure which specifies the values of the new file's catalog information fields. Specify which fields to set in the `whichInfo` field. This field is optional; specify `NULL` if you do not wish to set catalog information for the new file.

`newRef`

On output, a pointer to the `FSRef` for the new file. If you do not want the `FSRef` returned, set this field to `NULL` on input.

`spec`

On output, a pointer to the `FSSpec` (page 840) for the new file. If you do not want the `FSSpec` returned, set this field to `NULL` on input.

You may optionally set catalog information for the new file using the `whichInfo` and `catInfo` fields; this is equivalent to calling `FSSetCatalogInfo` (page 540) , or one of the corresponding parameter block functions, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751) , after creating the file.

If possible, you should set the `textEncodingHint` field of the catalog information structure specified in the `catInfo` field. This will be used by the volume format when converting the Unicode filename to other encodings.

Special Considerations

If the `PBCreateFileUnicodeSync` function is present, but is not implemented by a particular volume, the File Manager will emulate this function by making the appropriate call to `PBHCreateSync` (page 677). However, if the function is not directly supported by the volume, you will not be able to use the long Unicode filenames, or other features added with HFS Plus.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCreateForkAsync

Creates a named fork for a file or directory.

```
void PBCreateForkAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. If the named fork already exists, the function returns `errFSForkExists`. If the fork name is syntactically invalid or otherwise unsupported for the given volume, `PBCreateForkAsync` returns `errFSBadForkName` or `errFSNameTooLong`.

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory.

`forkNameLength`

On input, the length of the Unicode name of the new fork.

`forkName`
On input, a pointer to the Unicode name of the fork.

A newly created fork has zero length (that is, its logical end-of-file is zero). The data and resource forks of a file are automatically created and deleted as needed. This is done for compatibility with older APIs, and because data and resource forks are often handled specially. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), an attempt to create that fork when a zero-length fork already exists should return `noErr`; if a non-empty fork already exists then `errFSForkExists` should be returned.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBCreateForkSync

Creates a named fork for a file or directory.

```
OSErr PBCreateForkSync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). . If the named fork already exists, the function returns `errFSForkExists`. If the fork name is syntactically invalid or otherwise unsupported for the given volume, `PBCreateForkSync` returns `errFSBadForkName` or `errFSNameTooLong`.

Discussion
The relevant fields of the parameter block are:

`ioResult`
On output, the result code of the function. If the named fork already exists, the function returns `errFSForkExists`. If the fork name is syntactically invalid or otherwise unsupported for the given volume, `PBCreateForkAsync` returns `errFSBadForkName` or `errFSNameTooLong`.

`ref`
On input, a pointer to an `FSRef` (page 837) specifying the file or directory.

`forkNameLength`
On input, the length of the Unicode name of the new fork.

`forkName`
On input, a pointer to the Unicode name of the fork.

A newly created fork has zero length (that is, its logical end-of-file is zero). The data and resource forks of a file are automatically created and deleted as needed. This is done for compatibility with older APIs, and because data and resource forks are often handled specially. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), an attempt to create that fork when a zero-length fork already exists should return `noErr`; if a non-empty fork already exists then `errFSForkExists` should be returned.

Availability
Available in Mac OS X v10.0 and later.

`Files.h`

PBDeleteFileIDRefAsync

Deletes a file ID reference. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr PBDeleteFileIDRefAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `FIDParam` (page 818) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDs internally as part of its search algorithms for finding the target of an alias record.

The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname.

`ioVRefNum`
On input, a volume specification for the volume containing the file.

`ioFileID`
On input, the file ID reference to delete. After it has invalidated a file ID reference, the File Manager can no longer resolve that ID reference to a filename and parent directory ID.

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDeleteFileIDRefSync

Deletes a file ID reference. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr PBDeleteFileIDRefSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `FIDParam` (page 818) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDs internally as part of its search algorithms for finding the target of an alias record.

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a pathname.

`ioVRefNum`

On input, a volume specification for the volume containing the file.

`ioFileID`

On input, the file ID reference to delete. After it has invalidated a file ID reference, the File Manager can no longer resolve that ID reference to a filename and parent directory ID.

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDeleteForkAsync

Deletes a named fork of a file or directory.

```
void PBDeleteForkAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. If the named fork does not exist, the function returns `errFSForkNotFound`.

`ref`
On input, a pointer to an `FSRef` (page 837) for the file or directory from which to delete the fork.

`forkNameLength`
On input, the length of the fork's Unicode name.

`forkName`
On input, a pointer to the Unicode name of the fork to delete.

The `permissions`, `forkRefNum`, `positionMode`, and `positionOffset` fields of the parameter block may be modified by this call.

Any storage allocated to the fork is released. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), this is equivalent to setting the logical size of the fork to zero.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBDeleteForkSync

Deletes a named fork from a file or directory.

```
OSErr PBDeleteForkSync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the named fork does not exist, the function returns `errFSForkNotFound`.

Discussion
The relevant fields of the parameter block are:

`ref`
On input, a pointer to an `FSRef` (page 837) for the file or directory from which to delete the fork.

`forkNameLength`
On input, the length of the fork's Unicode name.

`forkName`
On input, a pointer to the Unicode name of the fork to delete.

The `permissions`, `forkRefNum`, `positionMode`, and `positionOffset` fields of the parameter block may be modified by this call.

Any storage allocated to the fork is released. If a given fork always exists for a given volume format (such as data and resource forks for HFS and HFS Plus, or data forks for most other volume formats), this is equivalent to setting the logical size of the fork to zero.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBDeleteObjectAsync

Deletes a file or an empty directory.

```
void PBDeleteObjectAsync (
   FSRefParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
A result code. See "File Manager Result Codes" (page 943). If you attempt to delete a folder for which there is an open catalog iterator, this function succeeds and returns `noErr`. Iteration, however, will continue to work until the iterator is closed.

`ref`
On input, a pointer to the `FSRef` (page 837) for the file or directory to be deleted. If the object to be deleted is a directory, it must be empty (it must contain no files or folders).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBDeleteObjectSync

Deletes a file or an empty directory.

```
OSErr PBDeleteObjectSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you attempt to delete a folder for which there is an open catalog iterator, this function succeeds and returns `noErr`. Iteration, however, will continue to work until the iterator is closed.

Discussion

The relevant field of the parameter block is:

`ref`

On input, a pointer to the `FSRef` (page 837) for the file or directory to be deleted. If the object to be deleted is a directory, it must be empty (it must contain no files or folders).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBDirCreateAsync

Creates a new directory. (Deprecated in Mac OS X v10.4. Use `PBCreateDirectoryUnicodeAsync` (page 587) instead.)

```
OSErr PBDirCreateAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the name for the new directory.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the parent directory ID. If the parent directory ID is 0 and the volume specified in the `ioVRefNum` field is the default volume, the new directory is placed in the default directory of the volume. If the parent directory ID is 0 and the volume specified in the `ioVRefNum` field is a volume other than the default volume, the new directory is placed in the root directory of the volume. To create a directory at the root of a volume, regardless of whether that volume is the current default volume, pass the constant `fsRtDirID` (2) in this field. On output, the directory ID of the new directory. Note that a directory ID, unlike a volume reference number, is a long integer.

The `PBDirCreateAsync` function is identical to `PBHCreateAsync` (page 676) except that it creates a new directory instead of a file. The date and time of the directory's creation and last modification are set to the current date and time.

To create a directory with a Unicode name, use the function `FSCreateDirectoryUnicode` (page 479) , or one of the corresponding parameter block calls, `PBCreateDirectoryUnicodeSync` (page 589) and `PBCreateDirectoryUnicodeAsync` (page 587).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDirCreateSync

Creates a new directory. (Deprecated in Mac OS X v10.4. Use `PBCreateDirectoryUnicodeSync` (page 589) instead.)

```
OSErr PBDirCreateSync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name for the new directory.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the parent directory ID. If the parent directory ID is 0 and the volume specified in the `ioVRefNum` field is the default volume, the new directory is placed in the default directory of the volume. If the parent directory ID is 0 and the volume specified in the `ioVRefNum` field is a volume other than the default volume, the new directory is placed in the root directory of the volume. To create a directory at the root of a volume, regardless of whether that volume is the current default volume, pass the constant `fsRtDirID` (2) in this field. On output, the directory ID of the new directory. Note that a directory ID, unlike a volume reference number, is a long integer.

The `PBDirCreateSync` function is identical to `PBHCreateSync` (page 677) except that it creates a new directory instead of a file. The date and time of the directory's creation and last modification are set to the current date and time.

To create a directory with a Unicode name, use the function `FSCreateDirectoryUnicode` (page 479) , or one of the corresponding parameter block calls, `PBCreateDirectoryUnicodeSync` (page 589) and `PBCreateDirectoryUnicodeAsync` (page 587).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTAddAPPLAsync

Adds an application to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTAddAPPLAsync (
   DTPBPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. See "File Manager Result Codes".

`ioNamePtr`
On input, a pointer to the application's name.

`ioDTRefNum`
On input, the desktop database reference number of the desktop database to which you wish to add an application.

`ioTagInfo`
Reserved; on input, this field must be set to 0.

`ioDirID`
On input, the ID of the application's parent directory.

`ioFileCreator`
On input, the application's signature.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTAddAPPLSync

Adds an application to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTAddAPPLSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`
On input, a pointer to the application's name.

`ioDTRefNum`
On input, the desktop database reference number of the desktop database to which you wish to add an application.

`ioTagInfo`
Reserved; on input, this field must be set to 0.

`ioDirID`
On input, the ID of the application's parent directory.

`ioFileCreator`
On input, the application's signature.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`Files.h`

PBDTAddIconAsync

Adds an icon definition to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTAddIconAsync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. See "File Manager Result Codes".

`ioDTRefNum`
On input, the desktop database reference number of the database to which you wish to add an icon.

`ioTagInfo`
Reserved; on input, this field must be set to 0.

`ioDTBuffer`
On input, a pointer to the buffer holding the icon's bitmap.

`ioDTReqCount`
On input, the size in bytes of the buffer that you've allocated for the icon's bitmap. This value depends on the icon type. Be sure to allocate enough storage for the icon data 1024 bytes is the largest amount

required for any icon in System 7. For a description of the values you can use to indicate the icon's size, see "Icon Size Constants" (page 921).

`ioIconType`
On input, the icon type. See "Icon Type Constants" (page 922) for a description of the values you can use in this field.

`ioFileCreator`
On input, the icon's file creator.

`ioFileType`
On input, the icon's file type.

If the database already contains an icon definition for an icon of that type, file type, and file creator, the new definition replaces the old.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTAddIconSync

Adds an icon definition to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTAddIconSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

`ioDTRefNum`
On input, the desktop database reference number of the database to which you wish to add an icon.

`ioTagInfo`
Reserved; on input, this field must be set to 0.

`ioDTBuffer`
On input, a pointer to the buffer holding the icon's bitmap.

`ioDTReqCount`
: On input, the size in bytes of the buffer that you've allocated for the icon's bitmap. This value depends on the icon type. Be sure to allocate enough storage for the icon data 1024 bytes is the largest amount required for any icon in System 7 For a description of the values you can use to indicate the icon's size, see "Icon Size Constants" (page 921).

`ioIconType`
: On input, the icon type. See "Icon Type Constants" (page 922) for a description of the values you can use in this field.

`ioFileCreator`
: On input, the icon's file creator.

`ioFileType`
: On input, the icon's file type.

If the database already contains an icon definition for an icon of that type, file type, and file creator, the new definition replaces the old.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTCloseDown

Closes the desktop database, though your application should never do this itself. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTCloseDown (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant field of the parameter block for this function is:

`ioDTRefNum`
: On input, the desktop database reference number.

System software uses the `PBDTCloseDown` function to close the desktop database; your application should never use this function, which is described here only for completeness. The system software closes the database when the volume is unmounted.

`PBDTCloseDown` runs synchronously only, and though it will not close down the desktop databases of remote volumes, it will invalidate all local desktop database reference values for remote desktop databases.

When the `PBDTCloseDown` function closes the database, it frees all resources allocated by `PBDTOpenInform` (page 623) or `PBDTGetPath` (page 622).

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTDeleteAsync

Removes the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTDeleteAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBDTDeleteAsync` function removes the desktop database from a local volume. You can call `PBDTDeleteAsync` only when the database is closed. Your application should not call `PBDTDeleteAsync` unless absolutely necessary.

The relevant fields of the parameter block for this function are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. See "File Manager Result Codes".

`ioVRefNum`

On input, the volume reference number of the desktop database to remove.

`ioIndex`
Reserved; on input, this field must be set to 0.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTDeleteSync

Removes the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTDeleteSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBDTDeleteSync` function removes the desktop database from a local volume. You can call `PBDTDeleteSync` only when the database is closed. Your application should not call `PBDTDeleteSync` unless absolutely necessary.

The relevant fields of the parameter block for this function are:

`ioVRefNum`
On input, the volume reference number of the desktop database to remove.

`ioIndex`
Reserved; on input, this field must be set to 0.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

PBDTFlushAsync

Saves your changes to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTFlushAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a desktop database parameter block. See DTPBRec (page 813) for a description of the DTPBRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If your application adds information to or removes information from the desktop database, use the PBDTFlushAsync function to save your changes. The PBDTFlushAsync function writes the contents of the desktop database specified in the ioDTRefNum field to the volume.

The relevant fields of the parameter block for this function are:

ioCompletion
On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
On output, the result code of the function. See "File Manager Result Codes".

ioDTRefNum
On input, the desktop database reference number of the desktop database to flush.

You must call PBDTFlushAsync or PBDTFlushSync (page 610) to update the copy of the desktop database stored on the volume if your application has manipulated information in the database using any of the following functions:

- PBDTAddIconSync (page 605)
- PBDTAddIconAsync (page 604)
- PBDTAddAPPLSync (page 603)
- PBDTAddAPPLAsync (page 602)
- PBDTSetCommentSync (page 630)
- PBDTSetCommentAsync (page 629)
- PBDTRemoveAPPLSync (page 625)
- PBDTRemoveAPPLAsync (page 624)
- PBDTRemoveCommentSync (page 627)
- PBDTRemoveCommentAsync (page 626)

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTFlushSync

Saves your changes to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTFlushSync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

If your application adds information to or removes information from the desktop database, use the `PBDTFlushSync` function to save your changes. The `PBDTFlushSync` function writes the contents of the desktop database specified in the `ioDTRefNum` field to the volume.

The relevant field of the parameter block for this function is:

`ioDTRefNum`

On input, the desktop database reference number of the desktop database to flush.

You must call `PBDTFlushSync` or `PBDTFlushAsync` (page 609) to update the copy of the desktop database stored on the volume if your application has manipulated information in the database using any of the following functions:

- `PBDTAddIconSync` (page 605)
- `PBDTAddIconAsync` (page 604)
- `PBDTAddAPPLSync` (page 603)
- `PBDTAddAPPLAsync` (page 602)
- `PBDTSetCommentSync` (page 630)
- `PBDTSetCommentAsync` (page 629)
- `PBDTRemoveAPPLSync` (page 625)
- `PBDTRemoveAPPLAsync` (page 624)

- PBDTRemoveCommentSync (page 627)
- PBDTRemoveCommentAsync (page 626)

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Files.h

PBDTGetAPPLAsync

Identifies the application that can open a file with a given creator. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetAPPLAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See DTPBRec (page 813) for a description of the DTPBRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code. See "File Manager Result Codes".

ioNamePtr

On output, a pointer to the application's name.

ioDTRefNum

On input, the desktop database reference number of the desktop database containing the specified application.

ioIndex

On input, an index into the application list.

ioTagInfo

On output, the application's creation date.

`ioFileCreator`
On input, the signature of the application.

`ioAPPLParID`
On output, the application's parent directory.

A single call, with the `ioIndex` field set to 0, finds the application file with the most recent creation date. If you want to retrieve information about all copies of the application with the given signature, start with `ioIndex` set to 1 and increment this value by 1 with each call to `PBDTGetAPPLAsync` until the result code `afpItemNotFound` is returned in the `ioResult` field; when called multiple times in this fashion, `PBDTGetAPPLAsync` returns information about all the application's copies, including the file with the most recent creation date, in arbitrary order.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTGetAPPLSync

Identifies the application that can open a file with a given creator. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetAPPLSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`
On output, a pointer to the application's name.

`ioDTRefNum`
On input, the desktop database reference number of the desktop database containing the specified application.

`ioIndex`
On input, an index into the application list.

`ioTagInfo`
On output, the application's creation date.

`ioFileCreator`
On input, the signature of the application.

`ioAPPLParID`
On output, the application's parent directory.

A single call, with the `ioIndex` field set to 0, finds the application file with the most recent creation date. If you want to retrieve information about all copies of the application with the given signature, start with `ioIndex` set to 1 and increment this value by 1 with each call to `PBDTGetAPPLSync` until the result code `afpItemNotFound` is returned in the `ioResult` field; when called multiple times in this fashion, `PBDTGetAPPLSync` returns information about all the application's copies, including the file with the most recent creation date, in arbitrary order.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTGetCommentAsync

Retrieves the user comments for a file or directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetCommentAsync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. See "File Manager Result Codes".

`ioNamePtr`
On input, a pointer to the name of the file or directory for which you want to retrieve comments.

`ioDTRefNum`
On input, the desktop database reference number of the database in which the specified file or directory is found.

`ioDTBuffer`
On input, a pointer to a buffer allocated to hold the comment text. On output, a pointer to the comment text. Allocate a buffer at least 255 bytes in size. The `PBDTGetCommentAsync` function places up to `ioDTReqCount` bytes of the comment into the buffer as a plain text string and places the actual length of the comment in the `ioDTActCount` field.

`ioDTReqCount`
On input, the size of the buffer allocated to hold the comment.

`ioDTActCount`
On output, the comment size.

`ioDirID`
On input, the parent directory of the file or directory.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTGetCommentSync

Retrieves the user comments for a file or directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetCommentSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`
On input, a pointer to the name of the file or directory for which you want to retrieve comments.

`ioDTRefNum`
: On input, the desktop database reference number of the database in which the specified file or directory is found.

`ioDTBuffer`
: On input, a pointer to a buffer allocated to hold the comment text. On output, a pointer to the comment text. Allocate a buffer at least 255 bytes in size. The `PBDTGetCommentSync` function places up to `ioDTReqCount` bytes of the comment into the buffer as a plain text string and places the actual length of the comment in the `ioDTActCount` field.

`ioDTReqCount`
: On input, the size of the buffer allocated to hold the comment.

`ioDTActCount`
: On output, the comment size.

`ioDirID`
: On input, the parent directory of the file or directory.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTGetIconAsync

Retrieves an icon definition. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetIconAsync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBDTGetIconAsync` function returns the bitmap for an icon that represents a file of a given type and creator. For example, to get the icon for a file of file type `'SFWR'` created by the application with a signature of `'WAVE'`, specify these two values in the `ioFileType` and `ioFileCreator` fields.

The relevant fields of the parameter block for this function are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. See "File Manager Result Codes".

`ioDTRefNum`
: On input, the desktop database reference number.

`ioTagInfo`
: Reserved; on input, this field must be set to 0.

`ioDTBuffer`
: On input, a pointer to a buffer to hold the icon's data. On return, a pointer to the bitmap returned in the buffer.

`ioDTReqCount`
: On input, the requested size of the icon's bitmap. Pass the size in bytes of the buffer that you've allocated for the icon's bitmap pointed to by the `ioDTBuffer` field; this value depends on the icon type. Be sure to allocate enough storage for the icon data; 1024 bytes is the largest amount required for any icon in System 7. You can use the constants described in "Icon Size Constants" (page 921) to indicate the amount of memory you have provided for the icon's data.

`ioDTActCount`
: On return, the actual size of the icon's bitmap. If this value is larger than the value specified in the `ioDTReqCount` field, only the amount of data allowed by the value in the `ioDTReqCount` field is valid.

`ioIconType`
: On input, the icon type. For a description of the constants which you can use in this field, see "Icon Type Constants" (page 922).

`ioFileCreator`
: On input, the icon's file creator.

`ioFileType`
: On input, the icon's file type.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTGetIconInfoAsync

Retrieves an icon type and the associated file type supported by a given creator in the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetIconInfoAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. See "File Manager Result Codes".

`ioDTRefNum`

On input, the desktop database reference number.

`ioIndex`

On input, an index into the icon list.

`ioTagInfo`

Reserved; on input, this field must be set to 0.

`ioDTActCount`

On output, the size of the icon's bitmap.

`ioIconType`

On output, the icon type, including the icon size and color depth. For a description of the values which may be returned in this field, see "Icon Type Constants" (page 922). Ignore any values returned in `ioIconType` that are not listed there; they represent special icons and information used only by the Finder.

`ioFileCreator`

On input, the icon's file creator.

`ioFileType`

On output, the icon's file type.

To step through a list of the icon types and file types supported by an application, make repeated calls to `PBDTGetIconInfoAsync`, specifying a creator and an index value in the `ioIndex` field for each call. Set the index to 1 on the first call, and increment it on each subsequent call until the result code `afpItemNotFound` is returned in the `ioResult` field.

To get a list of file types that an application can natively open, you can use the Translation Manager function, `GetFileTypesThatAppCanNativelyOpen`. For a description of this function, see the *Translation Manager Reference* .

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTGetIconInfoSync

Retrieves an icon type and the associated file type supported by a given creator in the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetIconInfoSync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioDTRefNum`
On input, the desktop database reference number.

`ioIndex`
On input, an index into the icon list.

`ioTagInfo`
Reserved; on input, this field must be set to 0.

`ioDTActCount`
On output, the size of the icon's bitmap.

`ioIconType`
On output, the icon type, including the icon size and color depth. For a description of the values which may be returned in this field, see "Icon Type Constants" (page 922). Ignore any values returned in `ioIconType` that are not listed there; they represent special icons and information used only by the Finder.

`ioFileCreator`
On input, the icon's file creator.

`ioFileType`
On output, the icon's file type.

To step through a list of the icon types and file types supported by an application, make repeated calls to `PBDTGetIconInfoSync`, specifying a creator and an index value in the `ioIndex` field for each call. Set the index to 1 on the first call, and increment it on each subsequent call until the result code `afpItemNotFound` is returned in the `ioResult` field.

To get a list of file types that an application can natively open, you can use the Translation Manager function, `GetFileTypesThatAppCanNativelyOpen`. For a description of this function, see the *Translation Manager Reference* .

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

`Files.h`

PBDTGetIconSync

Retrieves an icon definition. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetIconSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBDTGetIconSync` function returns the bitmap for an icon that represents a file of a given type and creator. For example, to get the icon for a file of file type `'SFWR'` created by the application with a signature of `'WAVE'`, specify these two values in the `ioFileType` and `ioFileCreator` fields.

The relevant fields of the parameter block for this function are:

`ioDTRefNum`

On input, the desktop database reference number.

`ioTagInfo`

Reserved; on input, this field must be set to 0.

`ioDTBuffer`

On input, a pointer to a buffer to hold the icon's data. On return, a pointer to the bitmap returned in the buffer.

`ioDTReqCount`

On input, the requested size of the icon's bitmap. Pass the size in bytes of the buffer that you've allocated for the icon's bitmap, pointed to by the `ioDTBuffer` field; this value depends on the icon type. Be sure to allocate enough storage for the icon data; 1024 bytes is the largest amount required for any icon in System 7. You can use the constants described in "Icon Size Constants" (page 921) to indicate the amount of memory you have provided for the icon's data.

`ioDTActCount`
: On output, the actual size of the icon's bitmap. If this value is larger than the value specified in the `ioDTReqCount` field, only the amount of data allowed by `ioDTReqCount` is valid.

`ioIconType`
: On input, the icon type. For a description of the constants which you can use in this field, see "Icon Type Constants" (page 922).

`ioFileCreator`
: On input, the icon's file creator.

`ioFileType`
: On input, the icon's file type.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTGetInfoAsync

Determines information about the location and size of the desktop database on a particular volume. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetInfoAsync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

`ioCompletion`
: On input, a pointer to a completion function. For more information on completion functions, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. See "File Manager Result Codes".

`ioVRefNum`
: On output, the volume reference number of the volume where the database files are stored.

`ioDTRefNum`
: On input, the desktop database reference number of the database which you wish to obtain information about.

`ioIndex`
: On output, the number of files comprising the desktop database on the volume.

`ioDirID`
: On output, the parent directory ID of the desktop database.

`ioDTLgLen`
: On output, the logical length of the database files (the sum of the logical lengths of the files that constitute the desktop database for a given volume).

`ioDTPyLen`
: On output, the physical length of the database files (the sum of the physical lengths of the files that constitute the desktop database for a given volume).

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTGetInfoSync

Determines information about the location and size of the desktop database on a particular volume. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetInfoSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

`ioVRefNum`
: On output, the volume reference number of the volume where the database files are stored.

`ioDTRefNum`
: On input, the desktop database reference number of the database which you wish to obtain information about.

`ioIndex`
On output, the number of files comprising the desktop database on the volume.

`ioDirID`
On output, the parent directory ID of the desktop database.

`ioDTLgLen`
On output, the logical length of the database files (the sum of the logical lengths of the files that constitute the desktop database for a given volume).

`ioDTPyLen`
On output, the physical length of the database files (the sum of the physical lengths of the files that constitute the desktop database for a given volume).

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTGetPath

Gets the reference number of the specified desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTGetPath (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`
On input, a pointer to the name of the volume associated with the desktop database or the full pathname of the desktop database.

`ioVRefNum`
On input, the volume reference number of the volume associated with the desktop database.

`ioDTRefNum`
On output, the desktop database reference number, which represents the access path to the database. You cannot use the desktop reference number as a file reference number in any File Manager functions other than the desktop database functions. If `PBDTGetPath` fails, it sets this field to 0.

If the desktop database is not already open, `PBDTGetPath` opens it and then returns the reference number. If the desktop database doesn't exist, `PBDTGetPath` creates it .

Special Considerations

`PBDTGetPath` allocates memory in the system heap; do not call it at interrupt time.

This function executes synchronously only.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTOpenInform

Gets the reference number of the specified desktop database, reporting whether the desktop database was empty when it was opened. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTOpenInform (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`
On input, a pointer to the name of the volume associated with the desktop database or the full pathname of the desktop database.

`ioVRefNum`
On input, the volume reference number of the volume associated with the desktop database.

`ioDTRefNum`
On output, the desktop database reference number, which represents the access path to the database. You cannot use the desktop reference number as a file reference number in any File Manager functions other than the desktop database functions. If `PBDTOpenInform` fails, it sets this field to 0.

`ioTagInfo`
On output, the return flag (in the low bit of this field). If the desktop database was just created in response to `PBDTOpenInform` (and is therefore empty), `PBDTOpenInform` sets the low bit in this field to 0. If the desktop database had been created before you called `PBDTOpenInform`, `PBDTOpenInform` sets the low bit in this field to 1.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

This function executes synchronously only.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`Files.h`

PBDTRemoveAPPLAsync

Removes an application from the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTRemoveAPPLAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). When called on an HFS CD volume, PBDTRemoveAPPL returns an afpItemNotFound error, instead of the expected volume locked error (wPrErr).

Discussion

The `PBDTRemoveAPPLAsync` function removes the mapping information for an application from the database specified in the `ioDTRefNum` field. You can call `PBDTRemoveAPPLAsync` even if the application is not present on the volume.

The relevant fields of the parameter block for this function are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. See "File Manager Result Codes".

`ioNamePtr`

On input, a pointer to the application's name.

`ioDTRefNum`

On input, the desktop database reference number of the desktop database containing the application.

`ioDirID`

On input, the application's parent directory.

`ioFileCreator`
On input, the application's signature.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTRemoveAPPLSync

Removes an application from the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTRemoveAPPLSync (
   DTPBPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBDTRemoveAPPLSync` function removes the mapping information for an application from the database specified in the `ioDTRefNum` field. You can call `PBDTRemoveAPPLSync` even if the application is not present on the volume.

The relevant fields of the parameter block for this function are:

`ioNamePtr`
On input, a pointer to the application's name.

`ioDTRefNum`
On input, the desktop database reference number of the desktop database containing the application.

`ioDirID`
On input, the application's parent directory.

`ioFileCreator`
On input, the application's signature.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTRemoveCommentAsync

Removes a user comment associated with a file or directory from the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTRemoveCommentAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. See "File Manager Result Codes".

`ioNamePtr`
On input, a pointer to the filename or directory name.

`ioDTRefNum`
On input, the desktop database reference number of the database in which the specified file or directory is found.

`ioDirID`
On input, the parent directory ID of the file or directory.

You cannot remove a comment if the file or directory it is associated with is not present on the volume. If no comment was stored for the file, `PBDTRemoveCommentAsync` returns an error.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTRemoveCommentSync

Removes a user comment associated with a file or directory from the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTRemoveCommentSync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioNamePtr`

On input, a pointer to the filename or directory name.

`ioDTRefNum`

On input, the desktop database reference number of the database in which the specified file or directory is found.

`ioDirID`

On input, the parent directory ID of the file or directory.

You cannot remove a comment if the file or directory it is associated with is not present on the volume. If no comment was stored for the file, `PBDTRemoveCommentSync` returns an error.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTResetAsync

Removes information from the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTResetAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See DTPBRec (page 813) for a description of the DTPBRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The PBDTResetAsync function removes all icons, application mappings, and comments from the desktop database specified in the ioDTRefNum field. You can call PBDTResetAsync only when the database is open. It remains open after the data is cleared. Your application should not call PBDTResetAsync unless absolutely necessary.

The relevant fields of the parameter block for this function are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function. See "File Manager Result Codes".

ioDTRefNum

On input, the desktop database reference number of the desktop database to clear.

ioIndex

Reserved; on input, this field must be set to 0.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Files.h

PBDTResetSync

Removes information from the desktop database. Unless you are manipulating the desktop database in the absence of the Finder, you should never use this function. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTResetSync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBDTResetSync` function removes all icons, application mappings, and comments from the desktop database specified in the `ioDTRefNum` field. You can call `PBDTResetSync` only when the database is open. It remains open after the data is cleared. Your application should not call `PBDTResetSync` unless absolutely necessary.

The relevant fields of the parameter block for this function are:

`ioDTRefNum`

On input, the desktop database reference number of the desktop database to clear.

`ioIndex`

Reserved; on input, this field must be set to 0.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBDTSetCommentAsync

Adds a user comment for a file or a directory to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTSetCommentAsync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block for this function are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. See "File Manager Result Codes".

`ioNamePtr`
: On input, a pointer to the name of the file or directory.

`ioDTRefNum`
: On input, the desktop database reference number for the desktop database to which to add the user comment.

`ioDTBuffer`
: On input, a pointer to the buffer containing the comment text. Put the comment in the buffer as a plain text string.

`ioDTReqCount`
: On input, the length of the buffer (in bytes) containing the comment text. The maximum length of a comment is 200 bytes; longer comments are truncated. Since the comment is a plain text string and not a Pascal string, the File Manager relies on the value in the `ioDTReqCount` field for determining the length of the buffer.

`ioDirID`
: On input, the parent directory ID of the file or directory.

If the specified object already has a comment in the database, the new comment replaces the old.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBDTSetCommentSync

Adds a user comment for a file or a directory to the desktop database. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBDTSetCommentSync (
   DTPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a desktop database parameter block. See `DTPBRec` (page 813) for a description of the `DTPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block for this function are:

`ioNamePtr`

On input, a pointer to the name of the file or directory.

`ioDTRefNum`

On input, the desktop database reference number for the desktop database to which to add the user comment.

`ioDTBuffer`

On input, a pointer to the buffer containing the comment text. Put the comment in the buffer as a plain text string.

`ioDTReqCount`

On input, the length of the buffer containing the comment text, in bytes. The maximum length of a comment is 200 bytes; longer comments are truncated. Since the comment is a plain text string and not a Pascal string, the File Manager relies on the value in the `ioDTReqCount` field for determining the length of the buffer.

`ioDirID`

On input, the parent directory ID of the file or directory.

If the specified object already has a comment in the database, the new comment replaces the old.

Special Considerations

All of the desktop database functions may move or purge memory blocks in the application heap or for some other reason should not be called from within an interrupt.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBExchangeFilesAsync

Exchanges the data stored in two files on the same volume. (Deprecated in Mac OS X v10.4. Use `PBExchangeObjectsAsync` (page 635) instead.)

```
OSErr PBExchangeFilesAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `FIDParam` (page 818) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the name of the first file to swap.

`ioVRefNum`

On input, a volume reference number, drive number, or 0 for the default volume.

`ioDestNamePtr`

On input, a pointer to the name of the second file to swap.

`ioDestDirID`

On input, the second file's parent directory ID.

`ioSrcDirID`

On input, the first file's parent directory ID.

Typically, you use `PBExchangeFilesAsync` after creating a new file during a safe save. The `PBExchangeFilesAsync` function changes the fields in the catalog entries that record the location of the data and the modification dates. It swaps both the data forks and the resource forks.

The `PBExchangeFilesAsync` function works on either open or closed files. `PBExchangeFilesAsync` swaps the data in two files by changing some of the information in the volume catalog. If either file is open, `PBExchangeFilesAsync` updates any file control blocks associated with the file. Exchanging the contents of two files requires essentially the same access privileges as opening both files for writing.

The following fields in the catalog entries for the files are exchanged:

- `ioFlStBlk`
- `ioFlLgLen`
- `ioFlPyLen`
- `ioFlRStBlk`
- `ioFlRLgLen`
- `ioFlRPyLen`
- `ioFlMdDat`

In the file control blocks, the `fcbFlNum`, `fcbDirID`, and `fcbCName` fields are exchanged.

You should use `PBExchangeFilesAsync` to preserve the file ID when updating an existing file, in case the file is being tracked through its file ID. The `PBExchangeFilesAsync` function does not require that file ID references exist for the files being exchanged.

To exchange the contents of files with named forks other than the data and resource forks, or of files larger than 2 GB, use the `FSExchangeObjects` (page 486) , `PBExchangeObjectsSync` (page 636) , or `PBExchangeObjectsAsync` (page 635) function.

Special Considerations

Your application will have to swap any open reference numbers to the two files because the file's name and parent directory ID are exchanged in the file control blocks.

Because other programs may have access paths open to one or both of the files exchanged, your application should have exclusive read/write access permission (`fsRdWrPerm`) to both files before calling `PBExchangeFilesAsync`. Exclusive read/write access to both files will ensure that `PBExchangeFilesAsync` doesn't affect another application because it prevents other applications from obtaining write access to one or both of the files exchanged.

`PBExchangeFilesAsync` does not respect the file-locked attribute; it will perform the exchange even if one or both of the files are locked. Obtaining exclusive read/write access to both files before calling `PBExchangeFilesAsync` ensures that the files are unlocked because locked files cannot be opened with write access.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBExchangeFilesSync

Exchanges the data stored in two files on the same volume. (Deprecated in Mac OS X v10.4. Use `PBExchangeObjectsSync` (page 636) instead.)

```
OSErr PBExchangeFilesSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `FIDParam` (page 818) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name of the first file to swap.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDestNamePtr`
On input, a pointer to the name of the second file to swap.

`ioDestDirID`
On input, the second file's parent directory ID.

`ioSrcDirID`
On input, the first file's parent directory ID.

Typically, you use `PBExchangeFilesSync` after creating a new file during a safe save. The `PBExchangeFilesSync` function changes the fields in the catalog entries that record the location of the data and the modification dates. It swaps both the data forks and the resource forks.

The `PBExchangeFilesSync` function works on either open or closed files. `PBExchangeFilesSync` swaps the data in two files by changing some of the information in the volume catalog. If either file is open, `PBExchangeFilesSync` updates any file control blocks associated with the file. Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

PBExchangeObjectsAsync

Swaps the contents of two files.

```
void PBExchangeObjectsAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Discussion
The relevant fields of the parameter block are:

ioCompletion
On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
On output, the result code of the function.

ref
On input, a pointer to an FSRef (page 837) for the first file.

parentRef
On input, a pointer to an FSRef for the second file.

The PBExchangeObjectsAsync function allows programs to implement a "safe save" operation by creating and writing a complete new file and swapping the contents. An alias, FSSpec, or FSRef that refers to the old file will now access the new data. The corresponding information in in-memory data structures are also exchanged.

Either or both files may have open access paths. After the exchange, the access path will refer to the opposite file's data (that is, to the same data it originally referred, which is now part of the other file).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBExchangeObjectsSync

Swaps the contents of two files.

```
OSErr PBExchangeObjectsSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) for the first file.

`parentRef`

On input, a pointer to an `FSRef` for the second file.

The `PBExchangeObjectsSync` function allows programs to implement a "safe save" operation by creating and writing a complete new file and swapping the contents. An alias, `FSSpec`, or `FSRef` that refers to the old file will now access the new data. The corresponding information in in-memory data structures are also exchanged.

Either or both files may have open access paths. After the exchange, the access path will refer to the opposite file's data (that is, to the same data it originally referred, which is now part of the other file).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBFlushFileAsync

Writes the contents of a file's access path buffer to the disk. (Deprecated in Mac OS X v10.4. Use `PBFlushForkAsync` (page 638) instead.)

```
OSErr PBFlushFileAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioRefNum`
On input, a file reference number for the file to flush.

After writing the contents of the file to the volume, the `PBFlushFileAsync` function updates the file's entry in the volume catalog.

In the event of a system crash, all cached data not yet written to disk is lost. If you have made changes to space that already exists within a file (you are overwriting existing data before the file's end-of-file), you must use `PBFlushFileAsync` to ensure that everything written to the file will be written to disk. If you flush the fork's cached blocks using `PBFlushFileAsync`, the only possible data loss in a system crash will be the file's modification date.

You do not, however, need to use `PBFlushFileAsync` to flush a file fork before it is closed; the file is automatically flushed when it is closed and all cache blocks associated with it are removed from the cache.

`PBFlushFileSync` flushes an open fork's dirty cached blocks, but may not flush catalog information associated with the file. To flush catalog information, call `FlushVol` (page 466) , or one of the related parameter block calls, `PBFlushVolSync` (page 641) and `PBFlushVolAsync` (page 640).

To update a file larger than 2GB, or a named fork other than the data and resource forks, you must use the `FSFlushFork` (page 490) function, or one of the corresponding parameter block calls, `PBFlushForkSync` (page 639) and `PBFlushForkAsync` (page 638).

Special Considerations

Some information stored on the volume won't be correct until `PBFlushVolAsync` is called.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBFlushFileSync

Writes the contents of a file's access path buffer to the disk. (Deprecated in Mac OS X v10.4. Use `PBFlushForkSync` (page 639) instead.)

```
OSErr PBFlushFileSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant field of the parameter block is:

`ioRefNum`

On input, a file reference number for the file to flush.

After writing the contents of the file to the volume, the `PBFlushFileSync` function updates the file's entry in the volume catalog.

In the event of a system crash, all cached data not yet written to disk is lost. If you have made changes to space that already exists within a file (you are overwriting existing data before the file's end-of-file), you must use `PBFlushFileSync` to ensure that everything written to the file will be written to disk. If you flush the fork's cached blocks using `PBFlushFileSync`, the only possible data loss in a system crash will be the file's modification date.

You do not, however, need to use `PBFlushFileSync` to flush a file fork before it is closed; the file is automatically flushed when it is closed and all cache blocks associated with it are removed from the cache.

`PBFlushFileSync` flushes an open fork's dirty cached blocks, but may not flush catalog information associated with the file. To flush catalog information, call `FlushVol` (page 466) , or one of the related parameter block calls, `PBFlushVolSync` (page 641) and `PBFlushVolAsync` (page 640).

To update a file larger than 2GB, or a named fork other than the data and resource forks, you must use the `FSFlushFork` (page 490) function, or one of the corresponding parameter block calls, `PBFlushForkSync` (page 639) and `PBFlushForkAsync` (page 638).

Special Considerations

Some information stored on the volume won't be correct until `PBFlushVolSync` is called.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBFlushForkAsync

Causes all data written to an open fork to be written to disk.

```
void PBFlushForkAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for more information on the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`forkRefNum`

On input, the reference number of the fork to flush.

The `PBFlushForkAsync` function causes the actual fork contents to be written to disk, as well as any other volume structures needed to access the fork. On HFS and HFS Plus, this includes the catalog, extents, and attribute B-trees; the volume bitmap; and the volume header and alternate volume header (the MDB and alternate MDB on HFS volumes), as needed.

On volumes that do not support `PBFlushForkAsync` directly, the entire volume is flushed to be sure all volume structures associated with the fork are written to disk.

You do not, need to use `PBFlushForkAsync` to flush a file fork before it is closed; the file is automatically flushed when it is closed and all cache blocks associated with it are removed from the cache.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBFlushForkSync

Causes all data written to an open fork to be written to disk.

```
OSErr PBFlushForkSync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for more information on the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant field of the parameter block is:

`forkRefNum`
On input, the reference number of the fork to flush.

The `PBFlushForkSync` function causes the actual fork contents to be written to disk, as well as any other volume structures needed to access the fork. On HFS and HFS Plus, this includes the catalog, extents, and attribute B-trees; the volume bitmap; and the volume header and alternate volume header (the MDB and alternate MDB on HFS volumes), as needed.

On volumes that do not support `PBFlushForkSync` directly, the entire volume is flushed to be sure all volume structures associated with the fork are written to disk.

You do not, need to use `PBFlushForkSync` to flush a file fork before it is closed; the file is automatically flushed when it is closed and all cache blocks associated with it are removed from the cache.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBFlushVolAsync

Writes the contents of the volume buffer and updates information about the volume. (Deprecated in Mac OS X v10.5. Use `PBFlushVolumeAsync` (page 642) instead.)

```
OSErr PBFlushVolAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to the `VolumeParam` (page 873) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the name of the volume to flush.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`PBFlushVolAsync` flushes all open files on the volume, and then flushes all volume data structures. On the volume specified by `ioNamePtr` or `ioVRefNum`, the `PBFlushVolAsync` function writes descriptive information about the volume, the contents of the associated volume buffer, and all access path buffers for the volume (if they've changed since the last time `PBFlushVolAsync` was called).

The date and time of the last modification to the volume are set when the modification is made, not when the volume is flushed.

To ensure that all changes to a volume are flushed to the volume, use `PBFlushVolAsync`. You do not, however, need to flush a volume before unmounting it, ejecting it, or putting it offline; this is done automatically.

If changes are made to a file that affect the file's end-of-file, the file's name, the file's Finder information, or the file's location on the volume, then you must use `PBFlushVolAsync`, or one of the other two volume flush functions in this section, to ensure that these changes are written to disk.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBFlushVolSync

Writes the contents of the volume buffer and updates information about the volume. (Deprecated in Mac OS X v10.5. Use `PBFlushVolumeSync` (page 642) instead.)

```
OSErr PBFlushVolSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `VolumeParam` (page 873) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name of the volume to flush.

`ioVRefNum`
On input, the volume reference number, drive number, or 0 for the default volume.

`PBFlushVolSync` flushes all open files on the volume, and then flushes all volume data structures. On the volume specified by `ioNamePtr` or `ioVRefNum`, the `PBFlushVolSync` function writes descriptive information about the volume, the contents of the associated volume buffer, and all access path buffers for the volume (if they've changed since the last time `PBFlushVolSync` was called).

The date and time of the last modification to the volume are set when the modification is made, not when the volume is flushed.

To ensure that all changes to a volume are flushed to the volume, use `PBFlushVolSync`. You do not, however, need to flush a volume before unmounting it, ejecting it, or putting it offline; this is done automatically.

If changes are made to a file that affect the file's end-of-file, the file's name, the file's Finder information, or the file's location on the volume, then you must use `PBFlushVolSync`, or one of the other two volume flush functions in this section, to ensure that these changes are written to disk.

PBGetCatalogInfoAsync

Returns catalog information about a file or directory. You can use this function to map from an `FSRef` to an `FSSpec`.

```
void PBGetCatalogInfoAsync (
   FSRefParam *paramBlock
);
```

Parameters

`paramBlock`

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) fro s description of the `FSRefParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ref`
: On input, a pointer to an `FSRef` (page 837) specifying the file or directory for which to retrieve information.

`whichInfo`
: On input, a bitmap specifying the catalog information fields to return. If you don't want any catalog information, set `whichInfo` to the constant `kFSCatInfoNone`. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

`catInfo`
: On output, a pointer to an `FSCatalogInfo` (page 826) structure containing the information about the file or directory. Only the information specified in the `whichInfo` field is returned. If you don't want any catalog information, pass `NULL` here.

`spec`
: On output, a pointer to the `FSSpec` (page 840) for the file or directory. This output is optional; if you do not wish the `FSSpec` returned, pass `NULL` here.

`parentRef`
: On output, a pointer to the `FSRef` for the object's parent directory. This output is optional; if you do not wish the parent directory returned, pass `NULL` here. If the object specified in the `ref` field is a volume's root directory, then the `FSRef` returned in this field will not be a valid `FSRef`, since the root directory has no parent object.

`outName`
: On output, a pointer to the Unicode name of the file or directory. On input, pass a pointer to an `HFSUniStr255` (page 855) structure if you wish the name returned; otherwise, pass `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetCatalogInfoBulkAsync

Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

```
void PBGetCatalogInfoBulkAsync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. When all of the iterator's objects have been returned, the call will return `errFSNoMoreItems`.

`iterator`
: On input, the iterator to use. You can obtain a catalog iterator with the function `FSOpenIterator` (page 515) , or with one of the related parameter block calls, `PBOpenIteratorSync` (page 742) and `PBOpenIteratorAsync` (page 741). Currently, the iterator must be created with the `kFSIterateFlat` option. See `FSIterator` (page 835) for a description of the `FSIterator` data type.

`maximumItems`
: On input, the maximum number of items to return for this call.

`actualItems`
: On output, the actual number of items found for this call.

`containerChanged`
: On output, a value indicating whether or not the container's contents have changed since the previous `PBGetCatalogInfoBulkAsync` call. If `true`, the contents have changed. Objects may still be returned, even though the container has changed. If so, note that if the container has changed, then the total set of items returned may be incorrect: some items may be returned multiple times, and some items may not be returned at all.

`whichInfo`
: On input, a bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant `kFSCatInfoNone` in this field. For a description of the bits in this field, see "Catalog Information Bitmap Constants" (page 891).

`catalogInfo`
: On output, a pointer to an array of catalog information structures; one for each returned item. On input, the `catalogInfo` field should point to an array of `maximumItems` catalog information structures. This field is optional; if you do not wish any catalog information returned, pass `NULL` here. See `FSCatalogInfo` (page 826) for a description of the `FSCatalogInfo` data type.

`refs`
: On input, a pointer to an array of `maximumItems FSRef` (page 837) structures. On output, an `FSRef` is filled out for each returned item. This field is optional; if you do not wish any `FSRef` structures returned, pass `NULL` here.

`names`
: On output, a pointer to an array of names; one for each returned item. If you want the Unicode name for each item found, set this field to point to an array of `maximumItems HFSUniStr255` (page 855) structures. Otherwise, set it to `NULL`.

`specs`
: On input, a pointer to an array of `maximumItems FSSpec` structures. On output, an `FSSpec` structure is filled out for each returned item. This field is optional; if you do not wish any `FSSpec` structures returned, pass `NULL` here.

The `PBGetCatalogInfoBulkAsync` call may complete and return `noErr` with fewer than `maximumItems` items returned. This may be due to various reasons related to the internal implementation. In this case, you may continue to make `PBGetCatalogInfoBulkSync` calls using the same iterator.

Before calling this function, you should determine whether it is available, by calling the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBGetCatalogInfoBulkSync

Returns information about one or more objects from a catalog iterator. This function can return information about multiple objects in a single call.

```
OSErr PBGetCatalogInfoBulkSync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a catalog information parameter block. See FSCatalogBulkParam (page 824) for a description of the FSCatalogBulkParam data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). When all of the iterator's objects have been returned, the call will return errFSNoMoreItems.

Discussion

The relevant fields of the parameter block are:

iterator
On input, the iterator to use. You can obtain a catalog iterator with the function FSOpenIterator (page 515) , or with one of the related parameter block calls, PBOpenIteratorSync (page 742) and PBOpenIteratorAsync (page 741). Currently, the iterator must be created with the kFSIterateFlat option. See FSIterator (page 835) for a description of the FSIterator data type.

maximumItems
On input, the maximum number of items to return for this call.

actualItems
On output, the actual number of items found for this call.

containerChanged
On output, a value indicating whether or not the container's contents have changed since the previous PBGetCatalogInfoBulkSync call. If true, the contents have changed. Objects may still be returned, even though the container has changed. If so, note that if the container has changed, then the total set of items returned may be incorrect: some items may be returned multiple times, and some items may not be returned at all.

whichInfo
On input, a bitmap specifying the catalog information fields to return for each item. If you don't wish any catalog information returned, pass the constant kFSCatInfoNone in this field. For a description of the bits in this field, see "Catalog Information Bitmap Constants" (page 891).

catalogInfo
On output, a pointer to an array of catalog information structures; one for each returned item. On input, the catalogInfo field should point to an array of maximumItems catalog information structures. This field is optional; if you do not wish any catalog information returned, pass NULL here. See FSCatalogInfo (page 826) for a description of the FSCatalogInfo data type.

refs
: On input, a pointer to an array of maximumItems HFSUniStr255 (page 855) structures. On output, an FSRef is filled out for each returned item. This field is optional; if you do not wish any FSRef structures returned, pass NULL here.

names
: On output, a pointer to an array of names; one for each returned item. If you want the Unicode name for each item found, set this field to point to an array of maximumItems HFSUniStr255 (page 855) structures. Otherwise, set it to NULL.

specs
: On input, a pointer to an array of maximumItems FSSpec structures. On output, an FSSpec structure is filled out for each returned item. This field is optional; if you do not wish any FSSpec structures returned, pass NULL here.

The PBGetCatalogInfoBulkSync call may complete and return noErr with fewer than maximumItems items returned. This may be due to various reasons related to the internal implementation. In this case, you may continue to make PBGetCatalogInfoBulkSync calls using the same iterator.

Before calling this function, you should determine whether it is available, by calling the Gestalt function.

Availability
Available in Mac OS X v10.0 and later.

Files.h

PBGetCatalogInfoSync

Returns catalog information about a file or directory. You can use this function to map from an FSRef to an FSSpec.

```
OSErr PBGetCatalogInfoSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock
: A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

ref
: On input, a pointer to an FSRef (page 837) specifying the file or directory for which to retrieve information.

whichInfo
: On input, a bitmap specifying the catalog information fields to return. If you don't want any catalog information, set whichInfo to the constant kFSCatInfoNone. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

`catInfo`
: On output, a pointer to an `FSCatalogInfo` (page 826) structure containing the information about the file or directory. Only the information specified in the `whichInfo` field is returned. If you don't want any catalog information, pass `NULL` here.

`spec`
: On output, a pointer to the `FSSpec` (page 840) for the file or directory. This output is optional; if you do not wish the `FSSpec` returned, pass `NULL` here.

`parentRef`
: On output, a pointer to the `FSRef` for the object's parent directory. This output is optional; if you do not wish the parent directory returned, pass `NULL` here. If the object specified in the `ref` field is a volume's root directory, then the `FSRef` returned in this field will not be a valid `FSRef`, since the root directory has no parent object.

`outName`
: On output, a pointer to the Unicode name of the file or directory. On input, pass a pointer to an `HFSUniStr255` (page 855) structure if you wish the name returned; otherwise, pass `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetCatInfoAsync

Returns catalog information about a file or directory. (Deprecated in Mac OS X v10.4. Use `PBGetCatalogInfoAsync` (page 643) instead.)

```
OSErr PBGetCatInfoAsync (
   CInfoPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to an HFS catalog information parameter block. See `CInfoPBRec` (page 802) for a description of the `CInfoPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBGetCatInfoAsync` function returns information about a file or directory, depending on the values you specify in the `ioFDirIndex`, `ioNamePtr`, `ioVRefNum`, and `ioDirID` or `ioDrDirID` fields. If you need to determine whether the information returned is for a file or a directory, you can test bit 4 of the `ioFlAttrib` field; if that bit is set, the information returned describes a directory.

The `PBGetCatInfoAsync` function selects a file or directory according to these rules:

- If the value of `ioFDirIndex` is positive, `ioNamePtr` is not used as an input parameter and `PBGetCatInfoAsync` returns information about the file or directory whose directory index is `ioFDirIndex` in the directory specified by `ioDirID` (or `ioDrDirID`) on the volume specified by `ioVRefNum` (this will be the root directory if `ioVRefNum` is a volume reference number or a drive number and `ioDirID` is 0). If `ioNamePtr` is not `NULL`, then it must point to a `Str31` buffer where the file or directory name will be returned.

- If the value of `ioFDirIndex` is 0, `PBGetCatInfoAsync` returns information about the file or directory specified by `ioNamePtr` in the directory specified by `ioDirID` (or `ioDrDirID`) on the volume specified by `ioVRefNum` (again, this will be the root directory if `ioVRefNum` is a volume reference number or a drive number and `ioDirID` is 0).
- If the value of `ioFDirIndex` is negative, `PBGetCatInfoAsync` ignores the `ioNamePtr` field and returns information about the directory specified in the `ioDrDirID` field. If `ioNamePtr` is not `NULL`, then it must point to a `Str31` buffer where the directory name will be returned.

With files, `PBGetCatInfoAsync` is similar to `PBHGetFInfoAsync` (page 682) but returns some additional information. If the object is a file, the relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname. On output, the name of the file is returned in this field, if the file is open. If you do not want the name of the file returned, pass `NULL` in this field.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioFRefNum`
On output, a file reference number. If the file is open, the reference number of the first access path found is returned here .

`ioFDirIndex`
On input, a directory index.

`ioFlAttrib`
On output, the file attributes. See "File Attribute Constants" (page 914) for the meaning of the file attributes.

`ioFlFndrInfo`
On output, information used by the Finder.

`ioDirID`
On input, a directory ID. On output, the file ID. You might need to save the value of `ioDirID` before calling `PBGetCatInfoAsync` if you make subsequent calls with the same parameter block.

`ioFlStBlk`
On output, the first allocation block of the data fork.

`ioFlLgLen`
On output, the logical size (the logical end-of-file) of the data fork, in bytes.

`ioFlPyLen`
On output, the physical size (the physical end-of-file) of the data fork, in bytes.

`ioFlRStBlk`
On output, the first allocation block of the resource fork.

`ioFlRLgLen`
On output, the logical size of the resource fork, in bytes.

`ioFlRPyLen`
On output, the physical size of the resource fork, in bytes.

`ioFlCrDat`
: On output, the date and time of the file's creation. Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates. For file systems which do not support creation dates, the File Manager sets the `ioFlCrDat` field to 0.

`ioFlMdDat`
: On output, the date and time of the file's last modification.

`ioFlBkDat`
: On output, the date and time of the file's last backup. Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates. For file systems which do not support backup dates, the File Manager sets the `ioFlBkDat` field to 0.

`ioFlXFndrInfo`
: On output, additional information used by the Finder.

`ioFlParID`
: On output, the directory ID of the file's parent directory.

`ioFlClpSiz`
: On output, the file's clump size.

You can also use `PBGetCatInfoAsync` to determine whether a file has a file ID reference. The value of the file ID is returned in the `ioDirID` field. Because that parameter could also represent a directory ID, call `PBResolveFileIDRefAsync` (page 749) to see if the value is a real file ID. If you want to determine whether a file ID reference exists for a file and create one if it doesn't, use `PBCreateFileIDRefAsync` (page 590) , which will either create a file ID or return `fidExists`.

If the object is a directory, the relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioNamePtr`
: On input, a pointer to a pathname. On output, a pointer to the directory name.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioFDirIndex`
: On input, a directory index.

`ioFlAttrib`
: On output, the directory attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field. The bits in this field for directories are read-only. You cannot alter directory attributes by setting these bits using the functions `PBSetCatInfoSync` (page 755) or `PBSetCatInfoAsync` (page 754). Instead, you can call the `PBHSetFLockSync` (page 724) and `PBHRstFLockSync` (page 718) functions to lock and unlock a directory, and the `PBShareSync` (page 769) and `PBUnshareSync` (page 773) functions to enable and disable file sharing on local directories.

`ioACUser`
: On output, the directory access rights. The `PBGetCatInfoAsync` function returns the information in this field only for shared volumes. As a result, you should set this field to 0 before calling `PBGetCatInfoAsync`.`PBGetCatInfoAsync` does not return the blank access privileges bit in this field; to determine whether a directory has blank access privileges, use the

PBHGetDirAccessAsync (page 680) function. See "User Privileges Constants" (page 930) for a description of the constants that may be returned in this field.

ioDrUsrWds
On output, information used by the Finder.

ioDrDirID
On input, if you wish to obtain information about a specific directory, that directory's ID. Otherwise, if the object returned is a directory, this field contains the directory ID on output.

ioDrNmFls
On output, the number of files in the directory.

ioDrCrDat
On output, the date and time of the directory's creation. Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates. For file systems which do not support creation dates, the File Manager sets the ioDrCrDat field to 0.

ioDrMdDat
On output, the date and time of the directory's last modification.

ioDrBkDat
On output, the date and time of the directory's last backup. Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates. For file systems which do not support backup dates, the File Manager sets the ioDrBkDat field to 0.

ioDrFndrInfo
On output, additional information used by the Finder.

ioDrParID
On output, the directory ID of the directory's parent directory.

To get information on a file or directory with named forks, or on a file larger than 2GB, use one of the FSGetCatalogInfo (page 494) , PBGetCatalogInfoSync (page 647) , or PBGetCatalogInfoAsync (page 643) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

PBGetCatInfoSync

Returns catalog information about a file or directory. (Deprecated in Mac OS X v10.4. Use PBGetCatalogInfoSync (page 647) instead.)

```
OSErr PBGetCatInfoSync (
   CInfoPBPtr paramBlock
);
```

Parameters

paramBlock
A pointer to an HFS catalog information parameter block. See CInfoPBRec (page 802) for a description of the CInfoPBRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBGetCatInfoSync` function returns information about a file or directory, depending on the values you specify in the `ioFDirIndex`, `ioNamePtr`, `ioVRefNum`, and `ioDirID` or `ioDrDirID` fields. If you need to determine whether the information returned is for a file or a directory, you can test bit 4 of the `ioFlAttrib` field; if that bit is set, the information returned describes a directory.

The `PBGetCatInfoSync` function selects a file or directory according to these rules:

- If the value of `ioFDirIndex` is positive, `ioNamePtr` is not used as an input parameter and `PBGetCatInfoSync` returns information about the file or directory whose directory index is `ioFDirIndex` in the directory specified by `ioDirID` (or `ioDrDirID`) on the volume specified by `ioVRefNum` (this will be the root directory if `ioVRefNum` is a volume reference number or a drive number and `ioDirID` is 0). If `ioNamePtr` is not `NULL`, then it must point to a `Str31` buffer where the file or directory name will be returned.
- If the value of `ioFDirIndex` is 0, `PBGetCatInfoSync` returns information about the file or directory specified by `ioNamePtr` in the directory specified by `ioDirID` (or `ioDrDirID`) on the volume specified by `ioVRefNum` (again, this will be the root directory if `ioVRefNum` is a volume reference number or a drive number and ioDirID is 0).
- If the value of `ioFDirIndex` is negative, `PBGetCatInfoSync` ignores the `ioNamePtr` field and returns information about the directory specified in the `ioDrDirID` field. If `ioNamePtr` is not `NULL`, then it must point to a `Str31` buffer where the directory name will be returned.

With files, `PBGetCatInfoSync` is similar to `PBHGetFInfoSync` (page 683) but returns some additional information. If the object is a file, the relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname. On output, the name of the file is returned in this field, if the file is open. If you do not want the name of the file returned, pass `NULL` in this field.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioFRefNum`
On output, a file reference number. If the file is open, the reference number of the first access path found is returned here.

`ioFDirIndex`
On input, a directory index.

`ioFlAttrib`
On output, the file attributes. See "File Attribute Constants" (page 914) for the meaning of the file attributes.

`ioFlFndrInfo`
On output, information used by the Finder.

`ioDirID`
On input, a directory ID. On output, the file ID. You might need to save the value of `ioDirID` before calling `PBGetCatInfoSync` if you make subsequent calls with the same parameter block.

`ioFlStBlk`
On output, the first allocation block of the data fork.

`ioFlLgLen`
On output, the logical size (the logical end-of-file) of the data fork, in bytes.

`ioFlPyLen`
On output, the physical size (the physical end-of-file) of the data fork, in bytes.

`ioFlRStBlk`
On output, the first allocation block of the resource fork.

`ioFlRLgLen`
On output, the logical size of the resource fork, in bytes.

`ioFlRPyLen`
On output, the physical size of the resource fork, in bytes.

`ioFlCrDat`
On output, the date and time of the file's creation. Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates. For file systems which do not support creation dates, the File Manager sets the `ioFlCrDat` field to 0.

`ioFlMdDat`
On output, the date and time of the file's last modification.

`ioFlBkDat`
On output, the date and time of the file's last backup. Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates. For file systems which do not support backup dates, the File Manager sets the `ioFlBkDat` field to 0.

`ioFlXFndrInfo`
On output, additional information used by the Finder.

`ioFlParID`
On output, the directory ID of the file's parent directory.

`ioFlClpSiz`
On output, the file's clump size.

You can also use `PBGetCatInfoSync` to determine whether a file has a file ID reference. The value of the file ID is returned in the `ioDirID` field. Because that parameter could also represent a directory ID, call `PBResolveFileIDRefSync` (page 750) to see if the value is a real file ID. If you want to determine whether a file ID reference exists for a file and create one if it doesn't, use `PBCreateFileIDRefSync` (page 591) , which will either create a file ID or return `fidExists`.

If the object is a directory, the relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname. On output, a pointer to the directory's name.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioFDirIndex`
On input, a directory index.

`ioFlAttrib`
On output, the directory attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field. The bits in this field for directories are read-only. You cannot alter directory attributes by setting these bits using the functions `PBSetCatInfoSync` (page 755) or `PBSetCatInfoAsync` (page 754). Instead, you can call the `PBHSetFLockSync` (page 724) and `PBHRstFLockSync` (page 718) functions to lock and unlock a directory, and the `PBShareSync` (page 769) and `PBUnshareSync` (page 773) functions to enable and disable file sharing on local directories.

`ioACUser`
: On output, the directory access rights. The `PBGetCatInfoSync` function returns the information in this field only for shared volumes. As a result, you should set this field to 0 before calling `PBGetCatInfoSync`. `PBGetCatInfoSync` does not return the blank access privileges bit in this field; to determine whether a directory has blank access privileges, use the `PBHGetDirAccessSync` (page 681) function. See "User Privileges Constants" (page 930) for a description of the constants that may be returned here.

`ioDrUsrWds`
: On output, information used by the Finder.

`ioDrDirID`
: On input, if you wish to obtain information about a specific directory, that directory's ID. Otherwise, if the object returned is a directory, this field contains the directory ID on output.

`ioDrNmFls`
: On output, the number of files in the directory.

`ioDrCrDat`
: On output, the date and time of the directory's creation. Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates. For file systems which do not support creation dates, the File Manager sets the `ioDrCrDat` field to 0.

`ioDrMdDat`
: On output, the date and time of the directory's last modification.

`ioDrBkDat`
: On output, the date and time of the directory's last backup. Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates. For file systems which do not support backup dates, the File Manager sets the `ioDrBkDat` field to 0.

`ioDrFndrInfo`
: On output, additional information used by the Finder.

`ioDrParID`
: On output, the directory ID of the directory's parent directory.

To get information on a file or directory with named forks, or on a file larger than 2GB, use one of the `FSGetCatalogInfo` (page 494) , `PBGetCatalogInfoSync` (page 647) , or `PBGetCatalogInfoAsync` (page 643) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBGetEOFAsync

Determines the current logical size of an open file. (Deprecated in Mac OS X v10.4. Use `PBGetForkSizeAsync` (page 664) instead.)

```
OSErr PBGetEOFAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function.

ioRefNum

On input, a file reference number for the open file.

ioMisc

On output, the logical size (the logical end-of-file) of the given file. Because the ioMisc field is of type Ptr, you'll need to coerce the value to a long integer to interpret the value correctly.

To determine the size of a named fork other than the data or resource forks, or of a fork larger than 2 GB, use the FSGetForkSize (page 499) function, or one of the corresponding parameter block functions, PBGetForkSizeSync (page 665) and PBGetForkSizeAsync (page 664).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Files.h

PBGetEOFSync

Determines the current logical size of an open file. (Deprecated in Mac OS X v10.4. Use PBGetForkSizeSync (page 665) instead.)

```
OSErr PBGetEOFSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioRefNum`
On input, a file reference number for the open file.

`ioMisc`
On output, a pointer to the logical size (the logical end-of-file) of the given file. Because the `ioMisc` field is of type `Ptr`, you'll need to coerce the value to a long integer to interpret the value correctly.

To determine the size of a named fork other than the data or resource forks, or of a fork larger than 2 GB, use the `FSGetForkSize` (page 499) function, or one of the corresponding parameter block functions, `PBGetForkSizeSync` (page 665) and `PBGetForkSizeAsync` (page 664).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBGetFCBInfoAsync

Gets information about an open file from the file control block. (Deprecated in Mac OS X v10.4. Use `PBGetForkCBInfoAsync` (page 660) instead.)

```
OSErr PBGetFCBInfoAsync (
   FCBPBPtr paramBlock
);
```

Parameters
paramBlock
A pointer to a file control block parameter block. See `FCBPBRec` (page 816) for a description of the `FCBPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname. You should pass a pointer to a `Str31` value if you want the name of the file returned. If you pass `NULL`, no filename is returned. On output, if `PBGetFCBInfoAsync` executes successfully, a pointer to the name of the specified open file.

`ioVRefNum`
: On input, a volume specification. If you specify a valid index number in the `ioFCBIndx` field, the File Manager returns information on the file having that index in the FCB buffer on the volume specified in this field. This field may contain a drive number or volume reference number. If the value of `ioVRefNum` is 0, all open files are indexed; otherwise, only open files on the specified volume are indexed.

`ioRefNum`
: On input, if the `ioFCBIndx` field is 0, the file reference number of the file to get information about. If the value of `ioFCBIndx` is positive, the `ioRefNum` field is ignored on input and contains the file reference number on output.

`ioFCBIndx`
: On input, an index. If the value of `ioFCBIndx` is positive, the File Manager returns information about the file whose index in the FCB buffer is `ioFCBIndx` and that is located on the volume specified in the `ioVRefNum` field. If the value of `ioFCBIndx` is 0, the File Manager returns information about the file whose file reference number is specified by the `ioRefNum` field.

`ioFCBFlNm`
: On output, the file ID.

`ioFCBFlags`
: On output, file status flags. See "FCB Flags" (page 906) for a description of the bits in this field.

`ioFCBStBlk`
: On output, the first allocation block of the file.

`ioFCBEOF`
: On output, the logical size (the logical end-of-file) of the file.

`ioFCBPLen`
: On output, the physical size (the physical end-of-file) of the file.

`ioFCBCrPs`
: On output, the position of the file mark.

`ioFCBVRefNum`
: On output, the volume reference number.

`ioFCBClpSiz`
: On output, the file clump size.

`ioFCBParID`
: On output, the directory ID of the file's parent directory.

To get information about a fork control block, use one of the functions, `FSGetForkCBInfo` (page 497) , `PBGetForkCBInfoSync` (page 661) , or `PBGetForkCBInfoAsync` (page 660).

Special Considerations

On OS X, the value returned by `PBGetFCBInfoAsync` in the `ioFCBPLen` field may differ from the physical file length reported by `FSGetCatalogInfo`, `PBGetCatInfo`, and related functions. When a write causes a file to grow in size, the physical length reported by `FSGetCatalogInfo` and similar calls increases by the clump size, which is a multiple of the allocation block size. However, the physical length returned by `PBGetFCBInfoAsync` changes according to the allocation block size and the file lengths returned by the respective functions get out of sync.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBGetFCBInfoSync

Gets information about an open file from the file control block. (Deprecated in Mac OS X v10.4. Use `PBGetForkCBInfoSync` (page 661) instead.)

```
OSErr PBGetFCBInfoSync (
   FCBPBPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to a file control block parameter block. See `FCBPBRec` (page 816) for a description of the `FCBPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a pathname. You should pass a pointer to a `Str31` value if you want the name of the file returned. If you pass `NULL`, no filename is returned. On output, if `PBGetFCBInfoSync` executes successfully, a pointer to the name of the specified open file.

`ioVRefNum`

On input, a volume specification. If you specify a valid index number in the `ioFCBIndx` field, the File Manager returns information on the file having that index in the FCB buffer on the volume specified in this field. This field may contain a drive number or volume reference number. If the value of `ioVRefNum` is 0, all open files are indexed; otherwise, only open files on the specified volume are indexed.

`ioRefNum`

On input, if the ioFCBIndx field is 0, the file reference number of the file to get information about. If the value of `ioFCBIndx` is positive, the `ioRefNum` field is ignored on input and contains the file reference number on output.

`ioFCBIndx`

On input, an index. If the value of `ioFCBIndx` is positive, the File Manager returns information about the file whose index in the FCB buffer is `ioFCBIndx` and that is located on the volume specified in the `ioVRefNum` field. If the value of `ioFCBIndx` is 0, the File Manager returns information about the file whose file reference number is specified by the `ioRefNum` field.

`ioFCBFlNm`

On output, the file ID.

`ioFCBFlags`

On output, file status flags. See "FCB Flags" (page 906) for a description of the bits in this field.

`ioFCBStBlk`

On output, the first allocation block of the file.

`ioFCBEOF`

On output, the logical size (the logical end-of-file) of the file.

`ioFCBPLen`
On output, the physical size (the physical end-of-file) of the file.

`ioFCBCrPs`
On output, the current position of the file mark.

`ioFCBVRefNum`
On output, the volume reference number.

`ioFCBClpSiz`
On output, the file clump size.

`ioFCBParID`
On output, the directory ID of the file's parent directory.

To get information about a fork control block, use one of the functions, `FSGetForkCBInfo` (page 497) , `PBGetForkCBInfoSync` (page 661) , or `PBGetForkCBInfoAsync` (page 660).

Special Considerations

On OS X, the value returned by `PBGetFCBInfoSync` in the `ioFCBPLen` field may differ from the physical file length reported by `FSGetCatalogInfo`, `PBGetCatInfo`, and related functions. When a write causes a file to grow in size, the physical length reported by `FSGetCatalogInfo` and similar calls increases by the clump size, which is a multiple of the allocation block size. However, the physical length returned by `PBGetFCBInfoSync` changes according to the allocation block size and the file lengths returned by the respective functions get out of sync.

Not available to 64-bit applications.

Declared In

`Files.h`

PBGetForkCBInfoAsync

Returns information about a specified open fork, or about all open forks.

```
void PBGetForkCBInfoAsync (
   FSForkCBInfoParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork control block parameter block. See `FSForkCBInfoParam` (page 830) for a description of the `FSForkCBInfoParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`desiredRefNum`

On input, if you want information on a specific fork, set this field to that fork's reference number. If you pass a non-zero value in this parameter, the function attempts to get information on the fork specified by that reference number the field is unchanged on output. Pass zero in this field to iterate over all open forks; on output, this field contains the fork's reference number. You can limit this iteration to a specific volume with the `volumeRefNum` field.

`volumeRefNum`

On input, the volume to search, when iterating over multiple forks. To iterate over all open forks on a single volume, specify the volume reference number in this field. To iterate over all open forks on all volumes, set this field to the constant `kFSInvalidVolumeRefNum`. This field is ignored if you specify a fork reference number in the `desiredRefNum` parameter. Set `desiredRefNum` to zero if

you wish to iterate over multiple forks. See `FSVolumeRefNum` (page 847) for a description of the `FSVolumeRefNum` data type.

`iterator`

On input, an iterator. If the `desiredRefNum` parameter is 0, the iterator maintains state between calls to `PBGetForkCBInfoAsync`. Set the `iterator` field to 0 before you begin iterating, on the first call to `PBGetForkCBInfoAsync`. On return, the iterator will be updated; pass this updated iterator in the `iterator` field of the next call to `PBGetForkCBInfoAsync` to continue iterating.

`actualRefNum`

On output, the actual reference number of the open fork that was found.

`ref`

On output, a pointer to the `FSRef` (page 837) for the file or directory that contains the fork. This information is optional; if you do not wish to the `FSRef`, set `ref` to `NULL`.

`forkInfo`

On output, a pointer to an `FSForkInfo` (page 832) structure containing information about the open fork. This information is optional; if you do not wish it returned, set `forkInfo` to `NULL`.

`forkName`

On output, a pointer to the name of the fork. This field is optional; if you do not wish the name returned, set `forkName` to `NULL`. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Carbon applications are no longer guaranteed access to the FCB table. Instead, applications should use `FSGetForkCBInfo` (page 497) , or one of the related parameter block functions, `PBGetForkCBInfoSync` (page 661) and `PBGetForkCBInfoAsync`, to access information about a fork control block.

Special Considerations

Returning the fork information in the `forkInfo` field generally does not require a disk access; returning the information in the `ref` or `forkName` fields may cause disk access for some volume formats.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBGetForkCBInfoSync

Returns information about a specified open fork, or about all open forks.

```
OSErr PBGetForkCBInfoSync (
   FSForkCBInfoParam *paramBlock
);
```

Parameters

`paramBlock`

A pointer to a fork control block parameter block. See `FSForkCBInfoParam` (page 830) for a description of the `FSForkCBInfoParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you are iterating over multiple forks, the function returns `errFSNoMoreItems` if there are no more open forks to return.

Discussion

The relevant fields of the parameter block are:

`desiredRefNum`
: On input, if you want information on a specific fork, set this field to that fork's reference number. If you pass a non-zero value in this parameter, the function attempts to get information on the fork specified by that reference number the field is unchanged on output. Pass zero in this field to iterate over all open forks; on output, this field contains the fork's reference number. You can limit this iteration to a specific volume with the `volumeRefNum` field.

`volumeRefNum`
: On input, the volume to search, when iterating over multiple forks. To iterate over all open forks on a single volume, specify the volume reference number in this field. To iterate over all open forks on all volumes, set this field to the constant `kFSInvalidVolumeRefNum`. This field is ignored if you specify a fork reference number in the `desiredRefNum` parameter. Set `desiredRefNum` to zero if you wish to iterate over multiple forks. See `FSVolumeRefNum` (page 847) for a description of the `FSVolumeRefNum` data type.

`iterator`
: On input, an iterator. If the `desiredRefNum` parameter is 0, the iterator maintains state between calls to `PBGetForkCBInfoSync`. Set the `iterator` field to 0 before you begin iterating, on the first call to `PBGetForkCBInfoSync`. On return, the iterator will be updated; pass this updated iterator in the `iterator` field of the next call to `PBGetForkCBInfoSync` to continue iterating.

`actualRefNum`
: On output, the actual reference number of the open fork that was found.

`ref`
: On output, a pointer to the `FSRef` (page 837) for the file or directory that contains the fork. This information is optional; if you do not wish to the `FSRef`, set `ref` to `NULL`.

`forkInfo`
: On output, a pointer to an `FSForkInfo` (page 832) structure containing information about the open fork. This information is optional; if you do not wish it returned, set `forkInfo` to `NULL`.

`forkName`
: On output, a pointer to the name of the fork. This field is optional; if you do not wish the name returned, set `forkName` to `NULL`. See `HFSUniStr255` (page 855) for a description of the `HFSUniStr255` data type.

Carbon applications are no longer guaranteed access to the FCB table. Instead, applications should use `FSGetForkCBInfo` (page 497) , or one of the related parameter block functions, `PBGetForkCBInfoSync` and `PBGetForkCBInfoAsync` (page 660) , to access information about a fork control block.

Special Considerations

Returning the fork information in the `forkInfo` field generally does not require a disk access; returning the information in the `ref` or `forkName` fields may cause disk access for some volume formats.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBGetForkPositionAsync

Returns the current position of an open fork.

```
void PBGetForkPositionAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`forkRefNum`

On input, the reference number of a fork previously opened by the `FSOpenFork` (page 514) , `PBOpenForkSync` (page 740) , or `PBOpenForkAsync` (page 739) function.

`positionOffset`

On output, the current position of the fork. The returned fork position is relative to the start of the fork (that is, it is an absolute offset in bytes).

Special Considerations

Before calling the `PBGetForkPositionAsync` function, call the `Gestalt` function with the `gestaltFSAttr` selector to determine if `PBGetForkPositionAsync` is available. If the function is available, but is not directly supported by a volume, the File Manager will automatically call `PBGetFPosAsync` (page 666); however, you will not be able to determine the fork position of a named fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBGetForkPositionSync

Returns the current position of an open fork.

```
OSErr PBGetForkPositionSync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`forkRefNum`
: On input, the reference number of a fork previously opened by the `FSOpenFork` (page 514) , `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739) function.

`positionOffset`
: On output, the current position of the fork. The returned fork position is relative to the start of the fork (that is, it is an absolute offset in bytes).

Special Considerations

Before calling the `PBGetForkPositionSync` function, call the `Gestalt` function with the `gestaltFSAttr` selector to determine if `PBGetForkPositionSync` is available. If the function is available, but is not directly supported by a volume, the File Manager will automatically call `PBGetFPosSync` (page 666); however, you will not be able to determine the fork position of a named fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetForkSizeAsync

Returns the size of an open fork.

```
void PBGetForkSizeAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock
: A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`forkRefNum`
: On input, the reference number of the open fork. You can obtain this fork reference number with the `FSOpenFork` (page 514) function, or with one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionOffset`
: On output, the logical size (the logical end-of-file) of the fork, in bytes. The size returned is the total number of bytes that can be read from the fork; the amount of space actually allocated on the volume (the physical size) will probably be larger.

Special Considerations

To determine whether the `PBGetForkSizeAsync` function is present, call the `Gestalt` function. If `PBGetForkSizeAsync` is present, but is not directly supported by a volume, the File Manager will call `PBGetEOFAsync` (page 654); however, you will not be able to determine the size of a fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetForkSizeSync

Returns the size of an open fork.

```
OSErr PBGetForkSizeSync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`forkRefNum`
: On input, the reference number of the open fork. You can obtain this fork reference number with the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionOffset`
: On output, the logical size (the logical end-of-file) of the fork, in bytes. The size returned is the total number of bytes that can be read from the fork; the amount of space actually allocated on the volume (the physical size) will probably be larger.

Special Considerations

To determine whether the `PBGetForkSizeSync` function is present, call the `Gestalt` function. If `PBGetForkSizeSync` is present, but is not directly supported by a volume, the File Manager will call `PBGetEOFSync` (page 655); however, you will not be able to determine the size of a fork other than the data or resource fork, or of a fork larger than 2 GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBGetFPosAsync

Returns the current position of the file mark. (Deprecated in Mac OS X v10.4. Use PBGetForkPositionAsync (page 663) instead.)

```
OSErr PBGetFPosAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information about completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function.

ioRefNum

On input, the file reference number of an open file.

ioPosOffset

On output, the current position of the mark. The value returned in ioPosOffset is zero-based. Thus, a call to PBGetFPosAsync returns 0 if you call it when the file mark is positioned at the beginning of the file. The ioReqCount, ioActCount, and ioPosMode fields of the parameter block are all set to 0 on output. To determine the current position of a named fork, or of a fork larger than 2GB, use the FSGetForkPosition (page 499) function, or one of the corresponding parameter block calls, PBGetForkPositionSync (page 663) and PBGetForkPositionAsync (page 663).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

PBGetFPosSync

Returns the current position of the file mark. (Deprecated in Mac OS X v10.4. Use PBGetForkPositionSync (page 663) instead.)

```
OSErr PBGetFPosSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioRefNum

On input, the file reference number of an open file.

ioPosOffset

On output, the current position of the mark. The value returned in ioPosOffset is zero-based. Thus, a call to PBGetFPosSync returns 0 if you call it when the file mark is positioned at the beginning of the file.

The ioReqCount, ioActCount, and ioPosMode fields of the parameter block are all set to 0 on output.

To determine the current position of a named fork, or of a fork larger than 2GB, use the FSGetForkPosition (page 499) function, or one of the corresponding parameter block calls, PBGetForkPositionSync (page 663) and PBGetForkPositionAsync (page 663).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Files.h

PBGetUGEntryAsync

Gets a user or group entry from the list of User and Group names and IDs on the local file server. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBGetUGEntryAsync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBGetUGEntrySync

Gets a user or group entry from the list of User and Group names and IDs on a local file server. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBGetUGEntrySync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBGetVolMountInfo

Retrieves a record containing all the information needed to mount a volume, except for passwords. (Deprecated in Mac OS X v10.5. Use `FSVolumeMount` (page 545) instead.)

```
OSErr PBGetVolMountInfo (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname

`ioVRefNum`
On input, a volume specification. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioBuffer`
On input, a pointer to a buffer to hold the mounting information. The length of the buffer is specified by the value pointed to by the `ioBuffer` field in a previous call to `PBGetVolMountInfoSize` (page 669). On output, the mounting information for the specified volume. You can later pass this structure

to the PBVolumeMount (page 773) function to mount the volume. The mounting information for an AppleShare volume is stored as an AFP mounting record. The PBGetVolMountInfo function does not return the user password or volume password in the AFPVolMountInfo structure. Your application should solicit these passwords from the user and fill in the structure before attempting to mount the remote volume.

This function allows your application to record the mounting information for a volume and then to mount the volume later. This programmatic mounting function stores the mounting information in a structure called the AFPVolMountInfo (page 797) structure.

Special Considerations

This function executes synchronously. You should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

Files.h

PBGetVolMountInfoSize

Determines how much space to allocate for a volume mounting information structure. (Deprecated in Mac OS X v10.5. Use FSVolumeMount (page 545) instead.)

```
OSErr PBGetVolMountInfoSize (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioNamePtr

On input, a pointer to a pathname

ioVRefNum

On input, a volume specification. This field can contain a volume reference number, drive number, or 0 for the default volume.

ioBuffer

On input, a pointer to storage for the size information, which is of type Integer (2 bytes). If PBGetVolMountInfoSize returns noErr, that integer contains the size of the volume mounting information structure on output.

You should call this function before you call PBGetVolMountInfo (page 668) , to obtain the size of the volume mounting information for which you must allocate storage. Then call PBGetVolMountInfo to retrieve the actual volume mounting information.

Special Considerations

This function executes synchronously. You should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBGetVolumeInfoAsync

Returns information about a volume.

```
void PBGetVolumeInfoAsync (
   FSVolumeInfoParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a volume information parameter block. See `FSVolumeInfoParam` (page 845) for a description of the `FSVolumeInfoParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioVRefNum`

On input, the volume whose information is to be returned. For information on a particular volume, pass that volume's reference number and set the `volumeIndex` field to 0. To index through the list of mounted volumes, pass the constant `kFSInvalidVolumeRefNum`.On output, the volume reference number of the volume. This is useful when indexing over all mounted volumes, when you have not specified a particular volume reference number on input.

`volumeIndex`

On input, the index of the desired volume, or 0 to use the volume reference number in the `ioVRefNum` field.

`whichInfo`

On input, a bitmap specifying which volume information fields to return in the `volumeInfo` field. If you don't want the information about the volume returned in the `volumeInfo` field, set `whichInfo` to `kFSVolInfoNone`. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this field.

`volumeInfo`

On output, a pointer to the volume information, as described by the `FSVolumeInfo` (page 842) data type. If you don't want this output, set this field to `NULL`.

`volumeName`

On output, a pointer to the Unicode name of the volume. If you do not wish the name returned, pass `NULL`. Otherwise, pass a pointer to an `HFSUniStr255` (page 855) structure.

`ref`

On output, a pointer to the `FSRef` (page 837) for the volume's root directory. If you do not wish the root directory returned, pass `NULL`.

You can specify a particular volume or index through the list of mounted volumes. To get information on a particular volume, pass the volume reference number of the desired volume in the `ioVRefNum` field and set the `volumeIndex` field to zero. To index through the list of mounted volumes, pass `kFSInvalidVolumeRefNum` in the `ioVRefNum` field and set `volumeIndex` to the index, starting at 1 with the first call to `PBGetVolumeInfoAsync`.

To get information about the root directory of a volume, use the `FSGetCatalogInfo` (page 494) function, or one of the corresponding parameter block calls, `PBGetCatalogInfoSync` (page 647) and `PBGetCatalogInfoAsync` (page 643).

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBGetVolumeInfoAsync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetVolumeInfoSync

Returns information about a volume.

```
OSErr PBGetVolumeInfoSync (
   FSVolumeInfoParam *paramBlock
);
```

Parameters

`paramBlock`

A pointer to a volume information parameter block. See `FSVolumeInfoParam` (page 845) for a description of the `FSVolumeInfoParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioVRefNum`

On input, the volume whose information is to be returned. For information on a particular volume, pass that volume's reference number and set the `volumeIndex` field to 0. To index through the list of mounted volumes, pass the constant `kFSInvalidVolumeRefNum`.On output, the volume reference

number of the volume. This is useful when indexing over all mounted volumes, when you have not specified a particular volume reference number on input.

`volumeIndex`
On input, the index of the desired volume, or 0 to use the volume reference number in the `ioVRefNum` field.

`whichInfo`
On input, a bitmap specifying which volume information fields to return in the `volumeInfo` field. If you don't want the information about the volume returned in the `volumeInfo` field, set `whichInfo` to `kFSVolInfoNone`. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this field.

`volumeInfo`
On output, a pointer to the volume information, as described by the `FSVolumeInfo` (page 842) data type. If you don't want this output, set this field to `NULL`.

`volumeName`
On output, a pointer to the Unicode name of the volume. If you do not wish the name returned, pass `NULL`. Otherwise, pass a pointer to an `HFSUniStr255` (page 855) structure.

`ref`
On output, a pointer to the `FSRef` (page 837) for the volume's root directory. If you do not wish the root directory returned, pass `NULL`.

You can specify a particular volume or index through the list of mounted volumes. To get information on a particular volume, pass the volume reference number of the desired volume in the `ioVRefNum` field and set the `volumeIndex` field to zero. To index through the list of mounted volumes, pass `kFSInvalidVolumeRefNum` in the `ioVRefNum` field and set `volumeIndex` to the index, starting at 1 with the first call to `PBGetVolumeInfoSync`.

To get information about the root directory of a volume, use the `FSGetCatalogInfo` (page 494) function, or one of the corresponding parameter block calls, `PBGetCatalogInfoSync` (page 647) and `PBGetCatalogInfoAsync` (page 643).

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBGetVolumeInfoSync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBGetXCatInfoAsync

Returns the short name (MS-DOS format name) and the ProDOS information for a file or directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBGetXCatInfoAsync (
   XCInfoPBPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBGetXCatInfoSync

Returns the short name (MS-DOS format name) and the ProDOS information for a file or directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBGetXCatInfoSync (
   XCInfoPBPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHCopyFileAsync

Duplicates a file and optionally renames it. (Deprecated in Mac OS X v10.5. Use `PBFSCopyFileAsync` (page 643) instead.)

```
OSErr PBHCopyFileAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a `CopyParam` (page 806) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioNamePtr`
: On input, a pointer to the name of the source file.

`ioVRefNum`
: On input, the volume reference number or drive number for the volume containing the source file. Pass 0 for the default volume.

`ioDstVRefNum`
: On input, the reference number or drive number of the destination volume. Pass 0 for the default volume.

`ioNewName`
: On input, a pointer to the partial pathname for the destination directory. If `ioNewName` is `NULL`, the destination directory is the directory having the ID specified in the `ioNewDirID` field.

`ioCopyName`
: On input, a pointer to the file's new name. The string pointed to by this field must be a filename, not a partial pathname. If you do not wish to rename the file, pass `NULL` in this field.

`ioNewDirID`
: On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, the parent directory ID of the destination directory.

`ioDirID`
: On input, the directory ID of the source directory.

This function is especially useful when you want to copy or move files located on a remote volume, because it allows you to forgo transmitting large amounts of data across a network. This function is used internally by the Finder; most applications do not need to use it.

Special Considerations

This is an optional call for AppleShare file servers. Your application should examine the information returned by the `PBHGetVolParmsAsync` (page 694) function to see if the volume supports `PBHCopyFileAsync`. If the `bHasCopyFile` bit is set in the `vMAttrib` field of the `GetVolParmsInfoBuffer` structure, then the volume supports `PBHCopyFileAsync`.

For AppleShare file servers, the source and destination pathnames must indicate the same file server; however, the parameter block may specify different source and destination volumes on that file server. A useful way to tell if two file server volumes are on the same file server is to call the `PBHGetVolParmsAsync` (page 694) function for each volume and compare the server addresses returned. The server opens source files with read/deny write enabled and destination files with write/deny read and write enabled.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Files.h`

PBHCopyFileSync

Duplicates a file and optionally renames it. (Deprecated in Mac OS X v10.5. Use `PBFSCopyFileSync` (page 643) instead.)

```
OSErr PBHCopyFileSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to a `CopyParam` (page 806) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to the name of the source file.

`ioVRefNum`

On input, the volume reference number or drive number for the volume containing the source file. Pass 0 for the default volume.

`ioDstVRefNum`

On input, the reference number or drive number of the destination volume. Pass 0 for the default volume.

`ioNewName`

On input, a pointer to the partial pathname for the destination directory. If `ioNewName` is `NULL`, the destination directory is the directory having the ID specified in the `ioNewDirID` field.

`ioCopyName`

On input, a pointer to the file's new name. The string pointed to by this field must be a filename, not a partial pathname. If you do not wish to rename the file, pass `NULL` in this field.

`ioNewDirID`

On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, the parent directory ID of the destination directory.

`ioDirID`

On input, the directory ID of the source directory.

This function is especially useful when you want to copy or move files located on a remote volume, because it allows you to forgo transmitting large amounts of data across a network. This function is used internally by the Finder; most applications do not need to use it.

Special Considerations

This is an optional call for AppleShare file servers. Your application should examine the information returned by the `PBHGetVolParmsSync` (page 695) function to see if the volume supports `PBHCopyFileSync`. If the `bHasCopyFile` bit is set in the `vMAttrib` field of the `GetVolParmsInfoBuffer` structure, then the volume supports `PBHCopyFileSync`.

For AppleShare file servers, the source and destination pathnames must indicate the same file server; however, the parameter block may specify different source and destination volumes on that file server. A useful way to tell if two file server volumes are on the same file server is to call the `PBHGetVolParmsSync` (page 695) function for each volume and compare the server addresses returned. The server opens source files with read/deny write enabled and destination files with write/deny read and write enabled.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHCreateAsync

Creates a new file. (Deprecated in Mac OS X v10.4. Use `PBCreateFileUnicodeAsync` (page 591) instead.)

```
OSErr PBHCreateAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion function. For more information on completion functions, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the name for the new file.

`ioVRefNum`

On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`

On input, the directory ID of the parent directory of the new file.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

The `PBHCreateAsync` function creates both forks of the file the new file is unlocked and empty. The date and time of its creation and last modification are set to the current date and time. If the file created isn't temporary (that is, if it will exist after the user quits the application), the application should call `PBHSetFInfoAsync` (page 721) , after the call to `PBHCreateAsync`, to fill in the information needed by the Finder.

Files created using `PBHCreateAsync` are not automatically opened. If you want to write data to the new file, you must first open the file using one of the file access functions, `FSpOpenDF` (page 531) , `HOpenDF` (page 554) , `PBHOpenDFSync` (page 708) or `PBHOpenDFAsync` (page 706).

The resource fork of the new file exists but is empty. You'll need to call one of the Resource Manager procedures `HCreateResFile` or `FSpCreateResFile` to create a resource map in the file before you can open it (by calling one of the Resource Manager functions `HOpenResFile` or `FSpOpenResFile`).

To create a file with a Unicode filename, use the function `FSCreateFileUnicode` (page 481) , or one of the corresponding parameter block calls, `PBCreateFileUnicodeSync` (page 593) and `PBCreateFileUnicodeAsync` (page 591).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHCreateSync

Creates a new file. (Deprecated in Mac OS X v10.4. Use `PBCreateFileUnicodeSync` (page 593) instead.)

```
OSErr PBHCreateSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
: On input, a pointer to the name for the new file.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the directory ID of the parent directory of the new file.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

The `PBHCreateSync` function creates both the data and resource fork of the file the new file is unlocked and empty. The date and time of its creation and last modification are set to the current date and time. If the file created isn't temporary (that is, if it will exist after the user quits the application), the application should call `PBHSetFInfoSync` (page 722) after the call to `PBHCreateSync` to fill in the information needed by the Finder.

Files created using `PBHCreateSync` are not automatically opened. If you want to write data to the new file, you must first open the file using one of the file access functions, `FSpOpenDF` (page 531) , `HOpenDF` (page 554) , `PBHOpenDFSync` (page 708) or `PBHOpenDFAsync` (page 706).

The resource fork of the new file exists but is empty. You'll need to call one of the Resource Manager procedures `HCreateResFile` or `FSpCreateResFile` to create a resource map in the file before you can open it (by calling one of the Resource Manager functions `HOpenResFile` or `FSpOpenResFile`).

To create a file with a Unicode filename, use the function `FSCreateFileUnicode` (page 481) , or one of the corresponding parameter block calls, `PBCreateFileUnicodeSync` (page 593) and `PBCreateFileUnicodeAsync` (page 591).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHDeleteAsync

Deletes a file or directory. (Deprecated in Mac OS X v10.4. Use `PBDeleteObjectAsync` (page 599) instead.)

```
OSErr PBHDeleteAsync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. If you attempt to delete an open file or a non-empty directory, `PBHDeleteAsync` returns the result code `fBsyErr`. `PBHDeleteAsync` also returns `fBsyErr` if you attempt to delete a directory that has an open working directory associated with it.

`ioNamePtr`
: On input, a pointer to the name of the file or directory to delete.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
: On input, the directory ID of the parent directory of the file or directory to delete.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the specified target is a file, both the data and the resource fork of the file are deleted. In addition, if a file ID reference for the specified file exists, that file ID reference is also removed. A file must be closed before you can delete it. Similarly, you cannot delete a directory unless it's empty.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHDeleteSync

Deletes a file or directory. (Deprecated in Mac OS X v10.4. Use `PBDeleteObjectSync` (page 600) instead.)

```
OSErr PBHDeleteSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If you attempt to delete an open file or a non-empty directory, `PBHDeleteSync` returns the result code `fBsyErr`. `PBHDeleteSync` also returns `fBsyErr` if you attempt to delete a directory that has an open working directory associated with it.

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
: On input, a pointer to the name of the file or directory to delete.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
: On input, the directory ID of the parent directory of the file or directory to delete.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the specified target is a file, both the data and the resource fork of the file are deleted. In addition, if a file ID reference for the specified file exists, that file ID reference is also removed. A file must be closed before you can delete it. Similarly, you cannot delete a directory unless it's empty.

`Files.h`

PBHGetDirAccessAsync

Returns the access control information for a directory or file. (Deprecated in Mac OS X v10.5. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr PBHGetDirAccessAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `AccessParam` (page 795) variant of an HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioNamePtr`
: On input, a pointer to a pathname for the directory or file.

`ioVRefNum`
: On input, a volume specification for the volume containing the directory or file. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioACOwnerID`
: On output, the user ID for the owner of the directory or file.

`ioACGroupID`
On output, the primary group ID of the directory or file.

`ioACAccess`
On output, the access rights for the directory or file. See "File and Folder Access Privilege Constants" (page 910) for more information on these access rights.

`ioDirID`
On input, the directory ID.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHGetDirAccessSync

Returns the access control information for a directory or file. (Deprecated in Mac OS X v10.5. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr PBHGetDirAccessSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to the `AccessParam` (page 795) variant of an HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname for the directory or file.

`ioVRefNum`
On input, a volume specification for the volume containing the directory or file. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioACOwnerID`
On output, the user ID for the owner of the directory or file.

`ioACGroupID`
On output, the primary group ID of the directory or file.

`ioACAccess`
On output, the access rights for the directory or file. See "File and Folder Access Privilege Constants" (page 910) for more information on these access rights.

`ioDirID`
On input, the directory ID.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHGetFInfoAsync

Obtains information about a file. (Deprecated in Mac OS X v10.4. Use `PBGetCatalogInfoAsync` (page 643) instead.)

```
OSErr PBHGetFInfoAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname. If the value of the `ioFDirIndex` field is negative or 0, `PBHGetFInfoAsync` returns information about the file in the volume specified by the reference number in the `ioVRefNum` field and having the name given here. On output, a pointer to the name of the file, if the file is open. If you do not wish the name returned, pass `NULL` here.

`ioVRefNum`
On input, a volume reference number or drive number for the volume containing the file, or 0 for the default volume.

`ioFRefNum`
On output, the reference number of the first access path found, if the file is open and if the `ioFDirIndex` field is negative or 0; if the `ioFDirIndex` field is positive...

`ioFDirIndex`
On input, a directory index. If this value is positive, the function returns information about the file having the directory index specified here, on the volume specified in the `ioVRefNum` field and in the directory specified in the `ioDirID` field. If this value is negative or 0, the function returns information about the file on the specified volume, having the name pointed to in the `ioNamePtr` field.

`ioFlAttrib`
: On output, the file attributes. See "File Attribute Constants" (page 914) for a description of the file attributes.

`ioFlFndrInfo`
: On output, Finder information about the file. For a description of the `FInfo` structure, see the *Finder Interface Reference* .

`ioDirID`
: On input, the parent directory ID of the file. On output, the file's file ID.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

`ioFlStBlk`
: On output, the first allocation block of the data fork.

`ioFlLgLen`
: On output, the logical size (the logical end-of-file) of the file's data fork, in bytes.

`ioFlPyLen`
: On output, the physical size (the physical end-of-file) of the file's data fork, in bytes.

`ioFlRStBlk`
: On output, the first allocation block of the resource fork.

`ioFlRLgLen`
: On output, the logical size of the file's resource fork, in bytes.

`ioFlRPyLen`
: On output, the physical size of the file's resource fork, in bytes.

`ioFlCrDat`
: On output, the date and time of the file's creation.

`ioFlMdDat`
: On output, the date and time of the file's last modification.

You should call `PBHGetFInfoAsync` just before `PBHSetFInfoAsync` (page 721) , so that the current information is present in the parameter block.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`Files.h`

PBHGetFInfoSync

Obtains information about a file. (Deprecated in Mac OS X v10.4. Use `PBGetCatalogInfoSync` (page 647) instead.)

```
OSErr PBHGetFInfoSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the HFileParam (page 852) variant of the basic HFS parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioNamePtr

On input, a pointer to a pathname. If the value of the ioFDirIndex field is negative or 0, PBHGetFInfoSync returns information about the file in the volume specified by the reference number in the ioVRefNum field and having the name given here. On output, a pointer to the name of the file, if the file is open. If you do not wish the name returned, pass NULL here.

ioVRefNum

On input, a volume reference number or drive number for the volume containing the file, or 0 for the default volume.

ioFRefNum

On output, the reference number of the first access path found, if the file is open and if the ioFDirIndex field is negative or 0; if the ioFDirIndex field is positive...

ioFDirIndex

On input, a directory index. If this value is positive, the function returns information about the file having the directory index specified here, on the volume specified in the ioVRefNum field and in the directory specified in the ioDirID field. If this value is negative or 0, the function returns information about the file on the specified volume, having the name pointed to in the ioNamePtr field.

ioFlAttrib

On output, the file attributes. See "File Attribute Constants" (page 914) for a description of the file attributes.

ioFlFndrInfo

On output, Finder information about the file. For a description of the FInfo data type, see the *Finder Interface Reference* .

ioDirID

On input, the parent directory ID of the file. On output, the file's file ID.

ioFVersNum

On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

ioFlStBlk

On output, the first allocation block of the data fork.

ioFlLgLen

On output, the logical size (the logical end-of-file) of the file's data fork, in bytes.

ioFlPyLen

On output, the physical size (the physical end-of-file) of the file's data fork, in bytes.

`ioFlRStBlk`
On output, the first allocation block of the resource fork.

`ioFlRLgLen`
On output, the logical size of the resource fork, in bytes.

`ioFlRPyLen`
On output, the physical size of the resource fork, in bytes.

`ioFlCrDat`
On output, the date and time of the file's creation.

`ioFlMdDat`
On output, the date and time of the file's last modification.

You should call `PBHGetFInfoSync` just before `PBHSetFInfoSync` (page 722) , so that the current information is present in the parameter block.

`Files.h`

PBHGetLogInInfoAsync

Determines the login method used to log on to a particular shared volume. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHGetLogInInfoAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `ObjParam` (page 865) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname

`ioVRefNum`
: On input, a volume specification for the shared volume. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioObjType`
: On output, the login method type. See "Authentication Method Constants" (page 888) for the values that are recognized. Values in the range 7–127 are reserved for future use by Apple Computer, Inc. Values in the range 128–255 are available to your application as user-defined values.

`ioObjNamePtr`
: On output, a pointer to the user name used to establish the session. The login user name is returned as a Pascal string. The maximum size of the user name is 31 characters.

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`Files.h`

PBHGetLogInInfoSync

Determines the login method used to log on to a particular shared volume. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHGetLogInInfoSync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVInfoAsync

Gets detailed information about a volume. (Deprecated in Mac OS X v10.4. Use `PBGetVolumeInfoAsync` (page 670) instead.)

```
OSErr PBHGetVInfoAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the HVolumeParam (page 859) variant of the basic HFS parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function.

ioNamePtr

On input, a pointer to a buffer. If you specify a negative number in the ioVolIndex field, this buffer should hold the name of the volume for which to return information. On output, a pointer to the volume's name. You should pass a pointer to a Str31 value if you want the name returned. If you pass NULL, no volume name is returned.

ioVRefNum

On input, a volume specification for the volume for which to return information. If the ioVolIndex field is negative, the File Manager uses the value in the ioNamePtr field, along with the value specified in the ioVRefNum field, to determine the volume. If the value in ioVolIndex is 0, the File Manager attempts to access the volume using only the value in this field. On output, the volume reference number.

ioVolIndex

On input, an index used for indexing through all mounted volumes. If this value is positive, the File Manager uses it to find the volume for which to return information. For instance, if the value of ioVolIndex is 2, the File Manager attempts to access the second mounted volume in the VCB queue. If ioVolIndex is negative, the File Manager uses the values in the ioNamePtr and ioVRefNum fields to access the requested volume. If ioVolIndex is 0, the File Manager uses only the value in the ioVRefNum field.

ioVCrDate

On output, the date and time of the volume's initialization.

ioVLsMod

On output, the date and time of the volume's last modification.

ioVAtrb

On output, the volume attributes. See "Volume Information Attribute Constants" (page 937) for a description of the volume attributes returned by this function.

ioVNmFls

On output, the number of files in the root directory of the volume. For performance reasons, the Carbon File Manager does not return the number of files in this field; instead, it sets ioVNmFls to 0.To determine the number of files in the root directory of a volume in Carbon, call PBGetCatInfoAsync (page 648) for the root directory. The number of files in the root directory is returned in the ioDrNmFls field.

`ioVBitMap`
On output, the first block of the volume bitmap.

`ioVAllocPtr`
On output, the block at which the search for the next new file allocation should start.

`ioVNmAlBlks`
On output, the number of allocation blocks on the volume.

`ioVAlBlkSiz`
On output, the size of the allocation blocks.

`ioVClpSiz`
On output, the default clump size.

`ioAlBlSt`
On output, the first block in the volume block map.

`ioVNxtCNID`
On output, the next unused catalog node ID.

`ioVFrBlk`
On output, the number of unused allocation blocks.

`ioVSigWord`
On output, the volume signature. For HFS volumes, this is 'BD' for HFS Plus volumes, this is 'H+'.

`ioVDrvInfo`
On output, the drive number. You can determine whether the given volume is online by inspecting the value of this field. For online volumes, the `ioVDrvInfo` field contains the drive number of the drive containing the specified volume and hence is always greater than 0. If the value returned in `ioVDrvInfo` is 0, the volume is either offline or ejected.

Mac OS X does not support drive numbers; in Mac OS X, the File Manager always returns a value of 1 in this field.

`ioVDRefNum`
On output, the driver reference number. You can determine whether the volume is offline or ejected by inspecting the value of this field. If the volume is offline, the value of `ioVDRefNum` is the negative of the drive number (which is cleared when the volume is placed offline; hence the `ioVDrvInfo` field for an offline volume is zero), and is a negative number. If the volume is ejected, the value of `ioVDRefNum` is the drive number itself, and thus is a positive number. For online volumes, `ioVDRefNum` contains a driver reference number; these numbers are always less than 0.

`ioVFSID`
On output, the file system handling this volume.

`ioVBkUp`
On output, the date and time of the volume's last backup.

`ioVSeqNum`
Used internally.

`ioVWrCnt`
On output, the volume write count.

`ioVFilCnt`
On output, the number of files on the volume.

`ioVDirCnt`
On output, the number of directories on the volume.

`ioVFndrInfo`

On output, Finder information for the volume.

You can get information about all the online volumes by making repeated calls to `PBHGetVInfoAsync`, starting with the value of the `ioVolIndex` field set to 1 and incrementing that value until `PBHGetVInfoAsync` returns `nsvErr`.

If you need to obtain information about HFS Plus volumes, you should use the `FSGetVolumeInfo` (page 500) function, or one of the corresponding parameter block calls, `PBGetVolumeInfoSync` (page 671) and `PBGetVolumeInfoAsync` (page 670). The `PBHGetVInfoAsync` function is still supported for HFS Plus volumes, but there is additional information returned by the `FSGetVolumeInfo` function (such as the date and time that the volume was last checked for consistency).

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBHGetVInfoAsync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

If the value of `ioVolIndex` is negative, the File Manager uses `ioNamePtr` and `ioVRefNum` in the standard way to determine the volume. However, because `PBHGetVInfoAsync` returns the volume name in the buffer whose address you passed in `ioNamePtr`, your input pathname will be modified. If you don't want your input pathname modified, make a copy of it and pass the copy to `PBHGetVInfoAsync`.

The volume name returned by `PBHGetVInfoAsync` is not a full pathname to the volume because it does not contain a colon.

For compatibility with older programs, some values returned by `PBHGetVInfoAsync` are not what is stored in the volume's Volume Control Block (VCB). Specifically:

- `ioVNmAlBlks` and `ioVFrBlk` are pinned to values which, when multiplied by `ioVAlBlkSiz`, are always less than 2 Gigabytes.
- `ioVNmAlBlks` may not include the allocation blocks used by the catalog and extents overflow files.
- $4244 is returned in `ioVSigWord` for both HFS and HFS Plus volumes.

For unpinned total and free byte counts, and for the real `ioVSigWord`, use `PBXGetVolInfoAsync` (page 779) instead of `PBHGetVInfoAsync`.

Version Notes

In non-Carbon applications, you may pass a working directory reference in the `ioVRefNum` field; if you pass a working directory reference in that field, the number of files and directories in the specified directory is returned in the `ioVNmFls` field.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVInfoSync

Gets detailed information about a volume. (Deprecated in Mac OS X v10.4. Use `PBGetVolumeInfoSync` (page 671) instead.)

```
OSErr PBHGetVInfoSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HVolumeParam` (page 859) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a buffer. If you specify a negative number in the `ioVolIndex` field, this buffer should hold the name of the volume for which to return information. On output, a pointer to the volume's name. You should pass a pointer to a `Str31` value if you want the name returned. If you pass `NULL`, no volume name is returned.

`ioVRefNum`

On input, a volume reference number or drive number for the volume for which to return information; or 0 for the default volume. If the `ioVolIndex` field is negative, the File Manager uses the value in the `ioNamePtr` field, along with the value specified in the `ioVRefNum` field, to determine the volume. If the value in `ioVolIndex` is 0, the File Manager attempts to access the volume using only the value in this field. On output, the volume reference number.

`ioVolIndex`

On input, an index used for indexing through all mounted volumes. If this value is positive, the File Manager uses it to find the volume for which to return information. For instance, if the value of `ioVolIndex` is 2, the File Manager attempts to access the second mounted volume in the VCB queue. If `ioVolIndex` is negative, the File Manager uses the values in the `ioNamePtr` and `ioVRefNum` fields to access the requested volume. If `ioVolIndex` is 0, the File Manager uses only the value in the `ioVRefNum` field.

`ioVCrDate`

On output, the date and time of the volume's initialization.

`ioVLsMod`

On output, the date and time of the volume's last modification.

`ioVAtrb`

On output, the volume attributes. See "Volume Information Attribute Constants" (page 937) for a description of the volume attributes returned by this function.

`ioVNmFls`

On output, the number of files in the root directory of the volume. For performance reasons, the Carbon File Manager does not return the number of files in this field; instead, it sets `ioVNmFls` to 0.To determine the number of files in the root directory of a volume in Carbon, call `PBGetCatInfoSync` (page 651) for the root directory. The number of files in the root directory is returned in the `ioDrNmFls` field.

`ioVBitMap`
On output, the first block of the volume bitmap.

`ioVAllocPtr`
On output, the block at which the search for the next new file allocation should start.

`ioVNmAlBlks`
On output, the number of allocation blocks on the volume.

`ioVAlBlkSiz`
On output, the size of the allocation blocks.

`ioVClpSiz`
On output, the default clump size.

`ioAlBlSt`
On output, the first block in the volume block map.

`ioVNxtCNID`
On output, the next unused catalog node ID.

`ioVFrBlk`
On output, the number of unused allocation blocks.

`ioVSigWord`
On output, the volume signature. For HFS volumes, this is 'BD' for HFS Plus volumes, this is 'H+'.

`ioVDrvInfo`
On output, the drive number. You can determine whether the given volume is online by inspecting the value of this field. For online volumes, the `ioVDrvInfo` field contains the drive number of the drive containing the specified volume and hence is always greater than 0. If the value returned in `ioVDrvInfo` is 0, the volume is either offline or ejected.

Mac OS X does not support drive numbers; in Mac OS X, the File Manager always returns a value of 1 in this field.

`ioVDRefNum`
On output, the driver reference number. You can determine whether the volume is offline or ejected by inspecting the value of this field. If the volume is offline, the value of `ioVDRefNum` is the negative of the drive number (which is cleared when the volume is placed offline; hence the `ioVDrvInfo` field for an offline volume is zero), and is a negative number. If the volume is ejected, the value of `ioVDRefNum` is the drive number itself, and thus is a positive number. For online volumes, `ioVDRefNum` contains a driver reference number; these numbers are always less than 0.

`ioVFSID`
On output, the file system handling this volume.

`ioVBkUp`
On output, the date and time of the volume's last backup.

`ioVSeqNum`
Used internally.

`ioVWrCnt`
On output, the volume write count.

`ioVFilCnt`
On output, the number of files on the volume.

`ioVDirCnt`
On output, the number of directories on the volume.

`ioVFndrInfo`

On output, Finder information for the volume.

You can get information about all the online volumes by making repeated calls to `PBHGetVInfoSync`, starting with the value of the `ioVolIndex` field set to 1 and incrementing that value until `PBHGetVInfoSync` returns `nsvErr`.

If you need to obtain information about HFS Plus volumes, you should use the `FSGetVolumeInfo` (page 500) function, or one of the corresponding parameter block calls, `PBGetVolumeInfoSync` (page 671) and `PBGetVolumeInfoAsync` (page 670). The `PBHGetVInfoSync` function is still supported for HFS Plus volumes, but there is additional information returned by the `FSGetVolumeInfo` function (such as the date and time that the volume was last checked for consistency).

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBHGetVInfoSync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

If the value of `ioVolIndex` is negative, the File Manager uses `ioNamePtr` and `ioVRefNum` in the standard way to determine the volume. However, because `PBHGetVInfoSync` returns the volume name in the buffer whose address you passed in `ioNamePtr`, your input pathname will be modified. If you don't want your input pathname modified, make a copy of it and pass the copy to `PBHGetVInfoSync`.

The volume name returned by `PBHGetVInfoSync` is not a full pathname to the volume because it does not contain a colon.

For compatibility with older programs, some values returned by `PBHGetVInfoSync` are not what is stored in the volume's Volume Control Block (VCB). Specifically:

- `ioVNmAlBlks` and `ioVFrBlk` are pinned to values which, when multiplied by `ioVAlBlkSiz`, are always less than 2 Gigabytes.
- `ioVNmAlBlks` may not include the allocation blocks used by the catalog and extents overflow files.
- $4244 is returned in `ioVSigWord` for both HFS and HFS Plus volumes.

For unpinned total and free byte counts, and for the real `ioVSigWord`, use `PBXGetVolInfoSync` (page 782) instead of `PBHGetVInfoSync`.

Version Notes

In non-Carbon applications, you may pass a working directory reference in the `ioVRefNum` field; if you pass a working directory reference in that field, the number of files and directories in the specified directory is returned in the `ioVNmFls` field.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVolAsync

Determines the default volume and default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHGetVolAsync (
   WDPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a working directory parameter block. See `WDPBRec` (page 877) for a description of the `WDPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBHGetVolAsync` function returns the default volume and directory last set by a call to `HSetVol` (page 559) or `PBHSetVolSync` (page 726). The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On output, a pointer to the default volume's name. You should pass a pointer to a `Str31` value if you want that name returned. If you pass `NULL` in this field, no volume name is returned.

`ioVRefNum`

On output, the volume reference number of the default volume.

`ioWDProcID`

On output, the working directory user identifier.

`ioWDVRefNum`

On output, the volume reference number of the volume on which the default directory exists.

`ioWDDirID`

On output, the directory ID of the default directory.

Version Notes

When CarbonLib is not present, the `PBHGetVolAsync` function returns a working directory reference number in the `ioVRefNum` parameter if the previous call to `HSetVol` (page 559) (or one of the corresponding parameter block calls) passed in a working directory reference number.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVolParmsAsync

Returns information about the characteristics of a volume. (Deprecated in Mac OS X v10.5. Use `FSGetVolumeParms` (page 503) instead.)

```
OSErr PBHGetVolParmsAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the volume's name. You can use a either a name or a volume specification to specify the volume. If you use a volume specification to specify the volume, you should set the `ioNamePtr` field to `NULL`.

`ioVRefNum`

On input, a volume specification. You can use a either a name or a volume specification to specify the volume. A volume specification can be a volume reference number, drive number, or 0 for the default volume.

`ioBuffer`

On input, a pointer to a `GetVolParmsInfoBuffer` (page 847) record; you must allocate this memory to hold the returned attributes. On return, the `PBHGetVolParmsAsync` function places the attributes information in the buffer. Volumes that implement the HFS Plus APIs must use version 3 (or newer) of the `GetVolParmsInfoBuffer` structure. If the version of the `GetVolParmsInfoBuffer` is 2 or less, or the `bSupportsHFSPlusAPIs` bit is clear, then the volume does not implement the HFS Plus APIs and they are being emulated for that volume by the File Manager.

`ioReqCount`

On input, the size, in bytes, of the buffer area pointed to in the `ioBuffer` field.

`ioActCount`

On output, the size of the data actually returned.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVolParmsSync

Returns information about the characteristics of a volume. (Deprecated in Mac OS X v10.5. Use `FSGetVolumeParms` (page 503) instead.)

```
OSErr PBHGetVolParmsSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to the volume's name. You can use a either a name or a volume specification to specify the volume. If you use a volume specification to specify the volume, you should set the `ioNamePtr` field to `NULL`.

`ioVRefNum`

On input, a volume specification. You can use a either a name or a volume specification to specify the volume. A volume specification can be a volume reference number, drive number, or 0 for the default volume.

`ioBuffer`

On input, a pointer to a `GetVolParmsInfoBuffer` (page 847) record; you must allocate this memory to hold the returned attributes. On return, the `PBHGetVolParmsSync` function places the attributes information in the buffer. Volumes that implement the HFS Plus APIs must use version 3 (or newer) of the `GetVolParmsInfoBuffer` structure. If the version of the `GetVolParmsInfoBuffer` is 2 or less, or the `bSupportsHFSPlusAPIs` bit is clear, then the volume does not implement the HFS Plus APIs and they are being emulated for that volume by the File Manager.

`ioReqCount`

On input, the size, in bytes, of the buffer area pointed to in the `ioBuffer` field.

`ioActCount`

On output, the size of the data actually returned.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHGetVolSync

Determines the default volume and default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHGetVolSync (
   WDPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a working directory parameter block. See `WDPBRec` (page 877) for a description of the `WDPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBHGetVolSync` function returns the default volume and directory last set by a call to `HSetVol` (page 559) or `PBHSetVolSync` (page 726). The relevant fields of the parameter block are:

`ioNamePtr`

On output, a pointer to the default volume's name. Pass a pointer to a `Str31` value if you want that name returned. If you pass `NULL` in this field, no volume name is returned.

`ioVRefNum`

On output, the volume reference number of the default volume.

`ioWDProcID`

On output, the working directory user identifier.

`ioWDVRefNum`

On output, the volume reference number of the volume on which the default directory exists.

`ioWDDirID`

On output, the directory ID of the default directory.

Version Notes

When CarbonLib is not present, the `PBHGetVolSync` function returns a working directory reference number in the `ioVRefNum` parameter if the previous call to `HSetVol` (page 559) (or one of the corresponding parameter block calls) passed in a working directory reference number.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHMapIDAsync

Determines the name of a user or group given the user or group ID. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr PBHMapIDAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `ObjParam` (page 865) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to a pathname.

`ioVRefNum`

On input, a volume specification.

`ioObjType`

On input, the mapping function code its value is 1 if you're mapping a user ID to a user name or 2 if you're mapping a group ID to a group name. See "Mapping Code Constants" (page 926) for more information about the values you can use in this field.

`ioObjNamePtr`

On output, a pointer to the user or group name; the maximum size of the name is 31 characters (preceded by a length byte).

`ioObjID`

On input, the user or group ID to be mapped. AppleShare uses the value 0 to signify Any User.

Special Considerations

See the BSD functions `getpwnam` and `getpwuid`, which correspond to this function on a conceptual level.

Version Notes

Because user and group IDs are interchangeable under AFP 2.1 and later volumes, you might not need to specify a value in the `ioObjType` field.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

PBHMapNameAsync

Determines the user ID or group ID from a user or group name. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr PBHMapNameAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `ObjParam` (page 865) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to a pathname.

`ioVRefNum`

On input, a volume specification.

`ioObjType`

On input, the mapping function code its value is 3 if you're mapping a user name to a user ID or 4 if you're mapping a group name to a group ID. See "Mapping Code Constants" (page 926) for more information on the values you can use in this field.

`ioObjNamePtr`

On input, a pointer to the user or group name. The maximum size of the name is 31 characters. If `NULL` is passed, the ID returned is always 0.

`ioObjID`

On output, the mapped user or group ID.

Special Considerations

See the BSD functions `getpwnam` and `getpwuid`, which correspond to this function on a conceptual level.

Version Notes

Because user and group IDs are interchangeable under AFP 2.1 and later volumes, you might need to set the `ioObjType` field to determine which database (user or group) to search first. If both a user and a group have the same name, this field determines which kind of ID you receive.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `ObjParam` (page 865) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a pathname.

`ioVRefNum`

On input, a volume specification.

`ioObjType`

On input, the mapping function code its value is 3 if you're mapping a user name to a user ID or 4 if you're mapping a group name to a group ID. See "Mapping Code Constants" (page 926) for more information on the values you can use in this field.

`ioObjNamePtr`

On input, a pointer to the user or group name. The maximum size of the name is 31 characters. If `NULL` is passed, the ID returned is always 0.

`ioObjID`

On output, the mapped user or group ID.

Special Considerations

See the BSD functions `getpwnam` and `getpwuid`, which correspond to this function on a conceptual level.

Version Notes

Because user and group IDs are interchangeable under AFP 2.1 and later volumes, you might need to set the `ioObjType` field to determine which database (user or group) to search first. If both a user and a group have the same name, this field determines which kind of ID you receive.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHMoveRenameAsync

Moves a file or directory and optionally renames it. (Deprecated in Mac OS X v10.4. Use `FSMoveObjectAsync` (page 511) instead.)

```
OSErr PBHMoveRenameAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a `CopyParam` (page 806) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBHMoveRenameAsync` function allows you to move (not copy) a file or directory. The source and destination pathnames must point to the same file server volume. This function is especially useful when you want to copy or move files located on a remote volume, because it allows you to forgo transmitting large amounts of data across a network. This function is used internally by the Finder; most applications do not need to use it.

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the pathname for the source file or directory.

`ioVRefNum`

On input, a volume reference number or drive number for the volume containing the source file or directory. Pass 0 for the default volume.

`ioNewName`

On input, a pointer to the destination pathname. If `ioNewName` is `NULL`, the destination directory is the directory having the ID specified in the `ioNewDirID` field. If `ioNewName` is not `NULL`, the destination directory is the directory having the partial pathname pointed to by `ioNewName` in the directory having ID `ioNewDirID` on the specified volume.

`ioCopyName`

On input, a pointer to the file's new name. The string pointed to by this field must be a filename, not a partial pathname. If you do not wish to rename the file, pass `NULL` in this field.

`ioNewDirID`

On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, the parent directory ID of the destination directory.

`ioDirID`

On input, the directory ID of the source directory.

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHMoveRenameSync

Moves a file or directory and optionally renames it. (Deprecated in Mac OS X v10.4. Use `FSMoveObjectSync` (page 512) instead.)

```
OSErr PBHMoveRenameSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a `CopyParam` (page 806) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBHMoveRenameSync` function allows you to move (not copy) a file or directory. The source and destination pathnames must point to the same file server volume. This function is especially useful when you want to copy or move files located on a remote volume, because it allows you to forgo transmitting large amounts of data across a network. This function is used internally by the Finder; most applications do not need to use it.

The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the pathname for the source file or directory.

`ioVRefNum`
On input, a volume reference number or drive number for the volume containing the source file or directory. Pass 0 for the default volume.

`ioNewName`
On input, a pointer to the destination pathname. If `ioNewName` is `NULL`, the destination directory is the directory having the ID specified in the `ioNewDirID` field. If `ioNewName` is not `NULL`, the destination directory is the directory having the partial pathname pointed to by `ioNewName` in the directory having ID `ioNewDirID` on the specified volume.

`ioCopyName`
On input, a pointer to the file's new name. The string pointed to by this field must be a filename, not a partial pathname. If you do not wish to rename the file, pass `NULL` in this field.

`ioNewDirID`
On input, if the `ioNewName` field is `NULL`, the directory ID of the destination directory. If `ioNewName` is not `NULL`, the parent directory ID of the destination directory.

`ioDirID`
On input, the directory ID of the source directory.

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`Files.h`

PBHOpenAsync

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkAsync` (page 739) instead.)

```
OSErr PBHOpenAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a basic HFS parameter block.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. If you attempt to open a locked file for writing, `PBHOpenAsync` returns the result code `permErr`. If you request exclusive read/write permission but another access path is already open, `PBHOpenAsync` returns the reference number of the existing access path in `ioRefNum` and `opWrErr` as its function result.

`ioNamePtr`
On input, a pointer to the name of the file.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`
On output, a file reference number for accessing the open data fork. If you request exclusive read/write permission but another access path is already open, `PBHOpenAsync` returns the reference number of the existing access path. You should not use this reference number unless your application originally opened the file.

`ioPermssn`
On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908). You can open

a path for writing even if it accesses a file on a locked volume, and no error is returned until a `PBWriteAsync`, `PBSetEOFAsync` (page 757) , or `PBAllocateAsync` (page 564) call is made.

`ioDirID`
On input, the directory ID of the file's parent directory.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If you use `PBHOpenAsync` to try to open a file whose name begins with a period, you might mistakenly open a driver instead; subsequent attempts to write data might corrupt data on the target device. To avoid these problems, you should always use `PBHOpenDFAsync` (page 706) instead of `PBHOpenAsync`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenDenyAsync

Opens a file's data fork using the access deny modes. (Deprecated in Mac OS X v10.5. Use `PBOpenForkAsync` (page 739) with deny modes in the permissions field.)

```
OSErr PBHOpenDenyAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to a basic HFS parameter block.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. The function returns the result code `opWrErr` if you've requested write permission and you have already opened the file for writing in that case, the existing file reference number is returned in `ioRefNum`. You should not use this reference number unless your application originally opened the file.

`ioNamePtr`
On input, a pointer to a pathname for the file.

`ioVRefNum`
On input, a volume reference number or drive number for the volume containing the file. Pass 0 to indicate the default volume.

`ioRefNum`
On output, the file reference number for the file.

`ioDenyModes`
On input, the type of access you are requesting to the fork. See "File Access Permission Constants" (page 908) for a description of the types of access that you can request.

`ioDirID`
On input, the parent directory ID of the file.

You should use the `PBHOpenDenyAsync` and `PBHOpenRFDenyAsync` (page 710) functions (or their synchronous counterparts, `PBHOpenDenySync` (page 705) and `PBHOpenRFDenySync` (page 711)) if you want to ensure that you get the access permissions and deny-mode permissions that you request. `PBHOpenDenyAsync` is not retried in any way. If the file cannot be opened because of a deny conflict, the error `afpDenyConflict` is returned and the `ioRefNum` field is set to 0.

You can check that the volume supports AFP deny-mode permissions by checking that the `bHasOpenDeny` bit is set in the `vMAttrib` field returned by the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function. If you don't want to special case volumes that support AFP deny mode permissions, you can use the File Manager permissions. See "File Access Permission Constants" (page 908) for a description of how File Manager permissions are translated to AFP deny-mode permissions.

To open a file's resource fork with access deny permissions, use the `PBHOpenRFDenySync` (page 711) or `PBHOpenRFDenyAsync` (page 710) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenDenySync

Opens a file's data fork using the access deny modes. (Deprecated in Mac OS X v10.5. Use `PBOpenForkSync` (page 740) with deny modes in the permissions field.)

```
OSErr PBHOpenDenySync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `AccessParam` (page 795) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). The function returns the result code `opWrErr` if you've requested write permission and you have already opened the file for writing in that case, the existing file reference number is returned in `ioRefNum`. You should not use this reference number unless your application originally opened the file.

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname for the file.

`ioVRefNum`
On input, a volume reference number or drive number for the volume containing the file. Pass 0 to indicate the default volume.

`ioRefNum`
On output, the file reference number for the file.

`ioDenyModes`
On input, the type of access you are requesting to the fork. See "File Access Permission Constants" (page 908) for a description of the types of access that you can request.

`ioDirID`
On input, the parent directory ID of the file.

You should use the `PBHOpenDenySync` and `PBHOpenRFDenySync` (page 711) functions (or their asynchronous counterparts, `PBHOpenDenyAsync` (page 704) and `PBHOpenRFDenyAsync` (page 710)) if you want to ensure that you get the access permissions and deny-mode permissions that you request. `PBHOpenDenySync` is not retried in any way. If the file cannot be opened because of a deny conflict, the error `afpDenyConflict` is returned and the `ioRefNum` field is set to 0.

You can check that the volume supports AFP deny-mode permissions by checking that the `bHasOpenDeny` bit is set in the `vMAttrib` field returned by the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function. If you don't want to special case volumes that support AFP deny mode permissions, you can use the File Manager permissions. See "File Access Permission Constants" (page 908) for a description of how File Manager permissions are translated to AFP deny-mode permissions.

To open a file's resource fork with access deny permissions, use the `PBHOpenRFDenySync` (page 711) or `PBHOpenRFDenyAsync` (page 710) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenDFAsync

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkAsync` (page 739) instead.)

```
OSErr PBHOpenDFAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
You should use `PBHOpenDFAsync` instead of the `PBHOpenAsync` (page 703) function; `PBHOpenDFAsync` allows you to safely open a file whose name begins with a period (.).

The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. If you attempt to open a locked file for writing, `PBHOpenDFAsync` returns the result code `permErr`. If you request exclusive read/write permission but another access path is already open, `PBHOpenDFAsync` returns the reference number of the existing access path in `ioRefNum` and `opWrErr` as its function result.

`ioNamePtr`
On input, a pointer to the name of the file.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`
On output, the file reference number for accessing the open data fork. If you request exclusive read/write permission but another access path is already open, `PBHOpenDFAsync` returns the reference number of the existing access path. You should not use this reference number unless your application originally opened the file.

`ioPermssn`
On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908). You can open a path for writing even if it accesses a file on a locked volume, and no error is returned until a `PBWriteAsync`, `PBSetEOFAsync` (page 757) , or `PBAllocateAsync` (page 564) call is made.

`ioDirID`
On input, the directory ID of the file's parent directory.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `PBHOpenDFAsync` function, you will receive an error message.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenDFSync

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkSync` (page 740) instead.)

```
OSErr PBHOpenDFSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). . If you attempt to open a locked file for writing, `PBHOpenDFSync` returns the result code `permErr`. If you request exclusive read/write permission but another access path is already open, `PBHOpenDFSync` returns the reference number of the existing access path in `ioRefNum` and `opWrErr` as its function result.

Discussion

You should use `PBHOpenDFSync` instead of the `PBHOpenSync` (page 714) function; `PBHOpenDFSync` allows you to safely open a file whose name begins with a period (.).

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to the name of the file.

`ioVRefNum`

On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`

On output, the file reference number for accessing the open data fork. If you request exclusive read/write permission but another access path is already open, `PBHOpenDFSync` returns the reference number of the existing access path. You should not use this reference number unless your application originally opened the file.

`ioPermssn`

On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908). You can open a path for writing even if it accesses a file on a locked volume, and no error is returned until a `PBWriteSync`, `PBSetEOFSync` (page 758) , or `PBAllocateSync` (page 568) call is made.

`ioDirID`

On input, the directory ID of the file's parent directory.

`ioFVersNum`

On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `PBHOpenDFSync` function, you will receive an error message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenRFAsync

Opens the resource fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkAsync` (page 739) instead.)

```
OSErr PBHOpenRFAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. On some file systems, `PBHOpenRFAsync` will return the error `eofErr` if you try to open the resource fork of a file for which no resource fork exists with read-only access.

`ioNamePtr`
On input, a pointer to the name of the file.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`
On output, a file reference number for accessing the open resource fork.

`ioPermssn`
On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908).

`ioDirID`
On input, the directory ID of the file's parent directory.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `PBHOpenRFAsync` function, you will receive an error message.

Special Considerations

Generally your application should use Resource Manager functions rather than File Manager functions to access a file's resource fork. The `PBHOpenRFAsync` function does not read the resource map into memory and is generally useful only for applications (such as utilities that copy files) that need block-level access to a resource fork.

You should not use the resource fork of a file to hold non-resource data. Many parts of the system software assume that a resource fork always contains resource data.

Because there is no support for locking and unlocking file ranges in Mac OS X, regardless of whether File Sharing is enabled, you cannot open more than one path to a resource fork with read/ write permission. If you try to open a more than one path to a file's resource fork with `fsRdWrShPerm` permission, only the first attempt will succeed. Subsequent attempts will return an invalid reference number and the `ResError` function will return the error `opWrErr`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBHOpenRFDenyAsync

Opens a file's resource fork using the access deny modes. (Deprecated in Mac OS X v10.5. Use `PBOpenForkAsync` (page 739) with deny modes in the permissions field.)

```
OSErr PBHOpenRFDenyAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `AccessParam` (page 795) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. The function returns the result code `opWrErr` if you've requested write permission and you have already opened the file for writing in that case, the existing file reference number is returned in `ioRefNum`. You should not use this reference number unless your application originally opened the file.

`ioNamePtr`

On input, a pointer to a pathname for the file.

`ioVRefNum`
: On input, a volume reference number or drive number for the volume containing the file. Pass 0 to indicate the default volume.

`ioRefNum`
: On output, the file reference number for the file.

`ioDenyModes`
: On input, the type of access you are requesting to the fork. See "File Access Permission Constants" (page 908) for a description of the types of access that you can request.

`ioDirID`
: On input, the parent directory ID of the file.

You should use the `PBHOpenRFDenyAsync` and `PBHOpenDenyAsync` (page 704) functions (or their synchronous counterparts, `PBHOpenRFDenySync` (page 711) and `PBHOpenDenySync` (page 705)) if you want to ensure that you get the access permissions and deny-mode permissions that you request. `PBHOpenRFDenyAsync` is not retried in any way. If the file cannot be opened because of a deny conflict, the error `afpDenyConflict` is returned and the `ioRefNum` field is set to 0.

You can check that the volume supports AFP deny-mode permissions by checking that the `bHasOpenDeny` bit is set in the `vMAttrib` field returned by the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function. If you don't want to special case volumes that support AFP deny mode permissions, you can use the File Manager permissions. See "File Access Permission Constants" (page 908) for a description of how File Manager permissions are translated to AFP deny-mode permissions.

To open a file's data fork with access deny permissions, use the `PBHOpenDenySync` (page 705) or `PBHOpenDenyAsync` (page 704) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenRFDenySync

Opens a file's resource fork using the access deny modes. (Deprecated in Mac OS X v10.5. Use `PBOpenForkSync` (page 740) with deny modes in the permissions field.)

```
OSErr PBHOpenRFDenySync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `AccessParam` (page 795) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). The function returns the result code `opWrErr` if you've requested write permission and you have already opened the file for writing in that case, the existing file reference number is returned in `ioRefNum`. You should not use this reference number unless your application originally opened the file.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function.

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname for the file.

`ioVRefNum`
On input, a volume reference number or drive number for the volume containing the file. Pass 0 to indicate the default volume.

`ioRefNum`
On output, the file reference number for the file.

`ioDenyModes`
On input, the type of access you are requesting to the fork. See "File Access Permission Constants" (page 908) for a description of the types of access that you can request.

`ioDirID`
On input, the parent directory ID of the file.

You should use the `PBHOpenRFDenySync` and `PBHOpenDenySync` (page 705) functions (or their asynchronous counterparts, `PBHOpenRFDenyAsync` (page 710) and `PBHOpenDenyAsync` (page 704)) if you want to ensure that you get the access permissions and deny-mode permissions that you request. `PBHOpenRFDenySync` is not retried in any way. If the file cannot be opened because of a deny conflict, the error `afpDenyConflict` is returned and the `ioRefNum` field is set to 0.

You can check that the volume supports AFP deny-mode permissions by checking that the `bHasOpenDeny` bit is set in the `vMAttrib` field returned by the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function. If you don't want to special case volumes that support AFP deny mode permissions, you can use the File Manager permissions. See "File Access Permission Constants" (page 908) for a description of how File Manager permissions are translated to AFP deny-mode permissions.

To open a file's data fork with access deny permissions, use the `PBHOpenDenySync` (page 705) or `PBHOpenDenyAsync` (page 704) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

`Files.h`

PBHOpenRFSync

Opens the resource fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkSync` (page 740) instead.)

```
OSErr PBHOpenRFSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). On some file systems, `PBHOpenRFSync` will return the error `eofErr` if you try to open the resource fork of a file for which no resource fork exists with read-only access.

Discussion

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to the name of the file.

`ioVRefNum`

On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`

On output, a file reference number for accessing the open resource fork.

`ioPermssn`

On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908).

`ioDirID`

On input, the directory ID of the file's parent directory.

`ioFVersNum`

On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Note that if you wish to access named forks other than the data and resource forks, or forks larger than 2GB, you will need to use the `FSOpenFork` (page 514) function, or one of its corresponding parameter block calls, `PBOpenForkSync` (page 740) or `PBOpenForkAsync` (page 739). If you try to open a fork larger than 2GB with the `PBOpenRFSync` function, you will receive an error message.

Special Considerations

Generally your application should use Resource Manager functions rather than File Manager functions to access a file's resource fork. The `PBHOpenRFSync` function does not read the resource map into memory and is generally useful only for applications (such as utilities that copy files) that need block-level access to a resource fork.

You should not use the resource fork of a file to hold non-resource data. Many parts of the system software assume that a resource fork always contains resource data.

Because there is no support for locking and unlocking file ranges on local disks in Mac OS X, regardless of whether File Sharing is enabled, you cannot open more than one path to a resource fork with read/ write permission. If you try to open a more than one path to a file's resource fork with `fsRdWrShPerm` permission, only the first attempt will succeed. Subsequent attempts will return an invalid reference number and the `ResError` function will return the error `opWrErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHOpenSync

Opens the data fork of a file. (Deprecated in Mac OS X v10.4. Use `PBOpenForkSync` (page 740) instead.)

```
OSErr PBHOpenSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If you attempt to open a locked file for writing, `PBHOpenSync` returns the result code `permErr`. If you request exclusive read/write permission but another access path is already open, `PBHOpenSync` returns the reference number of the existing access path in `ioRefNum` and `opWrErr` as its function result.

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name of the file.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioRefNum`
On output, a file reference number for accessing the open data fork. If you request exclusive read/write permission but another access path is already open, `PBHOpenSync` returns the reference number of the existing access path. You should not use this reference number unless your application originally opened the file.

`ioPermssn`
On input, a constant specifying the type of access with which to open the fork. For a description of the types of access you can request, see "File Access Permission Constants" (page 908). You can open a path for writing even if it accesses a file on a locked volume, and no error is returned until a `PBWriteSync`, `PBSetEOFSync` (page 758) , or `PBAllocateSync` (page 568) call is made.

`ioDirID`
On input, the directory ID of the file's parent directory.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If you use `PBHOpenSync` to try to open a file whose name begins with a period, you might mistakenly open a driver instead; subsequent attempts to write data might corrupt data on the target device. To avoid these problems, you should always use `PBHOpenDFSync` (page 708) instead of `PBHOpenSync`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHRenameAsync

Renames a file, directory, or volume. (Deprecated in Mac OS X v10.4. Use `PBRenameUnicodeAsync` (page 748) instead.)

```
OSErr PBHRenameAsync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the existing filename, directory name, or volume name.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioMisc`
On input, a pointer to the new name for the file, directory or volume.

`ioDirID`
On input, the parent directory ID of the file or directory to rename.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Given a pointer to the name of a file or directory in the `ioNamePtr` field, `PBHRenameAsync` changes it to the name pointed to in the `ioMisc` field. Given a pointer to a volume name in `ioNamePtr` or a volume reference number in `ioVRefNum`, the function changes the name of the volume to the name pointed to in `ioMisc`.

If a file ID reference exists for the file being renamed, the file ID remains with the file.

To rename a file or directory using a long Unicode name, use the `FSRenameUnicode` (page 539) function or one of the corresponding parameter block calls, `PBRenameUnicodeSync` (page 748) and `PBRenameUnicodeAsync` (page 748).

Special Considerations

You cannot use `PBHRenameAsync` to change the directory in which a file is located. To move a file or directory, use the `FSpCatMove` (page 524), `PBCatMoveSync` (page 576), or `PBCatMoveAsync` (page 575) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHRenameSync

Renames a file, directory, or volume. (Deprecated in Mac OS X v10.4. Use `PBRenameUnicodeSync` (page 748) instead.)

```
OSErr PBHRenameSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `HIOParam` (page 855) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
: On input, a pointer to the existing filename, directory name, or volume name.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioMisc`
: On input, a pointer to the new name for the file, directory or volume.

`ioDirID`
On input, the parent directory ID of the file or directory to rename.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

Given a pointer to the name of a file or directory in the `ioNamePtr` field, `PBHRenameSync` changes it to the name pointed to in the `ioMisc` field. Given a pointer to a volume name in `ioNamePtr` or a volume reference number in `ioVRefNum`, the function changes the name of the volume to the name pointed to in `ioMisc`.

If a file ID reference exists for the file being renamed, the file ID remains with the file.

To rename a file or directory using a long Unicode name, use the `FSRenameUnicode` (page 539) function or one of the corresponding parameter block calls, `PBRenameUnicodeSync` (page 748) and `PBRenameUnicodeAsync` (page 748).

Special Considerations

You cannot use `PBHRenameSync` to change the directory in which a file is located. To move a file or directory, use the `FSpCatMove` (page 524), `PBCatMoveSync` (page 576), or `PBCatMoveAsync` (page 575) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHRstFLockAsync

Unlocks a file or directory. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoAsync` (page 751) instead.)

```
OSErr PBHRstFLockAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the name for the file or directory o unlock.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the parent directory ID of the file or directory to unlock.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the `PBHGetVolParmsSync` (page 695) or `PBHGetVolParmsAsync` (page 694) function indicates that the volume supports folder locking (that is, the `bHasFolderLock` bit of the `vMAttrib` field is set), you can use `PBHRstFLockAsync` to unlock a directory. Otherwise, you can only use this function to unlock a file.

Access paths currently in use aren't affected by this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHRstFLockSync

Unlocks a file or directory. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoSync` (page 753) instead.)

```
OSErr PBHRstFLockSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the name for the file or directory to unlock.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the parent directory ID of the file or directory to unlock.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the PBHGetVolParmsSync (page 695) or PBHGetVolParmsAsync (page 694) function indicates that the volume supports folder locking (that is, the bHasFolderLock bit of the vMAttrib field is set), you can use PBHRstFLockSync to unlock a directory. Otherwise, you can only use this function to unlock a file.

Access paths currently in use aren't affected by this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Files.h

PBHSetDirAccessAsync

Changes the access control information for a directory. (Deprecated in Mac OS X v10.5. Use FSSetCatalogInfo (page 540) instead.)

```
OSErr PBHSetDirAccessAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to an AccessParam (page 795) variant of an HFS parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

ioCompletion
On input, a pointer to a completion function. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
On output, the result code of the function.

ioNamePtr
On input, a pointer to a pathname.

ioVRefNum
On input, a volume specification for the volume containing the directory. This field can contain a volume reference number, drive number, or 0 for the default volume.

ioACOwnerID
On input, the owner ID.

ioACGroupID
On input, the group ID.

ioACAccess
On input, the directory's access rights. You cannot set the owner or user rights bits of the ioACAccess field directly; if you try to do this, PBHSetDirAccessAsync returns the result code paramErr. Only

the blank access privileges can be set for a directory using this function. See "File and Folder Access Privilege Constants" (page 910) for more information on directory access privileges.

`ioDirID`
On input, the directory ID.

To change the owner or group, you should set the `ioACOwnerID` or `ioACGroupID` field to the appropriate ID. You must be the owner of the directory to change the owner or group ID. A guest on a server can manipulate the privileges of any directory owned by the guest.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetDirAccessSync

Changes the access control information for a directory. (Deprecated in Mac OS X v10.5. Use `FSSetCatalogInfo` (page 540) instead.)

```
OSErr PBHSetDirAccessSync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to an `AccessParam` (page 795) variant of an HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname.

`ioVRefNum`
On input, a volume specification for the volume containing the directory. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioACOwnerID`
On input, the owner ID.

`ioACGroupID`
On input, the group ID.

`ioACAccess`
On input, the directory's access rights. You cannot set the owner or user rights bits of the `ioACAccess` field directly; if you try to do this, `PBHSetDirAccessSync` returns the result code `paramErr`. Only the blank access privileges can be set for a directory using this function. See "File and Folder Access Privilege Constants" (page 910) for more information on directory access privileges.

`ioDirID`
On input, the directory ID.

To change the owner or group, you should set the `ioACOwnerID` or `ioACGroupID` field to the appropriate ID. You must be the owner of the directory to change the owner or group ID. A guest on a server can manipulate the privileges of any directory owned by the guest.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetFInfoAsync

Sets information for a file. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoAsync` (page 751) instead.)

```
OSErr PBHSetFInfoAsync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the name of the file.

`ioVRefNum`
On input, the volume reference number or drive number for the volume containing the file; or 0 for the default volume.

`ioFlFndrInfo`
On input, Finder information for the file. For a description of the `FInfo` data type, see the *Finder Interface Reference* .

`ioDirID`
On input, the parent directory ID for the file.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

`ioFlCrDat`
: On input, the date and time of the file's creation.

`ioFlMdDat`
: On input, the date and time of the file's last modification.

You should call the `PBHGetFInfoAsync` (page 682) function just before calling `PBHSetFInfoAsync`, so that the current information is present in the parameter block.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetFInfoSync

Sets information for a file. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoSync` (page 753) instead.)

```
OSErr PBHSetFInfoSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
: On input, a pointer to the name of the file.

`ioVRefNum`
: On input, the volume reference number or drive number for the volume containing the file; or 0 for the default volume.

`ioFlFndrInfo`
: On input, Finder information for the file. For a description of the `FInfo` data type, see the *Finder Interface Reference* .

`ioDirID`
: On input, the parent directory ID of the file.

`ioFVersNum`
: On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

`ioFlCrDat`
On input, the date and time of the file's creation.

`ioFlMdDat`
On input, the date and time of the file's last modification.

You should call the `PBHGetFInfoSync` (page 683) function just before calling `PBHSetFInfoSync`, so that the current information is present in the parameter block.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetFLockAsync

Locks a file or directory. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoAsync` (page 751) instead.)

```
OSErr PBHSetFLockAsync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HFileParam` (page 852) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a name for the file or directory to lock.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDirID`
On input, the parent directory ID of the file or directory to lock.

`ioFVersNum`
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the PBHGetVolParmsSync (page 695) or PBHGetVolParmsAsync (page 694) function indicates that the volume supports folder locking (that is, the bHasFolderLock bit of the vMAttrib field is set), you can use PBHSetFLockAsync to lock a directory. Otherwise, you can only use this function to lock a file.

After you lock a file, all new access paths to that file are read-only. Access paths currently in use aren't affected.

Availability

PBHSetFLockSync

Locks a file or directory. (Deprecated in Mac OS X v10.4. Use PBSetCatalogInfoSync (page 753) instead.)

```
OSErr PBHSetFLockSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the HFileParam (page 852) variant of the basic HFS parameter block. See HParamBlockRec (page 857) for a description of the HParamBlockRec data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

ioNamePtr
On input, a pointer to a name for the file or directory to lock.

ioVRefNum
On input, a volume reference number, drive number, or 0 for the default volume.

ioDirID
On input, the parent directory ID of the file or directory to lock.

ioFVersNum
On input, this field should be initialized to zero; if this field is not zero, the call will fall through to the now-obsolete Macintosh File System (MFS) code if the volume accessed is an MFS volume.

If the PBHGetVolParmsSync (page 695) or PBHGetVolParmsAsync (page 694) function indicates that the volume supports folder locking (that is, the bHasFolderLock bit of the vMAttrib field is set), you can use PBHSetFLockSync to lock a directory. Otherwise, you can only use this function to lock a file.

After you lock a file, all new access paths to that file are read-only. Access paths currently in use aren't affected.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetVolAsync

Sets the default volume and the default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHSetVolAsync (
   WDPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a working directory parameter block. See `WDPBRec` (page 877) for a description of the `WDPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to a pathname. If this field specifies a full pathname, the default volume is set to the volume whose name is contained in that pathname. (A full pathname overrides the `ioVRefNum` field.)If this field contains a partial pathname and the `ioVRefNum` field specifies a volume reference number, then the default directory is set to the directory having the partial pathname specified here, in the directory given in the `ioWDDirID` field. If this field is `NULL`, then the default directory is set to the directory having the ID specified in the `ioWDDirID` field.

`ioVRefNum`

On input, a volume reference number for the default volume. This field is ignored if the `ioNamePtr` field specifies a full pathname.

`ioWDDirID`

On input, a directory ID. If the `ioVRefNum` field contains a volume reference number and `ioNamePtr` contains a partial pathname, this field contains the directory ID of the directory containing the default directory. If `ioNamePtr` is `NULL`, this field contains the directory ID of the default directory.

Both the default volume and the default directory are used in calls made with no volume name, a volume reference number of 0, and a directory ID of 0.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBHSetVolSync

Sets the default volume and the default directory. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBHSetVolSync (
   WDPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a working directory parameter block. See `WDPBRec` (page 877) for a description of the `WDPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a pathname. If this field specifies a full pathname, the default volume is set to the volume whose name is contained in that pathname. (A full pathname overrides the `ioVRefNum` field.)If this field contains a partial pathname and the `ioVRefNum` field specifies a volume reference number, then the default directory is set to the directory having the partial pathname specified here, in the directory given in the `ioWDDirID` field. If this field is `NULL`, then the default directory is set to the directory having the ID specified in the `ioWDDirID` field.

`ioVRefNum`

On input, the volume reference number for the default volume. This field is ignored if the `ioNamePtr` field specifies a full pathname.

`ioWDDirID`

On input, a directory ID. If the `ioVRefNum` field contains a volume reference number and `ioNamePtr` contains a partial pathname, this field contains the directory ID of the directory containing the default directory. If `ioNamePtr` is `NULL`, this field contains the directory ID of the default directory.

Both the default volume and the default directory are used in calls made with no volume name, a volume reference number of 0, and a directory ID of 0.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBIterateForksAsync

Determines the name and size of every named fork belonging to a file or directory.

```
void PBIterateForksAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for more information on the `FSForkIOParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory to iterate.

`forkIterator`

A pointer to a structure which maintains state between calls to `PBIterateForksAsync`. Before the first call, set the `initialize` field of this structure to 0. The fork iterator will be updated after the call completes; the updated iterator should be passed into the next call. See `CatPositionRec` (page 801) for a description of the structure pointed to in this field.

`outForkName`

On output, a pointer to the Unicode name of the fork.

`positionOffset`

On output, the logical size of the fork, in bytes.

`allocationAmount`

On output, the fork's physical size (that is, the amount of space allocated on disk), in bytes.

Since information is returned about one fork at a time, several calls may be required to iterate through all the forks. There is no guarantee about the order in which forks are returned; the order may vary between iterations.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBIterateForksSync

Determines the name and size of every named fork belonging to a file or directory.

```
OSErr PBIterateForksSync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for more information on the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory to iterate.

`forkIterator`

A pointer to a structure which maintains state between calls to `PBIterateForksSync`. Before the first call, set the `initialize` field of this structure to 0. The fork iterator will be updated after the call completes; the updated iterator should be passed into the next call. See `CatPositionRec` (page 801) for a description of the structure pointed to in this field.

`outForkName`

On output, a pointer to the Unicode name of the fork.

`positionOffset`

On output, the logical size of the fork, in bytes.

`allocationAmount`

On output, the fork's physical size (that is, the amount of space allocated on disk), in bytes.

Since information is returned about one fork at a time, several calls may be required to iterate through all the forks. There is no guarantee about the order in which forks are returned; the order may vary between iterations.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBLockRangeAsync

Locks a portion of a file. (Deprecated in Mac OS X v10.4. Use `PBXLockRangeAsync` (page 785) instead.)

```
OSErr PBLockRangeAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. If you call `PBLockRangeAsync` on a file system that does not implement it—for example, SMB—`PBLockRangeAsync` returns `noErr` and does nothing.

`ioRefNum`
: On input, the file reference number of the file owning the range to lock.

`ioReqCount`
: On input, the number of bytes in the range. Set `ioReqCount` to –1 to lock the maximum number of bytes from the position specified in the `ioPosOffset` field.

`ioPosMode`
: On input, a constant specifying the base location for the start of the locked range. See "Position Mode Constants" (page 928) for more information on the constants you can use to specify the base location.

  You should not use the `fsFromLEOF` constant when locking a file range. `PBLockRangeAsync` does not return the start of the locked range; thus, there is no way to determine what range was actually locked when you specify `fsFromLEOF`.

`ioPosOffset`
: On input, the offset from the base location specified in the `ioPosMode` field for the start of the locked range.

The `PBLockRangeAsync` function locks a portion of a file that was opened with shared read/write permission. The beginning of the range to be locked is determined by the `ioPosMode` and `ioPosOffset` fields. The end of the range to be locked is determined by the beginning of the range and the `ioReqCount` field. For example, to lock the first 50 bytes in a file, set `ioReqCount` to 50, `ioPosMode` to `fsFromStart`, and `ioPosOffset` to 0.

The `PBLockRangeAsync` function uses the same parameters as both `PBReadAsync` and `PBWriteAsync`; by calling it immediately before `PBReadAsync`, you can use the information in the parameter block for the `PBReadAsync` call.

When you're finished with the data (typically after a call to `PBWriteSync`), you can call `PBUnlockRangeAsync` (page 770) to free that portion of the file for subsequent read and write calls. Closing a file also releases all locked ranges in that file.

Special Considerations

The `PBLockRangeAsync` function does nothing if the file specified in the `ioRefNum` field is open with shared read/write permission but is not located on a remote server volume or is not located under a share point on a sharable local volume. To check whether file sharing is currently on, check that the `bHasPersonalAccessPrivileges` bit in the `vMAttrib` field of the `GetVolParmsInfoBuffer` (page 847) returned by the `PBHGetVolParmsSync` (page 695) function is set.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
Files.h

PBLockRangeSync

Locks a portion of a file. (Deprecated in Mac OS X v10.4. Use PBXLockRangeSync (page 785) or FSLockRange (page 504) instead.)

```
OSErr PBLockRangeSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the IOParam (page 862) variant of the basic File Manager parameter block. See ParamBlockRec (page 866) for a description of the ParamBlockRec data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). If you call PBLockRangeSync on a file system that does not implement it—for example, SMB—PBLockRangeSync returns noErr and does nothing.

Discussion

The relevant fields of the parameter block are:

ioRefNum

On input, the file reference number of the file owning the range to lock.

ioReqCount

On input, the number of bytes in the range. Set ioReqCount to –1 to lock the maximum number of bytes from the position specified in the ioPosOffset field.

ioPosMode

On input, a constant specifying the base location for the start of the locked range. See "Position Mode Constants" (page 928) for more information about the constants you can use to specify the base location.

You should not use the fsFromLEOF constant when locking a file range. PBLockRangeSync does not return the start of the locked range; thus, there is no way to determine what range was actually locked when you specify fsFromLEOF.

ioPosOffset

On input, the offset from the base location specified in the ioPosMode field for the start of the locked range.

The PBLockRangeSync function locks a portion of a file that was opened with shared read/write permission. The beginning of the range to be locked is determined by the ioPosMode and ioPosOffset fields. The end of the range to be locked is determined by the beginning of the range and the ioReqCount field. For example, to lock the first 50 bytes in a file, set ioReqCount to 50, ioPosMode to fsFromStart, and ioPosOffset to 0.

The PBLockRangeSync function uses the same parameters as both PBReadSync and PBWriteSync; by calling it immediately before PBReadSync, you can use the information in the parameter block for the PBReadSync call.

When you're finished with the data (typically after a call to PBWriteSync), you can call PBUnlockRangeSync (page 771) to free that portion of the file for subsequent read and write calls. Closing a file also releases all locked ranges in that file.

Special Considerations

The `PBLockRangeSync` function does nothing if the file specified in the `ioRefNum` field is open with shared read/write permission but is not located on a remote server volume or is not located under a share point on a sharable local volume. To check whether file sharing is currently on, check that the `bHasPersonalAccessPrivileges` bit in the `vMAttrib` field of the `GetVolParmsInfoBuffer` (page 847) returned by the `PBHGetVolParmsSync` (page 695) function is set.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`Files.h`

PBMakeFSRefAsync

Creates an `FSRef` for a file or directory, given an `FSSpec`. (Deprecated in Mac OS X v10.5. Use `PBMakeFSRefUnicodeAsync` (page 733) instead.)

```
void PBMakeFSRefAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion

For the parameter block based calls, the fields of the source `FSSpec` are passed as separate parameters (in the `ioNamePtr`, `ioVRefNum`, and `ioDirID` fields). This allows the call to be dispatched to external file systems the same way as other `FSp` calls are.

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the name of the file or directory for which you wish to create an `FSRef`.

`ioVRefNum`

On input, a volume specification for the volume containing the file or directory. This can be a volume reference number, a drive number, or 0 for the default volume.

`ioDirID`

On input, the directory ID of the file or directory's parent directory.

`newRef`

On input, a pointer to an `FSRef` structure. On output, this `FSRef` refers to the specified file or directory.

To obtain an FSSpec from an FSRef, use the PBGetCatalogInfoAsync (page 643) call.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Files.h

PBMakeFSRefSync

Creates an FSRef for a file or directory, given an FSSpec. (Deprecated in Mac OS X v10.5. Use PBMakeFSRefUnicodeSync (page 733) instead.)

```
OSErr PBMakeFSRefSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
For the parameter block based calls, the fields of the source FSSpec are passed as separate parameters (in the ioNamePtr, ioVRefNum, and ioDirID fields). This allows the call to be dispatched to external file systems the same way as other FSp calls are.

The relevant fields of the parameter block are:

ioNamePtr
On input, a pointer to the name of the file or directory for which you wish to create an FSRef.

ioVRefNum
On input, a volume specification for the volume containing the file or directory. This can be a volume reference number, a drive number, or 0 for the default volume.

ioDirID
On input, the directory ID of the file or directory's parent directory.

newRef
On input, a pointer to an FSRef structure. On output, this FSRef refers to the specified file or directory.

To obtain an FSSpec from an FSRef, use the PBGetCatalogInfoSync (page 647) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Files.h

PBMakeFSRefUnicodeAsync

Constructs an FSRef for a file or directory, given a parent directory and a Unicode name.

```
void PBMakeFSRefUnicodeAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Discussion
The relevant fields of the parameter block are:

ioCompletion
On input, a pointer to a completion function. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
On output, the result code of the function.

ref
On input, a pointer to the FSRef of the parent directory of the file or directory for which to create a new FSRef. See FSRef (page 837) for a description of the FSRef data type.

nameLength
On input, the length of the file or directory name.

name
On input, a pointer to the Unicode name for the file or directory. The name must be a leaf name; partial or full pathnames are not allowed. If you have a partial or full pathname in Unicode, you will have to parse it yourself and make multiple calls to PBMakeFSRefUnicodeAsync.

textEncodingHint
On input, the suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant kTextEncodingUnknown, the File Manager will use a default value.

newRef
On output, if the function returns a result of noErr, a pointer to the new FSRef

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBMakeFSRefUnicodeSync

Constructs an FSRef for a file or directory, given a parent directory and a Unicode name.

```
OSErr PBMakeFSRefUnicodeSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to the `FSRef` of the parent directory of the file or directory for which to create a new `FSRef`. See `FSRef` (page 837) for a description of the `FSRef` data type.

`nameLength`

On input, the length of the file or directory name.

`name`

On input, a pointer to the Unicode name for the file or directory. The name must be a leaf name; partial or full pathnames are not allowed. If you have a partial or full pathname in Unicode, you will have to parse it yourself and make multiple calls to `PBMakeFSRefUnicodeSync`.

`textEncodingHint`

On input, the suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant `kTextEncodingUnknown`, the File Manager will use a default value.

`newRef`

On output, if the function returns a result of `noErr`, a pointer to the new `FSRef`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBMakeFSSpecAsync

Creates an `FSSpec` structure for a file or directory. (Deprecated in Mac OS X v10.4. Use `PBMakeFSRefUnicodeAsync` (page 733) instead.)

```
OSErr PBMakeFSSpecAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

If the specified volume is mounted and the specified parent directory exists, but the target file or directory doesn't exist in that location, PBMakeFSSpecAsync fills in the structure and returns fnfErr instead of noErr. The structure is valid, but it describes a target that doesn't exist. You can use the structure for another operation, such as creating a file.

PBMakeFSSpecAsync can return a number of different File Manager error codes. When PBMakeFSSpecAsync returns any result other than noErr or fnfErr, all fields of the resulting FSSpec structure are set to 0.

Discussion
The relevant fields of the parameter block are:

ioCompletion
: On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult
: On output, the result code of the function. When PBMakeFSSpecAsync returns any result other than noErr or fnfErr, all fields of the resulting FSSpec structure are set to 0. See "File Manager Result Codes".

ioNamePtr
: On input, a pointer to a full or partial pathname specifying the file or directory for which to create an FSSpec. If the ioNamePtr field specifies a full pathname, PBMakeFSSpecAsync ignores both the ioVRefNum and ioDirID fields. A partial pathname might identify only the final target, or it might include one or more parent directory names. If ioNamePtr specifies a partial pathname, then ioVRefNum, ioDirID, or both must be valid.

ioVRefNum
: On input, a volume specification for the volume containing the file or directory. This field can contain a volume reference number, a drive number, or 0 to specify the default volume.

ioMisc
: On input, a pointer to an FSSpec (page 840) structure. Given a complete specification for a file or directory, the PBMakeFSSpecAsync function fills in this FSSpec structure to identify the file or directory. On output, this field points to the initialized FSSpec. The file system specification structure that you pass in this field should not share storage space with the input pathname; the name field may be initialized to the empty string before the pathname has been processed. For example, ioNamePtr should not refer to the name field of the output file system specification.

ioDirID
: On input, a directory ID. This field usually specifies the parent directory ID of the target object. If the directory is sufficiently specified by the ioNamePtr field, the ioDirID field can be set to 0. If the ioNamePtr field contains an empty string, PBMakeFSSpecAsync creates an FSSpec structure for the directory specified by the ioDirID field.

If the specified volume is mounted and the specified parent directory exists, but the target file or directory doesn't exist in that location, PBMakeFSSpecAsync fills in the structure and returns fnfErr instead of noErr. The structure is valid, but it describes a target that doesn't exist. You can use the structure for another operation, such as creating a file.

Carbon Porting Notes

Non-Carbon applications can also specify a working directory reference number in the ioVRefNum field. However, because working directories are not supported in Carbon, you cannot specify a working directory reference number if you wish your application to be Carbon-compatible.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBMakeFSSpecSync

Creates an `FSSpec` structure for a file or directory. (Deprecated in Mac OS X v10.4. Use `PBMakeFSRefUnicodeSync` (page 733) instead.)

```
OSErr PBMakeFSSpecSync (
   HParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`

A pointer to a basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). When `PBMakeFSSpecSync` returns any result other than `noErr` or `fnfErr`, all fields of the resulting `FSSpec` structure are set to 0.

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a full or partial pathname specifying the file or directory for which to create an `FSSpec`. If the `ioNamePtr` field specifies a full pathname, `PBMakeFSSpecSync` ignores both the `ioVRefNum` and `ioDirID` fields. A partial pathname might identify only the final target, or it might include one or more parent directory names. If `ioNamePtr` specifies a partial pathname, then `ioVRefNum`, `ioDirID`, or both must be valid.

`ioVRefNum`

On input, a volume specification for the volume containing the file or directory. This field can contain a volume reference number, a drive number, or 0 to specify the default volume.

`ioMisc`

On input, a pointer to an `FSSpec` (page 840) structure. Given a complete specification for a file or directory, the `PBMakeFSSpecSync` function fills in this `FSSpec` structure to identify the file or directory. On output, this field points to the initialized `FSSpec`. The file system specification structure that you pass in this field should not share storage space with the input pathname; the `name` field may be initialized to the empty string before the pathname has been processed. For example, `ioNamePtr` should not refer to the `name` field of the output file system specification.

`ioDirID`

On input, a directory ID. This field usually specifies the parent directory ID of the target object. If the directory is sufficiently specified by the `ioNamePtr` field, the `ioDirID` field can be set to 0. If the `ioNamePtr` field contains an empty string, `PBMakeFSSpecSync` creates an `FSSpec` structure for the directory specified by the `ioDirID` field.

If the specified volume is mounted and the specified parent directory exists, but the target file or directory doesn't exist in that location, `PBMakeFSSpecSync` fills in the structure and returns `fnfErr` instead of `noErr`. The structure is valid, but it describes a target that doesn't exist. You can use the structure for another operation, such as creating a file.

Carbon Porting Notes

Non-Carbon applications can also specify a working directory reference number in the `ioVRefNum` field. However, because working directories are not supported in Carbon, you cannot specify a working directory reference number if you wish your application to be Carbon-compatible.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBMoveObjectAsync

Moves a file or directory into a different directory.

```
void PBMoveObjectAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. If the `parentRef` field specifies a non-existent object, `dirNFErr` is returned; if it refers to a file, then `errFSNotAFolder` is returned. If the directory specified in `parentRef` is on a different volume than the file or directory indicated by the `ref` field, `diffVolErr` is returned.

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory to move.

parentRef

On input, a pointer to an `FSRef` specifying the directory into which the file or directory given in the `ref` field will be moved.

`newRef`

On output, a pointer to the new `FSRef` for the file or directory in its new location. This field is optional; if you do not wish the `FSRef` returned, pass `NULL` here.

Moving an object may change its FSRef. If you want to continue to refer to the object, you should pass a non- NULL pointer in the newRef field and use the FSRef returned there to refer to the object after the move. The original FSRef passed in the ref field may or may not be usable after the move. The newRef field may point to the same storage as the parentRef or ref fields.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBMoveObjectSync

Moves a file or directory into a different directory.

```
OSErr PBMoveObjectSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If the the parentRef field of the parameter block specifies a non-existent object, dirNFErr is returned; if it refers to a file, errFSNotAFolder is returned. If the directory specified in the parentRef field is on a different volume than the file or directory indicated in the ref field, diffVolErr is returned.

Discussion
The relevant fields of the parameter block are:

ioResult
On output, the result code of the function. If the parentRef field specifies a non-existent object, dirNFErr is returned; if it refers to a file, then errFSNotAFolder is returned. If the directory specified in parentRef is on a different volume than the file or directory indicated by the ref field, diffVolErr is returned.

ref
On input, a pointer to an FSRef (page 837) specifying the file or directory to move.

parentRef
On input, a pointer to an FSRef specifying the directory into which the file or directory given in the ref field will be moved.

newRef
On output, a pointer to the new FSRef for the file or directory in its new location. This field is optional; if you do not wish the FSRef returned, pass NULL here.

Moving an object may change its FSRef. If you want to continue to refer to the object, you should pass a non- NULL pointer in the newRef field and use the FSRef returned there to refer to the object after the move. The original FSRef passed in the ref field may or may not be usable after the move. The newRef field may point to the same storage as the parentRef or ref fields.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBOpenForkAsync

Opens any fork of a file or directory for streaming access.

```
void PBOpenForkAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. On some file systems, `PBOpenForkAsync` will return the error `eofErr` if you try to open the resource fork of a file for which no resource fork exists with read-only access.

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory that owns the fork to open.

`forkNameLength`

On input, the length of the fork's Unicode name.

`forkName`

On input, a pointer to the Unicode name of the fork to open. You can obtain the string constants for the data and resource fork names using the `FSGetDataForkName` (page 497) and `FSGetResourceForkName` (page 500) functions. All volume formats should support data and resource forks; other named forks may be supported by some volume formats.

`permissions`

On input, a constant indicating the type of access that you wish to have to the fork via the returned fork reference. This parameter is the same as the `permission` parameter passed to the `FSpOpenDF` and `FSpOpenRF` functions. For a description of the types of access which you can request, see "File Access Permission Constants" (page 908).

`forkRefNum`

On output, the fork reference number for accessing the open fork.

If you wish to access named forks or forks larger than 2GB you must use the `FSOpenFork` function or one of the corresponding parameter block calls, `PBOpenForkSync` and `PBOpenForkAsync`. To determine if the `PBOpenForkSync` function is present, call the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Files.h

PBOpenForkSync

Opens any fork of a file or directory for streaming access.

```
OSErr PBOpenForkSync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a fork I/O parameter block. See FSForkIOParam (page 833) for a description of the FSForkIOParam data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). On some file systems, PBOpenForkSync will return the error eofErr if you try to open the resource fork of a file for which no resource fork exists with read-only access.

Discussion

The relevant fields of the parameter block are:

ref
On input, a pointer to an FSRef (page 837) specifying the file or directory that owns the fork to open.

forkNameLength
On input, the length of the fork's Unicode name.

forkName
On input, a pointer to the Unicode name of the fork to open. You can obtain the string constants for the data and resource fork names using the FSGetDataForkName (page 497) and FSGetResourceForkName (page 500) functions. All volume formats should support data and resource forks; other named forks may be supported by some volume formats.

permissions
On input, a constant indicating the type of access that you wish to have to the fork via the returned fork reference. This parameter is the same as the permission parameter passed to the FSpOpenDF and FSpOpenRF functions. For a description of the types of access which you can request, see "File Access Permission Constants" (page 908).

forkRefNum
On output, the fork reference number for accessing the open fork.

If you wish to access named forks or forks larger than 2GB you must use the FSOpenFork function or one of the corresponding parameter block calls, PBOpenForkSync and PBOpenForkAsync. To determine if the PBOpenForkSync function is present, call the Gestalt function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

Files.h

PBOpenIteratorAsync

Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

```
void PBOpenIteratorAsync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`iterator`

On output, the new `FSIterator` (page 835). You can pass this iterator to the `FSGetCatalogInfoBulk` (page 495) or `FSCatalogSearch` (page 472) functions and their parameter block-based counterparts. The iterator is automatically initialized so that the next use of the iterator returns the first item. The order that items are returned in is volume format dependent and may be different for two different iterators created with the same container and flags.

`iteratorFlags`

On input, a set of flags which controls whether the iterator iterates over subtrees or just the immediate children of the container. See "Iterator Flags" (page 924) for a description of the flags defined for this field. Iteration over subtrees which do not originate at the root directory of a volume are not currently supported, and passing the `kFSIterateSubtree` flag in this field returns `errFSBadIteratorFlags`. To determine whether subtree iterators are supported, check that the `bSupportsSubtreeIterators` bit returned by `PBHGetVolParmsAsync` (page 694) is set.

`container`

On input, a pointer to an `FSRef` (page 837) for the directory to iterate. The set of items to iterate over can either be the objects directly contained in the directory, or all items directly or indirectly contained in the directory (in which case, the specified directory is the root of the subtree to iterate).

Catalog iterators must be closed when you are done using them, whether or not you have iterated over all the items. Iterators are automatically closed upon process termination, just like open files. However, you should use the `FSCloseIterator` (page 475) function, or one of the related parameter block functions, `PBCloseIteratorSync` (page 584) and `PBCloseIteratorAsync` (page 584) , to close an iterator to free up any system resources allocated to the iterator.

Before calling this function, you should check that it is present, by calling the `Gestalt` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBOpenIteratorSync

Creates a catalog iterator that can be used to iterate over the contents of a directory or volume.

```
OSErr PBOpenIteratorSync (
   FSCatalogBulkParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a catalog information parameter block. See `FSCatalogBulkParam` (page 824) for a description of the `FSCatalogBulkParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`iterator`

On output, the new `FSIterator` (page 835). You can pass this iterator to the `FSGetCatalogInfoBulk` (page 495) or `FSCatalogSearch` (page 472) functions and their parameter block-based counterparts. The iterator is automatically initialized so that the next use of the iterator returns the first item. The order that items are returned in is volume format dependent and may be different for two different iterators created with the same container and flags.

`iteratorFlags`

On input, a set of flags which controls whether the iterator iterates over subtrees or just the immediate children of the container. See "Iterator Flags" (page 924) for a description of the flags defined for this field. Iteration over subtrees which do not originate at the root directory of a volume are not currently supported, and passing the `kFSIterateSubtree` flag in this field returns `errFSBadIteratorFlags`. To determine whether subtree iterators are supported, check that the `bSupportsSubtreeIterators` bit returned by `PBHGetVolParmsSync` (page 695) is set.

`container`

On input, a pointer to an `FSRef` (page 837) for the directory to iterate. The set of items to iterate over can either be the objects directly contained in the directory, or all items directly or indirectly contained in the directory (in which case, the specified directory is the root of the subtree to iterate).

Catalog iterators must be closed when you are done using them, whether or not you have iterated over all the items. Iterators are automatically closed upon process termination, just like open files. However, you should use the `FSCloseIterator` (page 475) function, or one of the related parameter block functions, `PBCloseIteratorSync` (page 584) and `PBCloseIteratorAsync` (page 584) , to close an iterator to free up any system resources allocated to the iterator.

Before calling this function, you should check that it is present, by calling the `Gestalt` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBReadAsync

Reads any number of bytes from an open file. (Deprecated in Mac OS X v10.5. Use `PBReadForkAsync` (page 744) instead.)

```
OSErr PBReadAsync (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a basic File Manager parameter block.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine.

`ioResult`
On output, the result code of the function.

`ioRefNum`
On input, a file reference number for an open file to be read.

`ioBuffer`
On input, a pointer to a data buffer into which the bytes are read.

`ioReqCount`
On input, the number of bytes requested. The value that you pass in this field should be greater than zero.

`ioActCount`
On output, the number of bytes actually read.

`ioPosMode`
On input, the positioning mode.

`ioPosOffset`
On input, the positioning offset. On output, the new position of the mark.

This function attempts to read `ioReqCount` bytes from the open file whose access path is specified in the `ioRefNum` field and transfer them to the data buffer pointed to by the `ioBuffer` field. The position of the mark is specified by `ioPosMode` and `ioPosOffset`. If your application tries to read past the logical end-of-file, `PBReadAsync` reads the data, moves the mark to the end-of-file, and returns `eofErr` as its function result. Otherwise, `PBReadAsync` moves the file mark to the byte following the last byte read and returns `noErr`.

You can specify that `PBReadAsync` read the file data 1 byte at a time until the requested number of bytes have been read or until the end-of-file is reached. To do so, set bit 7 of the `ioPosMode` field. Similarly, you can specify that `PBReadAsync` should stop reading data when it reaches an application-defined newline character. To do so, place the ASCII code of that character into the high-order byte of the `ioPosMode` field; you must also set bit 7 of that field to enable newline mode.

When reading data in newline mode, `PBReadAsync` returns the newline character as part of the data read and sets `ioActCount` to the actual number of bytes placed into the buffer (which includes the newline character).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBReadForkAsync

Reads data from an open fork.

```
void PBReadForkAsync (
    FSForkIOParam *paramBlock
);
```

Parameters

paramBlock
A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. If there are fewer than `requestCount` bytes from the specified position to the logical end-of-file, then all of those bytes are read, and `eofErr` is returned.

`forkRefNum`
On input, the reference number of the fork to read from. You should have previously opened this fork using the `FSOpenFork` (page 514) call, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`
On input, a constant specifying the base location within the fork for the start of the read. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location. The caller can also use this parameter to hint to the File Manager whether the data being read should or should not be cached. Caching reads appropriately can be important in ensuring that your program access files efficiently. If you add the `forceReadMask` constant to the value you pass in this parameter, this tells the File Manager to force the data to be read directly from the disk. This is different from adding the `noCacheMask` constant since `forceReadMask` tells the File Manager to flush the appropriate part of the cache first, then ignore any data already in the cache. However, data that is read may be placed in the cache for future reads. The `forceReadMask` constant is also passed to the device driver, indicating that the driver should avoid reading from any device caches. See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching the read.

`positionOffset`
On input, the offset from the base location for the start of the read.

`requestCount`
: On input, the number of bytes to read. The value that you pass in this field should be greater than zero.

`buffer`
: A pointer to the buffer where the data will be returned.

`actualCount`
: On output, the number of bytes actually read. The value in this field should be equal to the value in the `requestCount` field unless there was an error during the read operation.

`PBReadForkAsync` reads data starting at the position specified by the `positionMode` and `positionOffset` fields. The function reads up to `requestCount` bytes into the buffer pointed to by the `buffer` field and sets the fork's current position to the byte immediately after the last byte read (that is, the initial position plus `actualCount`).

To verify that data previously written has been correctly transferred to disk, read it back in using the `forceReadMask` constant in the `positionMode` field and compare it with the data you previously wrote.

When reading data from a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your read requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBReadForkSync

Reads data from an open fork.

```
OSErr PBReadForkSync (
    FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If there are fewer than `requestCount` bytes from the specified position to the logical end-of-file, then all of those bytes are read, and `eofErr` is returned.

Discussion
The relevant fields of the parameter block are:

`forkRefNum`
: On input, the reference number of the fork to read from. You should have previously opened this fork using the `FSOpenFork` (page 514) call, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`
: On input, a constant specifying the base location within the fork for the start of the read. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location. The caller can also use this parameter to hint to the File Manager whether the data being read should or should not be cached. Caching reads appropriately can be important in ensuring that your program access files efficiently. If you add the `forceReadMask` constant to the value you pass in this parameter, this tells the File Manager to force the data to be read directly from the disk. This is different from adding the `noCacheMask` constant since `forceReadMask` tells the File Manager to flush the appropriate part of the cache first, then ignore any data already in the cache. However, data that is read may be placed in the cache for future reads. The `forceReadMask` constant is also passed to the device driver, indicating that the driver should avoid reading from any device caches. See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching the read.

`positionOffset`
: On input, the offset from the base location for the start of the read.

`requestCount`
: On input, the number of bytes to read. The value that you pass in this field should be greater than zero.

`buffer`
: A pointer to the buffer where the data will be returned.

`actualCount`
: On output, the number of bytes actually read. The value in this field should be equal to the value in the `requestCount` field unless there was an error during the read operation.

`PBReadForkSync` reads data starting at the position specified by the `positionMode` and `positionOffset` fields. The function reads up to `requestCount` bytes into the buffer pointed to by the `buffer` field and sets the fork's current position to the byte immediately after the last byte read (that is, the initial position plus `actualCount`).

To verify that data previously written has been correctly transferred to disk, read it back in using the `forceReadMask` constant in the `positionMode` field and compare it with the data you previously wrote.

When reading data from a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your read requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability
Available in Mac OS X v10.0 and later.

PBReadSync

Reads any number of bytes from an open file. (Deprecated in Mac OS X v10.5. Use `PBReadForkSync` (page 745) instead.)

```
OSErr PBReadSync (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to a basic File Manager parameter block.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioRefNum`

On input, a file reference number for an open file to be read.

`ioBuffer`

On input, a pointer to a data buffer into which the bytes are read.

`ioReqCount`

On input, the number of bytes requested. The value that you pass in this field should be greater than zero.

`ioActCount`

On output, the number of bytes actually read.

`ioPosMode`

On input, the positioning mode.

`ioPosOffset`

On input, the positioning offset. On output, the new position of the mark.

This function attempts to read `ioReqCount` bytes from the open file whose access path is specified in the `ioRefNum` field and transfer them to the data buffer pointed to by the `ioBuffer` field. The position of the mark is specified by `ioPosMode` and `ioPosOffset`. If your application tries to read past the logical end-of-file, `PBReadSync` reads the data, moves the mark to the end-of-file, and returns `eofErr` as its function result. Otherwise, `PBReadSync` moves the file mark to the byte following the last byte read and returns `noErr`.

You can specify that `PBReadSync` read the file data 1 byte at a time until the requested number of bytes have been read or until the end-of-file is reached. To do so, set bit 7 of the `ioPosMode` field. Similarly, you can specify that `PBReadSync` should stop reading data when it reaches an application-defined newline character. To do so, place the ASCII code of that character into the high-order byte of the `ioPosMode` field; you must also set bit 7 of that field to enable newline mode.

When reading data in newline mode, `PBReadSync` returns the newline character as part of the data read and sets `ioActCount` to the actual number of bytes placed into the buffer (which includes the newline character).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Files.h`

PBRenameUnicodeAsync

Renames a file or folder.

```
void PBRenameUnicodeAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See FSRefParam (page 837) for a description of the FSRefParam data type.

Discussion

The relevant fields of the parameter block are:

ioCompletion

On input, a pointer to a completion routine. For more information on completion routines, see IOCompletionProcPtr (page 794).

ioResult

On output, the result code of the function.

ref

On input, a pointer to an FSRef (page 837) for the file or directory to rename.

nameLength

On input, the length of the new name in Unicode characters.

name

On input, a pointer to the new Unicode name of the file or directory.

textEncodingHint

On input, the suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant kTextEncodingUnknown, the File Manager will use a default value.

newRef

On output, a a pointer to the new FSRef for the file or directory. This field is optional; if you do not wish the FSRef returned, pass NULL.

Because renaming an object may change its FSRef, you should pass a non- NULL pointer in the newRef field and use the FSRef returned there to access the object after the renaming, if you wish to continue to refer to the object. The FSRef passed in the ref field may or may not be usable after the object is renamed. The FSRef returned in the newRef field may point to the same storage as the FSRef passed in ref.

Availability

Available in Mac OS X v10.0 and later.

Declared In

Files.h

PBRenameUnicodeSync

Renames a file or folder.

```
OSErr PBRenameUnicodeSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) for the file or directory to rename.

`nameLength`

On input, the length of the new name in Unicode characters.

`name`

On input, a pointer to the new Unicode name of the file or directory.

`textEncodingHint`

On input, the suggested text encoding to use when converting the Unicode name of the file or directory to some other encoding. If you pass the constant `kTextEncodingUnknown`, the File Manager will use a default value.

`newRef`

On output, a a pointer to the new `FSRef` for the file or directory. This field is optional; if you do not wish the `FSRef` returned, pass `NULL`.

Because renaming an object may change its `FSRef`, you should pass a non- `NULL` pointer in the `newRef` field and use the `FSRef` returned there to access the object after the renaming, if you wish to continue to refer to the object. The `FSRef` passed in the `ref` field may or may not be usable after the object is renamed. The `FSRef` returned in the `newRef` field may point to the same storage as the `FSRef` passed in `ref`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBResolveFileIDRefAsync

Retrieves the filename and parent directory ID of a file given its file ID. (Deprecated in Mac OS X v10.5. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr PBResolveFileIDRefAsync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to an `FIDParam` (page 818) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for more information on the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDS internally as part of its search algorithms for finding the target of an alias record.

The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. A return code of `fidNotFound` means that the specified file ID reference has become invalid, either because the file was deleted or because the file ID reference was destroyed by `PBDeleteFileIDRefSync` (page 597) or `PBDeleteFileIDRefAsync` (page 596).

`ioNamePtr`
: On input, a pointer to a pathname. If the name string is `NULL`, `PBResolveFileIDRefAsync` doe s not return the filename, but returns only the parent directory ID of the file in the `ioSrcDirID` field. If the name string is not `NULL` but is only a volume name, `PBResolveFileIDRefAsync` ignores the value in the `ioVRefNum` field and uses the volume name instead. On output, a pointer to the filename for the file with the given file ID.

`ioVRefNum`
: On input, a volume specification for the volume containing the file. This field can contain a volume reference number, a drive number, or 0 for the default volume.

`ioSrcDirID`
: On output, the file's parent directory ID.

`ioFileID`
: On input, a file ID for the file to retrieve information about.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBResolveFileIDRefSync

Retrieves the filename and parent directory ID of a file given its file ID. (Deprecated in Mac OS X v10.5. Use `FSGetCatalogInfo` (page 494) instead.)

```
OSErr PBResolveFileIDRefSync (
   HParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to an `FIDParam` (page 818) variant of the HFS parameter block. See `HParamBlockRec` (page 857) for more information on the `HParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943). A return code of `fidNotFound` means that the specified file ID reference has become invalid, either because the file was deleted or because the file ID reference was destroyed by `PBDeleteFileIDRefSync` (page 597) or `PBDeleteFileIDRefAsync` (page 596).

Discussion

Most applications do not need to use this function. In general, you should track files using alias records, as described in the Alias Manager documentation. The Alias Manager uses file IDs internally as part of its search algorithms for finding the target of an alias record.

The relevant fields of the parameter block are:

`ioNamePtr`

On input, a pointer to a pathname. If the name string is `NULL`, `PBResolveFileIDRefSync` doe s not return the filename, but returns only the parent directory ID of the file in the `ioSrcDirID` field. If the name string is not `NULL` but is only a volume name, `PBResolveFileIDRefSync` ignores the value in the `ioVRefNum` field and uses the volume name instead. On output, a pointer to the filename of the file with the given file ID.

`ioVRefNum`

On input, a volume specification for the volume containing the file. This field can contain a volume reference number, drive number, or 0 for the default volume.

`ioSrcDirID`

On output, the file's parent directory ID.

`ioFileID`

On input, a file ID for the file to retrieve information about.

PBSetCatalogInfoAsync

Sets the catalog information about a file or directory.

```
void PBSetCatalogInfoAsync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) for a description of the `FSRefParam` data type.

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function.

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory whose information is to be changed.

`whichInfo`

On input, a bitmap specifying which catalog information fields to set. Only some of the catalog information fields may be set. These fields are given by the constant `kFSCatInfoSettableInfo`; no other bits may be set in the `whichInfo` field. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

To set the user ID (UID) and group ID (GID), specify the `kFSCatInfoSetOwnership` flag in this field. The File Manager attempts to set the user and group ID to the values specified in the `permissions` field of the catalog information structure. If `PBSetCatalogInfoAsync` cannot set the user and group IDs, it returns an error.

`catInfo`

On input, a pointer to the `FSCatalogInfo` (page 826) structure containing the new catalog information. Only some of the catalog information fields may be set. The fields which may be set are:

- `createDate`
- `contentModDate`
- `attributeModDate`
- `accessDate`
- `backupDate`
- `permissions`
- `finderInfo`
- `extFinderInfo`
- `textEncodingHint`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBSetCatalogInfoSync

Sets the catalog information about a file or directory.

```
OSErr PBSetCatalogInfoSync (
   FSRefParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a file system reference parameter block. See `FSRefParam` (page 837) fro s description of the `FSRefParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ref`

On input, a pointer to an `FSRef` (page 837) specifying the file or directory whose information is to be changed.

`whichInfo`

On input, a bitmap specifying which catalog information fields to set. Only some of the catalog information fields may be set. These fields are given by the constant `kFSCatInfoSettableInfo`; no other bits may be set in the `whichInfo` field. See "Catalog Information Bitmap Constants" (page 891) for a description of the bits in this field.

To set the user ID (UID) and group ID (GID), specify the `kFSCatInfoSetOwnership` flag in this field. The File Manager attempts to set the user and group ID to the values specified in the `permissions` field of the catalog information structure. If `PBSetCatalogInfoSync` cannot set the user and group IDs, it returns an error.

`catInfo`

On input, a pointer to the `FSCatalogInfo` (page 826) structure containing the new catalog information. Only some of the catalog information fields may be set. The fields which may be set are:

- `createDate`
- `contentModDate`
- `attributeModDate`
- `accessDate`
- `backupDate`
- `permissions`
- `finderInfo`
- `extFinderInfo`
- `textEncodingHint`

Availability

Available in Mac OS X v10.0 and later.

`Files.h`

PBSetCatInfoAsync

Modifies catalog information for a file or directory. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoAsync` (page 751) instead.)

```
OSErr PBSetCatInfoAsync (
   CInfoPBPtr paramBlock
);
```

Parameters

paramBlock

A pointer to an HFS catalog information parameter block. See `CInfoPBRec` (page 802) for a description of the `CInfoPBRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The `PBSetCatInfoAsync` function sets information about a file or directory. When used to set information about a file, it works much as `PBHSetFInfoAsync` (page 721) does, but lets you set some additional information.

If the object is a file, the relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioNamePtr`
On input, a pointer to a pathname.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioFlFndrInfo`
On input, Finder information for the file.

`ioDirID`
On input, the parent directory ID of the file.

`ioFlCrDat`
On input, the date and time of the file's creation.

`ioFlMdDat`
On input, the date and time of the file's last modification.

`ioFlBkDat`
On input, the date and time of the file's last backup.

`ioFlXFndrInfo`
On input, extended Finder information.

If the object is a directory, the relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion function. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioNamePtr`
: On input, a pointer to a pathname.

`ioVRefNum`
: On input, a volume reference number, drive number, or 0 for the default volume.

`ioDrUsrWds`
: On input, information used by the Finder.

`ioDrDirID`
: On input, the directory ID.

`ioDrCrDat`
: On input, the date and time of the directory's creation.

`ioDrMdDat`
: On input, the date and time of the directory's last modification.

`ioDrBkDat`
: On input, the date and time of the directory's last backup.

`ioDrFndrInfo`
: On input, additional information used by the Finder.

To modify the catalog information for a named fork other than the data and resource fork, or to modify other catalog information maintained on HFS Plus volumes that is not modifiable through `PBSetCatInfoAsync`, use one of the functions, `FSSetCatalogInfo` (page 540) , `PBSetCatalogInfoSync` (page 753) , or `PBSetCatalogInfoAsync` (page 751).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetCatInfoSync

Modifies catalog information for a file or directory. (Deprecated in Mac OS X v10.4. Use `PBSetCatalogInfoSync` (page 753) instead.)

```
OSErr PBSetCatInfoSync (
   CInfoPBPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to an HFS catalog information parameter block. See `CInfoPBRec` (page 802) for a description of the `CInfoPBRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The `PBSetCatInfoSync` function sets information about a file or directory. When used to set information about a file, it works much as `PBHSetFInfoSync` (page 722) does, but lets you set some additional information.

If the object is a file, the relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioFlFndrInfo`
On input, Finder information for the file.

`ioDirID`
On input, the parent directory ID of the file.

`ioFlCrDat`
On input, the date and time of the file's creation.

`ioFlMdDat`
On input, the date and time of the file's last modification.

`ioFlBkDat`
On input, the date and time of the file's last backup.

`ioFlXFndrInfo`
On input, extended Finder information.

If the object is a directory, the relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a pathname.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume.

`ioDrUsrWds`
On input, information used by the Finder.

`ioDrDirID`
On input, the directory ID.

`ioDrCrDat`
On input, the date and time of the directory's creation.

`ioDrMdDat`
On input, the date and time of the directory's last modification.

`ioDrBkDat`
On input, the date and time of the directory's last backup.

`ioDrFndrInfo`
On input, additional information used by the Finder.

To modify the catalog information for a named fork other than the data and resource fork, or to modify other catalog information maintained on HFS Plus volumes that is not modifiable through `PBSetCatInfoSync`, use one of the functions, `FSSetCatalogInfo` (page 540) , `PBSetCatalogInfoSync` (page 753) , or `PBSetCatalogInfoAsync` (page 751).

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetEOFAsync

Sets the logical size of an open file. (Deprecated in Mac OS X v10.4. Use `PBSetForkSizeAsync` (page 761) instead.)

```
OSErr PBSetEOFAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioRefNum`
On input, a file reference number for the open file.

`ioMisc`
On input, the new logical size (the logical end-of-file) of the given file. Because the `ioMisc` field is of type `Ptr`, you must coerce the desired value from a long integer to type `Ptr`. If the value of the `ioMisc` field is 0, all space occupied by the file on the volume is released. The file still exists, but it contains 0 bytes. Setting a file fork's end-of-file to 0 is therefore not the same as deleting the file, which removes both file forks at once.

If you attempt to set the logical end-of-file beyond the current physical end-of-file, another allocation block is added to the file if there isn't enough space on the volume, no change is made and `PBSetEOFAsync` returns `dskFulErr` as its function result.

To ensure that your changes to the file are written to disk, call one of the functions, `FlushVol` (page 466) , `PBFlushVolSync` (page 641) , or `PBFlushVolAsync` (page 640). To set the size of a named fork other than the data and resource forks, or to grow the size of a file beyond 2GB, you must use the `FSSetForkSize` (page 542) function, or one of the corresponding parameter block calls, `PBSetForkSizeSync` (page 762) and `PBSetForkSizeAsync` (page 761).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Files.h`

PBSetEOFSync

Sets the logical size of an open file. (Deprecated in Mac OS X v10.4. Use `PBSetForkSizeSync` (page 762) instead.)

```
OSErr PBSetEOFSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioRefNum`

On input, a file reference number for the open file.

`ioMisc`

On input, the new logical size (the logical end-of-file) of the given file. Because the `ioMisc` field is of type `Ptr`, you must coerce the desired value from a long integer to type `Ptr`. If the value of the `ioMisc` field is 0, all space occupied by the file on the volume is released. The file still exists, but it contains 0 bytes. Setting a file fork's end-of-file to 0 is therefore not the same as deleting the file, which removes both file forks at once.

If you attempt to set the logical end-of-file beyond the current physical end-of-file, another allocation block is added to the file if there isn't enough space on the volume, no change is made and `PBSetEOFSync` returns `dskFulErr` as its function result.

To ensure that your changes to the file are written to disk, call one of the functions, `FlushVol` (page 466) , `PBFlushVolSync` (page 641) , or `PBFlushVolAsync` (page 640). To set the size of a named fork other than the data and resource forks, or to grow the size of a file beyond 2GB, you must use the `FSSetForkSize` (page 542) function, or one of the corresponding parameter block calls, `PBSetForkSizeSync` (page 762) and `PBSetForkSizeAsync` (page 761).

Availability
Available in Mac OS X v10.0 and later.

`Files.h`

PBSetForeignPrivsSync

Changes the native access-control information for a file or directory stored on a volume managed by a foreign file system. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBSetForeignPrivsSync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBSetForkPositionAsync

Sets the current position of an open fork.

```
void PBSetForkPositionAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function. This function returns the result code `posErr` if you attempt to set the current position of the fork to an offset before the start of the file.

`forkRefNum`
On input, the reference number of a fork previously opened by the `FSOpenFork` (page 514) , `PBOpenForkSync` (page 740) , or `PBOpenForkAsync` (page 739) function.

`positionMode`
On input, a constant specifying the base location within the fork for the new position. If this field is equal to `fsAtMark`, then the `positionOffset` field is ignored. See "Position Mode Constants" (page 928) for a description of the constants you can use to specify the base location.

`positionOffset`
On input, the offset of the new position from the base location specified in the `positionMode` field.

Special Considerations

To determine if the `PBSetForkPositionAsync` function is present, call the `Gestalt` function with the `gestaltFSAttr` selector. If the `PBSetForkPositionAsync` function is present, but the volume does not directly support it, the File Manager will automatically call the `PBSetFPosAsync` (page 763) function. However, if the volume does not directly support the `PBSetForkPositionAsync` function, you can only set the file position for the data and resource forks, and you cannot grow these files beyond 2GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBSetForkPositionSync

Sets the current position of an open fork.

```
OSErr PBSetForkPositionSync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). This function returns the result code `posErr` if you attempt to set the current position of the fork to an offset before the start of the file.

Discussion
The relevant fields of the parameter block are:

`forkRefNum`
: On input, the reference number of a fork previously opened by the `FSOpenFork` (page 514) , `PBOpenForkSync` (page 740) , or `PBOpenForkAsync` (page 739) function.

`positionMode`
: On input, a constant specifying the base location within the fork for the new position. If this field is equal to `fsAtMark`, then the `positionOffset` field is ignored. See "Position Mode Constants" (page 928) for a description of the constants you can use to specify the base location.

`positionOffset`
: On input, the offset of the new position from the base location specified in the `positionMode` field.

Special Considerations

To determine if the `PBSetForkPositionSync` function is present, call the `Gestalt` function with the `gestaltFSAttr` selector. If the `PBSetForkPositionSync` function is present, but the volume does not directly support it, the File Manager will automatically call the `PBSetFPosSync` (page 764) function. However, if the volume does not directly support the `PBSetForkPositionSync` function, you can only set the file position for the data and resource forks, and you cannot grow these files beyond 2GB.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBSetForkSizeAsync

Changes the size of an open fork.

```
void PBSetForkSizeAsync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. If there is not enough space on the volume to extend the fork, then `dskFulErr` is returned and the fork's size is unchanged.

`forkRefNum`
: On input, the reference number of the open fork. You can obtain a fork reference number with the `FSOpenFork` (page 514) function, or with one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`
: On input, a constant indicating the base location within the fork for the new size. See "Position Mode Constants" (page 928) for more information about the constants you can use to specify the base location.

`positionOffset`
: On input, the offset of the new size from the base location specified in the `positionMode` field.

The `PBSetForkSizeAsync` function sets the logical end-of-file to the position indicated by the `positionMode` and `positionOffset` fields. The fork's new size may be less than, equal to, or greater than the fork's current size. If the fork's new size is greater than the fork's current size, then the additional bytes, between the old and new size, will have an undetermined value.

If the fork's current position is larger than the fork's new size, then the current position will be set to the new fork size. That is, the current position will be equal to the logical end of file.

Special Considerations

You do not need to check that the volume supports the `PBSetForkSizeAsync` function. If a volume does not support the `PBSetForkSizeAsync` function, but the `PBSetForkSizeAsync` function is present, the File Manager automatically calls the `PBSetEOFAsync` (page 757) function and translates between the calls appropriately.

Note, however, that if the volume does not support the `PBSetForkSizeAsync` function, you can only access the data and resource forks, and you cannot grow the fork beyond 2GB. To check that the `PBSetForkSizeAsync` function is present, call the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBSetForkSizeSync

Changes the size of an open fork.

```
OSErr PBSetForkSizeSync (
   FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
: A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If there is not enough space on the volume to extend the fork, then `dskFulErr` is returned and the fork's size is unchanged.

Discussion
The relevant fields of the parameter block are:

`forkRefNum`
: On input, the reference number of the open fork. You can obtain a fork reference number with the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`
: On input, a constant indicating the base location within the fork for the new size. See "Position Mode Constants" (page 928) for more information about the constants you can use to specify the base location.

`positionOffset`
: On input, the offset of the new size from the base location specified in the `positionMode` field.

The `PBSetForkSizeSync` function sets the logical end-of-file to the position indicated by the `positionMode` and `positionOffset` fields. The fork's new size may be less than, equal to, or greater than the fork's current size. If the fork's new size is greater than the fork's current size, then the additional bytes, between the old and new size, will have an undetermined value.

If the fork's current position is larger than the fork's new size, then the current position will be set to the new fork size. That is, the current position will be equal to the logical end-of-file.

Special Considerations

You do not need to check that the volume supports the `PBSetForkSizeSync` function. If a volume does not support the `PBSetForkSizeSync` function, but the `PBSetForkSizeSync` function is present, the File Manager automatically calls the `PBSetEOFSync` (page 758) function and translates between the calls appropriately.

Note, however, that if the volume does not support the `PBSetForkSizeSync` function, you can only access the data and resource forks, and you cannot grow the fork beyond 2GB. To check that the `PBSetForkSizeSync` function is present, call the `Gestalt` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBSetFPosAsync

Sets the position of the file mark. (Deprecated in Mac OS X v10.4. Use `PBSetForkPositionAsync` (page 759) instead.)

```
OSErr PBSetFPosAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

`paramBlock`
: A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioRefNum`
: On input, the file reference number for an open file.

`ioPosMode`
: On input, a constant indicating how to position the mark; this field must contain one of the values described in "Position Mode Constants" (page 928).

`ioPosOffset`
: On input, the offset from the base location specified by the `ioPosMode` field for the file mark. If you specify `fsAtMark` in the `ioPosMode` field, the mark is left wherever it's currently positioned and the value in the `ioPosOffset` field is ignored. If you specify `fsFromLEOF`, the value in `ioPosOffset` must be less than or equal to 0. On output, the position at which the mark was actually set.

The `PBSetFPosAsync` function sets the mark of the specified file to the position specified by the `ioPosMode` and `ioPosOffset` fields. If you try to set the mark past the logical end-of-file, `PBSetFPosAsync` moves the mark to the end-of-file and returns `eofErr` as its function result.

To set the file mark position for a named fork other than the data and resource forks, or to position the file mark at a point more than 2GB into the file, use the `FSSetForkPosition` (page 541) function, or one of the corresponding parameter block calls, `PBSetForkPositionSync` (page 760) and `PBSetForkPositionAsync` (page 759).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetFPosSync

Sets the position of the file mark. (Deprecated in Mac OS X v10.4. Use `PBSetForkPositionSync` (page 760) instead.)

```
OSErr PBSetFPosSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
: A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioRefNum`
: On input, the file reference number for an open file.

`ioPosMode`
: On input, a constant indicating how to position the file mark; this field must contain one of the values described in "Position Mode Constants" (page 928).

`ioPosOffset`
: On input, the offset from the base location specified by the `ioPosMode` field for the file mark. If you specify `fsAtMark` in the `ioPosMode` field, the mark is left wherever it's currently positioned and the value in the `ioPosOffset` field is ignored. If you specify `fsFromLEOF`, the value in `ioPosOffset` must be less than or equal to 0. On output, the position at which the mark was actually set.

The `PBSetFPosSync` function sets the mark of the specified file to the position specified by the `ioPosMode` and `ioPosOffset` fields. If you try to set the mark past the logical end-of-file, `PBSetFPosSync` moves the mark to the end-of-file and returns `eofErr` as its function result.

To set the file mark position for a named fork other than the data and resource forks, or to position the file mark at a point more than 2GB into the file, use the `FSSetForkPosition` (page 541) function, or one of the corresponding parameter block calls, `PBSetForkPositionSync` (page 760) and `PBSetForkPositionAsync` (page 759).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetVInfoAsync

Changes information about a volume. (Deprecated in Mac OS X v10.4. Use `PBSetVolumeInfoAsync` (page 767) instead.)

```
OSErr PBSetVInfoAsync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
: A pointer to the `HVolumeParam` (page 859) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function.

`ioNamePtr`
On input, a pointer to the volume's name. You can specify a new name for the volume here. You cannot specify the volume by name you must use either the volume reference number or the drive number.

`ioVRefNum`
On input, a volume reference number or drive number for the volume whose information is to be changed; or 0 for the default volume.

`ioVCrDate`
On input, the date and time of the volume's initialization.

`ioVLsMod`
On input, the date and time of the volume's last modification.

`ioVAtrb`
On input, the volume attributes. Only bit 15 of the `ioVAtrb` field can be changed; setting it locks the volume. See "Volume Information Attribute Constants" (page 937) for a description of the volume attributes.

`ioVBkUp`
On input, the date and time of the volume's last backup.

`ioVSeqNum`
Used internally.

`ioVFndrInfo`
On input, Finder information for the volume.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetVInfoSync

Changes information about a volume. (Deprecated in Mac OS X v10.4. Use `PBSetVolumeInfoSync` (page 768) instead.)

```
OSErr PBSetVInfoSync (
   HParmBlkPtr paramBlock
);
```

Parameters
`paramBlock`
A pointer to the `HVolumeParam` (page 859) variant of the basic HFS parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to the volume's name. You can specify a new name for the volume here. You cannot specify the volume by name you must use either the volume reference number or the drive number.

`ioVRefNum`
On input, a volume reference number or drive number for the volume whose information is to be changed; or 0 for the default volume.

`ioVCrDate`
On input, the date and time of the volume's initialization.

`ioVLsMod`
On input, the date and time of the volume's last modification.

`ioVAtrb`
On input, the volume attributes. Only bit 15 of the `ioVAtrb` field can be changed; setting it locks the volume. See "Volume Information Attribute Constants" (page 937) for a description of the volume attributes.

`ioVBkUp`
On input, the date and time of the volume's last backup.

`ioVSeqNum`
Used internally.

`ioVFndrInfo`
On input, Finder information for the volume.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBSetVolumeInfoAsync

Sets information about a volume.

```
void PBSetVolumeInfoAsync (
   FSVolumeInfoParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a volume information parameter block. See `FSVolumeInfoParam` (page 845) for a description of the `FSVolumeInfoParam` data type.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
On output, the result code of the function.

`ioVRefNum`
On input, the volume reference number of the volume whose information is to be changed.

`whichInfo`
On input, a bitmap specifying which information to set. Only some of the volume information fields may be set. The settable fields are given by the constant `kFSVolInfoSettableInfo`; no other bits may be set in `whichInfo`. The fields which may be set are the backupDate, finderInfo, and `flags` fields. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this parameter.

`volumeInfo`
On input, the new volume information. See `FSVolumeInfo` (page 842) for more information about the volume information structure.

To set information about the root directory of a volume, use the `FSSetCatalogInfo` (page 540) function, or one of the corresponding parameter block calls, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBSetVolumeInfoSync

Sets information about a volume.

```
OSErr PBSetVolumeInfoSync (
   FSVolumeInfoParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a volume information parameter block. See `FSVolumeInfoParam` (page 845) for a description of the `FSVolumeInfoParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioVRefNum`
On input, the volume reference number of the volume whose information is to be changed.

`whichInfo`
On input, a bitmap specifying which information to set. Only some of the volume information fields may be set. The settable fields are given by the constant `kFSVolInfoSettableInfo`; no other bits may be set in `whichInfo`. The fields which may be set are the backupDate, finderInfo, and `flags` fields. See "Volume Information Bitmap Constants" (page 938) for a description of the bits in this parameter.

`volumeInfo`

On input, the new volume information. See `FSVolumeInfo` (page 842) for more information about the volume information structure.

To set information about the root directory of a volume, use the `FSSetCatalogInfo` (page 540) function, or one of the corresponding parameter block calls, `PBSetCatalogInfoSync` (page 753) and `PBSetCatalogInfoAsync` (page 751).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBShareAsync

Establishes a local volume or directory as a share point. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBShareAsync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBShareSync

Establishes a local volume or directory as a share point. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr PBShareSync (
   HParmBlkPtr paramBlock
);
```

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBUnlockRangeAsync

Unlocks a portion of a file. (Deprecated in Mac OS X v10.4. Use `PBXUnlockRangeAsync` (page 785) instead.)

```
OSErr PBUnlockRangeAsync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the result code of the function. If you call `PBUnlockRangeAsync` on a file system that does not implement it—for example, SMB—`PBUnlockRangeAsync` returns `noErr` and does nothing.

`ioRefNum`

On input, the file reference number of the file owning the range to unlock.

`ioReqCount`

On input, the number of bytes in the range.

`ioPosMode`

On input, a constant specifying the base location for the start of the locked range. See "Position Mode Constants" (page 928) for more information on the constants you can use to indicate the base location.

`ioPosOffset`

On input, the offset from the base location specified in the `ioPosMode` field for the start of the locked range.

The `PBUnlockRangeAsync` function unlocks a portion of a file that you locked with `PBLockRangeSync` (page 730) or `PBLockRangeAsync` (page 728). The beginning of the range to be unlocked is determined by the `ioPosMode` and `ioPosOffset` fields. The end of the range to be unlocked is determined by the beginning of the range and the `ioReqCount` field. For example, to unlock the first 50 bytes in a file, set `ioReqCount` to 50, `ioPosMode` to `fsFromStart`, and `ioPosOffset` to 0. The range of bytes to be unlocked must be the exact same range locked by a previous call to `PBLockRangeSync` (page 730) or `PBLockRangeAsync` (page 728).

If for some reason you need to unlock a range whose beginning or length is unknown, you can simply close the file. When a file is closed, all locked ranges held by the user are unlocked.

Special Considerations

The `PBUnlockRangeAsync` function does nothing if the file specified in the `ioRefNum` field is open with shared read/write permission but is not located on a remote server volume or is not located under a share point on a local volume. To check whether file sharing is currently on, check that the `bHasPersonalAccessPrivileges` bit in the `vMAttrib` field of the `GetVolParmsInfoBuffer` (page 847) returned by the `PBHGetVolParmsSync` (page 695) function is set.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBUnlockRangeSync

Unlocks a portion of a file. (Deprecated in Mac OS X v10.4. Use `PBXUnlockRangeSync` (page 786) or `FSUnlockRange` (page 543) instead.)

```
OSErr PBUnlockRangeSync (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943). If you call `PBUnlockRangeSync` on a file system that does not implement it—for example, SMB—`PBUnlockRangeSync` returns `noErr` and does nothing.

Discussion
The relevant fields of the parameter block are:

`ioRefNum`
On input, the file reference number of the file owning the range to unlock.

`ioReqCount`
On input, the number of bytes in the range.

`ioPosMode`
On input, a constant specifying the base location for the start of the locked range. See "Position Mode Constants" (page 928) for more information on the constants you can use to indicate the base location.

`ioPosOffset`
On input, the offset from the base location specified in the `ioPosMode` field for the start of the locked range.

The `PBUnlockRangeSync` function unlocks a portion of a file that you locked with `PBLockRangeSync` (page 730) or `PBLockRangeAsync` (page 728). The beginning of the range to be unlocked is determined by the `ioPosMode` and `ioPosOffset` fields. The end of the range to be unlocked is determined by the beginning of the range and the `ioReqCount` field. For example, to unlock the first 50 bytes in a file, set `ioReqCount` to 50, `ioPosMode` to `fsFromStart`, and `ioPosOffset` to 0. The range of bytes to be unlocked must be the exact same range locked by a previous call to `PBLockRangeSync` (page 730) or `PBLockRangeAsync` (page 728).

If for some reason you need to unlock a range whose beginning or length is unknown, you can simply close the file. When a file is closed, all locked ranges held by the user are unlocked.

Special Considerations

The `PBUnlockRangeSync` function does nothing if the file specified in the `ioRefNum` field is open with shared read/write permission but is not located on a remote server volume or is not located under a share point on a local volume. To check whether file sharing is currently on, check that the `bHasPersonalAccessPrivileges` bit in the `vMAttrib` field of the `GetVolParmsInfoBuffer` (page 847) returned by the `PBHGetVolParmsSync` (page 695) function is set.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

PBUnmountVol

Unmounts a volume. (Deprecated in Mac OS X v10.4. Use `FSEjectVolumeSync` (page 486) or `FSUnmountVolumeSync` (page 545) instead.)

```
OSErr PBUnmountVol (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `VolumeParam` (page 873) variant of the basic File Manager parameter block. See `ParamBlockRec` (page 866) for a description of the `ParamBlockRec` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioResult`

On output, the result code of the function.

`ioNamePtr`

On input, a pointer to the name of the volume.

`ioVRefNum`

On input, the volume reference number of the volume to unmount, or 0 for the default volume.

This function calls `PBFlushVolSync` to flush the specified volume, unmounts and ejects the volume, and releases the memory used for the volume. Prior to calling this function, all user files on the volume must be closed. Ejecting a volume results in the unmounting of other volumes on the same device.

The `PBUnmountVol` function always executes synchronously.

Special Considerations

Don't unmount the startup volume. Doing so will cause a system crash.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBUnshareAsync

Makes a share point unavailable on the network. (Deprecated in Mac OS X v10.4. There is no replacement function.)

PBVolumeMount

Mounts a volume. (Deprecated in Mac OS X v10.5. Use `FSVolumeMount` (page 545) instead.)

```
OSErr PBVolumeMount (
   ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the `IOParam` (page 862) variant of the basic File Manager parameter block. See `HParamBlockRec` (page 857) for a description of the `HParamBlockRec` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioVRefNum`

On output, a volume reference number for the mounted volume.

`ioBuffer`

On input, a pointer to mounting information. You can use the volume mounting information returned by the `PBGetVolMountInfo` (page 668) function or you can use a volume mounting information structure filled in by your application. If you're mounting an AppleShare volume, place the volume's AFP mounting information structure in the buffer pointed to by the `ioBuffer` field.

This function allows your application to record the mounting information for a volume and then to mount the volume later.

The `PBGetVolMountInfo` function does not return the user and volume passwords they're returned blank. Typically, your application asks the user for any necessary passwords and fills in those fields just before calling `PBVolumeMount`. If you want to mount a volume with guest status, pass an empty string as the user password.

If you have enough information about the volume, you can fill in the mounting structure yourself and call `PBVolumeMount`, even if you did not save the mounting information while the volume was mounted. To mount an AFP volume, you must fill in the structure with at least the zone name, server name, user name, user password, and volume password. You can lay out the fields in any order within the data field, as long as you specify the correct offsets.

In general, it is easier to mount remote volumes by creating and then resolving alias records that describe those volumes. The Alias Manager displays the standard user interface for user authentication when resolving alias records for remote volumes. As a result, this function is primarily of interest for applications that need to mount remote volumes with no user interface or with some custom user interface.

Special Considerations

AFP volumes currently ignore the user authentication method passed in the `uamType` field of the volume mounting information structure whose address is passed in the `ioBuffer` field of the parameter block. The most secure available method is used by default, except when a user mounts the volume as Guest and uses the `kNoUserAuthentication` authentication method.

This function executes synchronously. You should not call it at interrupt time.

Version Notes
The File Sharing workstation software introduced in system software version 7.0 does not currently pass the volume password. The AppleShare 3.0 workstation software does, however, pass the volume password.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBWaitIOComplete

Keeps the system idle until either an interrupt occurs or the specified timeout value is reached. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSErr PBWaitIOComplete (
    ParmBlkPtr paramBlock,
    Duration timeout
);
```

Parameters

paramBlock
A pointer to a basic File Manager parameter block.

timeout
The maximum length of time you want the system to be kept idle.

Return Value
A result code. If the timeout value is reached, returns `kMPTimeoutErr`.

Special Considerations

This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBWriteAsync

Writes any number of bytes to an open file. (Deprecated in Mac OS X v10.5. Use `PBWriteForkAsync` (page 776) instead.)

```
OSErr PBWriteAsync (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a basic File Manager parameter block.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
On input, a pointer to a completion routine.

`ioResult`
On output, the result code of the function.

`ioRefNum`
On input, a file reference number for the open file to which to write.

`ioBuffer`
On input, a pointer to a data buffer containing the bytes to write.

`ioReqCount`
On input, the number of bytes requested.

`ioActCount`
On output, the number of bytes actually written.

`ioPosMode`
On input, the positioning mode.

`ioPosOffset`
On input, the positioning offset. On output, the new position of the mark.

The `PBWriteAsync` function takes `ioReqCount` bytes from the buffer pointed to by `ioBuffer` and attempts to write them to the open file whose access path is specified by `ioRefNum`. The position of the mark is specified by `ioPosMode` and `ioPosOffset`. If the write operation completes successfully, `PBWriteAsync` moves the file mark to the byte following the last byte written and returns `noErr`. If you try to write past the logical end-of-file, `PBWriteAsync` moves the logical end-of-file. If you try to write past the physical end-of-file, `PBWriteAsync` adds one or more clumps to the file and moves the physical end-of-file accordingly.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Files.h`

PBWriteForkAsync

Writes data to an open fork.

```
void PBWriteForkAsync (
    FSForkIOParam *paramBlock
);
```

Parameters

`paramBlock`
A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam`.

Discussion
The relevant fields of the parameter block are:

`ioCompletion`
: On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`
: On output, the result code of the function. If there is not enough space on the volume to write `requestCount` bytes, then `dskFulErr` is returned.

`forkRefNum`
: On input, the reference number of the fork to which to write. You should have previously opened the fork using the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`
: On input, a constant specifying the base location within the fork for the start of the write. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location. The caller can also use this parameter to hint to the File Manager whether the data being written should or should not be cached. See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching.

`positionOffset`
: On input, the offset from the base location for the start of the write.

`requestCount`
: On input, the number of bytes to write.

`buffer`
: A pointer to a buffer containing the data to write.

`actualCount`
: On output, the number of bytes actually written. The value in the `actualCount` field will be equal to the value in the `requestCount` field unless there was an error during the write operation.

`PBWriteForkAsync` writes data starting at the position specified by the `positionMode` and `positionOffset` fields. The function attempts to write `requestCount` bytes from the buffer pointed to by the `buffer` field and sets the fork's current position to the byte immediately after the last byte written (that is, the initial position plus `actualCount`).

When writing data to a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your write requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

PBWriteForkSync

Writes data to an open fork.

```
OSErr PBWriteForkSync (
    FSForkIOParam *paramBlock
);
```

Parameters

paramBlock

A pointer to a fork I/O parameter block. See `FSForkIOParam` (page 833) for a description of the `FSForkIOParam`.

Return Value

A result code. See "File Manager Result Codes" (page 943). If there is not enough space on the volume to write `requestCount` bytes, then `dskFulErr` is returned.

Discussion

The relevant fields of the parameter block are:

`ioResult`

On output, the result code of the function. If there is not enough space on the volume to write `requestCount` bytes, then `dskFulErr` is returned.

`forkRefNum`

On input, the reference number of the fork to which to write. You should have previously opened the fork using the `FSOpenFork` (page 514) function, or one of the corresponding parameter block calls, `PBOpenForkSync` (page 740) and `PBOpenForkAsync` (page 739).

`positionMode`

On input, a constant specifying the base location within the fork for the start of the write. See "Position Mode Constants" (page 928) for a description of the constants which you can use to specify the base location. The caller can also use this parameter to hint to the File Manager whether the data being written should or should not be cached. See "Cache Constants" (page 889) for further description of the constants that you can use to indicate your preference for caching.

`positionOffset`

On input, the offset from the base location for the start of the write.

`requestCount`

On input, the number of bytes to write.

`buffer`

A pointer to a buffer containing the data to write.

`actualCount`

On output, the number of bytes actually written. The value in the `actualCount` field will be equal to the value in the `requestCount` field unless there was an error during the write operation.

`PBWriteForkSync` writes data starting at the position specified by the `positionMode` and `positionOffset` fields. The function attempts to write `requestCount` bytes from the buffer pointed to by the `buffer` field and sets the fork's current position to the byte immediately after the last byte written (that is, the initial position plus `actualCount`).

When writing data to a fork, it is important to pay attention to that way that your program accesses the fork, because this can have a significant performance impact. For best results, you should use an I/O size of at least 4KB and block align your write requests. In Mac OS X, you should align your requests to 4KB boundaries.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

PBWriteSync

Writes any number of bytes to an open file. (Deprecated in Mac OS X v10.5. Use `PBWriteForkSync` (page 777) instead.)

```
OSErr PBWriteSync (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock
A pointer to a basic File Manager parameter block.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioRefNum`
On input, a file reference number for the open file to which to write.

`ioBuffer`
On input, a pointer to a data buffer containing the bytes to write.

`ioReqCount`
On input, the number of bytes requested.

`ioActCount`
On output, the number of bytes actually written.

`ioPosMode`
On input, the positioning mode.

`ioPosOffset`
On input, the positioning offset. On output, the new position of the mark.

The `PBWriteSync` function takes `ioReqCount` bytes from the buffer pointed to by `ioBuffer` and attempts to write them to the open file whose access path is specified by `ioRefNum`. The position of the mark is specified by `ioPosMode` and `ioPosOffset`. If the write operation completes successfully, `PBWriteSync` moves the file mark to the byte following the last byte written and returns `noErr`. If you try to write past the logical end-of-file, `PBWriteSync` moves the logical end-of-file. If you try to write past the physical end-of-file, `PBWriteSync` adds one or more clumps to the file and moves the physical end-of-file accordingly.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In

`Files.h`

PBXGetVolInfoAsync

Returns information about a volume, including size information for volumes up to 2 terabytes. (Deprecated in Mac OS X v10.4. Use `FSGetVolumeInfo` (page 500) instead.)

```
OSErr PBXGetVolInfoAsync (
   XVolumeParamPtr paramBlock
);
```

Parameters

paramBlock

A pointer to an extended volume parameter block. See `XVolumeParam` (page 882) for a description of the `XVolumeParam` data type.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

The relevant fields of the parameter block are:

`ioCompletion`

On input, a pointer to a completion routine. For more information on completion routines, see `IOCompletionProcPtr` (page 794).

`ioResult`

On output, the function result.

`ioNamePtr`

On input, a pointer to a buffer. You should pass a pointer to a `Str31` value if you want the volume name returned; otherwise, pass `NULL`. If you specify a negative number in the `ioVolIndex` field, this buffer should hold the name of the volume for which to return information. On output, a pointer to the volume's name.

`ioVRefNum`

On input, a volume reference number, drive number, or 0 for the default volume. If the value in the `ioVolIndex` field is negative, the File Manager uses the name in the `ioNamePtr` field, along with the value in the `ioVRefNum` field, to determine the volume. If the value in `ioVolIndex` is 0, the File Manager attempts to access the volume using only the value in this field. On output, the volume reference number.

`ioXVersion`

On input, the version of the extended volume parameter block. Currently, this value is 0.

`ioVolIndex`

On input, an index used for indexing through all the mounted volumes. If this value is positive, the File Manager uses it to find the volume for which to return information. For instance, if the value of `ioVolIndex` is 2, the File Manager attempts to access the second mounted volume in the VCB queue. If `ioVolIndex` is negative, the File Manager uses the values in the `ioNamePtr` and `ioVRefNum` fields to access the requested volume. If `ioVolIndex` is 0, the File Manager uses only the value in the `ioVRefNum` field.

`ioVCrDate`

On output, the date and time of the volume's creation (initialization).

`ioVLsMod`

On output, the date and time that the volume was last modified.

`ioVAtrb`

On output, the volume attributes. See "Volume Information Attribute Constants" (page 937) for a description of these attributes.

`ioVNmFls`

On output, the number of files in the root directory of the volume. For performance reasons, the Carbon File Manager does not return the number of files in this field; instead, it sets `ioVNmFls` to

0.To determine the number of files in the root directory of a volume in Carbon, call `PBGetCatInfoAsync` (page 648) for the root directory. The number of files in the root directory is returned in the `ioDrNmFls` field.

`ioVBitMap`
On output, the first block of the volume bitmap.

`ioVAllocPtr`
On output, the block where the next new file allocation search should start.

`ioVNmAlBlks`
On output, the number of allocation blocks on the volume.

`ioVAlBlkSiz`
On output, the allocation block size for the volume.

`ioVClpSiz`
On output, the volume's default clump size.

`ioAlBlSt`
On output, the first block in the volume block map.

`ioVNxtCNID`
On output, the next unused catalog node ID.

`ioVFrBlk`
On output, the number of free (unused) allocation blocks on the volume.

`ioVSigWord`
On output, the volume signature. For HFS volumes, this is 'BD' for HFS Plus volumes, this is 'H+'.

`ioVDrvInfo`
On output, the drive number. You can determine whether the given volume is online by inspecting the value of this field. For online volumes, the `ioVDrvInfo` field contains the drive number of the drive containing the specified volume and hence is always greater than 0. If the value returned in `ioVDrvInfo` is 0, the volume is either offline or ejected.

`ioVDRefNum`
On output, the driver reference number. You can determine whether the volume is offline or ejected by inspecting the value of this field. If the volume is offline, the value of `ioVDRefNum` is the negative of the drive number (which is cleared when the volume is placed offline; hence the `ioVDrvInfo` field for an offline volume is zero), and is a negative number. If the volume is ejected, the value of `ioVDRefNum` is the drive number itself, and thus is a positive number. For online volumes, `ioVDRefNum` contains a driver reference number; these numbers are always less than 0.

`ioVFSID`
On output, the file system ID for the file system handling this volume.

`ioVBkUp`
On output, the date and time that the volume was last backed up.

`ioVSeqNum`
Used internally.

`ioVWrCnt`
On output, the volume write count.

`ioVFilCnt`
On output, the number of files on the volume.

`ioVDirCnt`
On output, the number of directories on the volume.

`ioVFndrInfo`
On output, Finder information for the volume.

`ioVTotalBytes`
On output, the total number of bytes on the volume.

`ioVFreeBytes`
On output, the number of free bytes on the volume.

The `PBXGetVolInfoAsync` function is similar to the `PBHGetVInfoAsync` (page 686) function except that it returns additional volume space information in 64-bit integers and does not modify the information copied from the volume's volume control block (VCB). Systems that support `PBXGetVolInfoAsync` will have the `gestaltFSSupports2TBVols` bit set in the response returned by the `gestaltFSAttr Gestalt` selector. See *Inside Mac OS X: Gestalt Manager Reference* for a description of the `gestaltFSAttr` selector and of the bits that may be returned in the response.

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBXGetVolInfoAsync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

PBXGetVolInfoSync

Returns information about a volume, including size information for volumes up to 2 terabytes. (Deprecated in Mac OS X v10.4. Use `FSGetVolumeInfo` (page 500) instead.)

```
OSErr PBXGetVolInfoSync (
   XVolumeParamPtr paramBlock
);
```

Parameters

`paramBlock`
A pointer to an extended volume parameter block. See `XVolumeParam` (page 882) for a description of the `XVolumeParam` data type.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
The relevant fields of the parameter block are:

`ioNamePtr`
On input, a pointer to a buffer. You should pass a pointer to a `Str31` value if you want the volume name returned; otherwise, pass `NULL`. If you specify a negative number in the `ioVolIndex` field, this

buffer should hold the name of the volume for which to return information. On output, a pointer to the volume's name.

`ioVRefNum`
On input, a volume reference number, drive number, or 0 for the default volume. If the value in the `ioVolIndex` field is negative, the File Manager uses the name in the `ioNamePtr` field, along with the value in the `ioVRefNum` field, to determine the volume. If the value in `ioVolIndex` is 0, the File Manager attempts to access the volume using only the value in this field. On output, the volume reference number.

`ioXVersion`
On input, the version of the extended volume parameter block. Currently, this value is 0.

`ioVolIndex`
On input, an index used for indexing through all the mounted volumes. If this value is positive, the File Manager uses it to find the volume for which to return information. For instance, if the value of `ioVolIndex` is 2, the File Manager attempts to access the second mounted volume in the VCB queue. If `ioVolIndex` is negative, the File Manager uses the values in the `ioNamePtr` and `ioVRefNum` fields to access the requested volume. If `ioVolIndex` is 0, the File Manager uses only the value in the `ioVRefNum` field.

`ioVCrDate`
On output, the date and time of the volume's creation (initialization).

`ioVLsMod`
On output, the date and time that the volume was last modified.

`ioVAtrb`
On output, the volume attributes. See "Volume Information Attribute Constants" (page 937) for a description of these attributes.

`ioVNmFls`
On output, the number of files in the root directory of the volume. For performance reasons, the Carbon File Manager does not return the number of files in this field; instead, it sets `ioVNmFls` to 0.To determine the number of files in the root directory of a volume in Carbon, call `PBGetCatInfoSync` (page 651) for the root directory. The number of files in the root directory is returned in the `ioDrNmFls` field.

`ioVBitMap`
On output, the first block of the volume bitmap.

`ioVAllocPtr`
On output, the block where the next new file allocation search should start.

`ioVNmAlBlks`
On output, the number of allocation blocks on the volume.

`ioVAlBlkSiz`
On output, the allocation block size for the volume.

`ioVClpSiz`
On output, the volume's default clump size.

`ioAlBlSt`
On output, the first block in the volume block map.

`ioVNxtCNID`
On output, the next unused catalog node ID.

`ioVFrBlk`
On output, the number of free (unused) allocation blocks on the volume.

`ioVSigWord`
: On output, the volume signature. For HFS volumes, this is 'BD' for HFS Plus volumes, this is 'H+'.

`ioVDrvInfo`
: On output, the drive number. You can determine whether the given volume is online by inspecting the value of this field. For online volumes, the `ioVDrvInfo` field contains the drive number of the drive containing the specified volume and hence is always greater than 0. If the value returned in `ioVDrvInfo` is 0, the volume is either offline or ejected.

`ioVDRefNum`
: On output, the driver reference number. You can determine whether the volume is offline or ejected by inspecting the value of this field. If the volume is offline, the value of `ioVDRefNum` is the negative of the drive number (which is cleared when the volume is placed offline; hence the `ioVDrvInfo` field for an offline volume is zero), and is a negative number. If the volume is ejected, the value of `ioVDRefNum` is the drive number itself, and thus is a positive number. For online volumes, `ioVDRefNum` contains a driver reference number; these numbers are always less than 0.

`ioVFSID`
: On output, the file system ID for the file system handling this volume.

`ioVBkUp`
: On output, the date and time that the volume was last backed up.

`ioVSeqNum`
: Used internally.

`ioVWrCnt`
: On output, the volume write count.

`ioVFilCnt`
: On output, the number of files on the volume.

`ioVDirCnt`
: On output, the number of directories on the volume.

`ioVFndrInfo`
: On output, Finder information for the volume.

`ioVTotalBytes`
: On output, the total number of bytes on the volume.

`ioVFreeBytes`
: On output, the number of free bytes on the volume.

The `PBXGetVolInfoSync` function is similar to the `PBHGetVInfoSync` (page 690) function except that it returns additional volume space information in 64-bit integers and does not modify the information copied from the volume's volume control block (VCB). Systems that support `PBXGetVolInfoSync` will have the `gestaltFSSupports2TBVols` bit set in the response returned by the `gestaltFSAttr Gestalt` selector. See *Inside Mac OS X: Gestalt Manager Reference* for a description of the `gestaltFSAttr` selector and of the bits that may be returned in the response.

Special Considerations

After an operation that changes the amount of free space on the volume—such as deleting a file—there may be a delay before a call to `PBXGetVolInfoSync` returns the updated amount. This is because the File Manager caches and periodically updates file system information, to reduce the number of calls made to retrieve the information from the file system. Currently, the File Manager updates its information every 15 seconds. This primarily affects NFS volumes. DOS, SMB, UFS and WebDAV volumes were also affected by this in previous versions of Mac OS X, but behave correctly in Mac OS X version 10.3 and later.

SetEOF

Sets the logical size of an open file. (Deprecated in Mac OS X v10.4. Use `FSSetForkSize` (page 542) instead.)

```
OSErr SetEOF (
   FSIORefNum refNum,
   SInt32 logEOF
);
```

Parameters

`refNum`

The file reference number of an open file.

`logEOF`

The new logical size (the logical end-of-file) of the given file. If you set the `logEOF` parameter to 0, all space occupied by the file on the volume is released. The file still exists, but it contains 0 bytes. Setting a file fork's end-of-file to 0 is therefore not the same as deleting the file, which removes both file forks at once.

Return Value
A result code. See "File Manager Result Codes" (page 943).

Discussion
If you attempt to set the logical end-of-file beyond the physical end-of-file, the physical end-of-file is set 1 byte beyond the end of the next free allocation block if there isn't enough space on the volume, no change is made, and `SetEOF` returns `dskFulErr` as its function result.

To ensure that your changes to the file are written to disk, call one of the functions, `FlushVol` (page 466) , `PBFlushVolSync` (page 641) , or `PBFlushVolAsync` (page 640). To set the size of a named fork other than the data and resource forks, or to grow the size of a file beyond 2GB, you must use the `FSSetForkSize` (page 542) function, or one of the corresponding parameter block calls, `PBSetForkSizeSync` (page 762) and `PBSetForkSizeAsync` (page 761).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Files.h`

SetFPos

Sets the position of the file mark. (Deprecated in Mac OS X v10.4. Use `FSSetForkPosition` (page 541) instead.)

```
OSErr SetFPos (
   FSIORefNum refNum,
   SInt16 posMode,
   SInt32 posOff
);
```

Parameters

refNum

The file reference number of an open file.

posMode

A constant specifying how to position the file mark; this parameter must contain one of the values described in "Position Mode Constants" (page 928).

posOff

The offset from the base location specified by the `posMode` parameter for the new file mark position. If you specify `fsFromLEOF` in the `posMode` parameter, the value in the `posOff` parameter must be less than or equal to 0. If you specify `fsAtMark`, the value in the `posOff` parameter is ignored.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

Because the read and write operations performed by the functions `FSRead` (page 536) and `FSWrite` (page 546) begin at the current mark, you may want to call `SetFPos` to reposition the file mark before reading from or writing to the file.

To set the file mark position for a named fork other than the data and resource forks, or to position the file mark at a point more than 2GB into the file, use the `FSSetForkPosition` (page 541) function, or one of the corresponding parameter block calls, `PBSetForkPositionSync` (page 760) and `PBSetForkPositionAsync` (page 759).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Files.h`

UnmountVol

Unmounts a volume that isn't currently being used. (Deprecated in Mac OS X v10.4. Use `FSUnmountVolumeSync` (page 545) instead.)

```
OSErr UnmountVol (
   ConstStr63Param volName,
   FSVolumeRefNum vRefNum
);
```

Parameters

volName

The name of a mounted volume. This parameter may be `NULL`.

vRefNum

The volume reference number, drive number, or 0 for the default volume.

Return Value

A result code. See "File Manager Result Codes" (page 943).

Discussion

All files on the volume (except those opened by the Operating System) must be closed before you call `UnmountVol`, which does not eject the volume.

Most applications do not need to use this function, because the user typically ejects (and possibly also unmounts) a volume in the Finder.

Special Considerations

Don't unmount the startup volume. Doing so will cause a system crash.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Callbacks by Task

File Operation Callbacks

`FSFileOperationStatusProcPtr` (page 790)

Defines a status callback function for an asynchronous file operation on an `FSRef` object.

`FSPathFileOperationStatusProcPtr` (page 791)

Defines a status callback function for an asynchronous file operation on an object specified with a pathname.

Miscellaneous Callbacks

`FNSubscriptionProcPtr` (page 789)

Callback delivered for directory notifications.

`FSVolumeEjectProcPtr` (page 792)

FSVolumeMountProcPtr (page 792)

FSVolumeUnmountProcPtr (page 793)

IOCompletionProcPtr (page 794)
Defines a pointer to a completion function. Your completion function is executed by the File Manager after the completion of an asynchronous File Manager function call.

Callbacks

FNSubscriptionProcPtr

Callback delivered for directory notifications.

```
typedef void (*FNSubscriptionProcPtr) (
    FNMessage message,
    OptionBits flags,
    void * refcon,
    FNSubscriptionRef subscription
);
```

If you name your function `MyFNSubscriptionProc`, you would declare it like this:

```
void MyFNSubscriptionProc (
    FNMessage message,
    OptionBits flags,
    void * refcon,
    FNSubscriptionRef subscription
);
```

Parameters

message
An indication of what happened.

flags
Options regarding the delivery of the notification; typically `kNilOptions`.

refcon
A pointer to a user reference supplied with subscription.

subscription
A subscription corresponding to this notification.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Files.h`

FSFileOperationStatusProcPtr

Defines a status callback function for an asynchronous file operation on an `FSRef` object.

```
typedef void (*FSFileOperationStatusProcPtr) (
    FSFileOperationRef fileOp,
    const FSRef *currentItem,
    FSFileOperationStage stage,
    OSStatus error,
    CFDictionaryRef statusDictionary,
    void *info
);
```

If you name your function `MyFSFileOperationStatusProc`, you would declare it like this:

```
void MyFSFileOperationStatusProc (
    FSFileOperationRef fileOp,
    const FSRef *currentItem,
    FSFileOperationStage stage,
    OSStatus error,
    CFDictionaryRef statusDictionary,
    void *info
);
```

Parameters

fileOp

The file operation.

currentItem

A pointer to an `FSRef` variable. On output, the variable contains the object currently being moved or copied. If the operation is complete, this parameter refers to the target (the new object corresponding to the source object in the destination directory).

stage

The current stage of the operation.

error

The current error status of the operation.

statusDictionary

A dictionary with more detailed status information. For information about the contents of the dictionary, see "File Operation Status Dictionary Keys" (page 919). You are not responsible for releasing the dictionary.

info

A pointer to user-defined data associated with this operation.

Discussion

When you call `FSCopyObjectAsync` (page 477), `FSMoveObjectAsync` (page 511), or `FSMoveObjectToTrashAsync` (page 513), you can specify a status callback function of this type. The function you provide is called by the File Manager whenever the file operation changes stages (including failing due to an error), or as updated information is available limited by the status change interval of the operation. If you need to save any of the status information beyond the scope of the callback, you should make a copy of the information.

Availability

Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSPathFileOperationStatusProcPtr

Defines a status callback function for an asynchronous file operation on an object specified with a pathname.

```
typedef void (*FSPathFileOperationStatusProcPtr) (
    FSFileOperationRef fileOp,
    const char *currentItem,
    FSFileOperationStage stage,
    OSStatus error,
    CFDictionaryRef statusDictionary,
    void *info
);
```

If you name your function `MyFSPathFileOperationStatusProc`, you would declare it like this:

```
void MyFSPathFileOperationStatusProc (
    FSFileOperationRef fileOp,
    const char *currentItem,
    FSFileOperationStage stage,
    OSStatus error,
    CFDictionaryRef statusDictionary,
    void *info
);
```

Parameters

fileOp
The file operation.

currentItem
The UTF-8 pathname of the object currently being moved or copied. If the operation is complete, this parameter refers to the target (the new object corresponding to the source object in the destination directory).

stage
The current stage of the operation.

error
The current error status of the operation.

statusDictionary
A dictionary with more detailed status information. For information about the contents of the dictionary, see "File Operation Status Dictionary Keys" (page 919). You are not responsible for releasing the dictionary.

info
A pointer to user-defined data associated with this operation.

Discussion

When you call `FSPathCopyObjectAsync` (page 517), `FSPathMoveObjectAsync` (page 521), or `FSPathMoveObjectToTrashAsync` (page 523), you can specify a status callback function of this type. The function you provide is called by the File Manager whenever the file operation changes stages (including failing due to an error), or as updated information is available limited by the status change interval of the operation. If you need to save any of the status information beyond the scope of the callback, you should make a copy of the information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSVolumeEjectProcPtr

```
typedef void (*FSVolumeEjectProcPtr) (
    FSVolumeOperation volumeOp,
    void * clientData,
    OSStatus err,
    FSVolumeRefNum volumeRefNum,
    pid_t dissenter
);
```

If you name your function `MyFSVolumeEjectProc`, you would declare it like this:

```
void MyFSVolumeEjectProc (
    FSVolumeOperation volumeOp,
    void * clientData,
    OSStatus err,
    FSVolumeRefNum volumeRefNum,
    pid_t dissenter
);
```

Parameters

volumeOp

clientData

err

volumeRefNum

dissenter

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeMountProcPtr

```
typedef void (*FSVolumeMountProcPtr) (
    FSVolumeOperation volumeOp,
    void * clientData,
    OSStatus err,
    FSVolumeRefNum mountedVolumeRefNum
);
```

If you name your function `MyFSVolumeMountProc`, you would declare it like this:

```
void MyFSVolumeMountProc (
    FSVolumeOperation volumeOp,
```

```
    void * clientData,
    OSStatus err,
    FSVolumeRefNum mountedVolumeRefNum
);
```

Parameters

volumeOp

clientData

err

mountedVolumeRefNum

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeUnmountProcPtr

```
typedef void (*FSVolumeUnmountProcPtr) (
    FSVolumeOperation volumeOp,
    void * clientData,
    OSStatus err,
    FSVolumeRefNum volumeRefNum,
    pid_t dissenter
);
```

If you name your function `MyFSVolumeUnmountProc`, you would declare it like this:

```
void MyFSVolumeUnmountProc (
    FSVolumeOperation volumeOp,
    void * clientData,
    OSStatus err,
    FSVolumeRefNum volumeRefNum,
    pid_t dissenter
);
```

Parameters

volumeOp

clientData

err

volumeRefNum

dissenter

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

IOCompletionProcPtr

Defines a pointer to a completion function. Your completion function is executed by the File Manager after the completion of an asynchronous File Manager function call.

```
typedef void (*IOCompletionProcPtr) (
    ParmBlkPtr paramBlock
);
```

If you name your function `MyIOCompletionProc`, you would declare it like this:

```
void MyIOCompletionProc (
    ParmBlkPtr paramBlock
);
```

Parameters

paramBlock

A pointer to the parameter block that was passed to the asynchronous File Manager function.

Return Value

Discussion

When you execute an asynchronous File Manager function (an `Async` function), you can specify a completion routine by passing the routine's address in the `ioCompletion` field of the parameter block passed to the function. Because you requested asynchronous execution, the File Manager places an I/O request in the file I/O queue and returns control to your application—possibly even before the actual I/O operation is completed. The File Manager takes requests from the queue one at a time and processes them meanwhile, your application is free to do other processing.

A function executed asynchronously returns control to your application with the result code `noErr` as soon as the call is placed in the file I/O queue. This result code does not indicate that the call has successfully completed, but simply indicates that the call was successfully placed in the queue. To determine when the call is actually completed, you can inspect the `ioResult` field of the parameter block. This field is set to a positive number when the call is made and set to the actual result code when the call is completed. If you specify a completion routine, it is executed after the result code is placed in `ioResult`.

The File Manager, when the File Sharing or AppleShare file server is active, will execute requests in arbitrary order. That means that if there is a request that depends on the completion of a previous request, it is an error for your program to issue the second request until the completion of the first request. For example, issuing a write request and then issuing a read request for the same data isn't guaranteed to read back what was written unless the read request isn't made until after the write request completes.

Request order can also change if a call results in a disk switch dialog to bring an offline volume back online.

Special Considerations

Because a completion routine is executed at interrupt time, it should not allocate, move, or purge memory (either directly or indirectly) and should not depend on the validity of handles to unlocked blocks.

If your completion routine uses application global variables, it must also ensure that register A5 contains the address of the boundary between your application global variables and your application parameters.

Availability

Available in Mac OS X v10.0 and later.

`Files.h`

Data Types

AccessParam

Defines a parameter block used by low-level HFS file and directory access rights manipulation functions.

```
struct AccessParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short filler3;
    short ioDenyModes;
    short filler4;
    SInt8 filler5;
    SInt8 ioACUser;
    long filler6;
    long ioACOwnerID;
    long ioACGroupID;
    long ioACAccess;
    long ioDirID;
};
typedef struct AccessParam AccessParam;
typedef AccessParam * AccessParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`filler3`
: Reserved.

`ioDenyModes`
: Access mode information.

`filler4`
: Reserved.

`filler5`
: Reserved.

`ioACUser`
: The user's access rights for the specified directory.

`filler6`
: Reserved.

`ioACOwnerID`
: The owner ID.

`ioACGroupID`
: The group ID.

`ioACAccess`
: The directory access privileges.

`ioDirID`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

AFPAlternateAddress

Defines a block of tagged addresses for AppleShare clients.

```
struct AFPAlternateAddress {
    UInt8 fVersion;
    UInt8 fAddressCount;
    UInt8 fAddressList[1];
};
typedef struct AFPAlternateAddress AFPAlternateAddress;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

AFPTagData

Defines a structure which contains tagged address information for AppleShare clients.

```
struct AFPTagData {
    UInt8 fLength;
    UInt8 fType;
    UInt8 fData[1];
};
typedef struct AFPTagData AFPTagData;
```

Fields

`fLength`

The length, in bytes, of this data tag, including the `fLength` field itself. See "AFP Tag Length Constants" (page 885).

`fType`

The type of the data tag. See "AFP Tag Type Constants" (page 886) for the constants which you can use here.

`fData`

Variable length data, containing the address.

Discussion

The new tagged data format for addressing allows for changes in addressing formats, allowing AppleShare clients to support new addressing standards without changing the interface. The `AFPAlternateAddress` (page 796) data structure uses the `AFPTagData` structure to specify a tagged address.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

AFPVolMountInfo

Defines a volume mounting structure for an AppleShare server.

```
struct AFPVolMountInfo {
    short length;
    VolumeType media;
    short flags;
    SInt8 nbpInterval;
    SInt8 nbpCount;
    short uamType;
    short zoneNameOffset;
    short serverNameOffset;
    short volNameOffset;
    short userNameOffset;
    short userPasswordOffset;
    short volPasswordOffset;
    char AFPData[144];
};
typedef struct AFPVolMountInfo AFPVolMountInfo;
typedef AFPVolMountInfo * AFPVolMountInfoPtr;
```

Fields

`length`
: The length of the `AFPVolMountInfo` structure (that is, the total length of the structure header described here plus the variable-length location data).

`media`
: The volume type of the remote volume. The value `AppleShareMediaType` (a constant that translates to `'afpm'`) represents an AppleShare volume.

`flags`
: If bit 0 is set, no greeting message from the server is displayed.

`nbpInterval`
: The NBP retransmit interval, in units of 8 ticks.

`nbpCount`
: The NBP retransmit count. This field specifies the total number of times a packet should be transmitted, including the first transmission.

`uamType`
: The user authentication method used by the remote volume. AppleShare uses four methods, defined by the constants described in "Authentication Method Constants" (page 888).

`zoneNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the AppleShare zone.

`serverNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the AppleShare server.

`volNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the volume.

`userNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the user.

`userPasswordOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the user's password (as a pascal string).

`volPasswordOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the volume's password (as a pascal string). Some versions of the AppleShare software do not pass the information in this field to the server.

`AFPData`
: The actual volume mounting information, offsets to which are contained in the preceding six fields. To mount an AFP volume, you must fill in the structure with at least the zone name, server name, user name, user password, and volume password. You can lay out the data in any order within this data field, as long as you specify the correct offsets in the offset fields.

Discussion
The only volumes that currently support the programmatic mounting functions are AppleShare servers, which use a volume mounting structure of type `AFPVolMountInfo`.

To mount an AppleShare server, fill out an `AFPVolMountInfo` structure using the `PBGetVolMountInfo` function and then pass this structure to the `PBVolumeMount` function to mount the volume.

Version Notes
AppleShare clients prior to version 3.7 mount volumes over AppleTalk only. For maximum compatibility set the `uamType` field to 1 for guest login or 3 for login using a password.

To mount volumes using IP addresses and other address formats, use the `AFPXVolMountInfo` (page 799) structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

AFPXVolMountInfo

Defines a volume mounting structure for an AppleShare server, for AppleShare 3.7 and later.

```
struct AFPXVolMountInfo {
    short length;
    VolumeType media;
    short flags;
    SInt8 nbpInterval;
    SInt8 nbpCount;
    short uamType;
    short zoneNameOffset;
    short serverNameOffset;
    short volNameOffset;
    short userNameOffset;
    short userPasswordOffset;
    short volPasswordOffset;
    short extendedFlags;
    short uamNameOffset;
    short alternateAddressOffset;
    char AFPData[176];
};
typedef struct AFPXVolMountInfo AFPXVolMountInfo;
typedef AFPXVolMountInfo * AFPXVolMountInfoPtr;
```

Fields

`length`
: The length of the `AFPXVolMountInfo` structure (that is, the total length of the structure header described here plus the variable-length location data).

`media`
: The volume type of the remote volume. The value `AppleShareMediaType` (a constant that translates to `'afpm'`) represents an AppleShare volume.

`flags`
: Volume mount flags. See "Volume Mount Flags" (page 942) for a description of the bits in this field. In order to use the new features of the extended AFP volume mount structure, you must set the `volMountExtendedFlagsBit` bit.

`nbpInterval`
: The NBP retransmit interval, in units of 8 ticks.

`nbpCount`
: The NBP retransmit count. This field specifies the total number of times a packet should be transmitted, including the first transmission.

`uamType`
: The user authentication method used by the remote volume. AppleShare uses four methods, defined by the constants described in "Authentication Method Constants" (page 888).

`zoneNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the AppleShare zone.

`serverNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the AppleShare server.

`volNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the volume.

`userNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the name (as a pascal string) of the user.

`userPasswordOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the user's password (as a pascal string).

`volPasswordOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the volume's password (as a pascal string). Some versions of the AppleShare software do not pass the information in this field to the server.

`extendedFlags`
: Extended flags. See "Extended AFP Volume Mounting Information Flag" (page 903).

`uamNameOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing the user authentication module name (as a pascal string).

`alternateAddressOffset`
: The offset in bytes from the beginning of the structure to the entry in the `AFPData` field containing IP addresses, specified as a block of tagged data. This block of tagged data begins with a version byte and a count byte, followed by up to 255 tagged addresses. See `AFPAlternateAddress` (page 796).

`AFPData`
: The actual volume mounting information, offsets to which are contained in the preceding fields. To mount an AFP volume, you must fill in the structure with at least the zone name, server name, user name, user password, and volume password. You can lay out the data in any order within this data field, as long as you specify the correct offsets in the offset fields.

Discussion
To mount an AppleShare server, fill out an `AFPXVolMountInfo` structure using the `PBGetVolMountInfo` function and then pass this structure to the `PBVolumeMount` function to mount the volume.

The extended AFP volume mount information structure requires AppleShare client 3.7 and later. The new fields and flag bits allow you to specify the information needed to support TCP/IP and User Authentication Modules.

Note that, for all fields specifying an offset, if you wish to leave the string field in the `AFPData` field empty, you must specify an empty string and have the offset in the corresponding offset field point to that empty string. You cannot simply pass 0 as the offset.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

CatPositionRec

Defines a catalog position structure, which maintains the current position of a catalog search between calls to `PBCatSearchSync` or `PBCatSearchAsync`.

```
struct CatPositionRec {
    long initialize;
    short priv[6];
};
typedef struct CatPositionRec CatPositionRec;
```

Fields

`initialize`

The starting point of the catalog search. To start searching at the beginning of a catalog, specify 0 in this field. To resume a previous search, pass the value returned by the previous call to `PBCatSearchSync` or `PBCatSearchAsync`.

`priv`

An array of integers that is used internally by `PBCatSearchSync` and `PBCatSearchAsync`.

Discussion

When you call the `PBCatSearchSync` or `PBCatSearchAsync` function to search a volume's catalog file, you can specify, in the `ioCatPosition` field of the parameter block passed to `PBCatSearchSync` and `PBCatSearchAsync`, a catalog position structure. If a catalog search consumes more time than is allowed by the `ioSearchTime` field, `PBCatSearchSync` and `PBCatSearchAsync` store a directory-location index in that structure; when you call `PBCatSearchSync` or `PBCatSearchAsync` again, it uses that structure to resume searching where it left off.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

CInfoPBRec

Defines a catalog information parameter block for file and directory information.

```
union CInfoPBRec {
    HFileInfo hFileInfo;
    DirInfo dirInfo;
};
typedef union CInfoPBRec CInfoPBRec;
typedef CInfoPBRec * CInfoPBPtr;
```

Fields

`hFileInfo`

`dirInfo`

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Files.h`

CMovePBRec

Defines a parameter block, used with the functions `PBCatMoveSync` and `PBCatMoveAsync`.

```
struct CMovePBRec {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long filler1;
    StringPtr ioNewName;
    long filler2;
    long ioNewDirID;
    long filler3[2];
    long ioDirID;
};
typedef struct CMovePBRec CMovePBRec;
typedef CMovePBRec * CMovePBPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type (This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`filler1`
Reserved.

`ioNewName`
The name of the directory into which the specified file or directory is to be moved.

`filler2`
Reserved.

`ioNewDirID`
: The directory ID of the directory into which the specified file or directory is to be moved.

`filler3`
: Reserved.

`ioDirID`
: The current directory ID of the file or directory to be moved (used in conjunction with the `ioVRefNum` and `ioNamePtr` fields).

Discussion
The low-level HFS function `PBCatMove` uses the catalog move parameter block defined by the `CMovePBRec` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

CntrlParam

Defines a parameter block used by control and status functions in the classic Device Manager.

```
struct CntrlParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioCRefNum;
    short csCode;
    short csParam[11];
};
typedef struct CntrlParam CntrlParam;
typedef CntrlParam * CntrlParamPtr;
```

Fields
`qLink`
: A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
: The queue type. This field is used internally by the File Manager.

`ioTrap`
: The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
: The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioCRefNum`
: The driver reference number for the I/O operation.

`csCode`
: A value identifying the type of control or status request. Each driver may interpret this number differently.

`csParam`
: The control or status information passed to or from the driver. This field is declared generically as an array of eleven integers. Each driver may interpret the contents of this field differently. Refer to the driver's documentation for specific information.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

ConstFSSpecPtr

Defines a pointer to an `FSSpec` structure.

```
typedef const FSSpec*  ConstFSSpecPtr;
```

Discussion
The only difference between "`const FSSpec*`" and the `ConstFSSpecPtr` data type is that, as a parameter, a `ConstFSSpecPtr` data type is allowed to be `NULL`. See `FSSpec` (page 840).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

ConstHFSUniStr255Param

Defines a pointer to an `HFSUniStr255` structure.

```
typedef const HFSUniStr255*  ConstHFSUniStr255Param;
```

Discussion
See `HFSUniStr255` (page 855).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

CopyParam

Defines a parameter block used by low-level HFS file copying functions.

```
struct CopyParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioDstVRefNum;
    short filler8;
    StringPtr ioNewName;
    StringPtr ioCopyName;
    long ioNewDirID;
    long filler14;
    long filler15;
    long ioDirID;
};
typedef struct CopyParam CopyParam;
typedef CopyParam * CopyParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioDstVRefNum`
: A volume reference number for the destination volume.

`filler8`
: Reserved.

`ioNewName`
: A pointer to the destination pathname.

`ioCopyName`
: A pointer to an optional name.

`ioNewDirID`
: A destination directory ID.

`filler14`
: Reserved.

`filler15`
: Reserved.

`ioDirID`
: A directory ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

CSParam

Defines a parameter block used by low-level HFS catalog search functions.

```
struct CSParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    FSSpecPtr ioMatchPtr;
    long ioReqMatchCount;
    long ioActMatchCount;
    long ioSearchBits;
    CInfoPBPtr ioSearchInfo1;
    CInfoPBPtr ioSearchInfo2;
    long ioSearchTime;
    CatPositionRec ioCatPosition;
    Ptr ioOptBuffer;
    long ioOptBufSize;
};
typedef struct CSParam CSParam;
typedef CSParam * CSParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioMatchPtr`

A pointer to an array of `FSSpec` (page 840) structures in which the file and directory names that match the selection criteria are returned. The array must be large enough to hold the largest possible number of `FSSpec` structures, as determined by the `ioReqMatchCount` field.

`ioReqMatchCount`

The maximum number of matches to return. This number should be the number of `FSSpec` structures that will fit in the memory pointed to by the `ioMatchPtr` field. You can use this field to avoid a possible excess of matches for criteria that prove to be too general (or to limit the length of a search if the `ioSearchTime` field isn't used).

`ioActMatchCount`

The number of actual matches found.

`ioSearchBits`

The fields of the parameter blocks in the `ioSearchInfo1` and `ioSearchInfo2` fields that are relevant to the search. See "Catalog Search Bits" (page 896) for more information.

`ioSearchInfo1`

A pointer to a `CInfoPBRec` parameter block that contains the search information. For values that match by mask and value (Finder information, for example), set the bits in the structure passed in the `ioSearchInfo2` field, and set the matching values in this structure. For values that match against a range (such as dates), set the lower bounds for the range in this structure.

`ioSearchInfo2`

A pointer to a second `CInfoPBRec` parameter block that contains the search information. For values that match by mask and value (Finder information, for example), set the bits in this structure, and set the matching values in the structure passed in the `ioSearchInfo1` field. For values that match against a range (such as dates), set the upper bounds for the range in this structure.

`ioSearchTime`

A time limit on a search, in Time Manager format. Use this field to limit the run time of a single call to `PBCatSearchSync` or `PBCatSearchAsync`. A value of 0 imposes no time limit. If the value of this field is positive, it is interpreted as milliseconds. If the value of this field is negative, it is interpreted as negated microseconds.

`ioCatPosition`

A position in the catalog where searching should begin. Use this field to keep an index into the catalog when breaking down the `PBCatSearchSync` or `PBCatSearchAsync` search into a number of smaller searches. This field is valid whenever `PBCatSearchSync` or `PBCatSearchAsync` exits because it either spends the maximum time allowed by `ioSearchTime` or finds the maximum number of matches allowed by `ioReqMatchCount`.

To start at the beginning of the catalog, set the `initialize` field of `ioCatPosition` to 0. Before exiting after an interrupted search, `PBCatSearchSync` or `PBCatSearchAsync` sets that field to the next catalog entry to be searched.

To resume where the previous call stopped, pass the entire `CatPositionRec` (page 801) structure returned by the previous call as input to the next.

`ioOptBuffer`

A pointer to an optional read buffer. The `ioOptBuffer` and `ioOptBufSize` fields let you specify a part of memory as a read buffer, increasing search speed.

`ioOptBufSize`

The size of the buffer pointed to by `ioOptBuffer`. Buffer size effectiveness varies with models and configurations, but a 16 KB buffer is likely to be optimal. The size should be at least 1024 bytes and should be an integral multiple of 512 bytes.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

DirInfo

Defines a structure which holds catalog information about a directory.

```
struct DirInfo {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioFRefNum;
    SInt8 ioFVersNum;
    SInt8 filler1;
    short ioFDirIndex;
    SInt8 ioFlAttrib;
    SInt8 ioACUser;
    DInfo ioDrUsrWds;
    long ioDrDirID;
    unsigned short ioDrNmFls;
    short filler3[9];
    unsigned long ioDrCrDat;
    unsigned long ioDrMdDat;
    unsigned long ioDrBkDat;
    DXInfo ioDrFndrInfo;
    long ioDrParID;
};
typedef struct DirInfo DirInfo;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioFRefNum`
: The file reference number of an open file.

`ioFVersNum`
: A file version number. This field is no longer used. File version numbers are an artifact of the obsolete MFS, and are not supported on HFS volumes. You should always set this field to 0.

`filler1`
: Reserved.

`ioFDirIndex`
: A file and directory index. If this field contains a positive number, `PBGetCatInfoSync` and `PBGetCatInfoAsync` return information about the file or directory having that directory index in the directory specified by the `ioVRefNum` field. (If `ioVRefNum` contains a volume reference number, the specified directory is that volume's root directory.)

  If this field contains 0, `PBGetCatInfoSync` and `PBGetCatInfoAsync` return information about the file or directory whose name is specified in the `ioNamePtr` field and that is located in the directory specified by the `ioVRefNum` field. (Once again, if `ioVRefNum` contains a volume reference number, the specified directory is that volume's root directory.)

  If this field contains a negative number, `PBGetCatInfoSync` and `PBGetCatInfoAsync` ignore the `ioNamePtr` field and returns information about the directory specified in the `ioDirID` field. If both `ioDirID` and `ioVRefNum` are set to 0, `PBGetCatInfoSync` and `PBGetCatInfoAsync` return information about the current default directory.

`ioFlAttrib`
: File or directory attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field.

`ioACUser`
: The user's access rights for the specified directory. See "User Privileges Constants" (page 930) for the meaning of the bits in this field.

`ioDrUsrWds`
: Information used by the Finder.

`ioDrDirID`
: A directory ID. On input to `PBGetCatInfoSync` and `PBGetCatInfoAsync` , this field contains a directory ID, which is used only if the value of the `ioFDirIndex` field is negative. On output, this field contains the directory ID of the specified directory.

`ioDrNmFls`
: The number of files in the directory.

`filler3`
: Reserved.

`ioDrCrDat`

The date and time of the directory's creation, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the creation date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970, and that is the value which will be returned if you later try to retrieve the creation date.

Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates.

`ioDrMdDat`

The date and time of the last modification to the directory, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the modification date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970.

`ioDrBkDat`

The date and time that the directory was last backed up, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the backup date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970.

Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates.

`ioDrFndrInfo`

Additional information used by the Finder.

`ioDrParID`

The directory ID of the specified directory's parent directory.

`refCon`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

DrvQEl

Defines a drive queue element.

```
struct DrvQEl {
    QElemPtr qLink;
    short qType;
    short dQDrive;
    short dQRefNum;
    short dQFSID;
    unsigned short dQDrvSz;
    unsigned short dQDrvSz2;
};
typedef struct DrvQEl DrvQEl;
typedef DrvQEl * DrvQElPtr;
```

Fields
`qLink`

A pointer to the next entry in the drive queue.

`qType`
: Used to specify the size of the drive. If the value of this field is 0, the number of logical blocks on the drive is contained in the `dQDrvSz` field alone. If the value of this field is 1, both the `dQDrvSz` field and the `dQDrvSz2` field are used to store the number of blocks; in that case, the `dQDrvSz2` field contains the high-order word of this number and `dQDrvSz` contains the low-order word.

`dQDrive`
: The drive number of the drive.

`dQRefNum`
: The driver reference number of the driver controlling the device on which the volume is mounted.

`dQFSID`
: An identifier for the file system handling the volume in the drive it's zero for volumes handled by the File Manager and nonzero for volumes handled by other file systems.

`dQDrvSz`
: The number of logical blocks on the drive.

`dQDrvSz2`
: An additional field to handle large drives. This field is only used if the `qType` field is 1.

Discussion
The File Manager maintains a list of all disk drives connected to the computer. It maintains this list in the drive queue, which is a standard operating system queue. The drive queue is initially created at system startup time. Elements are added to the queue at system startup time or when you call the `AddDrive` function. The drive queue can support any number of drives, limited only by memory space. Each element in the drive queue contains information about the corresponding drive.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

DTPBRec

Defines the desktop database parameter block used by the desktop database functions.

```
struct DTPBRec {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioDTRefNum;
    short ioIndex;
    long ioTagInfo;
    Ptr ioDTBuffer;
    long ioDTReqCount;
    long ioDTActCount;
    SInt8 ioFiller1;
    UInt8 ioIconType;
    short ioFiller2;
    long ioDirID;
    OSType ioFileCreator;
    OSType ioFileType;
    long ioFiller3;
    long ioDTLgLen;
    long ioDTPyLen;
    short ioFiller4[14];
    long ioAPPLParID;
};
typedef struct DTPBRec DTPBRec;
typedef DTPBRec * DTPBPtr;
```

Fields

`qLink`

A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`

The queue type. This field is used internally by the File Manager.

`ioTrap`

The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`

The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`

A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`

The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a file, directory, or volume name. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: The volume reference number.

`ioDTRefNum`
: The desktop database reference number.

`ioIndex`
: The index into icon list.

`ioTagInfo`
: The tag information.

`ioDTBuffer`
: The data buffer.

`ioDTReqCount`
: The requested length of data.

`ioDTActCount`
: The actual length of data.

`ioFiller1`
: Unused.

`ioIconType`
: The icon type.

`ioFiller2`
: Unused.

`ioDirID`
: The parent directory ID.

`ioFileCreator`
: The file creator.

`ioFileType`
: The file type.

`ioFiller3`
: Unused.

`ioDTLgLen`
: The logical length of the desktop database.

`ioDTPyLen`
: The physical length of the desktop database.

`ioFiller4`
: Unused.

`ioAPPLParID`
: The parent directory ID of an application.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Files.h`

FCBPBRec

Defines a file control block (FCB) parameter block used by the functions `PBGetFCBInfoSync` and `PBGetFCBInfoAsync`.

```
struct FCBPBRec {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioRefNum;
    short filler;
    short ioFCBIndx;
    short filler1;
    long ioFCBFlNm;
    short ioFCBFlags;
    unsigned short ioFCBStBlk;
    long ioFCBEOF;
    long ioFCBPLen;
    long ioFCBCrPs;
    short ioFCBVRefNum;
    long ioFCBClpSiz;
    long ioFCBParID;
};
typedef struct FCBPBRec FCBPBRec;
typedef FCBPBRec * FCBPBPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioRefNum`
: The file reference number of an open file.

`filler`
: Reserved.

`ioFCBIndx`
: An index for use with the `PBGetFCBInfoSync` and `PBGetFCBInfoAsync` functions.

`filler1`
: Reserved.

`ioFCBFlNm`
: The file ID.

`ioFCBFlags`
: Flags describing the status of the file. See "FCB Flags" (page 906) for the meanings of the bits in this field.

`ioFCBStBlk`
: The number of the first allocation block of the file.

`ioFCBEOF`
: The logical length (logical end-of-file) of the file.

`ioFCBPLen`
: The physical length (physical end-of-file) of the file.

`ioFCBCrPs`
: The current position of the file mark.

`ioFCBVRefNum`
: The volume reference number.

`ioFCBClpSiz`
: The file clump size.

`ioFCBParID`
: The file's parent directory ID.

Discussion
The low-level HFS function `PBGetFCBInfo` uses the file control block parameter block defined by the `FCBPBRec` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

FIDParam

Defines a parameter block used by low-level HFS file ID functions.

```
struct FIDParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long filler14;
    StringPtr ioDestNamePtr;
    long filler15;
    long ioDestDirID;
    long filler16;
    long filler17;
    long ioSrcDirID;
    short filler18;
    long ioFileID;
};
typedef struct FIDParam FIDParam;
typedef FIDParam * FIDParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`filler14`
: Reserved.

`ioDestNamePtr`
: A pointer to the name of the destination file.

`filler15`
: Reserved.

`ioDestDirID`
: The parent directory ID of the destination file.

`filler16`
: Reserved.

`filler17`
: Reserved.

`ioSrcDirID`
: The parent directory ID of the source file.

`filler18`
: Reserved.

`ioFileID`
: The file ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

FileParam

Defines a parameter block used by low-level functions for getting and setting file information.

```
struct FileParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioFRefNum;
    SInt8 ioFVersNum;
    SInt8 filler1;
    short ioFDirIndex;
    SInt8 ioFlAttrib;
    SInt8 ioFlVersNum;
    FInfo ioFlFndrInfo;
    unsigned long ioFlNum;
    unsigned short ioFlStBlk;
    long ioFlLgLen;
    long ioFlPyLen;
    unsigned short ioFlRStBlk;
    long ioFlRLgLen;
    long ioFlRPyLen;
    unsigned long ioFlCrDat;
    unsigned long ioFlMdDat;
};
typedef struct FileParam FileParam;
typedef FileParam * FileParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioFRefNum`
The file reference number of an open file.

`ioFVersNum`
A file version number. This field is no longer used. File version numbers are an artifact of the obsolete MFS, and are not supported on HFS volumes. You should always set this field to 0.

`filler1`
Reserved.

`ioFDirIndex`
A directory index for use with the `PBHGetFInfoSync` (page 683) and `PBHGetFInfoAsync` (page 682) functions.

`ioFlAttrib`
File attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field.

`ioFlVersNum`
A file version number. This feature is no longer supported, and you must always set this field to 0.

`ioFlFndrInfo`
Information used by the Finder.

`ioFlNum`
A file ID.

`ioFlStBlk`
The first allocation block of the data fork. This field contains 0 if the file's data fork is empty.

`ioFlLgLen`
The logical length (logical end-of-file) of the data fork.

`ioFlPyLen`
The physical length (physical end-of-file) of the data fork.

`ioFlRStBlk`
The first allocation block of the resource fork. This field contains 0 if the file's resource fork is empty.

`ioFlRLgLen`
The logical length (logical end-of-file) of the resource fork.

`ioFlRPyLen`
The physical length (physical end-of-file) of the resource fork.

`ioFlCrDat`
The date and time of the file's creation, specified in seconds since midnight, January 1, 1904.

`ioFlMdDat`
The date and time of the last modification to the file, specified in seconds since midnight, January 1, 1904.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

FNSubscriptionRef

```
typedef struct OpaqueFNSubscriptionRef * FNSubscriptionRef;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

FNSubscriptionUPP

```
typedef FNSubscriptionProcPtr FNSubscriptionUPP;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Files.h`

ForeignPrivParam

Defines a parameter block used by low-level HFS foreign privileges functions.

```
struct ForeignPrivParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long ioFiller21;
    long ioFiller22;
    Ptr ioForeignPrivBuffer;
    long ioForeignPrivActCount;
    long ioForeignPrivReqCount;
    long ioFiller23;
    long ioForeignPrivDirID;
    long ioForeignPrivInfo1;
    long ioForeignPrivInfo2;
    long ioForeignPrivInfo3;
    long ioForeignPrivInfo4;
};
typedef struct ForeignPrivParam ForeignPrivParam;
typedef ForeignPrivParam * ForeignPrivParamPtr;
```

Fields
`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioFiller21`
Reserved.

`ioFiller22`
Reserved.

`ioForeignPrivBuffer`
A pointer to a buffer containing access-control information about the foreign file system.

`ioForeignPrivActCount`
The size of the buffer pointed to by the `ioForeignPrivBuffer` field.

`ioForeignPrivReqCount`
The amount of the buffer pointed to by the `ioForeignPrivBuffer` field that was actually used to hold data.

`ioFiller23`
Reserved.

`ioForeignPrivDirID`
The parent directory ID of the foreign file or directory.

`ioForeignPrivInfo1`
A long word that may contain privileges data.

`ioForeignPrivInfo2`
A long word that may contain privileges data.

`ioForeignPrivInfo3`
A long word that may contain privileges data.

`ioForeignPrivInfo4`
A long word that may contain privileges data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

FSCatalogBulkParam

Defines a parameter block used to retrieve catalog information in bulk on HFS Plus volumes.

```
struct FSCatalogBulkParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    Boolean containerChanged;
    UInt8 reserved;
    FSIteratorFlags iteratorFlags;
    FSIterator iterator;
    const FSRef * container;
    ItemCount maximumItems;
    ItemCount actualItems;
    FSCatalogInfoBitmap whichInfo;
    FSCatalogInfo * catalogInfo;
    FSRef * refs;
    FSSpec * specs;
    HFSUniStr255 * names;
    const FSSearchParams * searchParams;
};
typedef struct FSCatalogBulkParam FSCatalogBulkParam;
typedef FSCatalogBulkParam * FSCatalogBulkParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`containerChanged`
: A Boolean value indicating whether or not the container has changed since the last call to `PBGetCatalogInfoBulkSync` or `PBGetCatalogInfoBulkAsync`.

`reserved`
: Reserved.

`iteratorFlags`
: A set of flags which specifies how the iterator should iterate over the container. See "Iterator Flags" (page 924) for the meaning of the constants used here.

`iterator`
: A catalog iterator.

`container`
: An `FSRef` for the directory or volume to iterate over.

`maximumItems`
: The maximum number of items to return information about.

`actualItems`
: The actual number of items returned.

`whichInfo`
: A bitmap indicating which fields of the catalog information structure to return. See "Catalog Information Bitmap Constants" (page 891) for the bits defined for this field.

`catalogInfo`
: A pointer to an array of catalog information structures. On input, you should pass a pointer to an array of `maximumItemsFSCatalogInfo` (page 826) structures. On return, `actualItems` structures will be filled out with the information requested in the `whichInfo` field. If you do not wish any catalog information to be returned, pass a `NULL` pointer in this field and pass the constant `kFSCatInfoNone` in the `whichInfo` field.

`refs`
: A pointer to an array of `FSRef` structures. On input, you should pass a pointer to `maximumItemsFSRef` structures. On return, `actualItems` structures will be filled out. If you do not wish any `FSRef` structures to be returned, pass a `NULL` pointer in this field.

`specs`
: A pointer to an array of `FSSpec` structures. On input, you should pass a pointer to `maximumItems` file system specifications. On return, `actualItemsFSSpec` structures will be filled in. If you do not wish any `FSSpec` information to be returned, pass a `NULL` pointer in this field.

`names`
: A pointer to an array of Unicode names. On input, you should pass a pointer to an array of `maximumItemsHFSUniStr255` structures. On return, `actualItems` structures will contain Unicode names. If you do not wish any file or directory names to be returned, pass a `NULL` pointer in this field.

`searchParams`
: A pointer to an `FSSearchParams` (page 839) structure, specifying the values to match against.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCatalogInfo

Holds basic information about a file or directory.

```
struct FSCatalogInfo {
    UInt16 nodeFlags;
    FSVolumeRefNum volume;
    UInt32 parentDirID;
    UInt32 nodeID;
    UInt8 sharingFlags;
    UInt8 userPrivileges;
    UInt8 reserved1;
    UInt8 reserved2;
    UTCDateTime createDate;
    UTCDateTime contentModDate;
    UTCDateTime attributeModDate;
    UTCDateTime accessDate;
    UTCDateTime backupDate;
    UInt32 permissions[4];
    UInt8 finderInfo[16];
    UInt8 extFinderInfo[16];
    UInt64 dataLogicalSize;
    UInt64 dataPhysicalSize;
    UInt64 rsrcLogicalSize;
    UInt64 rsrcPhysicalSize;
    UInt32 valence;
    TextEncoding textEncodingHint;
};
typedef struct FSCatalogInfo FSCatalogInfo;
typedef FSCatalogInfo * FSCatalogInfoPtr;
```

Fields

`nodeFlags`
Node flags. This field has two defined bits that indicate whether an object is a file or folder, and whether a file is locked (constants `kFSNodeIsDirectoryMask` and `kFSNodeLockedMask`). See "Catalog Information Node Flags" (page 894) for the values you can use here.

`volume`
The object's volume reference.

`parentDirID`
The ID of the directory that contains the given object. The root directory of a volume always has ID `fsRtDirID` (2); the parent of the root directory is ID `fsRtParID` (1). Note that there is no object with ID `fsRtParID`; this is merely used when the File Manager is asked for the parent of the root directory.

`nodeID`
The file or directory ID.

`sharingFlags`
The object's sharing flags. See "Catalog Information Sharing Flags " (page 896) for the meaning of the bits defined for this field.

`userPrivileges`
The user's effective AFP privileges (same as `ioACUser` in the old `HFileInfo` and `DirInfo` structures). See "User Privileges Constants" (page 930).

`reserved1`
Reserved.

`reserved2`
Reserved.

`createDate`
The date and time of the creation of the object. Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates. For file systems which do not support creation dates, `FSGetCatalogInfo`, `PBGetCatalogInfoSync`, and `PBGetCatalogInfoAsync` return 0 in this field.

`contentModDate`
The date and time that the data or resource fork was last modified.

`attributeModDate`
The date and time that an attribute of the object (such as a fork other than the data or resource fork) was last modified.

`accessDate`
The date and time that the object was last accessed. The Mac OS 9 File Manager does not automatically update the `accessDate` field; it exists primarily for use by other operating systems (notably Mac OS X).

`backupDate`
The date and time of the object's last backup. This field is not updated by the File Manager a backup utility may use this field if it wishes. Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates. For file systems which do not support backup dates, `FSGetCatalogInfo`, `PBGetCatalogInfoSync`, and `PBGetCatalogInfoAsync` return 0 in this field.

`permissions`
User and group permission information. The Mac OS 8 and 9 File Manager does not use or enforce this permission information. It could be used by a file server program or other operating system (primarily Mac OS X). In Mac OS X, this array contains the file system permissions of the returned item. To use this information, coerce the parameter to a `FSPermissionInfo` (page 836) structure.

`finderInfo`
Basic Finder information for the object. This information is available in the catalog information, instead of in a named fork, for historical reasons. The File Manager does not interpret the contents of these fields. To use this information, coerce the parameter to a `FileInfo` (page 2258) or `FolderInfo` (page 2255) structure.

`extFinderInfo`
Extended Finder information for the object. This information is available in the catalog information, instead of in a named fork, for historical reasons. The File Manager does not interpret the contents of these fields. To use this information, coerce the parameter to an `ExtendedFileInfo` (page 2257) or `ExtendedFolderInfo` (page 2254) structure.

`dataLogicalSize`
The size of the data fork in bytes (the fork's logical size). The information in this field is only valid for files do not rely upon the value returned in this field for folders.

`dataPhysicalSize`
The amount of disk space, in bytes, occupied by the data fork (the fork's physical size). The information in this field is only valid for files do not rely upon the value returned in this field for folders.

`rsrcLogicalSize`
The size of the resource fork (the fork's logical size). The information in this field is only valid for files do not rely upon the value returned in this field for folders.

`rsrcPhysicalSize`

The amount of disk space occupied by the resource fork (the fork's physical size). The information in this field is only valid for files do not rely upon the value returned in this field for folders.

`valence`

For folders only, the number of items (files plus directories) contained within the directory. For files, it is set to zero. Many volume formats do not store a field containing a directory's valence. For those volume formats, this field is very expensive to compute. Think carefully before you ask the File Manager to return this field.

`textEncodingHint`

The `textEncodingHint` field is used in conjunction with the Unicode filename of the object. It is an optional hint that can be used by the volume format when converting the Unicode to some other encoding. For example, HFS Plus stores this value and uses it when converting the name to a Mac OS encoding, such as when the name is returned by `PBGetCatInfoSync` or `PBGetCatInfoAsync`. As another example, HFS volumes use this value to convert the Unicode name to a Mac OS encoded name stored on disk. If the entire Unicode name can be converted to a single Mac OS encoding, then that encoding should be used as the `textEncodingHint`; otherwise, a text encoding corresponding to the first characters of the name will probably provide the best user experience.

If a `textEncodingHint` is not supplied when a file or directory is created or renamed, the volume format will use a default value. This default value may not be the best possible choice for the given filename. Whenever possible, a client should supply a `textEncodingHint`.

Discussion
The `FSCatalogInfoBitmap` type is used to indicate which fields of the `FSCatalogInfo` should be set or retrieved. If the bit corresponding to a particular field is not set, then that field is not changed if the `FSCatalogInfo` is an output parameter, and that field is ignored if the `FSCatalogInfo` is an input parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSCatalogInfoBitmap

Describes which fields of the `FSCatalogInfo` structure you wish to retrieve or set.

```
typedef UInt32 FSCatalogInfoBitmap;
```

Discussion
If the bit corresponding to a particular field is not set in the bitmap, then that field is not changed in the `FSCatalogInfo` structure if it is an output parameter, and that field is ignored if the `FSCatalogInfo` structure is an input parameter. See "Catalog Information Bitmap Constants" (page 891) for a description of the constants you should use with this data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSEjectStatus

```
typedef UInt32 FSEjectStatus;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSFileOperationClientContext

Specifies user-defined data and callbacks associated with an asynchronous file operation.

```
struct FSFileOperationClientContext {
    CFIndex version;
    void *info;
    CFAllocatorRetainCallBack retain;
    CFAllocatorReleaseCallBack release;
    CFAllocatorCopyDescriptionCallBack copyDescription;
};
typedef struct FSFileOperationClientContext FSFileOperationClientContext;
```

Fields

`version`
: The version number of the structure; this field should always contain 0.

`info`
: A generic pointer to your user-defined data. This pointer is passed back to your application when you check the status of the file operation. There are two ways you can ask the File Manager for status information about a file operation: by supplying a status callback function when you start the operation, or by calling a file operation status function directly.

`retain`
: An optional callback function that the File Manager can use to retain the user-defined data specified in the `info` parameter. If your data is a Core Foundation object, you can simply specify the function `CFRetain`. If no callback is needed, set this field to `NULL`.

`release`
: An optional callback function that the File Manager can use to release the user-defined data specified in the `info` parameter. If your data is a Core Foundation object, you can simply specify the function `CFRelease`. If no callback is needed, set this field to `NULL`.

`copyDescription`
: An optional callback function that the File Manager can use to create a descriptive string representation of your user-defined data for debugging purposes. If no callback is needed, set this field to `NULL`.

Discussion
You supply a client context when calling functions such as `FSCopyObjectAsync` (page 477) or `FSMoveObjectAsync` (page 511) that start an asynchronous copy or move operation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSFileOperationRef

Defines an opaque type that represents an asynchronous file operation.

```
typedef struct __FSFileOperation * FSFileOperationRef;
```

Discussion
You supply a file operation object when calling functions such as `FSCopyObjectAsync` (page 477) or `FSMoveObjectAsync` (page 511) to start an asynchronous copy or move operation. You can also use a file operation object to check the status of a file operation or to cancel the operation.

To perform an asynchronous file operation:

1. Create a file operation object using the function `FSFileOperationCreate` (page 488).
2. Pass the object to the function `FSFileOperationScheduleWithRunLoop` (page 489) to schedule the operation.
3. Pass the object to one of the asynchronous file operation functions to start the operation.

The `FSFileOperationRef` opaque type is a standard Core Foundation data type. It is derived from CFType and inherits the properties that all Core Foundation types have in common. For more information, see *CFType Reference*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSForkCBInfoParam

Defines a parameter block used by low-level HFS Plus fork control block functions.

```
struct FSForkCBInfoParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    SInt16 desiredRefNum;
    SInt16 volumeRefNum;
    SInt16 iterator;
    SInt16 actualRefNum;
    FSRef * ref;
    FSForkInfo * forkInfo;
    HFSUniStr255 * forkName;
};
typedef struct FSForkCBInfoParam FSForkCBInfoParam;
typedef FSForkCBInfoParam * FSForkCBInfoParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`desiredRefNum`
A fork reference number.

`volumeRefNum`
The volume reference number of the volume to match, or zero to match all volumes.

`iterator`
An iterator. Set to zero to start iteration.

`actualRefNum`
On return, the actual fork reference number found.

`ref`
A pointer to an `FSRef` for the specified fork.

`forkInfo`
A pointer to a fork information structure, `FSForkInfo` (page 832).

`forkName`
A pointer to the fork's Unicode name.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSForkInfo

Contains information about an open fork.

```
struct FSForkInfo {
    SInt8 flags;
    SInt8 permissions;
    FSVolumeRefNum volume;
    UInt32 reserved2;
    UInt32 nodeID;
    UInt32 forkID;
    UInt64 currentPosition;
    UInt64 logicalEOF;
    UInt64 physicalEOF;
    UInt64 process;
};
typedef struct FSForkInfo FSForkInfo;
typedef FSForkInfo * FSForkInfoPtr;
```

Fields

`flags`
Flags describing the status of the fork. See "FCB Flags" (page 906) for a description of the bits in this field.

`permissions`
User and group permission information.

`volume`
A volume specification. This can be a volume reference number, drive number, or 0 for the default volume.

`reserved2`
Reserved.

`nodeID`
The file or directory ID of the file or directory with which the fork is associated.

`forkID`
The fork ID.

`currentPosition`
The current position within the fork.

`logicalEOF`
The logical size of the fork.

`physicalEOF`
The physical size of the fork.

`process`
The process which opened the fork.

Discussion
This data type is used in the `forkInfo` parameter of the `FSGetForkCBInfo` function, and in the `forkInfo` field of the `FSForkCBInfoParam` parameter block passed to the `PBGetForkCBInfoSync` and `PBGetForkCBInfoAsync` functions. When these functions return, the `FSForkInfo` structure contains information about the specified open fork.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSForkIOParam

Defines a parameter block used by low-level HFS Plus fork I/O functions.

```
struct FSForkIOParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    void * reserved1;
    SInt16 reserved2;
    SInt16 forkRefNum;
    UInt8 reserved3;
    SInt8 permissions;
    const FSRef * ref;
    Ptr buffer;
    UInt32 requestCount;
    UInt32 actualCount;
    UInt16 positionMode;
    SInt64 positionOffset;
    FSAllocationFlags allocationFlags;
    UInt64 allocationAmount;
    UniCharCount forkNameLength;
    const UniChar * forkName;
    CatPositionRec forkIterator;
    HFSUniStr255 * outForkName;
};
typedef struct FSForkIOParam FSForkIOParam;
typedef FSForkIOParam * FSForkIOParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`reserved1`
: Reserved.

`reserved2`
: Reserved.

`forkRefNum`
: A reference number for a fork.

`reserved3`
: Reserved.

`permissions`
: The desired type of access to the specified fork. See "File Access Permission Constants" (page 908) for a description of the types of access that you can request.

`ref`
: An `FSRef` for the file or directory to open.

`buffer`
: A pointer to a data buffer.

`requestCount`
: The number of bytes requested for the given operation.

`actualCount`
: The actual number of bytes completed by the call.

`positionMode`
: A constant indicating the base location within the file for the start of the operation. See "Position Mode Constants" (page 928) for the meaning of the constants you can use in this field.

`positionOffset`
: The offset from the base location specified in the `positionMode` offset for the start of the operation.

`allocationFlags`
: A set of bit flags used by the `FSAllocateFork` (page 470) function to control how space is allocated. See "Allocation Flags" (page 887) for a description of the defined flags.

`allocationAmount`
: For the `FSAllocateFork` (page 470) function, the amount of space, in bytes, to allocate.

`forkNameLength`
: The length of the file or directory name passed in the `forkName` field, in Unicode characters.

`forkName`
: A pointer to the file or directory's Unicode name. This field is an input parameter functions which return the file or directory name in the parameter block use the `outForkName` field.

`forkIterator`
: A fork iterator.

`outForkName`

A pointer to the file or directory's Unicode name this is an output parameter. For functions which require the file or directory name as an input argument, you should pass a pointer to that name in the `forkName` field and pass the length of the name in the `forkNameLength` field.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSIterator

Refers to a position within the catalog, used when iterating over files and folders in a directory.

```
typedef struct OpaqueFSIterator * FSIterator;
```

Discussion
This data type is like a file reference number because it maintains state internally to the File Manager and must be explicitly opened and closed.

An `FSIterator` is returned by `FSOpenIterator` and is passed as input to `FSGetCatalogInfoBulk`, `FSCatalogSearch` and `FSCloseIterator`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSMountStatus

```
typedef UInt32 FSMountStatus;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSPermissionInfo

```
struct FSPermissionInfo {
    UInt32 userID;
    UInt32 groupID;
    UInt8 reserved1;
    UInt8 userAccess;
    UInt16 mode;
    UInt32 reserved2;
};
typedef struct FSPermissionInfo FSPermissionInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSRangeLockParam

Defines a parameter block for use with 64-bit range locking functions.

```
struct FSRangeLockParam {
    QElemPtr qLink;
    SInt16 qType;
    SInt16 ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    FSIORefNum forkRefNum;
    UInt64 requestCount;
    UInt16 positionMode;
    SInt64 positionOffset;
    UInt64 rangeStart;
};
typedef struct FSRangeLockParam FSRangeLockParam;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSRangeLockParamPtr

Defines a pointer to a range lock parameter block.

```
typedef FSRangeLockParam *FSRangeLockParamPtr;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Files.h`

FSRef

Identifies a directory or file, including a volume's root directory.

```
struct FSRef {
    UInt8 hidden[80];
};
typedef struct FSRef FSRef;
typedef FSRef * FSRefPtr;
```

Discussion
This data type's purpose is similar to an `FSSpec` except that an `FSRef` is completely opaque. An `FSRef` contains whatever information is needed to find the given object; the internal structure of an `FSRef` is likely to vary based on the volume format, and may vary based on the particular object being identified.

The client of the File Manager cannot examine the contents of an `FSRef` to extract information about the parent directory or the object's name. Similarly, an `FSRef` cannot be constructed directly by the client; the `FSRef` must be constructed and returned via the File Manager. There is no need to call the File Manager to dispose an `FSRef`.

To determine the volume, parent directory and name associated with an `FSRef`, or to get an equivalent `FSSpec`, use the `FSGetCatalogInfo` call.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSRefParam

Defines a parameter block used by low-level HFS Plus functions.

```
struct FSRefParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    ConstStringPtr ioNamePtr;
    short ioVRefNum;
    SInt16 reserved1;
    UInt8 reserved2;
    UInt8 reserved3;
    const FSRef * ref;
    FSCatalogInfoBitmap whichInfo;
    FSCatalogInfo * catInfo;
    UniCharCount nameLength;
    const UniChar * name;
    long ioDirID;
    FSSpec * spec;
    FSRef * parentRef;
    FSRef * newRef;
    TextEncoding textEncodingHint;
    HFSUniStr255 * outName;
};
typedef struct FSRefParam FSRefParam;
typedef FSRefParam * FSRefParamPtr;
```

Fields

`qLink`

A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`

The queue type. This field is used internally by the File Manager.

`ioTrap`

The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`

The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`

A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`

The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`

A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—you should set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, or 0 for the default volume.

`reserved1`
Reserved.

`reserved2`
Reserved.

`reserved3`
Reserved.

`ref`
The `FSRef` describing the file or directory which is the target of the call.

`whichInfo`
An `FSCatalogInfoBitmap` which describes the fields of the catalog information structure passed in the `catInfo` field which are to be retrieved or set.

`catInfo`
A catalog information structure containing information about the specified file or directory.

`nameLength`
The length of the file or directory's name, for the `PBCreateSync`, `PBCreateAsync`, `PBRenameSync`, and `PBRenameAsync` functions.

`name`
A pointer to the file or directory's Unicode name, for the `PBCreateSync`, `PBCreateAsync`, `PBRenameSync`, and `PBRenameAsync` functions.

`ioDirID`
The directory ID of the specified file or directory's parent directory.

`spec`
The target or source `FSRef`.

`parentRef`
The secondary or destination `FSRef`. (Or the ref of the directory to move another file or directory to).

`newRef`
The output `FSRef` (ie, a new `FSRef`).

`textEncodingHint`
A text encoding hint for the file or directory's Unicode name, used by the `PBMakeFSRefSync`, `PBMakeFSRefAsync`, `PBRenameSync`, and `PBRenameAsync` functions.

`outName`
On output, a pointer to the Unicode name of the file or directory, used by the `PBGetCatalogInfoSync` and `PBGetCatalogInfoAsync` functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSSearchParams

Describes the search criteria for a catalog information search.

```
struct FSSearchParams {
    Duration searchTime;
    OptionBits searchBits;
    UniCharCount searchNameLength;
    const UniChar * searchName;
    FSCatalogInfo * searchInfo1;
    FSCatalogInfo * searchInfo2;
};
typedef struct FSSearchParams FSSearchParams;
typedef FSSearchParams * FSSearchParamsPtr;
```

Fields

`searchTime`

A Time Manager duration for the duration of the search. If you specify a non-zero value in this field, the search may terminate after the specified time, even if the maximum number of requested objects has not been returned and the entire catalog has not been scanned.

If this value is negative, the time is interpreted in microseconds; if positive, it is interpreted as milliseconds. If `searchTime` is zero, there is no time limit on the search.

`searchBits`

A set of bits specifying which catalog information fields to search on. See "Catalog Search Constants" (page 899) for the constants which you can use here.

`searchNameLength`

The length of the Unicode name to search by.

`searchName`

A pointer to the Unicode name to search by.

`searchInfo1`

An `FSCatalogInfo` (page 826) structure which specifies the values and lower bounds of a search.

`searchInfo2`

A `FSCatalogInfo` (page 826) structure which specifies the masks and upper bounds of a search.

Discussion

Used by `FSCatalogSearch`, `PBCatalogSearchSync`, and `PBCatalogSearchAsync` to specify the criteria for a catalog search.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSSpec

Specifies the name and location of a file or directory.

```
struct FSSpec {
    short vRefNum;
    long parID;
    StrFileName name;
};
typedef struct FSSpec FSSpec;
typedef FSSpec * FSSpecPtr;
```

Fields

`vRefNum`

The volume reference number of the volume containing the specified file or directory.

`parID`

The parent directory ID of the specified file or directory (the directory ID of the directory containing the given file or directory).

`name`

The name of the specified file or directory. In Carbon, this name must be a leaf name; the name cannot contain a semicolon.

Discussion

The `FSSpec` structure can describe only a file or a directory, not a volume. A volume can be identified by its root directory, although the system software never uses an `FSSpec` structure to describe a volume. The directory ID of the root's parent directory is `fsRtParID`. The name of the root directory is the same as the name of the volume.

If you need to convert a file specification into an `FSSpec` structure, call the function `FSMakeFSSpec` (page 505) . Do not fill in the fields of an `FSSpec` structure yourself.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSSpecArrayPtr

Defines a pointer to an array of `FSSpec` structures.

```
typedef FSSpecPtr FSSpecArrayPtr;
```

Discussion

See `FSSpec` (page 840).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

FSUnmountStatus

```
typedef UInt32 FSUnmountStatus;
```

Availability
Available in Mac OS X v10.2 and later.

FSVolumeEjectUPP

```
typedef FSVolumeEjectProcPtr FSVolumeEjectUPP;
```

Discussion
For more information, see the description of the `FSVolumeEjectProcPtr` (page 792) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeInfo

Used when getting or setting information about a volume.

```
struct FSVolumeInfo {
    UTCDateTime createDate;
    UTCDateTime modifyDate;
    UTCDateTime backupDate;
    UTCDateTime checkedDate;
    UInt32 fileCount;
    UInt32 folderCount;
    UInt64 totalBytes;
    UInt64 freeBytes;
    UInt32 blockSize;
    UInt32 totalBlocks;
    UInt32 freeBlocks;
    UInt32 nextAllocation;
    UInt32 rsrcClumpSize;
    UInt32 dataClumpSize;
    UInt32 nextCatalogID;
    UInt8 finderInfo[32];
    UInt16 flags;
    UInt16 filesystemID;
    UInt16 signature;
    UInt16 driveNumber;
    short driverRefNum;
};
typedef struct FSVolumeInfo FSVolumeInfo;
typedef FSVolumeInfo * FSVolumeInfoPtr;
```

Fields

`createDate`
: The date and time the volume was created. A value of 0 means that the volume creation date is unknown.

`modifyDate`
: The last time when the volume was modified in any way. A value of 0 means “never” or “unknown.

`backupDate`
: Indicates when the volume was last backed up. This field is for use by backup utilities. A value of 0 means “never” or “unknown.

`checkedDate`
: The last date and time that the volume was checked for consistency. A value of 0 means “never” or “unknown.

`fileCount`
: The total number of files on the volume, or 0 if unknown.

`folderCount`
: The total number of folders on the volume, or 0 if unknown. Note that no root directory counts.

`totalBytes`
: The size of the volume in bytes.

`freeBytes`
: The number of bytes of free space on the volume.

`blockSize`
: The size of an allocation block, in bytes. This field is only appropriate for volume formats (such as HFS and HFS Plus) that allocate space in fixed-size pieces; other volume formats may not have a similar concept, and may set this field to zero.

`totalBlocks`
: The total number of allocation blocks on the volume. This field is only appropriate for volume formats (such as HFS and HFS Plus) that allocate space in fixed-size pieces; other volume formats may not have a similar concept, and may set this field to zero.

`freeBlocks`
: The number of unused allocation blocks on the volume. This field is only appropriate for volume formats (such as HFS and HFS Plus) that allocate space in fixed-size pieces; other volume formats may not have a similar concept, and may set this field to zero.

`nextAllocation`
: A hint for where to start searching for free space during an allocation. This field is only appropriate for volume formats (such as HFS and HFS Plus) that allocate space in fixed-size pieces; other volume formats may not have a similar concept, and may set this field to zero.

`rsrcClumpSize`
: Default resource fork clump size. When a fork is automatically grown as it is written, the File Manager attempts to allocate space that is a multiple of the clump size. This field is zero for volume formats that don't support the notion of a clump size.

`dataClumpSize`
: Default data fork clump size. When a fork is automatically grown as it is written, the File Manager attempts to allocate space that is a multiple of the clump size. This field is zero for volume formats that don't support the notion of a clump size.

`nextCatalogID`
: The next unused catalog node ID. Some volume formats (such as HFS and HFS Plus) use a monotonically increasing number for the catalog node ID (i.e. File ID or Directory ID) of newly created files and directories. For those volume formats, the `nextCatalogID` is the next file/directory ID that will be assigned. For other volume formats, this field will be zero.

`finderInfo`
: Information used by Finder, such as the Directory ID of the System Folder. Some volume formats do not support Finder information for a volume and will set this field to all zeroes.

`flags`
: This field contains bit flags holding information about the volume. See "Volume Information Flags" (page 940) for the attribute constants you can use here.

`filesystemID`
: Identifies the filesystem implementation that is handling the volume; this is zero for HFS and HFS Plus volumes.

`signature`
: This field is used to distinguish between volume formats supported by a single filesystem implementation.

`driveNumber`
: The drive number for the drive (drive queue element) associated with the volume. Mac OS X does not support drive numbers; in Mac OS X, the File Manager always returns a value of 1 in this field.

`driverRefNum`
: The driver reference number for the drive (drive queue element) associated with the volume.

Discussion
This structure contains information about a volume as a whole information about a volume's root directory would use the `FSCatalogInfo` (page 826) structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSVolumeInfoBitmap

Describes which fields of the `FSVolumeInfo` structure you wish to retrieve or set.

```
typedef UInt32 FSVolumeInfoBitmap;
```

Discussion
If the bit corresponding to a particular field is not set in the bitmap, then that field is not changed in the `FSVolumeInfo` structure if it is an output parameter, and that field is ignored if the `FSVolumeInfo` structure is an input parameter. See "Volume Information Bitmap Constants" (page 938) for a description of the constants you should use with this data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSVolumeInfoParam

Defines a parameter block used by low-level HFS Plus volume manipulation functions.

```
struct FSVolumeInfoParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    FSVolumeRefNum ioVRefNum;
    UInt32 volumeIndex;
    FSVolumeInfoBitmap whichInfo;
    FSVolumeInfo * volumeInfo;
    HFSUniStr255 * volumeName;
    FSRef * ref;
};
typedef struct FSVolumeInfoParam FSVolumeInfoParam;
typedef FSVolumeInfoParam * FSVolumeInfoParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a volume name. This field is unused.

`ioVRefNum`
: The volume reference number.

`volumeIndex`
: The volume index. If this field is 0, the value in the `ioVRefNum` field only is used to identify the target volume.

`whichInfo`
: A bitmap indicating which volume information fields to retrieve or set in the `FSVolumeInfo` (page 842) structure passed in the `volumeInfo` field. See "Volume Information Bitmap Constants" (page 938) for the meaning of the bits in this field.

`volumeInfo`
: A pointer to a volume information structure containing the requested volume information on return, or the new values of the volume information to set on input. See `FSVolumeInfo` (page 842).

`volumeName`
: On output, a pointer to the volume's name.

`ref`
: A pointer to an `FSRef` for the specified volume's root directory.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSVolumeMountUPP

```
typedef FSVolumeMountProcPtr FSVolumeMountUPP;
```

Discussion
For more information, see the description of the `FSVolumeMountProcPtr` (page 792) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeOperation

```
typedef struct OpaqueFSVolumeOperation * FSVolumeOperation;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

FSVolumeRefNum

Identifies a particular mounted volume.

```
typedef SInt16 FSVolumeRefNum;
```

Discussion
This data type is the same as the 16-bit volume refnum previously passed in the `ioVRefNum` fields of a parameter block; this is simply a new type name for the old data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

FSVolumeUnmountUPP

```
typedef FSVolumeUnmountProcPtr FSVolumeUnmountUPP;
```

Discussion
For more information, see the description of the `FSVolumeUnmountProcPtr` (page 793) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Files.h`

GetVolParmsInfoBuffer

Defines a volume attributes buffer, used by the `PBHGetVolParmsSync` and `PBHGetVolParmAsync` functions to return volume information.

```
struct GetVolParmsInfoBuffer {
    short vMVersion;
    long vMAttrib;
    Handle vMLocalHand;
    long vMServerAdr;
    long vMVolumeGrade;
    short vMForeignPrivID;
    long vMExtendedAttributes;
    void * vMDeviceID;
    UniCharCount vMMaxNameLength;
};
typedef struct GetVolParmsInfoBuffer GetVolParmsInfoBuffer;
```

Fields

`vMVersion`

The version number of the attributes buffer structure. Currently this field returns 1, 2, 3 or 4. Version 3 is introduced to support the HFS Plus APIs.

`vMAttrib`

A 32-bit quantity that encodes information about the volume attributes. See "Volume Attribute Constants" (page 931) for the meaning of the bits in this field.

`vMLocalHand`

A handle to private data for shared volumes. On creation of the VCB (right after mounting), this field is a handle to a 2-byte block of memory. The Finder uses this for its local window list storage, allocating and deallocating memory as needed. It is disposed of when the volume is unmounted. Your application should treat this field as reserved.

`vMServerAdr`

For AppleTalk server volumes, this field contains the internet address of an AppleTalk server volume. Your application can inspect this field to tell which volumes belong to which server; the value of this field is 0 if the volume does not have a server.

`vMVolumeGrade`

The relative speed rating of the volume. The scale used to determine these values is currently uncalibrated. In general, lower values indicate faster speeds. A value of 0 indicates that the volume's speed is unrated. The buffer version returned in the `vMVersion` field must be greater than 1 for this field to be meaningful.

`vMForeignPrivID`

An integer representing the privilege model supported by the volume. Currently two values are defined for this field: 0 represents a standard HFS or HFS Plus volume that might or might not support the AFP privilege model; `fsUnixPriv` represents a volume that supports the A/UX privilege model. The buffer version returned in the `vMVersion` field must be greater than 1 for this field to be meaningful.

`vMExtendedAttributes`

Contains bits that describe a volume's extended attributes. For this field to be meaningful, the `vMVersion` must be greater than 2. See "Extended Volume Attributes" (page 903) for the meaning of the bits in this field.

`vMDeviceID`

A device name identifying the device in /dev that corresponds to the volume. You can use this string to build a POSIX path to the device for use with IOKit APIs.

`vMMaxNameLength`

Discussion
Volumes that implement the HFS Plus APIs must use version 3 (or newer) of the `GetVolParmsInfoBuffer`. Volumes that don't implement the HFS Plus APIs may still implement version 3 of the `GetVolParmsInfoBuffer`. If the version of the `GetVolParmsInfoBuffer` is 2 or less, or the `bSupportsHFSPlusAPIs` bit is clear (zero), then the volume does not implement the HFS Plus APIs, and they are being emulated for that volume by the File Manager itself.

If a volume does not implement the HFS Plus APIs, and supports version 2 or earlier of the `GetVolParmsInfoBuffer`, it cannot itself describe whether it supports the `FSCatalogSearch` (page 472) or `FSExchangeObjects` calls. The compatibility layer will implement the `FSCatalogSearch` call if the volume supports the `PBCatSearch` call (i.e. the `bHasCatSearch` bit of `vMAttrib` is set). The compatibility layer will implement the `FSExchangeObjects` call if the volume supports `PBExchangeFiles` (i.e. the `bHasFileIDs` bit of `vMAttrib` is set).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

HFileInfo

Defines a structure which holds catalog information about a file.

```
struct HFileInfo {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioFRefNum;
    SInt8 ioFVersNum;
    SInt8 filler1;
    short ioFDirIndex;
    SInt8 ioFlAttrib;
    SInt8 ioACUser;
    FInfo ioFlFndrInfo;
    long ioDirID;
    unsigned short ioFlStBlk;
    long ioFlLgLen;
    long ioFlPyLen;
    unsigned short ioFlRStBlk;
    long ioFlRLgLen;
    long ioFlRPyLen;
    unsigned long ioFlCrDat;
    unsigned long ioFlMdDat;
    unsigned long ioFlBkDat;
    FXInfo ioFlXFndrInfo;
    long ioFlParID;
    long ioFlClpSiz;
};
typedef struct HFileInfo HFileInfo;
```

Fields

`qLink`
: A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
: The queue type. This field is used internally by the File Manager.

`ioTrap`
: The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
: The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioFRefNum`
: The file reference number of an open file.

`ioFVersNum`
: A file version number. This field is no longer used. File version numbers are an artifact of the obsolete MFS, and are not supported on HFS volumes. You should always set this field to 0.

`filler1`
: Reserved.

`ioFDirIndex`
: A file and directory index. If this field contains a positive number, `PBGetCatInfoSync` and `PBGetCatInfoAsync` return information about the file or directory having that directory index in the directory specified by the `ioVRefNum` field. (If `ioVRefNum` contains a volume reference number, the specified directory is that volume's root directory.)

  If this field contains 0, `PBGetCatInfoSync` or `PBGetCatInfoAsync` returns information about the file or directory whose name is specified in the `ioNamePtr` field and that is located in the directory specified by the `ioVRefNum` field. (Once again, if `ioVRefNum` contains a volume reference number, the specified directory is that volume's root directory.)

  If this field contains a negative number, `PBGetCatInfoSync` or `PBGetCatInfoAsync` ignores the `ioNamePtr` field and returns information about the directory specified in the `ioDirID` field. If both `ioDirID` and `ioVRefNum` are set to 0, `PBGetCatInfoSync` or `PBGetCatInfoAsync` returns information about the current default directory.

`ioFlAttrib`
: File or directory attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field.

`ioACUser`
: The user's access rights for the specified directory. See "User Privileges Constants" (page 930) for the meaning of the bits in this field.

`ioFlFndrInfo`
: Finder information.

`ioDirID`
: A directory ID or file ID. On input to `PBGetCatInfoSync` or `PBGetCatInfoAsync`, this field contains a directory ID (which is used only if the `ioFDirIndex` field is negative). On output, this field contains the file ID of the specified file.

`ioFlStBlk`
: The first allocation block of the data fork. This field contains 0 if the file's data fork is empty.

`ioFlLgLen`
: The logical length (logical end-of-file) of the data fork.

`ioFlPyLen`
: The physical length (physical end-of-file) of the data fork.

`ioFlRStBlk`
: The first allocation block of the resource fork.

`ioFlRLgLen`
: The logical length (logical end-of-file) of the resource fork.

`ioFlRPyLen`
: The physical length (physical end-of-file) of the resource fork.

`ioFlCrDat`
: The date and time of the file's creation, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the creation date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970, and that is the value which will be returned if you later try to retrieve the creation date.

  Note that file systems other than AFP, HFS and HFS Plus do not generally support creation dates.

`ioFlMdDat`
: The date and time of the last modification to the file, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the modification date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970.

`ioFlBkDat`
: The date and time that the file was last backed up, in seconds since midnight, January 1, 1904. However, on Mac OS X, if you set the backup date to a date between January 1, 1904 and January 1, 1970, it will be clipped to January 1, 1970.

  Note that file systems other than AFP, HFS and HFS Plus do not generally support backup dates.

`ioFlXFndrInfo`
: Additional Finder information.

`ioFlParID`
: The directory ID of the file's parent directory.

`ioFlClpSiz`
: The clump size to be used when writing the file if it's 0, the volume's clump size is used when the file is opened.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Files.h`

HFileParam

Defines a parameter block used by low-level HFS functions for file creation, deletion, and information retrieval.

```
struct HFileParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioFRefNum;
    SInt8 ioFVersNum;
    SInt8 filler1;
    short ioFDirIndex;
    SInt8 ioFlAttrib;
    SInt8 ioFlVersNum;
    FInfo ioFlFndrInfo;
    long ioDirID;
    unsigned short ioFlStBlk;
    long ioFlLgLen;
    long ioFlPyLen;
    unsigned short ioFlRStBlk;
    long ioFlRLgLen;
    long ioFlRPyLen;
    unsigned long ioFlCrDat;
    unsigned long ioFlMdDat;
};
typedef struct HFileParam HFileParam;
typedef HFileParam * HFileParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioFRefNum`
The file reference number of an open file.

`ioFVersNum`
A file version number. This field is no longer used. File version numbers are an artifact of the obsolete MFS, and are not supported on HFS volumes. You should always set this field to 0.

`filler1`
Reserved.

`ioFDirIndex`
A directory index for use with the `PBHGetFInfoSync` (page 683) and `PBHGetFInfoAsync` (page 682) functions.

`ioFlAttrib`
File attributes. See "File Attribute Constants" (page 914) for the meaning of the bits in this field.

`ioFlVersNum`
A file version number. This feature is no longer supported, and you must always set this field to 0.

`ioFlFndrInfo`
Information used by the Finder.

`ioDirID`
A directory ID.

`ioFlStBlk`
The first allocation block of the data fork. This field contains 0 if the file's data fork is empty.

`ioFlLgLen`
The logical length (logical end-of-file) of the data fork.

`ioFlPyLen`
The physical length (physical end-of-file) of the data fork.

`ioFlRStBlk`
The first allocation block of the resource fork. This field contains 0 if the file's resource fork is empty.

`ioFlRLgLen`
The logical length (logical end-of-file) of the resource fork.

`ioFlRPyLen`
The physical length (physical end-of-file) of the resource fork.

`ioFlCrDat`
The date and time of the file's creation, specified in seconds since midnight, January 1, 1904.

`ioFlMdDat`
The date and time of the last modification to the file, specified in seconds since midnight, January 1, 1904.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

HFSUniStr255

Used by the File Manager to return Unicode strings.

```
struct HFSUniStr255 {
    UInt16 length;
    UniChar unicode[255];
};
typedef struct HFSUniStr255 HFSUniStr255;
```

Fields

`length`

The number of unicode characters in the string.

`unicode`

The string, in unicode characters.

Discussion

This data type is a string of up to 255 16-bit Unicode characters, with a preceding 16-bit length (number of characters). Note that only the first length characters have meaningful values; the remaining characters may be set to arbitrary values. A caller should always assume that the entire structure will be modified, even if the actual string length is less than 255.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Files.h`

HIOParam

Defines a parameter block used by low-level HFS I/O functions.

```
struct HIOParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioRefNum;
    SInt8 ioVersNum;
    SInt8 ioPermssn;
    Ptr ioMisc;
    Ptr ioBuffer;
    long ioReqCount;
    long ioActCount;
    short ioPosMode;
    long ioPosOffset;
};
typedef struct HIOParam HIOParam;
typedef HIOParam * HIOParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioRefNum`
The file reference number of an open file.

`ioVersNum`
: A version number. This field is no longer used and you should always set it to 0.

`ioPermssn`
: The access mode. See "File Access Permission Constants" (page 908).

`ioMisc`
: Depending on the function called, this field contains either a logical end-of-file, a new version number, a pointer to an access path buffer, or a pointer to a new pathname. Because `ioMisc` is of type `Ptr`, you'll need to perform type coercion to interpret the value of `ioMisc` correctly when it contains an end-of-file (a `LongInt` value) or version number (a `SignedByte` value).

`ioBuffer`
: A pointer to a data buffer into which data is written by `PBReadSync` and `PBReadAsync` calls, and from which data is read by `PBWriteSync` and `PBWriteAsync` calls.

`ioReqCount`
: The requested number of bytes to be read, written, or allocated.

`ioActCount`
: The number of bytes actually read, written, or allocated.

`ioPosMode`
: The positioning mode (base location) for setting the mark. Bits 0 and 1 of this field indicate how to position the mark; you can use the constants described in "Position Mode Constants" (page 928) to set or test their value.

  You can also use the constants described in "Cache Constants" (page 889) to indicate whether or not to cache the data.

`ioPosOffset`
: The offset to be used in conjunction with the base location specified in the `ioPosMode` field.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Files.h`

HParamBlockRec

Describes the HFS parameter block.

```
union HParamBlockRec {
    HIOParam ioParam;
    HFileParam fileParam;
    HVolumeParam volumeParam;
    AccessParam accessParam;
    ObjParam objParam;
    CopyParam copyParam;
    WDParam wdParam;
    FIDParam fidParam;
    CSParam csParam;
    ForeignPrivParam foreignPrivParam;
};
typedef union HParamBlockRec HParamBlockRec;
typedef HParamBlockRec * HParmBlkPtr;
```

Fields

`ioParam`
A parameter block used by low-level HFS I/O functions. See `HIOParam` (page 855).

`fileParam`
A parameter block used by low-level HFS functions for file creation, deletion, and information retrieval. See `HFileParam` (page 852).

`volumeParam`
A parameter block used by low-level HFS volume manipulation functions. See `HVolumeParam` (page 859).

`accessParam`
A parameter block used by low-level HFS file and directory access rights manipulation functions. See `AccessParam` (page 795).

`objParam`
A parameter block used by low-level HFS user and group information functions. See `ObjParam` (page 865).

`copyParam`
A parameter block used by low-level HFS file copying functions. See `CopyParam` (page 806).

`wdParam`
A parameter block used by low-level HFS working directory functions. See `WDParam` (page 876).

`fidParam`
A parameter block used by low-level HFS file ID functions. See `FIDParam` (page 818).

`csParam`
A parameter block used by low-level HFS catalog search functions. See `CSParam` (page 807).

`foreignPrivParam`
A parameter block used by low-level HFS foreign privileges functions. See `ForeignPrivParam` (page 822).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

HVolumeParam

Defines a parameter block used by low-level HFS volume manipulation functions.

```
struct HVolumeParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long filler2;
    short ioVolIndex;
    unsigned long ioVCrDate;
    unsigned long ioVLsMod;
    short ioVAtrb;
    unsigned short ioVNmFls;
    unsigned short ioVBitMap;
    unsigned short ioAllocPtr;
    unsigned short ioVNmAlBlks;
    unsigned long ioVAlBlkSiz;
    unsigned long ioVClpSiz;
    unsigned short ioAlBlSt;
    unsigned long ioVNxtCNID;
    unsigned short ioVFrBlk;
    unsigned short ioVSigWord;
    short ioVDrvInfo;
    short ioVDRefNum;
    short ioVFSID;
    unsigned long ioVBkUp;
    short ioVSeqNum;
    unsigned long ioVWrCnt;
    unsigned long ioVFilCnt;
    unsigned long ioVDirCnt;
    long ioVFndrInfo[8];
};
typedef struct HVolumeParam HVolumeParam;
typedef HVolumeParam * HVolumeParamPtr;
```

Fields

`qLink`
: A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
: The queue type. This field is used internally by the File Manager.

`ioTrap`
: The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
: The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`filler2`
: Reserved.

`ioVolIndex`
: A volume index for use with the `PBHGetVInfoSync` (page 690) and `PBHGetVInfoAsync` (page 686) functions.

`ioVCrDate`
: The date and time of the volume's initialization.

`ioVLsMod`
: The date and time the volume information was last modified. (This field is not changed when information is written to a file and does not necessarily indicate when the volume was flushed.

`ioVAtrb`
: The volume attributes. See "Volume Information Attribute Constants" (page 937) for the meanings of the bits in this field.

`ioVNmFls`
: The number of files in the root directory of the volume. For performance reasons, the Carbon File Manager does not return the number of files in this field; instead, it sets `ioVNmFls` to 0.

  To determine the number of files in the root directory of a volume in Carbon, call `PBGetCatInfoAsync` (page 648) or `PBGetCatInfoSync` (page 651) for the root directory. The number of files in the root directory is returned in the `ioDrNmFls` field.

`ioVBitMap`
: The first block of the volume bitmap.

`ioAllocPtr`
: The block at which the next new file starts. Used internally.

`ioVNmAlBlks`
: The number of allocation blocks.

`ioVAlBlkSiz`
: The size of allocation blocks.

`ioVClpSiz`
: The clump size.

`ioAlBlSt`
The first block in the volume map.

`ioVNxtCNID`
The next unused catalog node ID.

`ioVFrBlk`
The number of unused allocation blocks.

`ioVSigWord`
A signature word identifying the type of volume it's $D2D7 for MFS volumes and $4244 for volumes that support HFS calls.

`ioVDrvInfo`
The drive number of the drive containing the volume.

`ioVDRefNum`
For online volumes, the reference number of the I/O driver for the drive identified by the `ioVDrvInfo` field.

`ioVFSID`
The file-system identifier. It indicates which file system is servicing the volume it's zero for File Manager volumes and nonzero for volumes handled by an external file system.

`ioVBkUp`
The date and time the volume was last backed up; this is 0 if the volume has never been backed up.

`ioVSeqNum`
Used internally.

`ioVWrCnt`
The volume write count.

`ioVFilCnt`
The total number of files on the volume.

`ioVDirCnt`
The total number of directories (not including the root directory) on the volume.

`ioVFndrInfo`
Information used by the Finder.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

IOCompletionUPP

A universal procedure pointer to an application-defined completion function.

```
typedef IOCompletionProcPtr IOCompletionUPP;
```

Discussion
See `IOCompletionProcPtr` (page 794).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

IOParam

Defines a parameter block used by low-level I/O functions.

```
struct IOParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioRefNum;
    SInt8 ioVersNum;
    SInt8 ioPermssn;
    Ptr ioMisc;
    Ptr ioBuffer;
    long ioReqCount;
    long ioActCount;
    short ioPosMode;
    long ioPosOffset;
};
typedef struct IOParam IOParam;
typedef IOParam * IOParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioRefNum`
: The file reference number of an open file.

`ioVersNum`
: A version number. This field is no longer used and you should always set it to 0.

`ioPermssn`
: The access mode. See "File Access Permission Constants" (page 908).

`ioMisc`
: Depending on the function called, this field contains either a new logical end-of-file (for the `PBGetEOFSync/ PBGetEOFAsync` and `PBSetEOFSync/ PBSetEOFAsync` functions), a new version number, or a pointer to a new pathname (for the `PBHRenameSync/ PBHRenameAsync` functions). Because `ioMisc` is of type `Ptr`, you'll need to perform type coercion to interpret the value of `ioMisc` correctly when it contains an end-of-file (a `LongInt` value) or version number (a `SignedByte` value).

`ioBuffer`
: A pointer to a data buffer into which data is written by `PBReadSync` and `PBReadAsync` calls; and from which data is read by `PBWriteSync` and `PBWriteAsync` calls.

`ioReqCount`
: The requested number of bytes to be read, written, or allocated.

`ioActCount`
: The number of bytes actually read, written, or allocated.

`ioPosMode`
: The positioning mode (base location) for positioning the file mark. Bits 0 and 1 of this field indicate how to position the mark; you can use the constants described in "Position Mode Constants" (page 928) to set or test their value.

  You can also use the constants described in "Cache Constants" (page 889) to indicate whether the data should be cached.

`ioPosOffset`
: The offset to be used in conjunction with the base location specified in the `ioPosMode` field.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

MultiDevParam

Defines a parameter block used by low-level functions in the classic Device Manager to access multiple devices.

```
struct MultiDevParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioMRefNum;
    SInt8 ioMVersNum;
    SInt8 ioMPermssn;
    Ptr ioMMix;
    short ioMFlags;
    Ptr ioSEBlkPtr;
};
typedef struct MultiDevParam MultiDevParam;
typedef MultiDevParam * MultiDevParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioMRefNum`
The driver reference number.

`ioMVersNum`
The slot version number.

`ioMPermssn`
Permissions.

`ioMMix`
Reserved.

`ioMFlags`
Flags specifying the number of additional fields. You should set the `fMulti` bit (bit 0) of this field and clear all of the other bits.

`ioSEBlkPtr`
A pointer to an external parameter block that is customized for the devices installed in the slot.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

ObjParam

Defines a parameter block used by low-level HFS user and group information functions.

```
struct ObjParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short filler7;
    short ioObjType;
    StringPtr ioObjNamePtr;
    long ioObjID;
};
typedef struct ObjParam ObjParam;
typedef ObjParam * ObjParamPtr;
```

Fields
`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`filler7`
: Reserved.

`ioObjType`
: A function code. The values passed in this field are determined by the function to which you pass this parameter block.

`ioObjNamePtr`
: A pointer to the returned creator/group name.

`ioObjID`
: The creator/group ID.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Files.h`

ParamBlockRec

Describes the basic File Manager parameter block.

```
union ParamBlockRec {
    IOParam ioParam;
    FileParam fileParam;
    VolumeParam volumeParam;
    CntrlParam cntrlParam;
    SlotDevParam slotDevParam;
    MultiDevParam multiDevParam;
};
typedef union ParamBlockRec ParamBlockRec;
typedef ParamBlockRec * ParmBlkPtr;
```

Fields

`ioParam`

`fileParam`

`volumeParam`

`cntrlParam`

`slotDevParam`

`multiDevParam`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

SlotDevParam

Defines a parameter block used by low-level functions in the classic Device Manager to access a single slot device.

```
struct SlotDevParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioSRefNum;
    SInt8 ioSVersNum;
    SInt8 ioSPermssn;
    Ptr ioSMix;
    short ioSFlags;
    SInt8 ioSlot;
    SInt8 ioID;
};
typedef struct SlotDevParam SlotDevParam;
typedef SlotDevParam * SlotDevParamPtr;
```

Fields

`qLink`

A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioSRefNum`
The driver reference number.

`ioSVersNum`
The slot version number.

`ioSPermssn`
Permissions.

`ioSMix`
Reserved.

`ioSFlags`
Flags determining the number of additional fields. You should clear all of the bits in this field.

`ioSlot`
The slot number.

`ioID`
The slot resource ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

VCB

Defines a volume control block.

```
struct VCB {
    QElemPtr qLink;
    short qType;
    short vcbFlags;
    unsigned short vcbSigWord;
    unsigned long vcbCrDate;
    unsigned long vcbLsMod;
    short vcbAtrb;
    unsigned short vcbNmFls;
    short vcbVBMSt;
    short vcbAllocPtr;
    unsigned short vcbNmAlBlks;
    long vcbAlBlkSiz;
    long vcbClpSiz;
    short vcbAlBlSt;
    long vcbNxtCNID;
    unsigned short vcbFreeBks;
    Str27 vcbVN;
    short vcbDrvNum;
    short vcbDRefNum;
    short vcbFSID;
    short vcbVRefNum;
    Ptr vcbMAdr;
    Ptr vcbBufAdr;
    short vcbMLen;
    short vcbDirIndex;
    short vcbDirBlk;
    unsigned long vcbVolBkUp;
    unsigned short vcbVSeqNum;
    long vcbWrCnt;
    long vcbXTClpSiz;
    long vcbCTClpSiz;
    unsigned short vcbNmRtDirs;
    long vcbFilCnt;
    long vcbDirCnt;
    long vcbFndrInfo[8];
    unsigned short vcbVCSize;
    unsigned short vcbVBMCSiz;
    unsigned short vcbCtlCSiz;
    unsigned short vcbXTAlBlks;
    unsigned short vcbCTAlBlks;
    short vcbXTRef;
    short vcbCTRef;
    Ptr vcbCtlBuf;
    long vcbDirIDM;
    short vcbOffsM;
};
typedef struct VCB VCB;
typedef VCB * VCBPtr;
```

Fields

`qLink`

A pointer to the next entry in the VCB queue.

`qType`

The queue type. When the volume is mounted and the VCB is created, this field is cleared. Thereafter, bit 7 of this field is set whenever a file on that volume is opened.

`vcbFlags`
: Volume flags. Bit 15 is set if the volume information has been changed by a File Manager call since the volume was last flushed by a `FlushVol` (page 466) call. See "Volume Control Block Flags" (page 935).

`vcbSigWord`
: The volume signature.

`vcbCrDate`
: The date and time of the volume's creation (initialization).

`vcbLsMod`
: The date and time of the volume's last modification. This is not necessarily when the volume was last flushed.

`vcbAtrb`
: The volume attributes.

`vcbNmFls`
: The number of files in the root directory of the volume.

`vcbVBMSt`
: The first block of the volume bitmap.

`vcbAllocPtr`
: The start block of the next allocation search. This field is used internally.

`vcbNmAlBlks`
: The number of allocation blocks in the volume.

`vcbAlBlkSiz`
: The allocation block size, in bytes. This value must always be a multiple of 512 bytes.

`vcbClpSiz`
: The default clump size.

`vcbAlBlSt`
: The first allocation block in the volume.

`vcbNxtCNID`
: The next unused catalog node ID (directory or file ID).

`vcbFreeBks`
: The number of unused allocation blocks on the volume.

`vcbVN`
: The volume name. Note that a volume name can occupy at most 27 characters; this is an exception to the normal file and directory name limit of 31 characters.

`vcbDrvNum`
: The drive number of the drive on which the volume is located. When a mounted drive is placed offline or ejected, this field is set to 0.

`vcbDRefNum`
: The driver reference number of the driver used to access the volume When a volume is ejected, this field is set to the previous value of the `vcbDrvNum` field (and hence is a positive number). When a volume is placed offline, this field is set to the negative of the previous value of the `vcbDrvNum` field (and hence is a negative number).

`vcbFSID`
: An identifier for the file system handling the volume it's zero for volumes handled by the File Manager and nonzero for volumes handled by other file systems.

`vcbVRefNum`
The volume reference number of the volume.

`vcbMAdr`
Used internally.

`vcbBufAdr`
Used internally.

`vcbMLen`
Used internally.

`vcbDirIndex`
Used internally.

`vcbDirBlk`
Used internally.

`vcbVolBkUp`
The date and time that the volume was last backed up.

`vcbVSeqNum`
Used internally.

`vcbWrCnt`
The volume write count.

`vcbXTClpSiz`
The clump size of the extents overflow file.

`vcbCTClpSiz`
The clump size of the catalog file.

`vcbNmRtDirs`
The number of directories in the root directory.

`vcbFilCnt`
The total number of files on the volume.

`vcbDirCnt`
The total number of directories on the volume.

`vcbFndrInfo`
Finder information.

`vcbVCSize`
Used internally.

`vcbVBMCSiz`
Used internally.

`vcbCtlCSiz`
Used internally.

`vcbXTAlBlks`
The size, in allocation blocks, of the extents overflow file.

`vcbCTAlBlks`
The size, in allocation blocks, of the catalog file.

`vcbXTRef`
The path reference number for the extents overflow file.

`vcbCTRef`
The path reference number for the catalog file.

`vcbCtlBuf`
A pointer to the extents and catalog caches.

`vcbDirIDM`
The directory last searched.

`vcbOffsM`
The offspring index at the last search.

Discussion
The volume control block queue is a standard operating system queue that's maintained in the system heap. It contains a volume control block for each mounted volume. A volume control block is a nonrelocatable block that contains volume-specific information.

Each time a volume is mounted, the File Manager reads its volume information from the master directory block and uses the information to build a new volume control block (VCB) in the volume control block queue (unless an ejected or offline volume is being remounted). The File Manager also creates a volume buffer in the system heap. When a volume is placed offline, its buffer is released. When a volume is unmounted, its VCB is removed from the VCB queue as well.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

VolMountInfoHeader

Defines a volume mounting information header structure for remote volumes.

```
struct VolMountInfoHeader {
    short length;
    VolumeType media;
};
typedef struct VolMountInfoHeader VolMountInfoHeader;
typedef VolMountInfoHeader * VolMountInfoPtr;
```

Fields
`length`
The length of the `VolMountInfoHeader` structure, which is the total length of the structure header described here, plus the variable-length location data which follows the header.

`media`
The volume type of the remote volume. The `AppleShareMediaType` represents an AppleShare volume.

If you are adding support for the programmatic mounting functions to a non-Macintosh file system, you should register a four-character identifier for your volumes with DTS.

Discussion
To mount a remote server, fill out an `VolMountInfoHeader` structure using the `PBGetVolMountInfo` function and then pass this structure to the `PBVolumeMount` function to mount the volume.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

VolumeMountInfoHeader

Defines an extended volume mounting information header structure for remote volumes.

```
struct VolumeMountInfoHeader {
    short length;
    VolumeType media;
    short flags;
};
typedef struct VolumeMountInfoHeader VolumeMountInfoHeader;
typedef VolumeMountInfoHeader * VolumeMountInfoHeaderPtr;
```

Fields

`length`

The length of the `VolumeMountInfoHeader` structure, which is the total length of the structure header described here, plus the variable-length location data which follows the header.

`media`

The volume type of the remote volume. The `AppleShareMediaType` represents an AppleShare volume.

If you are adding support for the programmatic mounting functions to a non-Macintosh file system, you should register a four-character identifier for your volumes with DTS.

`flags`

The volume mount flags. See "Volume Mount Flags" (page 942).

Discussion
This volume mount info record supersedes the `VolMountInfoHeader` (page 872) structure; `VolMountInfoHeader` is included for compatibility. The `VolumeMountInfoHeader` record allows access to the volume mount flags by foreign filesystem writers.

To mount a remote server, fill out an `VolumeMountInfoHeader` structure using the `PBGetVolMountInfo` function and then pass this structure to the `PBVolumeMount` function to mount the volume.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

VolumeParam

Defines a parameter block used by low-level volume manipulation functions.

```
struct VolumeParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long filler2;
    short ioVolIndex;
    unsigned long ioVCrDate;
    unsigned long ioVLsBkUp;
    unsigned short ioVAtrb;
    unsigned short ioVNmFls;
    unsigned short ioVDirSt;
    short ioVBlLn;
    unsigned short ioVNmAlBlks;
    unsigned long ioVAlBlkSiz;
    unsigned long ioVClpSiz;
    unsigned short ioAlBlSt;
    unsigned long ioVNxtFNum;
    unsigned short ioVFrBlk;
};
typedef struct VolumeParam VolumeParam;
typedef VolumeParam * VolumeParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`filler2`
Reserved.

`ioVolIndex`
The volume index.

`ioVCrDate`
The date and time of the volume's initialization.

`ioVLsBkUp`
The date and time the volume information was last modified. (This field is not changed when information is written to a file and does not necessarily indicate when the volume was flushed.

`ioVAtrb`
The volume attributes. See "Volume Information Attribute Constants" (page 937) for the meanings of the bits in this field.

`ioVNmFls`
The number of files in the root directory.

`ioVDirSt`
The first block of the volume directory.

`ioVBlLn`
Length of directory in blocks.

`ioVNmAlBlks`
The number of allocation blocks.

`ioVAlBlkSiz`
The size of allocation blocks.

`ioVClpSiz`
The volume clump size.

`ioAlBlSt`
The first block in the volume map.

`ioVNxtFNum`
The next unused file number.

`ioVFrBlk`
The number of unused allocation blocks.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

VolumeType

Defines the "signature" of the file system.

```
typedef OSType VolumeType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Files.h`

WDParam

Defines a parameter block used by low-level HFS working directory functions.

```
struct WDParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioWDCreated;
    short ioWDIndex;
    long ioWDProcID;
    short ioWDVRefNum;
    short filler10;
    long filler11;
    long filler12;
    long filler13;
    long ioWDDirID;
};
typedef struct WDParam WDParam;
typedef WDParam * WDParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioWDCreated`

`ioWDIndex`
: An index to working directories.

`ioWDProcID`

`ioWDVRefNum`
: The volume reference number for the working directory.

`filler10`
: Reserved.

`filler11`
: Reserved.

`filler12`
: Reserved.

`filler13`
: The working directory's directory ID.

`ioWDDirID`
: The working directory's directory ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

WDPBRec

Defines a working directory parameter block.

```
struct WDPBRec {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short filler1;
    short ioWDIndex;
    long ioWDProcID;
    short ioWDVRefNum;
    short filler2[7];
    long ioWDDirID;
};
typedef struct WDPBRec WDPBRec;
typedef WDPBRec * WDPBPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`filler1`
Reserved.

`ioWDIndex`
An index.

`ioWDProcID`
: An identifier that's used to distinguish between working directories set up by different users you should set `ioWDProcID` to your application's signature.

`ioWDVRefNum`
: The working directory's volume reference number.

`filler2`
: Reserved.

`ioWDDirID`
: The working directory's directory ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

XCInfoPBRec

Defines an extended catalog information parameter block.

```
struct XCInfoPBRec {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    ProcPtr ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    long filler1;
    StringPtr ioShortNamePtr;
    short filler2;
    short ioPDType;
    long ioPDAuxType;
    long filler3[2];
    long ioDirID;
};
typedef struct XCInfoPBRec XCInfoPBRec;
typedef XCInfoPBRec * XCInfoPBPtr;
```

Fields
`qLink`
: A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
: The queue type. This field is used internally by the File Manager.

`ioTrap`
: The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
: The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
: A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`filler1`
: Reserved; set this field to 0.

`ioShortNamePtr`
: A pointer to a Pascal string buffer, of a minimum 13 bytes, which holds the file or directory's short name (MS-DOS format name). This field is required and cannot be `NULL`.

`filler2`
: Reserved; set this field to 0.

`ioPDType`
: The ProDOS file type of the file or directory.

`ioPDAuxType`
: The ProDOS auxiliary type of the file or directory.

`filler3`
: Reserved; set this field to 0.

`ioDirID`
: A directory ID.

Discussion
The `PBGetXCatInfoSync` and `PBGetXCatInfoAsync` functions use this parameter block to return the short name and ProDOS information for files and directories.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

XIOParam

Defines an extended I/O parameter block structure.

```
struct XIOParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    short ioRefNum;
    SInt8 ioVersNum;
    SInt8 ioPermssn;
    Ptr ioMisc;
    Ptr ioBuffer;
    long ioReqCount;
    long ioActCount;
    short ioPosMode;
    wide ioWPosOffset;
};
typedef struct XIOParam XIOParam;
typedef XIOParam * XIOParamPtr;
```

Fields

`qLink`
A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`
The queue type. This field is used internally by the File Manager.

`ioTrap`
The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`
The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`
A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
A volume reference number, 0 for the default volume, or a drive number.

`ioRefNum`
The file reference number of an open file.

`ioVersNum`
: A version number. This field is no longer used and you should always set it to 0.

`ioPermssn`
: The access mode. See "File Access Permission Constants" (page 908).

`ioMisc`
: Depending on the function called, this field contains either a logical end-of-file, a new version number, a pointer to an access path buffer, or a pointer to a new pathname. Because `ioMisc` is of type `Ptr`, you'll need to perform type coercion to interpret the value of `ioMisc` correctly when it contains an end-of-file (a `LongInt` value) or version number (a `SignedByte` value).

`ioBuffer`
: A pointer to a data buffer into which data is written by `_Read` calls and from which data is read by `_Write` calls.

`ioReqCount`
: The requested number of bytes to be read or written.

`ioActCount`
: The number of bytes actually read or written.

`ioPosMode`
: The positioning mode (base location) for setting the mark. Bits 0 and 1 of this field indicate how to position the mark; you can use the constants described in "Position Mode Constants" (page 928) to set or test their value. For the functions which use this parameter block, you must have the `kUseWidePositioning` bit set. See "Large Volume Constants" (page 926) for a description of this and other constants.

  You can also use the constants described in "Cache Constants" (page 889) to indicate whether or not to cache the data.

`ioWPosOffset`
: The wide positioning offset to be used in conjunction with the positioning mode specified in the `ioPosMode` field.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

XVolumeParam

Defines an extended volume information parameter block.

```
struct XVolumeParam {
    QElemPtr qLink;
    short qType;
    short ioTrap;
    Ptr ioCmdAddr;
    IOCompletionUPP ioCompletion;
    volatile OSErr ioResult;
    StringPtr ioNamePtr;
    short ioVRefNum;
    unsigned long ioXVersion;
    short ioVolIndex;
    unsigned long ioVCrDate;
    unsigned long ioVLsMod;
    short ioVAtrb;
    unsigned short ioVNmFls;
    unsigned short ioVBitMap;
    unsigned short ioAllocPtr;
    unsigned short ioVNmAlBlks;
    unsigned long ioVAlBlkSiz;
    unsigned long ioVClpSiz;
    unsigned short ioAlBlSt;
    unsigned long ioVNxtCNID;
    unsigned short ioVFrBlk;
    unsigned short ioVSigWord;
    short ioVDrvInfo;
    short ioVDRefNum;
    short ioVFSID;
    unsigned long ioVBkUp;
    short ioVSeqNum;
    unsigned long ioVWrCnt;
    unsigned long ioVFilCnt;
    unsigned long ioVDirCnt;
    long ioVFndrInfo[8];
    UInt64 ioVTotalBytes;
    UInt64 ioVFreeBytes;
};
typedef struct XVolumeParam XVolumeParam;
typedef XVolumeParam * XVolumeParamPtr;
```

Fields

`qLink`

A pointer to the next entry in the file I/O queue. (This field is used internally by the File Manager to keep track of asynchronous calls awaiting execution.

`qType`

The queue type. This field is used internally by the File Manager.

`ioTrap`

The trap number of the function that was called. This field is used internally by the File Manager.

`ioCmdAddr`

The address of the function that was called. This field is used internally by the File Manager.

`ioCompletion`

A universal procedure pointer to a completion routine to be executed at the end of an asynchronous call. It should be 0 for asynchronous calls with no completion routine and is automatically set to 0 for all synchronous calls. See `IOCompletionProcPtr` (page 794) for information about completion routines.

`ioResult`
: The result code of the function. For synchronous calls, this field is the same as the result code of the function call itself. To determine when an asynchronous call has actually been completed, your application can poll this field it's set to a positive number when the call is made and receives the actual result code when the call is completed.

`ioNamePtr`
: A pointer to a pathname. Whenever a function description specifies that `ioNamePtr` is used—whether for input, output, or both—it's very important that you set this field to point to storage for a `Str255` value (if you're using a pathname) or to `NULL` (if you're not).

`ioVRefNum`
: A volume reference number, 0 for the default volume, or a drive number.

`ioXVersion`
: The version of the `XVolumeParam` parameter block; currently, this is 0.

`ioVolIndex`
: A volume index for use with the `PBXGetVolInfoSync` (page 782) and `PBXGetVolInfoAsync` (page 779) functions.

`ioVCrDate`
: The date and time that the volume was created (initialized).

`ioVLsMod`
: The date and time that the volume information was last modified. This field is not changed when information is written to a file and does not necessarily indicate when the volume was flushed.

`ioVAtrb`
: The volume attributes. See "Volume Information Attribute Constants" (page 937) for the meanings of the bits in this field.

`ioVNmFls`
: The number of files in the root directory.

`ioVBitMap`
: The first block of the volume bitmap.

`ioAllocPtr`
: The block at which the next new file starts. Used internally.

`ioVNmAlBlks`
: The number of allocation blocks.

`ioVAlBlkSiz`
: The size of the allocation blocks.

`ioVClpSiz`
: The clump size.

`ioAlBlSt`
: The first block in the volume map.

`ioVNxtCNID`
: The next unused catalog node ID.

`ioVFrBlk`
: The number of unused allocation blocks.

`ioVSigWord`
: A signature word identifying the type of volume it's $D2D7 for MFS volumes and $4244 for volumes that support HFS calls.

`ioVDrvInfo`
The drive number of the drive containing the volume.

`ioVDRefNum`
For online volumes, the reference number of the I/O driver for the drive identified by the `ioVDrvInfo` field.

`ioVFSID`
The file-system identifier. It indicates which file system is servicing the volume it's zero for File Manager volumes and nonzero for volumes handled by an external file system.

`ioVBkUp`
The date and time that the volume was last backed up; this is 0 if the volume has never been backed up.

`ioVSeqNum`
Used internally.

`ioVWrCnt`
The volume write count.

`ioVFilCnt`
The total number of files on the volume.

`ioVDirCnt`
The total number of directories (not including the root directory) on the volume.

`ioVFndrInfo`
Information used by the Finder.

`ioVTotalBytes`
The total number of bytes on the volume.

`ioVFreeBytes`
The number of free bytes on the volume.

Discussion
The functions `PBXGetVolInfoSync` and `PBXGetVolInfoAsync` use this parameter block structure to pass arguments and return values.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Files.h`

Constants

AFP Tag Length Constants

Specify the length of tagged address information for AppleShare volumes.

```
enum {
    kAFPTagLengthIP = 0x06,
    kAFPTagLengthIPPort = 0x08,
    kAFPTagLengthDDP = 0x06
};
```

Constants

`kAFPTagLengthIP`
The length of a 4 byte IP address.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kAFPTagLengthIPPort`
The length of a 4 byte IP address and a 2 byte port.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kAFPTagLengthDDP`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion
These constants are used in the `fLength` field of the `AFPTagData` (page 797) structure to indicate the length, in bytes, of the tagged address information. This length includes the fLength field itself.

AFP Tag Type Constants

Specify the type of tagged address information for AppleShare clients.

```
enum {
    kAFPTagTypeIP = 0x01,
    kAFPTagTypeIPPort = 0x02,
    kAFPTagTypeDDP = 0x03,
    kAFPTagTypeDNS = 0x04
};
```

Constants

`kAFPTagTypeIP`
A basic 4 byte IP address, most significant byte first.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kAFPTagTypeIPPort`
A 4 byte IP address and a 2 byte port number, most significant byte first.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kAFPTagTypeDDP`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kAFPTagTypeDNS`
The address is a DNS name in address:port format. The total length of the DNS name is variable up to 254 characters.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `fType` field of the tagged address structure, `AFPTagData` (page 797), to specify the type of address represented by the structure.

Allocation Flags

Indicate how new space is to be allocated.

```
typedef UInt16 FSAllocationFlags;
enum {
    kFSAllocDefaultFlags = 0x0000,
    kFSAllocAllOrNothingMask = 0x0001,
    kFSAllocContiguousMask = 0x0002,
    kFSAllocNoRoundUpMask = 0x0004,
    kFSAllocReservedMask = 0xFFF8
};
```

Constants
`kFSAllocDefaultFlags`
Allocate as much as possible, not necessarily contiguous.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSAllocAllOrNothingMask`
This bit is set when an allocation must allocate the total requested amount, or else fail with nothing allocated; when this bit is not set, the allocation may complete successfully but allocate less than requested.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSAllocContiguousMask`
This bit is set when an allocation should allocate one contiguous range of space on the volume. If this bit is clear, multiple discontiguous extents may be allocated to fulfill the request.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSAllocNoRoundUpMask`
This bit is set when an allocation should no round up to the clump size. If this bit is clear, then additional space beyond the amount requested may be allocated; this is done by some volume formats (including HFS and HFS Plus) to avoid many small allocation requests. If the bit is set, no additional allocation is done (except where required by the volume format, such as rounding up to a multiple of the allocation block size).

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSAllocReservedMask`
Reserved; set to zero.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
If the `kFSAllocContiguousMask` bit is set, then then any newly allocated space must be in one contiguous extent (preferably contiguous with any space already allocated). If `kFSAllocAllOrNothingMask` is set, then the entire `requestCount` bytes must be allocated for the call to succeed; if not set, as many bytes as possible will be allocated (without error). If `kFSAllocNoRoundUpMask` is set, then no additional space is allocated (such as rounding up to a multiple of a clump size); if clear, the volume format may allocate more space than requested as an attempt to reduce fragmentation.

AppleShare Volume Signature

Defines the volume signature for AppleShare volumes.

```
enum {
    AppleShareMediaType = 'afpm'
};
```

Authentication Method Constants

Define the login methods for remote volumes.

```
enum {
    kNoUserAuthentication = 1,
    kPassword = 2,
    kEncryptPassword = 3,
    kTwoWayEncryptPassword = 6
};
```

Constants
`kNoUserAuthentication`
No password.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kPassword`
8-byte password.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kEncryptPassword`
Encrypted 8-byte password.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kTwoWayEncryptPassword`
Two-way random encryption.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `uamType` field of an `AFPVolMountInfo` (page 797) structure and in the `ioObjType` field of the parameter block passed to the `PBHGetLogInInfoSync` and `PBHGetLogInInfoAsync` functions to specify the type of user authentication used by a remote volume.

Cache Constants

Indicate whether or not data should be cached.

```
enum {
    pleaseCacheBit = 4,
    pleaseCacheMask = 0x0010,
    noCacheBit = 5,
    noCacheMask = 0x0020,
    rdVerifyBit = 6,
    rdVerifyMask = 0x0040,
    rdVerify = 64,
    forceReadBit = 6,
    forceReadMask = 0x0040,
    newLineBit = 7,
    newLineMask = 0x0080,
    newLineCharMask = 0xFF00
};
```

Constants

`pleaseCacheBit`
Indicates that the data should be cached.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`pleaseCacheMask`
Requests that the data be cached, if possible. You should cache reads and writes if you read or write the same portion of a file multiple times.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`noCacheBit`
Indicates that data should not be cached.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`noCacheMask`
Requests that the data not be cached, if possible. You should not cache reads and writes if you read or write data from a file only once.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`rdVerifyBit`
Indicates that all reads should come from the source and be verified against the data in memory.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`rdVerifyMask`
Requests that all reads (not writes) come directly from the source and be verified against the data in memory. This flushes the cache and sends all read requests to the data source.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`rdVerify`
This is the old name of `rdVerifyMask`. Both request that all reads come directly from the source of the data and be compared against the data in memory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`forceReadBit`
Indicates that reads should come from the disk.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`forceReadMask`
Forces reads from disk, bypassing all caches. Clients can use this to verify that data is stored correctly on the media (for example, to verify after writing) by reading the data into a different buffer while setting the bit, and then comparing the newly read data with the previously written data.

The `forceReadMask` is the same as the `rdVerifyMask` used in the older APIs. The actual implementation of the `rdVerifyMask` in the older APIs actually caused the "force read" behavior, and only compared the data in partial sectors. `FSReadFork` cleans up this behavior by always letting the client do all of the compares.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`newLineBit`
Indicates that newline mode should be used for reads.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`newLineMask`
Requests that newline mode be used for reads. In newline mode, the read stops when one of the following conditions is met:

- The requested number of bytes have been read.
- The end-of-file is reached.
- The newline character has been read. If the newline character is found, it will be the last character put into the buffer and the number of bytes read will include it.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`newLineCharMask`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
For the `FSReadFork` and `FSWriteFork` functions, and their parameter block equivalents, you may add either of the `pleaseCacheMask` or `noCacheMask` constants to one of the "Position Mode Constants" (page 928) to hint whether the data should be cached or not.

The `pleaseCacheBit` and the `noCacheBit` are mutually exclusive and only one should be set at a time. If neither bit is set, the program has indicated that it doesn't care if the data is cached or not.

Catalog Information Bitmap Constants

Specify what file or fork information to get or set.

```
enum {
    kFSCatInfoNone = 0x00000000,
    kFSCatInfoTextEncoding = 0x00000001,
    kFSCatInfoNodeFlags = 0x00000002,
    kFSCatInfoVolume = 0x00000004,
    kFSCatInfoParentDirID = 0x00000008,
    kFSCatInfoNodeID = 0x00000010,
    kFSCatInfoCreateDate = 0x00000020,
    kFSCatInfoContentMod = 0x00000040,
    kFSCatInfoAttrMod = 0x00000080,
    kFSCatInfoAccessDate = 0x00000100,
    kFSCatInfoBackupDate = 0x00000200,
    kFSCatInfoPermissions = 0x00000400,
    kFSCatInfoFinderInfo = 0x00000800,
    kFSCatInfoFinderXInfo = 0x00001000,
    kFSCatInfoValence = 0x00002000,
    kFSCatInfoDataSizes = 0x00004000,
    kFSCatInfoRsrcSizes = 0x00008000,
    kFSCatInfoSharingFlags = 0x00010000,
    kFSCatInfoUserPrivs = 0x00020000,
    kFSCatInfoUserAccess = 0x00080000,
    kFSCatInfoSetOwnership = 0x00100000,
    kFSCatInfoAllDates = 0x000003E0,
    kFSCatInfoGettableInfo = 0x0003FFFF,
    kFSCatInfoSettableInfo = 0x00001FE3,
    kFSCatInfoReserved = 0xFFFC0000
};
```

Constants

`kFSCatInfoNone`

No catalog information.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoTextEncoding`

Retrieve or set the text encoding hint, in the `textEncodingHint` field.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoNodeFlags`

Retrieve or set the catalog node flags. Currently, you can only set bits 0 and 4. See "Catalog Information Node Flags" (page 894) for more information on these flags.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoVolume`
Retrieve the volume reference number of the volume on which the file or directory resides.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoParentDirID`
Retrieve the parent directory ID.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoNodeID`
Retrieve the file or directory ID.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoCreateDate`
Retrieve or set the creation date.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoContentMod`
Retrieve or set the date that the resource or data fork was last modified.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoAttrMod`
Retrieve or set the date that an attribute or named fork was last modified.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoAccessDate`
Retrieve or set the date that the fork or file was last accessed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoBackupDate`
Retrieve or set the date that the fork or file was last backed up.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoPermissions`
Retrieve or set the file or fork's permissions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoFinderInfo`
Retrieve or set the file or fork's Finder information.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSCatInfoFinderXInfo`
Retrieve or set the file or fork's extended Finder information.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoValence`
For folders only, retrieve the valence of the folder. For files, this is zero.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoDataSizes`
Retrieve the logical and physical size of the data fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoRsrcSizes`
Retrieve the logical and physical size of the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoSharingFlags`
Retrieve the fork or file's sharing flags: `kioFlAttribMountedBit`, `kioFlAttribSharePointBit`. See "File Attribute Constants" (page 914) for more information on these bits.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoUserPrivs`
Retrieve the file's user privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoUserAccess`
Available in Mac OS X v10.1 and later.

Declared in `Files.h`.

`kFSCatInfoSetOwnership`
Attempt to set the file's user and group (UID and GID). If the File Manager cannot set the the user or group ID, the call fails. (Mac OS X only).

Available in Mac OS X v10.3 and later.

Declared in `Files.h`.

`kFSCatInfoAllDates`
Retrieve or set all of the date information for the fork or file: creation date, modification dates, access date, backup date, etc.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoGettableInfo`
Retrieve all gettable data.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoSettableInfo`
Set all settable data. This includes the flags, dates, permissions, Finder info, and text encoding hint.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSCatInfoReserved`
Represents bits that are currently reserved.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `FSCatalogInfoBitmap` type to specify what file or fork information to get or set. If used with the `FSGetCatalogInfo` or `FSGetCatalogInfoBulk` functions, these constants tell the File Manager which fields to return information in. If used with the `FSSetCatalogInfo` function, these constants tell the File Manager which fields you've filled out with values that it should use to change the fork or file's catalog information.

Catalog Information Node Flags

Define the values used in the `nodeFlags` field of the `FSCatalogInfo` structure.

```
enum {
    kFSNodeLockedBit = 0,
    kFSNodeLockedMask = 0x0001,
    kFSNodeResOpenBit = 2,
    kFSNodeResOpenMask = 0x0004,
    kFSNodeDataOpenBit = 3,
    kFSNodeDataOpenMask = 0x0008,
    kFSNodeIsDirectoryBit = 4,
    kFSNodeIsDirectoryMask = 0x0010,
    kFSNodeCopyProtectBit = 6,
    kFSNodeCopyProtectMask = 0x0040,
    kFSNodeForkOpenBit = 7,
    kFSNodeForkOpenMask = 0x0080,
    kFSNodeHardLinkBit = 8,
    kFSNodeHardLinkMask = 0x00000100
};
```

Constants
`kFSNodeLockedBit`
Set if the file or directory is locked.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSNodeLockedMask`
Indicates that the file or directory is locked.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSNodeResOpenBit`
Set if the resource fork is open.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSNodeResOpenMask`
Indicates that the resource fork is open.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeDataOpenBit`
Set if the data fork is open.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeDataOpenMask`
Indicates that the data fork is open.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsDirectoryBit`
Set if the object is a directory.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsDirectoryMask`
Indicates that the object is a directory.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeCopyProtectBit`
Set of the file or directory is copy protected.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeCopyProtectMask`
Indicates that the file or directory is copy protected.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeForkOpenBit`
Set if the file or directory has any open fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeForkOpenMask`
Indicates that the file or directory has an open fork of any type.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeHardLinkBit`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kFSNodeHardLinkMask`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

Catalog Information Sharing Flags

Indicate the status of a shared directory.

```
enum {
    kFSNodeInSharedBit = 2,
    kFSNodeInSharedMask = 0x0004,
    kFSNodeIsMountedBit = 3,
    kFSNodeIsMountedMask = 0x0008,
    kFSNodeIsSharePointBit = 5,
    kFSNodeIsSharePointMask = 0x0020
};
```

Constants

`kFSNodeInSharedBit`
Set if a directory is within a share point.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeInSharedMask`
Indicates that the directory is within a share point.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsMountedBit`
Set if a directory is a share point currently mounted by some user.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsMountedMask`
Indicates that the directory is a share point currently mounted by some user.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsSharePointBit`
Set if a directory is a share point (an exported volume).
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSNodeIsSharePointMask`
Indicates that the directory is a share point (an exported volume).
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion

The `FSCatalogInfo` (page 826) structure uses these constants in its `sharingFlags` field.

Catalog Search Bits

Indicate the criteria for a catalog search.

```
enum {
    fsSBPartialNameBit = 0,
    fsSBFullNameBit = 1,
    fsSBFlAttribBit = 2,
    fsSBFlFndrInfoBit = 3,
    fsSBFlLgLenBit = 5,
    fsSBFlPyLenBit = 6,
    fsSBFlRLgLenBit = 7,
    fsSBFlRPyLenBit = 8,
    fsSBFlCrDatBit = 9,
    fsSBFlMdDatBit = 10,
    fsSBFlBkDatBit = 11,
    fsSBFlXFndrInfoBit = 12,
    fsSBFlParIDBit = 13,
    fsSBNegateBit = 14,
    fsSBDrUsrWdsBit = 3,
    fsSBDrNmFlsBit = 4,
    fsSBDrCrDatBit = 9,
    fsSBDrMdDatBit = 10,
    fsSBDrBkDatBit = 11,
    fsSBDrFndrInfoBit = 12,
    fsSBDrParIDBit = 13
};
```

Constants

`fsSBPartialNameBit`
Indicates a search by a substring of the name.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFullNameBit`
Indicates a search by the full name.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlAttribBit`
Indicates a search by the file or directory attributes.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlFndrInfoBit`
For files only indicates a search by the file's Finder info.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlLgLenBit`
For files only; indicates a search by the logical length of the data fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlPyLenBit`
For files only; indicates a search by the physical length of the data fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlRLgLenBit`
For files only; indicates a search for the logical length of the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlRPyLenBit`
For files only; indicates a search by the physical length of the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlCrDatBit`
For files only indicates a search by the file's creation date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlMdDatBit`
For files only indicates a search by the date of the file's last modification.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlBkDatBit`
For files only indicates a search by the date of the file's last backup.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlXFndrInfoBit`
For files only indicates a search by the file's extended Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlParIDBit`
For files only indicates a search by the file's parent ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBNegateBit`
Indicates a search for all non-matches. That is, if a file or directory matches one of the other specified criteria, it is not returned; if it does not match any of the specified criteria, it is returned.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrUsrWdsBit`
For directories only indicates a search by the directory's Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrNmFlsBit`
For directories only; indicates a search by the number of files in the directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrCrDatBit`
For directories only indicates a search by the directory's creation date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrMdDatBit`
For directories only indicates a search by the date of the directory's last modification.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrBkDatBit`
For directories only indicates a search by the date of the directory's last backup.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrFndrInfoBit`
For directories only indicates a search by the directory's additional Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrParIDBit`
For directories only indicates a search by the directory's parent ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Catalog Search Constants

Specify the which catalog information fields to use as search criteria.

```
enum {
    fsSBNodeID = 0x00008000,
    fsSBAttributeModDate = 0x00010000,
    fsSBAccessDate = 0x00020000,
    fsSBPermissions = 0x00040000,
    fsSBNodeIDBit = 15,
    fsSBAttributeModDateBit = 16,
    fsSBAccessDateBit = 17,
    fsSBPermissionsBit = 18
};
```

Constants

`fsSBNodeID`
Search by a range of catalog node ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBAttributeModDate`
Search by a range of attribute (fork) modification date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBAccessDate`
Search by a range of access date.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBPermissions`
Search by a value or mask of permissions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBNodeIDBit`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBAttributeModDateBit`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBAccessDateBit`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBPermissionsBit`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Catalog Search Masks

Specify the criteria for a catalog search.

```
enum {
    fsSBPartialName = 1,
    fsSBFullName = 2,
    fsSBFlAttrib = 4,
    fsSBFlFndrInfo = 8,
    fsSBFlLgLen = 32,
    fsSBFlPyLen = 64,
    fsSBFlRLgLen = 128,
    fsSBFlRPyLen = 256,
    fsSBFlCrDat = 512,
    fsSBFlMdDat = 1024,
    fsSBFlBkDat = 2048,
    fsSBFlXFndrInfo = 4096,
    fsSBFlParID = 8192,
    fsSBNegate = 16384,
    fsSBDrUsrWds = 8,
    fsSBDrNmFls = 16,
    fsSBDrCrDat = 512,
    fsSBDrMdDat = 1024,
    fsSBDrBkDat = 2048,
    fsSBDrFndrInfo = 4096,
    fsSBDrParID = 8192
};
```

Constants

`fsSBPartialName`
Search by a substring of the name.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFullName`
Search by the full name.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlAttrib`
Search by the file or directory attributes. You can use the attributes to specify that you are searching for a directory, or for a file or directory that is locked by software.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlFndrInfo`
For files only search by the file's Finder info.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlLgLen`
For files only; search by the logical length of the data fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlPyLen`
For files only; search by the physical length of the data fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`fsSBFlRLgLen`
For files only; search for the logical length of the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlRPyLen`
For files only; search by the physical length of the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlCrDat`
For files only search by the file's creation date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlMdDat`
For files only search by the date of the file's last modification.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlBkDat`
For files only search by the date of the file's last backup.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlXFndrInfo`
For files only search by the file's extended Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBFlParID`
For files only search by the file's parent ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBNegate`
Search for all non-matches. That is, if a file or directory matches one of the other specified criteria, it is not returned; if it does not match any of the specified criteria, it is returned.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrUsrWds`
For directories only search by the directory's Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrNmFls`
For directories only; search by the number of files in the directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrCrDat`
For directories only search by the directory's creation date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrMdDat`
For directories only search by the date of the directory's last modification.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrBkDat`
For directories only search by the date of the directory's last backup.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrFndrInfo`
For directories only search by the directory's additional Finder info.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsSBDrParID`
For directories only search by the directory's parent ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
Use these constants in the `ioSearchBits` field of the `PBCatSearchSync` and `PBCatSearchAsync` functions to specify the criteria for your search.

Extended AFP Volume Mounting Information Flag

Specifies a flag used in the `extendedFlags` field of the `AFPXVolMountInfo` structure.

```
enum {
    kAFPExtendedFlagsAlternateAddressMask = 1
};
```

Constants
`kAFPExtendedFlagsAlternateAddressMask`
Indicates that the `alternateAddressOffset` field in the `AFPXVolMountInfo` record is used.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
See the `AFPXVolMountInfo` (page 799) structure for more information.

Extended Volume Attributes

Describe a volume's extended attributes.

```
enum {
    bIsEjectable = 0,
    bSupportsHFSPlusAPIs = 1,
    bSupportsFSCatalogSearch = 2,
    bSupportsFSExchangeObjects = 3,
    bSupports2TBFiles = 4,
    bSupportsLongNames = 5,
    bSupportsMultiScriptNames = 6,
    bSupportsNamedForks = 7,
    bSupportsSubtreeIterators = 8,
    bL2PCanMapFileBlocks = 9
    bParentModDateChanges = 10,
    bAncestorModDateChanges = 11
    bSupportsSymbolicLinks = 13,
    bIsAutoMounted = 14,
    bAllowCDiDataHandler = 17,
    bSupportsExclusiveLocks = 18
    bSupportsJournaling = 19,
    bNoVolumeSizes = 20,
    bIsCaseSensitive = 22,
    bIsCasePreserving = 23,
    bDoNotDisplay = 24
};
```

Constants

`bIsEjectable`
The volume is in an ejectable disk drive .

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsHFSPlusAPIs`
The volume supports the HFS Plus APIs directly, i.e., the File Manager does not emulate them.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsFSCatalogSearch`
The volume supports the `FSCatalogSearch` (page 472) operation.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsFSExchangeObjects`
The volume supports the `FSExchangeObjects` (page 486) function.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupports2TBFiles`
The volume supports 2 terabyte files.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsLongNames`
The volume supports file, directory, and volume names longer than 31 characters.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsMultiScriptNames`
The volume supports file, directory, and volume names with characters from multiple script systems.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsNamedForks`
The volume supports named forks other than the data and resource forks.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsSubtreeIterators`
The volume supports recursive iterators, not at the volume root.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bL2PCanMapFileBlocks`
The volume supports the `Lg2Phys` SPI correctly.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bParentModDateChanges`
On this volume, changing a file or folder causes its parent's modification date to change.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bAncestorModDateChanges`
On this volume, changing a file or folder causes all ancestor modification dates to change.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bSupportsSymbolicLinks`
The volume supports the creation and use of symbolic links (Mac OS X only).

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bIsAutoMounted`
The volume was mounted automatically (Mac OS X only).

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bAllowCDiDataHandler`
QuickTime's CDi data handler is allowed to examine the volume.

Available in Mac OS X v10.1 and later.

Declared in `Files.h`.

`bSupportsExclusiveLocks`
The volume supports exclusive access to files opened for writing.

Available in Mac OS X v10.2 and later.

Declared in `Files.h`.

`bSupportsJournaling`
: The volume supports journaling. This does not indicate whether journaling is currently enabled on the volume.

  Available in Mac OS X v10.3 and later.

  Declared in `Files.h`.

`bNoVolumeSizes`
: The volume is unable to report volume size or free space.

  Available in Mac OS X v10.3 and later.

  Declared in `Files.h`.

`bIsCaseSensitive`
: The volume is case-sensitive.

  Available in Mac OS X v10.3 and later.

  Declared in `Files.h`.

`bIsCasePreserving`
: The volume is preserves case.

  Available in Mac OS X v10.3 and later.

  Declared in `Files.h`.

`bDoNotDisplay`
: The volume should not be displayed in the user interface.

  Available in Mac OS X v10.3 and later.

  Declared in `Files.h`.

Discussion
The `GetVolParmsInfoBuffer` (page 847) structure uses these constants in its `vMExtendedAttributes` field.

FCB Flags

Specify flags that describe the state of a file.

```
enum {
    kioFCBWriteBit = 8,
    kioFCBWriteMask = 0x0100,
    kioFCBResourceBit = 9,
    kioFCBResourceMask = 0x0200,
    kioFCBWriteLockedBit = 10,
    kioFCBWriteLockedMask = 0x0400,
    kioFCBLargeFileBit = 11,
    kioFCBLargeFileMask = 0x0800,
    kioFCBSharedWriteBit = 12,
    kioFCBSharedWriteMask = 0x1000,
    kioFCBFileLockedBit = 13,
    kioFCBFileLockedMask = 0x2000,
    kioFCBOwnClumpBit = 14,
    kioFCBOwnClumpMask = 0x4000,
    kioFCBModifiedBit = 15,
    kioFCBModifiedMask = 0x8000
};
```

Constants

`kioFCBWriteBit`
Set if data can be written to this file.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBWriteMask`
Tests if data can be written to this file.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBResourceBit`
Set if this FCB describes a resource fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBResourceMask`
Tests if this FCB describes a resource fork.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBWriteLockedBit`
Set if this file has a locked byte range.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBWriteLockedMask`
Tests if this file has a locked byte range.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBLargeFileBit`
Set if this file may grow beyond 2GB and the cache uses file blocks, not bytes.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBLargeFileMask`
Tests if this file may grow beyond 2GB and the cache uses file blocks, not bytes.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBSharedWriteBit`
Set if this file has shared write permissions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBSharedWriteMask`
Tests if this file has shared write permissions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBFileLockedBit`
Set if this file is locked (write-protected).
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBFileLockedMask`
Tests if this file is locked (write-protected).
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBOwnClumpBit`
Set if this file's clump size is specified in the FCB.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBOwnClumpMask`
Tests if this file's clump size is specified in the FCB.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBModifiedBit`
Set if this file has changed since it was last flushed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioFCBModifiedMask`
Tests if this file has changed since it was last flushed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion
These constants are used in the `ioFCBFlags` field of the `FCBPBRec` (page 816) returned by the functions `PBGetFCBInfoSync` and `PBGetFCBInfoAsync`.

File Access Permission Constants

Specify the type of read and write access to a file or fork.

```
enum {
    fsCurPerm = 0x00,
    fsRdPerm = 0x01,
    fsWrPerm = 0x02,
    fsRdWrPerm = 0x03,
    fsRdWrShPerm = 0x04,
    fsRdDenyPerm = 0x10,
    fsWrDenyPerm = 0x20
};
```

Constants

`fsCurPerm`

Requests whatever permissions are currently allowed. If write access in unavailable (because the file is locked or the file is already open with write permission), then read permission is granted. Otherwise read/write permission is granted.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsRdPerm`

Requests permission to read the file.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsWrPerm`

Requests permission to write to the file. If write permission is granted, no other access paths are granted write permission. Note, however, that the File Manager does not support write-only access to a file. Thus, `fsWrPerm` is synonymous with `fsRdWrPerm`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsRdWrPerm`

Requests exclusive read and write permission. If exclusive read/ write permission is granted, no other users are granted permission to write to the file. Other users may, however, be granted permission to read the file.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsRdWrShPerm`

Requests shared read and write permission. Shared read and write permission allows multiple access paths for reading and writing. This is safe only if there is some way of locking portions of the file before writing to them. On volumes that support range locking, you can use the functions `PBLockRangeSync` and `PBUnlockRangeSync` to lock and unlock ranges of bytes within a file. Applications running in Mac OS X version 10.4 or later should use the functions `FSLockRange` and `FSUnlockRange` for this purpose.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsRdDenyPerm`

Requests that any other paths be prevented from having read access. A path cannot be opened if you request read permission (with the `fsRdPerm` constant) but some other path has requested deny-read access. Similarly, the path cannot be opened if you request deny-read permission, but some other path already has read access. This constant is only supported on volumes which return the `bHasOpenDeny` attribute when you call `FSGetVolumeParms`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsWrDenyPerm`

Requests that any other paths be prevented from having write access. A path cannot be opened if you request write permission (with the `fsWrPerm` constant) but some other path has requested deny-write access. Similarly, the path cannot be opened if you request deny-write permission, but some other path already has write access. This constant is only supported on volumes which return the `bHasOpenDeny` attribute when you call `FSGetVolumeParms`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
Use these constants to request a type of access to a file or fork, or to deny a type of access to a file or fork to other paths that may request access.

Note that it is possible, in Mac OS 8 and 9, to open a file residing on read-only media with write access. In Mac OS X, however, you cannot open a file with write access on read-only media; the attempt to open the file fails with a `wrPermErr` error.

File and Folder Access Privilege Constants

Specify access privileges for files and directories in the `ioACAccess` field of the `AccessParam` data type.

```
enum {
    kioACAccessOwnerBit = 31,
    kioACAccessOwnerMask = 0x80000000,
    kioACAccessBlankAccessBit = 28,
    kioACAccessBlankAccessMask = 0x10000000,
    kioACAccessUserWriteBit = 26,
    kioACAccessUserWriteMask = 0x04000000,
    kioACAccessUserReadBit = 25,
    kioACAccessUserReadMask = 0x02000000,
    kioACAccessUserSearchBit = 24,
    kioACAccessUserSearchMask = 0x01000000,
    kioACAccessEveryoneWriteBit = 18,
    kioACAccessEveryoneWriteMask = 0x00040000,
    kioACAccessEveryoneReadBit = 17,
    kioACAccessEveryoneReadMask = 0x00020000,
    kioACAccessEveryoneSearchBit = 16,
    kioACAccessEveryoneSearchMask = 0x00010000,
    kioACAccessGroupWriteBit = 10,
    kioACAccessGroupWriteMask = 0x00000400,
    kioACAccessGroupReadBit = 9,
    kioACAccessGroupReadMask = 0x00000200,
    kioACAccessGroupSearchBit = 8,
    kioACAccessGroupSearchMask = 0x00000100,
    kioACAccessOwnerWriteBit = 2,
    kioACAccessOwnerWriteMask = 0x00000004,
    kioACAccessOwnerReadBit = 1,
    kioACAccessOwnerReadMask = 0x00000002,
    kioACAccessOwnerSearchBit = 0,
    kioACAccessOwnerSearchMask = 0x00000001,
    kfullPrivileges = 0x00070007,
    kownerPrivileges = 0x00000007
};
```

Constants

`kioACAccessOwnerBit`
Indicates that the user is the owner of the directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessOwnerMask`
The user is the owner of the directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessBlankAccessBit`
Indicates that the directory has blank access privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessBlankAccessMask`
The directory has blank access privileges. A directory with blank access privileges set ignores the other access privilege bits and uses the access privilege bits of its parent directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessUserWriteBit`
Indicates that the user has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessUserWriteMask`
The user has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessUserReadBit`
Indicates that the user has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessUserReadMask`
The user has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessUserSearchBit`
Indicates that the user has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessUserSearchMask`
The user has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneWriteBit`
Indicates that everyone has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneWriteMask`
Everyone has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneReadBit`
Indicates that everyone has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneReadMask`
Everyone has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneSearchBit`
Indicates that everyone has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessEveryoneSearchMask`
Everyone has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupWriteBit`
Indicates that the group has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupWriteMask`
The group has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupReadBit`
Indicates that the group has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupReadMask`
The group has read privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupSearchBit`
Indicates that the group has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessGroupSearchMask`
The group has search privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessOwnerWriteBit`
Indicates that the owner has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessOwnerWriteMask`
The owner has write privileges.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kioACAccessOwnerReadBit`
Indicates that the owner has read privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessOwnerReadMask`
The owner has read privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessOwnerSearchBit`
Indicates that the owner has search privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACAccessOwnerSearchMask`
The owner has search privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kfullPrivileges`
Indicates that everyone, including the owner, have all privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kownerPrivileges`
Indicates that only the owner has all privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
See `AccessParam` (page 795).

File Attribute Constants

Define file and directory attributes returned by the `PBGetCatInfoSync` and `PBGetCatInfoAsync` functions.

```
enum {
    kioFlAttribLockedBit = 0,
    kioFlAttribLockedMask = 0x01,
    kioFlAttribResOpenBit = 2,
    kioFlAttribResOpenMask = 0x04,
    kioFlAttribDataOpenBit = 3,
    kioFlAttribDataOpenMask = 0x08,
    kioFlAttribDirBit = 4,
    kioFlAttribDirMask = 0x10,
    ioDirFlg = 4,
    ioDirMask = 0x10,
    kioFlAttribCopyProtBit = 6,
    kioFlAttribCopyProtMask = 0x40,
    kioFlAttribFileOpenBit = 7,
    kioFlAttribFileOpenMask = 0x80,
    kioFlAttribInSharedBit = 2,
    kioFlAttribInSharedMask = 0x04,
    kioFlAttribMountedBit = 3,
    kioFlAttribMountedMask = 0x08,
    kioFlAttribSharePointBit = 5,
    kioFlAttribSharePointMask = 0x20
};
```

Constants

`kioFlAttribLockedBit`
Indicates that the file or directory is locked. Use the functions `PBHSetFLockSync` and `PBHSetFLockAsync` to lock a file or directory. Use the functions `PBHRstFLockSync` and `PBHRstFLockAsync` to unlock a file or directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribLockedMask`
Tests if the file or directory is locked.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribResOpenBit`
Indicates that the resource fork is open. On Mac OS X, this bit is not set if the resource fork of the file has been opened by a process other than the process making the call to `PBHGetCatInfo` or `PBHGetFInfo`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribResOpenMask`
Tests if the resource fork is open.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribDataOpenBit`
Indicates that the data fork is open. On Mac OS X, this bit is not set if the data fork of the file has been opened by a process other than the process making the call to `PBHGetCatInfo` or `PBHGetFInfo`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribDataOpenMask`
Tests if the data fork is open.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribDirBit`
Indicates that this is a directory, not a file. This bit is always clear for files, and is always set for directories.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribDirMask`
Tests if this is a directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`ioDirFlg`
Indicates that this is a directory; this is the old name of the `kioFlAttribDirBit`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`ioDirMask`
Tests if this is a directory; this is the old name of the `kioFlAttribDirMask`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribCopyProtBit`
Indicates that the file is "copy-protected" by the AppleShare server.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribCopyProtMask`
Tests if the file is "copy-protected" by the AppleShare server.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribFileOpenBit`
Indicates that the file is open. This bit is set if either the data or the resource fork are open. On Mac OS X, this bit is not set if the file has been opened by a process other than the process making the call to `PBHGetCatInfo` or `PBHGetFInfo`.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribFileOpenMask`
Tests if the file is open. The file is open if either the data or the resource fork are open.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribInSharedBit`
Indicates that the directory is within a shared area of the directory hierarchy.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribInSharedMask`
Tests if the directory is within a shared area of the directory hierarchy.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribMountedBit`
Indicates that the directory is a share point that is mounted by a user.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribMountedMask`
Tests if the directory is a share point that is mounted by a user.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribSharePointBit`
Indicates that the directory is a share point.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioFlAttribSharePointMask`
Tests if the directory is a share point.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `ioFlAttrib` fields of the `HFileInfo` (page 849) and `DirInfo` (page 810) structures returned by the functions `PBGetCatInfoSync` and `PBGetCatInfoAsync`.

File Operation Options

Flags you can use to specify how to perform a file operation.

```
enum {
    kFSFileOperationDefaultOptions = 0,
    kFSFileOperationOverwrite = 0x01,
    kFSFileOperationSkipSourcePermissionErrors = 0x02,
    kFSFileOperationDoNotMoveAcrossVolumes = 0x04,
    kFSFileOperationSkipPreflight = 0x08
};
```

Constants
`kFSFileOperationDefaultOptions`
Use the following default options:

- If the destination directory contains an object with the same name as a source object, abort the operation.
- If a source object cannot be read, abort the operation.
- If asked to move an object across volume boundaries, perform the operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSFileOperationOverwrite`
If the destination directory contains an object with the same name as a source object, overwrite the destination object.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSFileOperationSkipSourcePermissionErrors`
If a source object cannot be read, skip the object and continue the operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSFileOperationDoNotMoveAcrossVolumes`
If asked to move an object across volume boundaries, abort the operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSFileOperationSkipPreflight`
Skip the preflight stage for a directory move or copy operation. This option limits the status information that can be returned during the operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

Discussion
These flags may be passed to any of the functions that initiate a file operation. For more information, see "Copying and Moving Objects Using Asynchronous High-Level File Operations" (page 443).

File Operation Stages

Constants used by the File Manager to indicate the current stage of an asynchronous file operation.

```
typedef UInt32 FSFileOperationStage;
enum {
    kFSOperationStageUndefined = 0,
    kFSOperationStagePreflighting = 1,
    kFSOperationStageRunning = 2,
    kFSOperationStageComplete = 3
};
```

Constants
`kFSOperationStageUndefined`
The File Manager has not started the file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationStagePreflighting`
The File Manager is performing tasks such as calculating the sizes and number of objects in the operation, and checking to make sure there is enough space on the destination volume to complete the operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationStageRunning`
The File Manager is copying or moving the file or directory.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationStageComplete`
The file operation is complete.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

Discussion
These constants are passed back to your file operation status callback function. For more information, see "File Operation Callbacks" (page 788). You can also get the current stage of a file operation by calling a status accessor function such as `FSFileOperationCopyStatus` (page 487).

File Operation Status Dictionary Keys

Keys used to determine the status of a file operation as reported in a status dictionary.

```
const CFStringRef kFSOperationTotalBytesKey;
const CFStringRef kFSOperationBytesCompleteKey;
const CFStringRef kFSOperationBytesRemainingKey;
const CFStringRef kFSOperationTotalObjectsKey;
const CFStringRef kFSOperationObjectsCompleteKey;
const CFStringRef kFSOperationObjectsRemainingKey;
const CFStringRef kFSOperationTotalUserVisibleObjectsKey;
const CFStringRef kFSOperationUserVisibleObjectsCompleteKey;
const CFStringRef kFSOperationUserVisibleObjectsRemainingKey;
const CFStringRef kFSOperationThroughputKey;
```

Constants
`kFSOperationTotalBytesKey`
The value for this key is a CFNumber that represents the total number of bytes that will be moved or copied by this file operation. This value is not available for a directory operation if the `kFSFileOperationSkipPreflight` (page 918) option flag is specified.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationBytesCompleteKey`
The value for this key is a CFNumber that represents the total number of bytes that have already been moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationBytesRemainingKey`
The value for this key is a CFNumber that represents the total number of bytes that remain to be moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationTotalObjectsKey`
The value for this key is a CFNumber that represents the total number of objects that will be moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationObjectsCompleteKey`
The value for this key is a CFNumber that represents the total number of objects that have already been moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationObjectsRemainingKey`
The value for this key is a CFNumber that represents the total number of objects that remain to be moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationTotalUserVisibleObjectsKey`
The value for this key is a CFNumber that represents the total number of user-visible objects that will be moved or copied by this file operation. In general, an object is user-visible if it is displayed in a Finder window. For example, a package is counted as a single user-visible object even though it typically contains many other objects.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationUserVisibleObjectsCompleteKey`
The value for this key is a CFNumber that represents the total number of user-visible objects that have already been moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationUserVisibleObjectsRemainingKey`
The value for this key is a CFNumber that represents the total number of user-visible objects that remain to be moved or copied by this file operation.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSOperationThroughputKey`
The value for this key is a CFNumber that represents the current throughput of this file operation in bytes per second.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

Discussion
The status dictionary for a file operation is passed back to your status callback function. For more information, see "File Operation Callbacks" (page 788). You can also get the status dictionary for a file operation by calling a status accessor function such as `FSFileOperationCopyStatus` (page 487).

FNMessage

```
typedef UInt32 FNMessage;
enum {
    kFNDirectoryModifiedMessage = 1
};
```

Constants

`kFNDirectoryModifiedMessage`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Foreign Privilege Model Constant

Identifies the A/UX privilege model.

```
enum {
    fsUnixPriv = 1
};
```

Constants

`fsUnixPriv`
Represents a volume that supports the A/UX privilege model.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion

Used in the `vMForeignPrivID` field of the `GetVolParmsInfoBuffer` (page 847).

Group ID Constant

```
enum {
    knoGroup = 0
};
```

Constants

`knoGroup`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Icon Size Constants

Specify the sizes of the desktop database icon types.

```
enum {
    kLargeIconSize = 256,
    kLarge4BitIconSize = 512,
    kLarge8BitIconSize = 1024,
    kSmallIconSize = 64,
    kSmall4BitIconSize = 128,
    kSmall8BitIconSize = 256
};
```

Constants

`kLargeIconSize`
Large black-and-white icon with mask. Corresponding resource type: '`ICN#`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kLarge4BitIconSize`
Large 4-bit color icon. Corresponding resource type: '`icl4`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kLarge8BitIconSize`
Large 8-bit color icon. Corresponding resource type: '`icl8`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kSmallIconSize`
Small black-and-white icon with mask. Corresponding resource type: '`ics#`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kSmall4BitIconSize`
Small 4-bit color icon. Corresponding resource type: '`ics4`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kSmall8BitIconSize`
Small 8-bit color icon. Corresponding resource type: '`ics8`'.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion

These constants indicate the amount of storage you should allocate for the icon data for each of the icon types specified by the "Icon Type Constants" (page 922). The desktop database functions which set or retrieve icon data–namely, `PBDTAddIconSync`, `PBDTAddIconAsync`, `PBDTGetIconSync`, `PBDTGetIconAsync`, `PBDTGetIconInfoSync`, and `PBDTGetIconInfoAsync` –expect a pointer to the the storage in the `ioDTBuffer` field of the `DTPBRec` (page 813) parameter block and the appropriate constant in the `ioDTReqCount` field.

Icon Type Constants

Specify the icon types for the desktop database.

```
enum {
    kLargeIcon = 1,
    kLarge4BitIcon = 2,
    kLarge8BitIcon = 3,
    kSmallIcon = 4,
    kSmall4BitIcon = 5,
    kSmall8BitIcon = 6,
    kicnsIconFamily = 239
};
```

Constants

`kLargeIcon`
Large black-and-white icon with mask. Corresponding resource type: '`ICN#`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kLarge4BitIcon`
Large 4-bit color icon. Corresponding resource type: '`icl4`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kLarge8BitIcon`
Large 8-bit color icon. Corresponding resource type: '`icl8`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kSmallIcon`
Small black-and-white icon with mask. Corresponding resource type: '`ics#`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kSmall4BitIcon`
Small 4-bit color icon. Corresponding resource type: '`ics4`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kSmall8BitIcon`
Small 8-bit color icon. Corresponding resource type: '`ics8`'.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

`kicnsIconFamily`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Files.h`.

Discussion
These constants are used in the `ioIconType` field of the `DTPBRec` (page 813) parameter block.

Invalid Volume Reference Constant

Represents an invalid volume reference number.

```
enum {
    kFSInvalidVolumeRefNum = 0
};
```

Constants
`kFSInvalidVolumeRefNum`
Invalid volume reference number.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Iterator Flags

Indicate whether an iterator iterates over subtrees or just the immediate children of the container.

```
enum {
    kFSIterateFlat = 0,
    kFSIterateSubtree = 1,
    kFSIterateDelete = 2,
    kFSIterateReserved = 0xFFFFFFFC
};
typedef OptionBits FSIteratorFlags;
```

Constants
`kFSIterateFlat`
Iterate over the immediate children of the container only.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSIterateSubtree`
Iterate over the entire subtree rooted at the container.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSIterateDelete`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kFSIterateReserved`
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

kAsyncMountInProgress

```
enum {
    kAsyncMountInProgress = 1,
    kAsyncMountComplete = 2,
    kAsyncUnmountInProgress = 3,
    kAsyncUnmountComplete = 4,
    kAsyncEjectInProgress = 5,
    kAsyncEjectComplete = 6
};
```

Constants

`kAsyncMountInProgress`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kAsyncMountComplete`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kAsyncUnmountInProgress`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kAsyncUnmountComplete`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kAsyncEjectInProgress`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

`kAsyncEjectComplete`
Available in Mac OS X v10.2 and later.
Declared in `Files.h`.

Notification Subscription Options

Options that can be specified at subscription time.

```
enum {
    kFNNoImplicitAllSubscription = (1 << 0),
    kFNNotifyInBackground = (1 << 1)
};
```

Constants

`kFNNoImplicitAllSubscription`
Specify this option if you do not want to receive notifications on this subscription when `FNNotifyAll` is called. By default, any subscription is also implicitly a subscription to wildcard notifications.
Available in Mac OS X v10.1 and later.
Declared in `Files.h`.

`kFNNotifyInBackground`
Specify this option if you want to receive notifications on this subscription when your application is in background. By default, notifications will be coalesced and and delivered when your application becomes foreground.

Available in Mac OS X v10.3 and later.

Declared in `Files.h`.

kHFSCatalogNodeIDsReusedBit

```
enum {
    kHFSCatalogNodeIDsReusedBit = 12,
    kHFSCatalogNodeIDsReusedMask = 1 << kHFSCatalogNodeIDsReusedBit
};
```

Constants

`kHFSCatalogNodeIDsReusedBit`
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `HFSVolumes.h`.

`kHFSCatalogNodeIDsReusedMask`
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `HFSVolumes.h`.

Large Volume Constants

```
enum {
    kWidePosOffsetBit = 8,
    kUseWidePositioning = (1 << kWidePosOffsetBit),
    kMaximumBlocksIn4GB = 0x007FFFFF
};
```

Constants

`kWidePosOffsetBit`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kUseWidePositioning`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kMaximumBlocksIn4GB`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Mapping Code Constants

Specify the type of object to map or return.

```
enum {
    kOwnerID2Name = 1,
    kGroupID2Name = 2,
    kOwnerName2ID = 3,
    kGroupName2ID = 4,
    kReturnNextUser = 1,
    kReturnNextGroup = 2,
    kReturnNextUG = 3
};
```

Constants

`kOwnerID2Name`
Map a user ID to the user name. Used with the `PBHMapIDSync` or `PBHMapIDAsync` functions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kGroupID2Name`
Map a group ID to the group name. Used with the `PBHMapIDSync` or `PBHMapIDAsync` functions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kOwnerName2ID`
Map a user name to the user ID. Used with the `PBHMapNameSync` or `PBHMapNameAsync` functions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kGroupName2ID`
Map a group name to the group ID. Used with the `PBHMapNameSync` or `PBHMapNameAsync` functions.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kReturnNextUser`
Return the next user entry.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kReturnNextGroup`
Return the next group entry.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kReturnNextUG`
Return the next user or group entry.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion

These constants are used in the `ioObjType` field of the `ObjParam` (page 865) parameter block. The first four constants are passed to the `PBHMapIDSync`, `PBHMapIDAsync`, `PBHMapNameSync`, and `PBHMapNameAsync` functions to specify the mapping to be performed. The last three constants are passed to the `PBGetUGEntrySync` or `PBGetUGEntryAsync` functions to specify the type of object to be returned.

Path Conversion Options

Specify how a pathname is converted to an `FSRef` structure by the function `FSPathMakeRefWithOptions` (page 520).

```
enum {
    kFSPathMakeRefDefaultOptions = 0,
    kFSPathMakeRefDoNotFollowLeafSymlink = 0x01
};
```

Constants

`kFSPathMakeRefDefaultOptions`

Use the default options.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

`kFSPathMakeRefDoNotFollowLeafSymlink`

When converting a path that refers to a symbolic link, do not follow the link. The new `FSRef` should refer to the link itself.

Available in Mac OS X v10.4 and later.

Declared in `Files.h`.

Position Mode Constants

Together with an offset, specify a position within a fork.

```
enum {
    fsAtMark = 0,
    fsFromStart = 1,
    fsFromLEOF = 2,
    fsFromMark = 3
};
```

Constants

`fsAtMark`

The starting point is the access path's current position. The offset is ignored.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsFromStart`

The starting point is offset bytes from the start of the fork. The offset must be non-negative.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsFromLEOF`

The starting point is offset bytes from the logical end of the fork. The offset must not be positive.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsFromMark`
The starting point is offset bytes from the access path's current position. The offset may be positive or negative.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `ioPosMode` and `positionMode` fields and parameters of the HFS and HFS Plus file access functions. These functions include those for reading from and writing to files or forks, changing the current position within a file or fork, changing the size of a file or fork, and allocating space to a file or fork.

For the `FSReadFork` and `FSWriteFork` calls, you may also add either of the `pleaseCacheMask` or `noCacheMask` constants to hint whether the data should be cached or not. See "Cache Constants" (page 889).

Root Directory Constants

Specify the directory IDs of the root directory of a volume and its parent.

```
enum {
    fsRtParID = 1,
    fsRtDirID = 2
};
```

Constants
`fsRtParID`
Represents the directory ID of the root directory's parent directory. The root directory has no parent this constant is used when specifying the root directory to functions which require the parent directory ID to identify directories.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`fsRtDirID`
Represents the directory ID of the volume's root directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

User ID Constants

Specify basic user IDs for shared directories.

```
enum {
    knoUser = 0,
    kadministratorUser = 1
};
```

Constants
`knoUser`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kadministratorUser`
Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

User Privileges Constants

Specify the user privileges for a directory on a remote volume.

```
enum {
    kioACUserNoSeeFolderBit = 0,
    kioACUserNoSeeFolderMask = 0x01,
    kioACUserNoSeeFilesBit = 1,
    kioACUserNoSeeFilesMask = 0x02,
    kioACUserNoMakeChangesBit = 2,
    kioACUserNoMakeChangesMask = 0x04,
    kioACUserNotOwnerBit = 7,
    kioACUserNotOwnerMask = 0x80
};
```

Constants

`kioACUserNoSeeFolderBit`
Set if the user does not have "See Folders" privileges. Without "See Folders" privileges, the user cannot see other directories in the specified directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNoSeeFolderMask`
Tests if the user has "See Folders" privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNoSeeFilesBit`
Set if the user does not have "See Files" privileges. Without "See Files" privileges, the user cannot open documents or applications in the specified directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNoSeeFilesMask`
Tests if the user has "See Files" privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNoMakeChangesBit`
Set if the user does not have "Make Changes" privileges. Without "Make Changes" privileges, the user cannot create, modify, rename, or delete any file or directory within the specified directory.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNoMakeChangesMask`
Tests if the user has "Make Changes" privileges.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioACUserNotOwnerBit`
: Set if the user is not the owner of the directory.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`kioACUserNotOwnerMask`
: Tests whether the user is the owner of the directory.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

Discussion
These constants are used in the `ioACUser` field of the `HFileInfo` (page 849) and `DirInfo` (page 810) structures returned by the `PBGetCatInfoSync` and `PBGetCatInfoAsync` functions.

Volume Attribute Constants

Bit position constants that specify volume attributes.

```
enum {
    bLimitFCBs = 31,
    bLocalWList = 30,
    bNoMiniFndr = 29,
    bNoVNEdit = 28,
    bNoLclSync = 27,
    bTrshOffLine = 26,
    bNoSwitchTo = 25,
    bNoDeskItems = 20,
    bNoBootBlks = 19,
    bAccessCntl = 18,
    bNoSysDir = 17,
    bHasExtFSVol = 16,
    bHasOpenDeny = 15,
    bHasCopyFile = 14,
    bHasMoveRename = 13,
    bHasDesktopMgr = 12,
    bHasShortName = 11,
    bHasFolderLock = 10,
    bHasPersonalAccessPrivileges = 9,
    bHasUserGroupList = 8,
    bHasCatSearch = 7,
    bHasFileIDs = 6,
    bHasBTreeMgr = 5,
    bHasBlankAccessPrivileges = 4,
    bSupportsAsyncRequests = 3,
    bSupportsTrashVolumeCache = 2
};
enum {
    bHasDirectIO = 1
};
```

Constants

`bLimitFCBs`

The Finder limits the number of file control blocks used during copying to 8 instead of 16.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bLocalWList`

The Finder uses the returned shared volume handle for its local window list.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoMiniFndr`

Reserved; always set to 1.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoVNEdit`

This volume's name cannot be edited.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoLclSync`
Don't let the Finder change the modification date.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bTrshOffLine`
Any time this volume goes offline, it is zoomed to the Trash and unmounted.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoSwitchTo`
The Finder will not switch launch to any application on this volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoDeskItems`
Don't place objects in this volume on the Finder desktop.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoBootBlks`
This volume is not a startup volume. The Startup menu item is disabled. Boot blocks are not copied during copy operations.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bAccessCntl`
This volume supports AppleTalk AFP access-control interfaces. The following functions are supported:

- `PBHGetLogInInfoSync`
- `PBHGetLogInInfoAsync`
- `PBHGetDirAccessSync`
- `PBHGetDirAccessAsync`
- `PBHSetDirAccessSync`
- `PBHSetDirAccessAsync`
- `PBHMapIDSync`
- `PBHMapIDAsync`
- `PBHMapNameSync`
- `PBHMapNameAsync`

Special folder icons are used. The Access Privileges menu command is enabled for disk and folder items. The `ioFlAttrib` field of the parameter block passed to the `PBGetCatInfoSync` and `PBGetCatInfoSync` functions is assumed to be valid.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bNoSysDir`
This volume doesn't support a system directory. Do not switch launch to this volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasExtFSVol`
This volume is an external file system volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasOpenDeny`
This volume supports the `PBHOpenDenySync` , `PBHOpenDenyAsync`, `PBHOpenRFDenySync` and `PBHOpenRFDenyAsync` functions.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasCopyFile`
This volume supports the `PBHCopyFileSync` and `PBHCopyFileAsync` functions, which is used in copy and duplicate operations if both source and destination volumes have the same server address.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasMoveRename`
This volume supports the `PBHMoveRenameSync` and `PBHMoveRenameAsync` functions.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasDesktopMgr`
This volume supports all of the desktop functions.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasShortName`
This volume supports AFP short names.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasFolderLock`
Folders on the volume can be locked, and so they cannot be deleted or renamed.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasPersonalAccessPrivileges`
This volume has local file sharing enabled.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasUserGroupList`
This volume supports the Users and Groups file and thus the AFP privilege functions.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`bHasCatSearch`
: This volume supports the `PBCatSearchSync` and `PBCatSearchAsync` functions.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`bHasFileIDs`
: This volume supports the file ID functions, including the `PBExchangeFilesSync` and `PBExchangeFilesAsync` functions.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`bHasBTreeMgr`
: Reserved for internal use.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`bHasBlankAccessPrivileges`
: This volume supports inherited access privileges for folders (blank access privileges).

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`bSupportsAsyncRequests`
: This volume correctly handles asynchronous requests at any time.

  Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

`bSupportsTrashVolumeCache`
: Available in Mac OS X v10.0 and later.

  Declared in `Files.h`.

Discussion
These constants correspond to bit positions in the `vMAttrib` field of the `GetVolParmsInfoBuffer` (page 847) structure returned by the `PBHGetVolParmsSync` (page 695) and `PBHGetVolParmsAsync` (page 694) functions.

Volume Control Block Flags

Used in the `vcbFlags` field of a volume control block to specify information about a volume.

```
enum {
    kVCBFlagsIdleFlushBit = 3,
    kVCBFlagsIdleFlushMask = 0x0008,
    kVCBFlagsHFSPlusAPIsBit = 4,
    kVCBFlagsHFSPlusAPIsMask = 0x0010,
    kVCBFlagsHardwareGoneBit = 5,
    kVCBFlagsHardwareGoneMask = 0x0020,
    kVCBFlagsVolumeDirtyBit = 15,
    kVCBFlagsVolumeDirtyMask = 0x8000
};
```

Constants

`kVCBFlagsIdleFlushBit`
Indicates that the volume should be flushed at idle time.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsIdleFlushMask`
Flushes the volume at idle time.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsHFSPlusAPIsBit`
Indicates that the volume directly implements the HFS Plus APIs (rather than emulating them).
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsHFSPlusAPIsMask`
The volume directly implements the HFS Plus APIs.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsHardwareGoneBit`
Indicates that the disk driver returned a `hardwareGoneErr` in response to a read or write call.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsHardwareGoneMask`
Tests if the disk driver returned a `hardwareGoneErr` in response to a read or write call.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsVolumeDirtyBit`
Indicates that the volume information has changed since the last time the volume was flushed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`kVCBFlagsVolumeDirtyMask`
The volume has changed since the last time the volume was flushed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

Discussion

See `VCB` (page 868) for a description of the volume control block.

Volume Information Attribute Constants

Define volume attributes returned by the functions `PBHGetVInfoSync`, `PBHGetVInfoAsync`, `PBXGetVolInfoSync`, and `PBXGetVolInfoAsync`.

```
enum {
    kioVAtrbDefaultVolumeBit = 5,
    kioVAtrbDefaultVolumeMask = 0x0020,
    kioVAtrbFilesOpenBit = 6,
    kioVAtrbFilesOpenMask = 0x0040,
    kioVAtrbHardwareLockedBit = 7,
    kioVAtrbHardwareLockedMask = 0x0080,
    kioVAtrbSoftwareLockedBit = 15,
    kioVAtrbSoftwareLockedMask = 0x8000
};
```

Constants

`kioVAtrbDefaultVolumeBit`
Indicates that the volume is the default volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbDefaultVolumeMask`
Tests if the volume is the default volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbFilesOpenBit`
Indicates that there are open files or iterators.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbFilesOpenMask`
Tests if there are open files or iterators.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbHardwareLockedBit`
Indicates that the volume is locked by a hardware setting. On Mac OS X, the File Manager only sets the software locked bit for CDs and other read-only media; it does not set the hardware locked bit.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbHardwareLockedMask`
Tests if the volume is locked by a hardware setting.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbSoftwareLockedBit`
Indicates that the volume is locked by software.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kioVAtrbSoftwareLockedMask`
Tests if the volume is locked by software.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used in the `ioVAtrb` field of the `HVolumeParam` (page 859) parameter block returned by the `PBHGetVInfoSync` (page 690) and `PBHGetVInfoAsync` (page 686) functions, and in the `ioVAtrb` field of the `XVolumeParam` (page 882) parameter block returned by the `PBXGetVolInfoSync` (page 782) and `PBXGetVolInfoAsync` (page 779) functions.

Volume Information Bitmap Constants

Indicate what volume information to set or retrieve.

```
enum {
    kFSVolInfoNone = 0x0000,
    kFSVolInfoCreateDate = 0x0001,
    kFSVolInfoModDate = 0x0002,
    kFSVolInfoBackupDate = 0x0004,
    kFSVolInfoCheckedDate = 0x0008,
    kFSVolInfoFileCount = 0x0010,
    kFSVolInfoDirCount = 0x0020,
    kFSVolInfoSizes = 0x0040,
    kFSVolInfoBlocks = 0x0080,
    kFSVolInfoNextAlloc = 0x0100,
    kFSVolInfoRsrcClump = 0x0200,
    kFSVolInfoDataClump = 0x0400,
    kFSVolInfoNextID = 0x0800,
    kFSVolInfoFinderInfo = 0x1000,
    kFSVolInfoFlags = 0x2000,
    kFSVolInfoFSInfo = 0x4000,
    kFSVolInfoDriveInfo = 0x8000,
    kFSVolInfoGettableInfo = 0xFFFF,
    kFSVolInfoSettableInfo = 0x3004
};
```

Constants
`kFSVolInfoNone`
No volume information.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoCreateDate`
Retrieve the creation date of the volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoModDate`
Retrieve the date of the volume's last modification.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoBackupDate`
Retrieve or set the date of the volume's last backup.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoCheckedDate`
Retrieve the date that the volume was last checked for consistency.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoFileCount`
Retrieve the number of files on the volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoDirCount`
Retrieve the number of directories on the volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoSizes`
Retrieve the total number of bytes on the volume and the number of unused bytes on the volume (in the `totalBytes` and `freeBytes` fields).

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoBlocks`
Retrieve the block information: the block size, the number of total blocks on the volume, and the number of free blocks on the volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoNextAlloc`
Retrieve the address at which to start the next allocation.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoRsrcClump`
Retrieve the resource fork clump size.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoDataClump`
Retrieve the data fork clump size.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoNextID`
Retrieve the next available catalog node ID.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoFinderInfo`
Retrieve or set the volume's Finder information.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoFlags`
Retrieve or set the volume's flags. See "Volume Information Flags" (page 940) for more information on the volume's flags.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoFSInfo`
Retrieve the filesystem ID and signature.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoDriveInfo`
Retrieve the drive information: the drive number and driver reference number.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoGettableInfo`
Retrieve all of the gettable information.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolInfoSettableInfo`
Set all of the settable information. Currently, this is the backup date, Finder information, and flags.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
These constants are used with the `FSVolumeInfoBitmap` (page 845) data type to indicate what volume information to set or retrieve with the functions `FSSetVolumeInfo` (page 543) and `FSGetVolumeInfo` (page 500) , and their corresponding parameter block calls.

Volume Information Flags

Used by the `FSVolumeInfo` structure to specify characteristics of a volume.

```
enum {
    kFSVolFlagDefaultVolumeBit = 5,
    kFSVolFlagDefaultVolumeMask = 0x0020,
    kFSVolFlagFilesOpenBit = 6,
    kFSVolFlagFilesOpenMask = 0x0040,
    kFSVolFlagHardwareLockedBit = 7,
    kFSVolFlagHardwareLockedMask = 0x0080,
    kFSVolFlagSoftwareLockedBit = 15,
    kFSVolFlagSoftwareLockedMask = 0x8000
};
```

Constants

`kFSVolFlagDefaultVolumeBit`
Set if the volume is the default volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagDefaultVolumeMask`
Indicates that the volume is the default volume.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagFilesOpenBit`
Set if there are open files or iterators.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagFilesOpenMask`
Indicates that there are open files or iterators.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagHardwareLockedBit`
Set if the volume is locked by a hardware setting. On Mac OS X, the File Manager only sets the software locked bit for CDs and other read-only media; it does not set the hardware locked bit.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagHardwareLockedMask`
Indicates that the volume is locked by a hardware setting.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagSoftwareLockedBit`
Set if the volume is locked by software.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`kFSVolFlagSoftwareLockedMask`
Indicates that the volume is locked by software.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
See the `flags` field of the `FSVolumeInfo` (page 842) structure.

Volume Mount Flags

Define flags used by the volume mounting information structures.

```
enum {
    volMountNoLoginMsgFlagBit = 0,
    volMountNoLoginMsgFlagMask = 0x0001,
    volMountExtendedFlagsBit = 7,
    volMountExtendedFlagsMask = 0x0080,
    volMountInteractBit = 15,
    volMountInteractMask = 0x8000,
    volMountChangedBit = 14,
    volMountChangedMask = 0x4000,
    volMountFSReservedMask = 0x00FF,
    volMountSysReservedMask = 0xFF00
};
```

Constants

`volMountNoLoginMsgFlagBit`
Indicates that any log-in message or greeting dialog will be suppressed.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountNoLoginMsgFlagMask`
Tells the file system to suppress any log-in message or greeting dialog.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountExtendedFlagsBit`
Indicates that the mounting information is a `AFPXVolMountInfo` record for AppleShare Client version 3.7 and later.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountExtendedFlagsMask`
Tells the file system that the mounting information is an `AFPXVolMountInfo` (page 799) record for AppleShare Client version 3.7 and later.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountInteractBit`
Indicates that it's safe for the file system to perform user interaction to mount the volume.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountInteractMask`
Tells the file system that it's safe to perform user interaction to mount the volume.
Available in Mac OS X v10.0 and later.
Declared in `Files.h`.

`volMountChangedBit`
Indicates that the volume was mounted, but the volume mounting information record needs to be updated.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`volMountChangedMask`
Tests if the volume mounting information record needs to be updated.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`volMountFSReservedMask`
Reserved.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

`volMountSysReservedMask`
Reserved.

Available in Mac OS X v10.0 and later.

Declared in `Files.h`.

Discussion
Bits 0-7 are defined by each file system for its own use; bits 8-15 are reserved for Apple system use. These constants are used in the `flags` fields of the `AFPVolMountInfo` (page 797), `AFPXVolMountInfo` (page 799), and `VolumeMountInfoHeader` (page 873) structures.

Result Codes

The most common result codes returned by File Manager functions are listed below.

Result Code	Value	Description
`dirFulErr`	-33	File directory full. Available in Mac OS X v10.0 and later.
`dskFulErr`	-34	Disk or volume full. Available in Mac OS X v10.0 and later.
`nsvErr`	-35	Volume not found. Available in Mac OS X v10.0 and later.
`ioErr`	-36	I/O error. Available in Mac OS X v10.0 and later.
`bdNamErr`	-37	Bad filename or volume name. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
fnOpnErr	-38	File not open. Available in Mac OS X v10.0 and later.
eofErr	-39	Logical end-of-file reached. Available in Mac OS X v10.0 and later.
posErr	-40	Attempt to position mark before the start of the file. Available in Mac OS X v10.0 and later.
mFulErr	-41	Memory full (open) or file won't fit (load) Available in Mac OS X v10.0 and later.
tmfoErr	-42	Too many files open. Available in Mac OS X v10.0 and later.
fnfErr	-43	File or directory not found; incomplete pathname. Available in Mac OS X v10.0 and later.
wPrErr	-44	Volume is locked through hardware. Available in Mac OS X v10.0 and later.
fLckdErr	-45	File is locked. Available in Mac OS X v10.0 and later.
vLckdErr	-46	Volume is locked through software. Available in Mac OS X v10.0 and later.
fBsyErr	-47	One or more files are open File is busy Directory is not empty. Available in Mac OS X v10.0 and later.
dupFNErr	-48	Duplicate filename and version Destination file already exists File found instead of folder Available in Mac OS X v10.0 and later.
opWrErr	-49	File already open for writing. Available in Mac OS X v10.0 and later.
paramErr	-50	Invalid value passed in a parameter. Your application passed an invalid parameter for dialog options. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
rfNumErr	-51	Invalid reference number. Available in Mac OS X v10.0 and later.
gfpErr	-52	Error during GetFPos, PBGetFPosSync or PBGetFPosAsync. Available in Mac OS X v10.0 and later.
volOffLinErr	-53	Volume is offline. Available in Mac OS X v10.0 and later.
permErr	-54	Attempt to open locked file for writing Permissions error Available in Mac OS X v10.0 and later.
volOnLinErr	-55	Volume already online. Available in Mac OS X v10.0 and later.
nsDrvErr	-56	No such drive. Available in Mac OS X v10.0 and later.
noMacDskErr	-57	Not a Macintosh disk. Available in Mac OS X v10.0 and later.
extFSErr	-58	Volume belongs to an external file system. Available in Mac OS X v10.0 and later.
fsRnErr	-59	Problem during rename. Available in Mac OS X v10.0 and later.
badMDBErr	-60	Bad master directory block. Available in Mac OS X v10.0 and later.
wrPermErr	-61	Read/ write permission doesn't allow writing. Available in Mac OS X v10.0 and later.
lastDskErr	-64	Available in Mac OS X v10.0 and later.
noDriveErr	-64	Drive not installed. Available in Mac OS X v10.0 and later.
firstDskErr	-84	Available in Mac OS X v10.0 and later.
dirNFErr	-120	Directory not found or incomplete pathname. Available in Mac OS X v10.0 and later.
tmwdoErr	-121	Too many working directories open. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
badMovErr	-122	Attempt to move. Available in Mac OS X v10.0 and later.
wrgVolTypErr	-123	Volume does not support Desktop Manager Not an HFS volume Available in Mac OS X v10.0 and later.
volGoneErr	-124	Server volume has been disconnected. Available in Mac OS X v10.0 and later.
fsDSIntErr	-127	non-hardware internal file system error. Available in Mac OS X v10.0 and later.
fsmFFSNotFoundErr	-431	Foreign file system does not exist. Available in Mac OS X v10.0 and later.
fsmBusyFFSErr	-432	File system is busy, cannot be removed. Available in Mac OS X v10.0 and later.
fsmBadFFSNameErr	-433	Name length not 1 <= length <= 31 Available in Mac OS X v10.0 and later.
fsmBadFSDLenErr	-434	FSD size incompatible with current FSM vers Available in Mac OS X v10.0 and later.
fsmDuplicateFSIDErr	-435	FSID already exists. Available in Mac OS X v10.0 and later.
fsmBadFSDVersionErr	-436	FSM version incompatible with FSD Available in Mac OS X v10.0 and later.
fsmNoAlternateStackErr	-437	no alternate stack for HFS CI Available in Mac OS X v10.0 and later.
fsmUnknownFSMMessageErr	-438	unknown message passed to FSM Available in Mac OS X v10.0 and later.
driverHardwareGoneErr	-503	disk driver's hardware was disconnected Available in Mac OS X v10.0 and later.
fidNotFound	-1300	File ID not found Available in Mac OS X v10.0 and later.
fidExists	-1301	File ID already exists Available in Mac OS X v10.0 and later.

Result Code	Value	Description
notAFileErr	-1302	Specified file is a directory Available in Mac OS X v10.0 and later.
diffVolErr	-1303	Files on different volumes Available in Mac OS X v10.0 and later.
catChangedErr	-1304	Catalog has changed and catalog position record may be invalid Available in Mac OS X v10.0 and later.
sameFileErr	-1306	Can't exchange a file with itself Available in Mac OS X v10.0 and later.
badFidErr	-1307	File ID is dangling or doesn't match with the file number Available in Mac OS X v10.0 and later.
notARemountErr	-1308	_Mount allows only remounts and doesn't get one Available in Mac OS X v10.0 and later.
fileBoundsErr	-1309	File's EOF, offset, mark or size is too big Available in Mac OS X v10.0 and later.
fsDataTooBigErr	-1310	File or volume is too big for system Available in Mac OS X v10.0 and later.
volVMBusyErr	-1311	Can't eject because volume is in use by VM Available in Mac OS X v10.0 and later.
badFCBErr	-1327	FCBRecPtr is not valid Available in Mac OS X v10.0 and later.
errFSUnknownCall	-1400	Selector is not recognized by this file system Available in Mac OS X v10.0 and later.
errFSBadFSRef	-1401	An FSRef parameter was invalid. There are several possible causes: The parameter was not optional, but the pointer was NULL. The volume reference number contained within the FSRef does not match a currently mounted volume. This can happen if the volume was unmounted after the FSRef was created. Some other private field inside the FSRef contains a value that could never be valid. If the field value could be valid, but doesn't happen to match the existing volume or in-memory structures, a "not found" error would be returned instead. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errFSBadForkName	-1402	A supplied fork name was invalid (i.e., was syntactically illegal for the given volume). For example, the fork name might contain characters that cannot be stored on the given volume (such as a colon on HFS volumes). Some volume formats do not store fork names in Unicode. These volume formats will attempt to convert the Unicode name to the kind of encoding used by the volume format. If the name could not be converted, errFSBadForkName is returned. Some volume formats only support a limited set of forks, such as the data and resource forks on HFS volumes. For those volumes, if any other fork name is passed, this error is returned. Available in Mac OS X v10.0 and later.
errFSBadBuffer	-1403	A non-optional buffer pointer was NULL , or its size was invalid for the type of data it was expected to contain. In a protected memory system, this could also mean the buffer space is not part of the address space for the calling process. Available in Mac OS X v10.0 and later.
errFSBadForkRef	-1404	A file reference number does not correspond to a fork opened with the FSOpenFork, PBOpenForkSync , or PBOpenForkAsync functions. This could be because that fork has already been closed. Or, you may have passed a reference number created with older APIs (e.g., by the PBHOpenDF functions). A value of zero is never a valid file reference number. Available in Mac OS X v10.0 and later.
errFSBadInfoBitmap	-1405	A FSCatalogInfoBitmap or FSVolumeInfoBitmap has one or more reserved or undefined bits set. This error code can also be returned if a defined bit is set, but the corresponding FSCatalogInfo or FSVolumeInfo field cannot be operated on with that call (for example, trying to use FSSetCatalogInfo to set the valence of a directory). Available in Mac OS X v10.0 and later.
errFSMissingCatInfo	-1406	A FSCatalogInfo pointer is NULL , but is not optional. Or, the FSCatalogInfo is optional and NULL, but the corresponding FSCatalogInfoBitmap is not zero (that is,the bitmap says that one or more of the FSCatalogInfo fields is being passed, but the supplied pointer was NULL). Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errFSNotAFolder	-1407	A parameter was expected to identify a folder, but it identified some other kind of object (e.g., a file) instead. This implies that the specified object exists, but is of the wrong type. For example, one of the parameters to FSCreateFileUnicode is an FSRef of the directory where the file will be created; if the FSRef actually refers to a file, this error is returned. Available in Mac OS X v10.0 and later.
errFSForkNotFound	-1409	An attempt to specify a fork of a given file or directory, but that particular fork does not exist. Available in Mac OS X v10.0 and later.
errFSNameTooLong	-1410	A file or fork name was too long. This means that the given name could never exist; this is different from a "file not found" or errFSForkNotFound error. Available in Mac OS X v10.0 and later.
errFSMissingName	-1411	A required file or fork name parameter was a NULL pointer, or the length of a filename was zero. Available in Mac OS X v10.0 and later.
errFSBadPosMode	-1412	Reserved or invalid bits in a positionMode field were set. For example, the FSReadFork call does not support newline mode, so setting the newline bit or a newline character in the positionMode parameter would cause this error. Available in Mac OS X v10.0 and later.
errFSBadAllocFlags	-1413	Reserved or invalid bits were set in an FSAllocationFlags parameter. Available in Mac OS X v10.0 and later.
errFSNoMoreItems	-1417	There are no more items to return when enumerating a directory or searching a volume. Note that FSCatalogSearch returns this error, whereas the PBCatSearch functions would return eofErr. Available in Mac OS X v10.0 and later.
errFSBadItemCount	-1418	The maximumObjects parameter to FSGetCatalogInfoBulk or FSCatalogSearch was zero. Available in Mac OS X v10.0 and later.
errFSBadSearchParams	-1419	The search criteria to FSCatalogSearch are invalid or inconsistent. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errFSRefsDifferent	-1420	The two FSRef structures passed to FSCompareFSRefs are for different files or directories. Note that a volume format may be able to compare the FSRef structures without searching for the files or directories, so this error may be returned even if one or both of the FSRef structures refers to non-existent objects. Available in Mac OS X v10.0 and later.
errFSForkExists	-1421	An attempt to create a fork, but that fork already exists. Available in Mac OS X v10.0 and later.
errFSBadIteratorFlags	-1422	The flags passed to FSOpenIterator are invalid. Available in Mac OS X v10.0 and later.
errFSIteratorNotFound	-1423	The value of an FSIterator parameter does not correspond to any currently open iterator. Available in Mac OS X v10.0 and later.
errFSIteratorNotSupported	-1424	The iterator flags or container of an FSIterator are not supported by that call. For example, in the initial release, the FSCatalogSearch call only supports an iterator whose container is in the volume's root directory and whose flags are kFSIterateSubtree (i.e., an iterator for the entire volume's contents). Similarly, in the initial release, FSGetCatalogInfoBulk only supports an iterator whose flags are kFSIterateFlat. Available in Mac OS X v10.0 and later.
errFSQuotaExceeded	-1425	The user's quota of disk blocks has been exhausted. Available in Mac OS X v10.2 and later.
afpAccessDenied	-5000	User does not have the correct access to the file Directory cannot be shared Available in Mac OS X v10.0 and later.
afpAuthContinue	-5001	Further information required to complete AFPLogin call. Available in Mac OS X v10.0 and later.
afpBadUAM	-5002	User authentication method is unknown. Available in Mac OS X v10.0 and later.
afpBadVersNum	-5003	Workstation is using an AFP version that the server doesn't recognize. Available in Mac OS X v10.0 and later.
afpBitmapErr	-5004	Bitmap contained bits undefined for call. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
afpCantMove	-5005	Move destination is offspring of source or root was specified. Available in Mac OS X v10.0 and later.
afpDenyConflict	-5006	Requested user permission not possible. Available in Mac OS X v10.0 and later.
afpDirNotEmpty	-5007	Cannot delete non-empty directory. Available in Mac OS X v10.0 and later.
afpDiskFull	-5008	Insufficient free space on volume for operation. Available in Mac OS X v10.0 and later.
afpEofError	-5009	Read beyond logical end-of-file. Available in Mac OS X v10.0 and later.
afpFileBusy	-5010	Cannot delete an open file. Available in Mac OS X v10.0 and later.
afpFlatVol	-5011	Cannot create directory on specified volume. Available in Mac OS X v10.0 and later.
afpItemNotFound	-5012	Unknown user name/ user ID or missing comment / APPL entry. Available in Mac OS X v10.0 and later.
afpLockErr	-5013	Some or all of requested range is locked by another user. Available in Mac OS X v10.0 and later.
afpMiscErr	-5014	Unexpected error encountered during execution. Available in Mac OS X v10.0 and later.
afpNoMoreLocks	-5015	No more ranges can be locked. Available in Mac OS X v10.0 and later.
afpNoServer	-5016	Server is not responding. Available in Mac OS X v10.0 and later.
afpObjectExists	-5017	Specified destination file or directory already exists. Available in Mac OS X v10.0 and later.
afpObjectNotFound	-5018	Specified file or directory does not exist. Available in Mac OS X v10.0 and later.
afpParmErr	-5019	A specified parameter was out of allowable range. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
afpRangeNotLocked	-5020	Specified range was not locked. Available in Mac OS X v10.0 and later.
afpRangeOverlap	-5021	Part of range is already locked. Available in Mac OS X v10.0 and later.
afpSessClosed	-5022	Session closed. Available in Mac OS X v10.0 and later.
afpUserNotAuth	-5023	User authentication failed (usually, password is not correct). Available in Mac OS X v10.0 and later.
afpCallNotSupported	-5024	Unsupported AFP call was made. Available in Mac OS X v10.0 and later.
afpObjectTypeErr	-5025	A directory exists with that name Directory not found Folder locking not supported by volume Object was a file, not a directory Available in Mac OS X v10.0 and later.
afpTooManyFilesOpen	-5026	Maximum open file count reached. Available in Mac OS X v10.0 and later.
afpServerGoingDown	-5027	Server is shutting down. Available in Mac OS X v10.0 and later.
afpCantRename	-5028	AFPRename cannot rename volume. Available in Mac OS X v10.0 and later.
afpDirNotFound	-5029	Unknown directory specified. Available in Mac OS X v10.0 and later.
afpIconTypeError	-5030	Icon size specified is different from existing icon size. Available in Mac OS X v10.0 and later.
afpVolLocked	-5031	Volume is read-only. Available in Mac OS X v10.0 and later.
afpObjectLocked	-5032	Object is M/R/D/W inhibited. Available in Mac OS X v10.0 and later.
afpContainsSharedErr	-5033	The directory contains a share point. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
afpIDNotFound	-5034	File ID not found. Available in Mac OS X v10.0 and later.
afpIDExists	-5035	File ID already exists. Available in Mac OS X v10.0 and later.
afpDiffVolErr	-5036	Available in Mac OS X v10.0 and later.
afpCatalogChanged	-5037	Catalog has changed and search cannot be resumed. Available in Mac OS X v10.0 and later.
afpSameObjectErr	-5038	Source and destination files are the same. Available in Mac OS X v10.0 and later.
afpBadIDErr	-5039	File ID not found. Available in Mac OS X v10.0 and later.
afpPwdSameErr	-5040	Someone tried to change their password to the same password on a mandatory password change. Available in Mac OS X v10.0 and later.
afpPwdTooShortErr	-5041	The password being set is too short: there is a minimum length that must be met or exceeded. Available in Mac OS X v10.0 and later.
afpPwdExpiredErr	-5042	Password has expired on server. Available in Mac OS X v10.0 and later.
afpInsideSharedErr	-5043	The directory is inside a shared directory. Available in Mac OS X v10.0 and later.
afpInsideTrashErr	-5044	The folder being shared is inside the trash folder OR the shared folder is being moved into the trash folder. Available in Mac OS X v10.0 and later.
afpPwdNeedsChangeErr	-5045	The password needs to be changed. Available in Mac OS X v10.0 and later.
afpPwdPolicyErr	-5046	Password does not conform to server's password policy. Available in Mac OS X v10.0 and later.
afpAlreadyLoggedInErr	-5047	User has been authenticated but is already logged in from another machine (and that's not allowed on this server). Available in Mac OS X v10.0 and later.
afpCallNotAllowed	-5048	Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`afpBadDirIDType`	-5060	Not a fixed directory ID volume. Available in Mac OS X v10.0 and later.
`afpCantMountMoreSrvre`	-5061	Maximum number of volumes has been mounted. Available in Mac OS X v10.0 and later.
`afpAlreadyMounted`	-5062	Volume already mounted. Available in Mac OS X v10.0 and later.
`afpSameNodeErr`	-5063	Attempt to log on to a server running on the same machine. Available in Mac OS X v10.0 and later.

Folder Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Folders.h

Overview

The Folder Manager allows you to find and search folders, create new folders, and control how files are routed between folders. Because you can use the Folder Manager to manipulate standard Mac OS folders without relying on their names, your program is tolerant of changes to folder names and easier to localize.

Carbon supports the Folder Manager, although some functions have been deprecated in Mac OS X. You should always check the value of `gestaltFindFolderAttr` in Mac OS X to determine what functionality is available.

Functions by Task

Describing Folders

`GetFolderTypes` (page 970)
Obtains the folder types contained in the global descriptor list.

`IdentifyFolder` (page 971)
Obtains the folder type for the specified folder.

`InvalidateFolderDescriptorCache` (page 972)
Invalidates any prior `FindFolder` results for the specified folder.

`GetFolderName` (page 969) Deprecated in Mac OS X v10.5
Obtains the name of the specified folder.

Manipulating Folders

`FSFindFolder` (page 966)
Obtains location information for system-related directories.

`FindFolder` (page 960)
Obtains location information for system-related directories.

`FindFolderExtended` (page 962) Deprecated in Mac OS X v10.3
Obtains location information for system-related directories. (Deprecated. Use `FindFolder` (page 960) instead.)

`FSFindFolderExtended` (page 966) Deprecated in Mac OS X v10.3
Locates a system-related folder and returns a reference to the folder. (Deprecated. Use `FSFindFolder` (page 966) instead.)

`ReleaseFolder` (page 973) Deprecated in Mac OS X v10.3
Releases the Trash folder in preparation for unmounting a server volume. (Deprecated. This function is not needed in Mac OS X.)

Routing Files

`AddFolderRouting` (page 958) Deprecated in Mac OS X v10.4
Adds a folder routing structure to the global routing list. (Deprecated. There is no replacement function.)

`FindFolderRouting` (page 962) Deprecated in Mac OS X v10.4
Finds the destination folder from a matching folder routing structure for the specified file. (Deprecated. There is no replacement function.)

`GetFolderRoutings` (page 970) Deprecated in Mac OS X v10.4
Obtains folder routing information from the global routing list. (Deprecated. There is no replacement function.)

`RemoveFolderRouting` (page 975) Deprecated in Mac OS X v10.4
Deletes a folder routing structure from the global routing list. (Deprecated. There is no replacement function.)

Working With Folder Manager Notification Functions

`NewFolderManagerNotificationUPP` (page 973)
Creates a new universal procedure pointer (UPP) to a notification function.

`DisposeFolderManagerNotificationUPP` (page 960)
Disposes of the universal procedure pointer (UPP) to a notification function.

`InvokeFolderManagerNotificationUPP` (page 973)
Calls your notification function.

`FolderManagerRegisterCallNotificationProcs` (page 963) Deprecated in Mac OS X v10.3
Calls the registered Folder Manager notification procs. (Deprecated. There is no replacement function.)

`FolderManagerRegisterNotificationProc` (page 964) Deprecated in Mac OS X v10.3
Registers your notification function with the Folder Manager. (Deprecated. There is no replacement function.)

`FolderManagerUnregisterNotificationProc` (page 964) Deprecated in Mac OS X v10.3
Removes your notification function from the Folder Manager's queue. (Deprecated. There is no replacement function.)

Working With Folder Descriptors

`AddFolderDescriptor` (page 957)
Copies the supplied information into a new folder descriptor entry in the system folder list.

`RemoveFolderDescriptor` (page 974)
Deletes the specified folder descriptor entry from the system folder list.

`GetFolderDescriptor` (page 968) Deprecated in Mac OS X v10.3
Obtains the folder descriptor information for the specified folder type from the global descriptor list. (Deprecated. There is no replacement function.)

Finding Files in Special Folders

`FSpDetermineIfSpecIsEnclosedByFolder` (page 967)
Determines whether a file of type `FSSpec` (page 840) is enclosed inside a special folder type for the given domain.

`FSDetermineIfRefIsEnclosedByFolder` (page 965)
Determines whether a file of type `FSRef` (page 837) is enclosed inside a special folder type for the given domain.

`DetermineIfPathIsEnclosedByFolder` (page 959)
Determines whether a file path is enclosed inside a special folder type for the given domain.

Functions

AddFolderDescriptor

Copies the supplied information into a new folder descriptor entry in the system folder list.

```
OSErr AddFolderDescriptor (
   FolderType foldType,
   FolderDescFlags flags,
   FolderClass foldClass,
   FolderLocation foldLocation,
   OSType badgeSignature,
   OSType badgeType,
   ConstStrFileNameParam name,
   Boolean replaceFlag
);
```

Parameters

foldType
Pass a constant identifying the type of the folder you wish the Folder Manager to be able to find. See Folder Type Constants (page 985).

flags
Set these flags to indicate whether a folder is created during startup, if the folder name is locked, and if the folder is created invisible; see Folder Descriptor Flags (page 982).

foldClass
Pass the class of the folder which you wish the Folder Manager to be able to find. The folder class determines how the `foldLocation` parameter is interpreted. See Folder Descriptor Classes (page 981) for a discussion of relative and special folder classes.

foldLocation
For a relative folder, specify the folder type of the parent folder of the target. For a special folder, specify the location of the folder; see Folder Descriptor Locations (page 984).

badgeSignature
Reserved. Pass 0.

badgeType
Reserved. Pass 0.

name
A string specifying the name of the desired folder. For relative folders, this is the exact name of the desired folder. For special folders, the actual target folder may have a different name than the name specified in the folder descriptor. For example, the System Folder is often given a different name, but it can still be located with `FindFolder` (page 960).

replaceFlag
Pass a `Boolean` value indicating whether you wish to replace a folder descriptor that already exists for the specified folder type. If `true`, it replaces the folder descriptor for the specified folder type. If `false`, it does not replace the folder descriptor for the specified folder type.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001). The result code `duplicateFolderDescErr` indicates that a folder descriptor is already installed with the specified folder type and `replaceFlag` is false.

Discussion
The `AddFolderDescriptor` function copies the supplied information into a new descriptor entry in the system folder list. You need to provide folder descriptors for each folder you wish the Folder Manager to be able to find via the function `FindFolder` (page 960). For example, a child folder located in a parent folder needs to have a descriptor created both for it and its parent folder, so that the child can be found. This function is supported under Mac OS 8 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

AddFolderRouting

Adds a folder routing structure to the global routing list. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr AddFolderRouting (
   OSType fileType,
   FolderType routeFromFolder,
   FolderType routeToFolder,
   RoutingFlags flags,
   Boolean replaceFlag
);
```

Parameters
fileType
Pass the `OSType` of the file to be routed.

routeFromFolder

Pass the folder type of the "from" folder see Folder Type Constants (page 985) for descriptions of possible values. An item dropped on the folder specified in this parameter will be routed to the folder specified in the `routeToFolder` parameter.

routeToFolder

The folder type of the "to" folder see Folder Type Constants (page 985) for descriptions of possible values.

flags

Reserved for future use; pass 0.

replaceFlag

Pass a `Boolean` value indicating whether you wish to replace a folder routing that already exists. If `true`, it replaces the folder to which the item is being routed. If `false`, it leaves the folder to which the item is being routed.

Return Value

A result code. See "Folder Manager Result Codes" (page 1001). The result code `duplicateRoutingErr` indicates that a folder routing is already installed with the specified folder type and `replaceFlag` is false.

Discussion

Your application can use the `AddFolderRouting` function to specify how the Finder routes a given file type.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Folders.h`

DetermineIfPathIsEnclosedByFolder

Determines whether a file path is enclosed inside a special folder type for the given domain.

```
OSErr DetermineIfPathIsEnclosedByFolder (
   FSVolumeRefNum domainOrVRefNum,
   OSType folderType,
   const UInt8 *utf8Path,
   Boolean pathIsRealPath,
   Boolean *outResult
);
```

Parameters

domainOrVRefNum

The domain or volume reference number to check. For information about the possible domains, see Disk and Domain Constants (page 997). You can also pass `0` to check all domains and volumes, or you can pass `kOnAppropriateDisk` to check the appropriate volume for the specified file.

folderType

The special folder type to check. For information about the possible folder types, see Folder Type Constants (page 985).

utf8Path

A UTF-8 encoded path to the file for which to search.

pathIsRealPath

A Boolean value that indicates whether the `utf8Path` parameter is guaranteed to be a full and complete path, as opposed to a path containing a symbolic link, an alias, or a relative path.

outResult

A pointer to a Boolean variable. On return, indicates whether or not the file is enclosed inside the special folder type for the given domain.

Discussion
This function provides an efficient way to check to see if a file (or folder) is inside a special folder for a given domain. A typical use for this function is to determine if a given file is inside the trash on a volume:

```
err = DetermineIfPathIsEnclosedByFolder (kOnAppropriateDisk, kTrashFolderType,
 path, false, &result);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Folders.h`

DisposeFolderManagerNotificationUPP

Disposes of the universal procedure pointer (UPP) to a notification function.

```
void DisposeFolderManagerNotificationUPP (
   FolderManagerNotificationUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

FindFolder

Obtains location information for system-related directories.

```
OSErr FindFolder (
   FSVolumeRefNum vRefNum,
   OSType folderType,
   Boolean createFolder,
   FSVolumeRefNum *foundVRefNum,
   SInt32 *foundDirID
);
```

Parameters

vRefNum

Pass the volume reference number of the volume on which you want to locate a directory, or a constant specifying a disk or domain. The constants which you can use in this parameter are described in Disk and Domain Constants (page 997).

Note that, on Mac OS X, passing a volume reference number in this parameter does not make sense for most of the folder type selectors which you can specify in the `folderType` parameter. On Mac OS X, folders are "domain-oriented"; because there may be more than one domain on any given physical volume, asking for these folders on a per-volume basis yields undefined results. For example, if you were to request the Fonts folder (represented by the selector `kFontsFolderType`) on volume -100, are you requesting the folder /System/Library/Fonts, /Library/Fonts, or ~/Fonts? On Mac OS X you should pass a disk or domain constant in this parameter.

folderType

Pass a four-character folder type, or a constant that represents the type, for the folder you want to find; see Folder Type Constants (page 985).

createFolder

A value of type `Boolean`, as defined in Create Folder Flags (page 981). Pass the constant `kCreateFolder` to create a directory if it does not already exist; otherwise, pass the constant `kDontCreateFolder`. Directories inside the System Folder are created only if the System Folder directory exists. The `FindFolder` function will not create a System Folder directory even if you specify the `kCreateFolder` constant in the `createFolder` parameter. Passing `kCreateFolder` will also not create a parent folder; if the parent of the target folder does not already exist, attempting to create the target will fail.

foundVRefNum

A pointer to a value of type `short`. On return, the value specifies the volume reference number for the volume containing the directory specified in the `folderType` parameter.

foundDirID

A pointer to a value of type `long`. On return, the value specifies the directory ID number for the directory specified in the `folderType` parameter.

Return Value

A result code. See "Folder Manager Result Codes" (page 1001). The result code `fnfErr` indicates that the type has not been found in the `'fld#'` resource, or the disk doesn't have System Folder support, or the disk does not have desktop database support for Desktop Folder—in all cases, the folder has not been found. The result code `dupFNErr` indicates that a file has been found instead of a folder.

Discussion

As of Mac OS 8 and later, your application can add folders to the System Folder—or nest folders within other folders—and locate the folders via the `FindFolder` function. Prior to Mac OS 8, your application could only use `FindFolder` to find folders that were immediately inside of the System Folder, and a few other special folders such as the Trash folder and the System Folder itself. Now, once a folder (and any folders that it is nested within) is described in a folder descriptor—that is, registered using the function `AddFolderDescriptor` (page 957) —your application can use `FindFolder` to find the folder no matter where it is located.

Those folders you're most likely to want to access are Preferences and Trash. For example, you might wish to check for the existence of a user's configuration file in Preferences or, if your application runs out of disk storage when trying to save a file, check how much disk storage is taken by items in the Trash directory and report this to the user.

The specified folder used for a given volume might be located on a different volume; therefore, do not assume the volume that you specify in `vRefNum` and the volume returned through `foundVRefNum` will be the same.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Simple DrawSprocket

Declared In
`Folders.h`

FindFolderExtended

Obtains location information for system-related directories. (Deprecated in Mac OS X v10.3. Use `FindFolder` (page 960) instead.)

```
OSErr FindFolderExtended (
   FSVolumeRefNum vRefNum,
   OSType folderType,
   Boolean createFolder,
   UInt32 flags,
   void *data,
   FSVolumeRefNum *foundVRefNum,
   SInt32 *foundDirID
);
```

Parameters

foldType

createFolder

flags

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Folders.h`

FindFolderRouting

Finds the destination folder from a matching folder routing structure for the specified file. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr FindFolderRouting (
   OSType fileType,
   FolderType routeFromFolder,
   FolderType *routeToFolder,
   RoutingFlags *flags
);
```

Parameters

fileType

Pass the file type specified in the appropriate folder routing structure for the file for which you wish to find a destination folder.

routeFromFolder

Pass the folder type of the "from" folder for which you wish to find a "to" folder see Folder Type Constants (page 985) for descriptions of possible values. An item dropped on the folder specified in this parameter will be routed to the folder specified in the `routeToFolder` parameter.

routeToFolder

A pointer to a value of type `FolderType`. On return, the value is set to the folder type of the destination folder.

flags

Reserved; pass 0.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
Both the file type and the folder type specified must match those of a folder routing structure in the global routing list for the `FindFolderRouting` function to succeed.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Folders.h`

FolderManagerRegisterCallNotificationProcs

Calls the registered Folder Manager notification procs. (Deprecated in Mac OS X v10.3. There is no replacement function.)

```
OSStatus FolderManagerRegisterCallNotificationProcs (
   OSType message,
   void *arg,
   UInt32 options
);
```

Parameters

message

options

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Folders.h`

FolderManagerRegisterNotificationProc

Registers your notification function with the Folder Manager. (Deprecated in Mac OS X v10.3. There is no replacement function.)

```
OSErr FolderManagerRegisterNotificationProc (
   FolderManagerNotificationUPP notificationProc,
   void *refCon,
   UInt32 options
);
```

Parameters

notificationProc
A UPP to your notification function.

refCon
A pointer to client-defined data. This value is passed to your notification function each time it is called.

options
A value specifying registration options. See FolderManagerCallNotificationProcs Options (page 1000).

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Folders.h`

FolderManagerUnregisterNotificationProc

Removes your notification function from the Folder Manager's queue. (Deprecated in Mac OS X v10.3. There is no replacement function.)

```
OSErr FolderManagerUnregisterNotificationProc (
   FolderManagerNotificationUPP notificationProc,
   void *refCon
);
```

Parameters

notificationProc
The UPP to your notification function that you passed to the `FolderManagerRegisterNotificationProc` function.

refCon

A pointer to the same value that you passed to the `FolderManagerRegisterNotificationProc` function in the *refCon* parameter.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`Folders.h`

FSDetermineIfRefIsEnclosedByFolder

Determines whether a file of type `FSRef` (page 837) is enclosed inside a special folder type for the given domain.

```
OSErr FSDetermineIfRefIsEnclosedByFolder (
   FSVolumeRefNum domainOrVRefNum,
   OSType folderType,
   const FSRef *inRef,
   Boolean *outResult
);
```

Parameters

domainOrVRefNum

The domain or volume reference number to check. For information about the possible domains, see Disk and Domain Constants (page 997). You can also pass `0` to check all domains and volumes, or you can pass `kOnAppropriateDisk` to check the appropriate volume for the specified file.

folderType

The special folder type to check. For information about the possible folder types, see Folder Type Constants (page 985).

inRef

The file for which to search.

outResult

A pointer to a Boolean variable. On return, indicates whether or not the file is enclosed inside the special folder type for the given domain.

Discussion
This function provides an efficient way to check to see if a file (or folder) is inside a special folder for a given domain. A typical use for this function is to determine if a given file is inside the trash on a volume:

```
err = FSDetermineIfRefIsEnclosedByFolder (kOnAppropriateDisk, kTrashFolderType,
 &ref, &result);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Folders.h`

FSFindFolder

Obtains location information for system-related directories.

```
OSErr FSFindFolder (
   FSVolumeRefNum vRefNum,
   OSType folderType,
   Boolean createFolder,
   FSRef *foundRef
);
```

Parameters

vRefNum

Pass the volume reference number of the volume on which you want to locate a directory, or a constant specifying a disk or domain. The constants which you can use in this parameter are described in Disk and Domain Constants (page 997).

Note that, on Mac OS X, passing a volume reference number in this parameter does not make sense for most of the folder type selectors which you can specify in the `folderType` parameter. On Mac OS X, folders are "domain-oriented"; because there may be more than one domain on any given physical volume, asking for these folders on a per-volume basis yields undefined results. For example, if you were to request the Fonts folder (represented by the selector `kFontsFolderType`)on volume -100, are you requesting the folder /System/Library/Fonts, /Library/Fonts, or ~/Fonts? On Mac OS X you should pass a disk or domain constant in this parameter.

folderType

Pass a four-character folder type, or a constant that represents the type, for the folder you want to find; see Folder Type Constants (page 985).

createFolder

A value of type `Boolean`, as defined in Create Folder Flags (page 981). Pass the constant `kCreateFolder` to create a directory if it does not already exist; otherwise, pass the constant `kDontCreateFolder`. Passing `kCreateFolder` will not create a parent folder; if the parent of the target folder does not already exist, attempting to create the target will fail.

foundRef

A pointer to a file system reference. On return, the `FSRef` refers to the directory specified by the `vRefNum` and `folderType` parameters.

Return Value

A result code. See "Folder Manager Result Codes" (page 1001).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

BSDLLCTest

Declared In

`Folders.h`

FSFindFolderExtended

Locates a system-related folder and returns a reference to the folder. (Deprecated in Mac OS X v10.3. Use `FSFindFolder` (page 966) instead.)

```
OSErr FSFindFolderExtended (
   FSVolumeRefNum vRefNum,
   OSType folderType,
   Boolean createFolder,
   UInt32 flags,
   void *data,
   FSRef *foundRef
);
```

Parameters

vRefNum

The volume reference number or domain in which you want to locate a folder. To specify the startup disk, use the constant `kOnSystemDisk`. To specify a domain, use a domain constant such as `kUserDomain`. See Disk and Domain Constants (page 997).

foldType

The type of folder you want to find. See Folder Type Constants (page 985).

createFolder

A value of type `Boolean`, as defined in Create Folder Flags (page 981). Pass the constant `kCreateFolder` to create a folder if it does not already exist; otherwise, pass the constant `kDontCreateFolder`.

flags

An extended behavior constant. See FSFindFolderExtended Flags (page 999).

data

User data which is interpreted differently depending on the constant specified in the `flags` parameter.

foundRef

A pointer to a `FSRef` variable. On return, the variable contains a file system reference to the specified folder.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
The specified folder might be relocated in future versions of system software; therefore, do not assume the volume that you specify in the `vRefNum` constant and the volume returned in the file system reference will be the same.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`Folders.h`

FSpDetermineIfSpecIsEnclosedByFolder

Determines whether a file of type `FSSpec` (page 840) is enclosed inside a special folder type for the given domain. (Deprecated in Mac OS X v10.5.)

```
OSErr FSpDetermineIfSpecIsEnclosedByFolder (
   FSVolumeRefNum domainOrVRefNum,
   OSType folderType,
   const FSSpec *inSpec,
   Boolean *outResult
);
```

Parameters

domainOrVRefNum

The domain or volume reference number to check. For information about the possible domains, see Disk and Domain Constants (page 997). You can also pass `0` to check all domains and volumes, or you can pass `kOnAppropriateDisk` to check the appropriate volume for the specified file.

folderType

The special folder type to check. For information about the possible folder types, see Folder Type Constants (page 985).

inSpec

The file for which to search.

outResult

A pointer to a Boolean variable. On return, indicates whether or not the file is enclosed inside the special folder type for the given domain.

Discussion

This function provides an efficient way to check to see if a file (or folder) is inside a special folder for a given domain. A typical use for this function is to determine if a given file is inside the trash on a volume:

```
err = FSpDetermineIfSpecIsEnclosedByFolder (kOnAppropriateDisk, kTrashFolderType,
 &spec, &result);
```

Availability

Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Folders.h`

GetFolderDescriptor

Obtains the folder descriptor information for the specified folder type from the global descriptor list. (Deprecated in Mac OS X v10.3. There is no replacement function.)

```
OSErr GetFolderDescriptor (
   FolderType foldType,
   Size descSize,
   FolderDesc *foldDesc
);
```

Parameters

foldType

Pass a constant identifying the type of the folder for which you wish to get descriptor information. See Folder Type Constants (page 985).

descSize

Pass the size (in bytes) of the folder descriptor structure for which a pointer is passed in the `foldDesc` parameter. This value is needed in order to determine the version of the structure being used.

foldDesc

Pass a pointer to a folder descriptor structure. On return, the folder descriptor structure contains information from the global descriptor list for the specified folder type.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Folders.h`

GetFolderName

Obtains the name of the specified folder. (Deprecated in Mac OS X v10.5.)

```
OSErr GetFolderName (
   FSVolumeRefNum vRefNum,
   OSType foldType,
   FSVolumeRefNum *foundVRefNum,
   StrFileName name
);
```

Parameters

vRefNum

Pass the volume reference number (or the constant `kOnSystemDisk` for the startup disk) of the volume containing the folder for which you wish the name to be identified.

foldType

Pass a constant identifying the type of the folder for which you wish the name to be identified. See Folder Type Constants (page 985).

foundVRefNum

On return, a pointer to the volume reference number for the volume containing the folder specified in the `foldType` parameter.

name

On return, a string containing the title of the folder specified in the `foldType` and `vRefNum` parameters.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
The `GetFolderName` function obtains the name of the folder in the folder descriptor, not the name of the folder on the disk. The names may differ for a few special folders such as the System Folder. For relative folders, however, the actual name is always returned. You typically do not need to call this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Folders.h`

GetFolderRoutings

Obtains folder routing information from the global routing list. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr GetFolderRoutings (
   UInt32 requestedRoutingCount,
   UInt32 *totalRoutingCount,
   Size routingSize,
   FolderRouting *theRoutings
);
```

Parameters

requestedRoutingCount
An unsigned 32-bit value. Pass the number of folder routing structures that can fit in the buffer pointed to by the `theRoutings` parameter.

totalRoutingCount
A pointer to an unsigned 32-bit value. On return, the value is set to the number of folder routing structures in the global list. If this value is less than or equal to `requestedRoutingCount`, all folder routing structures were returned to the caller.

routingSize
Pass the size (in bytes) of the `FolderRouting` structure.

theRoutings
Pass a pointer to an array of `FolderRouting` (page 978) structures. On return the structure(s) contain the requested routing information. You may pass `null` if you do not wish this information.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
The folder routing information in the global routing list determines how the Finder routes files.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Folders.h`

GetFolderTypes

Obtains the folder types contained in the global descriptor list.

```
OSErr GetFolderTypes (
   UInt32 requestedTypeCount,
   UInt32 *totalTypeCount,
   FolderType *theTypes
);
```

Parameters

requestedTypeCount

Pass the number of `FolderType` values that can fit in the buffer pointed to by the `theTypes` parameter; see Folder Type Constants (page 985).

totalTypeCount

Pass a pointer to an unsigned 32-bit integer value. On return, the value is set to the total number of `FolderType` values in the list. The `totalTypeCount` parameter may produce a value that is larger or smaller than that of the `requestedTypeCount` parameter. If `totalTypeCount` is equal to or smaller than the value passed in for `requestedTypeCount` and the value produced by the `theTypes` parameter is non-null, then all folder types were returned to the caller.

theTypes

Pass a pointer to an array of `FolderType` values; see Folder Type Constants (page 985). On return, the array contains the folder types for the installed descriptors. You can step through the array and call `GetFolderDescriptor` for each folder type. Pass `null` if you only want to know the number of descriptors installed in the system's global list, rather than the actual folder types of those descriptors.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

IdentifyFolder

Obtains the folder type for the specified folder.

```
OSErr IdentifyFolder (
   FSVolumeRefNum vRefNum,
   SInt32 dirID,
   FolderType *foldType
);
```

Parameters

vRefNum

Pass the volume reference number (or the constant `kOnSystemDisk` for the startup disk) of the volume containing the folder whose type you wish to identify.

dirID

Pass the directory ID number for the folder whose type you wish to identify.

foldType

Pass a pointer to a value of type `FolderType`. On return, the value is set to the folder type of the folder with the specified `vRefNum` and `dirID` parameters; see Folder Type Constants (page 985) for descriptions of possible values.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
The folder type is identified for the folder specified by the `vRefNum` and `dirID` parameters, if such a folder exists. Note that if there are multiple folder descriptors that map to an individual folder, `IdentifyFolder` returns the folder type of only the first matching descriptor that it finds.

Carbon Porting Notes

This function is not useful on Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

InvalidateFolderDescriptorCache

Invalidates any prior `FindFolder` results for the specified folder.

```
OSErr InvalidateFolderDescriptorCache (
   FSVolumeRefNum vRefNum,
   SInt32 dirID
);
```

Parameters

vRefNum

Pass the volume reference number (or the constant `kOnSystemDisk` for the startup disk) of the volume containing the folder for which you wish the descriptor cache to be invalidated. Pass 0 to completely invalidate all folder cache information.

dirID

Pass the directory ID number for the folder for which you wish the descriptor cache to be invalidated. Pass 0 to invalidate the cache for all folders on the specified disk.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
The `InvalidateFolderDescriptorCache` function searches to see if there is currently a cache of results from `FindFolder` calls on the specified folder. If so, it invalidates the cache from the previous calls to the `FindFolder` function in order to force the Folder Manager to reexamine the disk when `FindFolder` is called again on the specified directory ID or volume reference number.

If you remove a directory on disk which you know is a Folder Manager folder, you should call this function to update the Folder Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

InvokeFolderManagerNotificationUPP

Calls your notification function.

```
OSStatus InvokeFolderManagerNotificationUPP (
   OSType message,
   void *arg,
   void *userRefCon,
   FolderManagerNotificationUPP userUPP
);
```

Discussion
You should not need to use the `InvokeFolderManagerNotificationUPP` function, as the system calls your notification function for you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

NewFolderManagerNotificationUPP

Creates a new universal procedure pointer (UPP) to a notification function.

```
FolderManagerNotificationUPP NewFolderManagerNotificationUPP (
   FolderManagerNotificationProcPtr userRoutine
);
```

Parameters
`userRoutine`
A pointer to your notification function.

Return Value
The UPP to the notification function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

ReleaseFolder

Releases the Trash folder in preparation for unmounting a server volume. (Deprecated in Mac OS X v10.3. This function is not needed in Mac OS X.)

```
OSErr ReleaseFolder (
   FSVolumeRefNum vRefNum,
   OSType folderType
);
```

Parameters

vRefNum

Pass the volume reference number of the server volume on which you want to release the Trash folder.

folderType

Always pass the `kTrashFolderType` constant. Other folder types are currently ignored.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
When you call `FindFolder` (page 960) with the `kTrashFolderType` constant, it opens a file on a server volume that ensures each server volume user gets a unique Trash folder. Because a server volume's Trash folder may contain files or folders put there by the user, applications should delete the contents of the server volume's Trash folder. To do this, before your application unmounts a server volume, your application should call `ReleaseFolder`, or the `UnmountVol` request could fail with a `fBsyErr` result code. `ReleaseFolder` closes the file `FindFolder` may have opened and releases the Trash folder on that volume.

Your application should not use this function unless you want to unmount one or more server volumes. Normally, applications should not unmount servers; they should let users use the Finder to unmount volumes. In particular, applications should have no need to release the Trash folder explicitly; rather, unmounting volumes should be left to users to do with the Finder or by restarting.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

Declared In
`Folders.h`

RemoveFolderDescriptor

Deletes the specified folder descriptor entry from the system folder list.

```
OSErr RemoveFolderDescriptor (
   FolderType foldType
);
```

Parameters

foldType

Pass a constant identifying the type of the folder for which you wish to remove a descriptor. See Folder Type Constants (page 985).

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
Once a folder descriptor has been removed, the function `FindFolder` (page 960) will no longer be able to locate the folder type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

RemoveFolderRouting

Deletes a folder routing structure from the global routing list. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr RemoveFolderRouting (
   OSType fileType,
   FolderType routeFromFolder
);
```

Parameters

`fileType`

Pass the file type value contained in the folder routing structure to be removed.

`routeFromFolder`

Pass the folder type of the "from" folder see Folder Type Constants (page 985) for descriptions of possible values.

Return Value
A result code. See "Folder Manager Result Codes" (page 1001).

Discussion
Both the file type and the folder type specified must match those of an existing folder routing structure for the *`RemoveFolderRouting`* function to succeed.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Folders.h`

Callbacks

FolderManagerNotificationProcPtr

Defines a pointer to a notification function, called for all Folder Manager notifications.

```
typedef OSStatus (*FolderManagerNotificationProcPtr)
(
                OSType message,
                void * arg,
                void * userRefCon);
```

If you name your function `MyFolderManagerNotificationProc`, you would declare it like this:

```
OSStatus MyFolderManagerNotificationProc
(
            OSType message,
            void * arg,
            void * userRefCon);
```

Parameters

message

The type of notification (user login, user logout, etc.). See "Notification Messages" (page 999).

arg

A pointer to additional information, if any. For most messages, this is a pointer to a `FindFolderUserRedirectionGlobals` structure. If the message is `kFolderManagerNotificationDiscardCachedData`, `arg` is undefined.

userRefCon

A pointer to a value for your own use; this may be any value you want, such as a pointer to your globals or other state information.

Return Value

A result code. See "Folder Manager Result Codes" (page 1001).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Folders.h`

Data Types

FindFolderUserRedirectionGlobals

Used in the `arg` parameter of a notification function.

```
struct FindFolderUserRedirectionGlobals {
    UInt32 version;
    UInt32 flags;
    Str31 userName;
    short userNameScript;
    short currentUserFolderVRefNum;
    long currentUserFolderDirID;
    short remoteUserFolderVRefNum;
    long remoteUserFolderDirID;
};
typedef struct FindFolderUserRedirectionGlobals FindFolderUserRedirectionGlobals;
typedef FindFolderUserRedirectionGlobals * FindFolderUserRedirectionGlobalsPtr;
```

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In

`Folders.h`

FolderDesc

Used to find existing folder descriptors and create new ones.

```
struct FolderDesc {
    Size descSize;
    FolderType foldType;
    FolderDescFlags flags;
    FolderClass foldClass;
    FolderType foldLocation;
    OSType badgeSignature;
    OSType badgeType;
    UInt32 reserved;
    StrFileName name;
};
typedef struct FolderDesc FolderDesc;
typedef FolderDesc * FolderDescPtr;
```

Fields

`descSize`
The size (in bytes) of this structure.

`foldType`
A constant of type `FolderType` that identifies the kind of target folder. See "Folder Type Constants" (page 985) for a list of possible folder types.

`flags`
Flags indicating whether a folder is created during startup, if the folder name is locked, and if the folder created is invisible; see "Folder Descriptor Flags" (page 982).

`foldClass`
The class indicating whether the folder is relative to the parent folder or special; see "Folder Descriptor Classes" (page 981).

`foldLocation`
For a relative folder, the `foldLocation` field specifies the `FolderType` of the parent folder of the target. For special folders, the location of the folder. See "Folder Descriptor Locations" (page 984).

`badgeSignature`
Reserved. Set this field to 0.

`badgeType`
Reserved. Set this field to 0.

`reserved`
Reserved. Set this field to 0.

`name`
A string specifying the name of the desired folder. For relative folders, this will be the exact name of the desired folder. For special folders, the actual target folder may have a different name than the name specified in the folder descriptor. For example, the System Folder is often given a different name, but it can still be located with `FindFolder` (page 960).

Discussion

The `FolderDesc` structure is supported under Mac OS 8 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Folders.h`

FolderManagerNotificationUPP

Defines a universal procedure pointer (UPP) to a notification function.

```
typedef FolderManagerNotificationProcPtr FolderManagerNotificationUPP;
```

Discussion
For more information, see the description of the `FolderManagerNotificationProcPtr` (page 975) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

FolderRouting

Specifies the folder that files are routed to, based on the folder they are routed from.

```
struct FolderRouting {
    Size descSize;
    OSType fileType;
    FolderType routeFromFolder;
    FolderType routeToFolder;
    RoutingFlags flags;
};
typedef struct FolderRouting FolderRouting;
typedef FolderRouting * FolderRoutingPtr;
```

Fields

`descSize`
The size (in bytes) of this structure.

`fileType`
A constant of type `OSType` that describes the file type of the item to be routed.

`routeFromFolder`
The folder type identifying the folder from which an item will be routed. If an item is dropped on the folder specified in the `routeFromFolder` field, it will be routed to the folder described in the `routeToFolder` field. See "Folder Type Constants" (page 985) for a list of possible values.

`routeToFolder`
The folder type identifying the folder to which an item will be routed; see "Folder Type Constants" (page 985) for a list of possible values.

`flags`
Reserved. Set this field to 0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Folders.h`

MultiUserGestalt

```
struct MultiUserGestalt {
    short giVersion;
    short giReserved0;
    short giReserved1;
    short giReserved2;
    short giReserved3;
    FSSpec giReserved4;
    short giDocsVRefNum;
    long giDocsDirID;
    short giForceSaves;
    short giForceOpens;
    Str31 giSetupName;
    Str31 giUserName;
    Str31 giFrontAppName;
    short giReserved5;
    short giIsOn;
    short giUserLoggedInType;
    char giUserEncryptPwd[16];
    short giUserEnvironment;
    long giReserved6;
    long giReserved7;
    Boolean giDisableScrnShots;
    Boolean giSupportsAsyncFSCalls;
    short giPrefsVRefNum;
    long giPrefsDirID;
    unsigned long giUserLogInTime;
    Boolean giUsingPrintQuotas;
    Boolean giUsingDiskQuotas;
    Boolean giInSystemAccess;
    Boolean giUserFolderEnabled;
    short giReserved8;
    long giReserved9;
    Boolean giInLoginScreen;
};
typedef struct MultiUserGestalt MultiUserGestalt;
typedef MultiUserGestalt * MultiUserGestaltPtr;
```

Fields

`giVersion`
The structure version. A structure version of 0 is invalid.

`giReserved0`
Obsolete with structure version 3.

`giReserved1`
Obsolete.

`giReserved2`
Obsolete with structure version 6.]

`giReserved3`
Obsolete.

`giReserved4`
Obsolete with structure version 6.

`giDocsVRefNum`
The volume reference number associated with the user's documents location.

`giDocsDirID`
The directory ID of the user's documents folder.

`giForceSaves`
`True` if the user is forced to save to their documents folder.

`giForceOpens`
`True` if the user is forced to open from their documents folder.

`giSetupName`
The name of the current setup.

`giUserName`
The name of the current user.

`giFrontAppName`
The name of the frontmost application.

`giReserved5`
Obsolete with structure version 6.

`giIsOn`
`True` if Multiple Users or Macintosh Manager is currently on.

`giUserLoggedInType`
The logged in user type. Zero indicates a normal user, 1 indicates a workgroup administrator, and 2 indicates a global administrator.

`giUserEncryptPwd`
The encrypted user password.

`giUserEnvironment`
The environment that the user has logged into.

`giReserved6`
Obsolete.

`giReserved7`
Obsolete.

`giDisableScrnShots`
`True` if screen shots are not allowed.

`giSupportsAsyncFSCalls`
The Finder uses this to tell if our patches support asynchronous trap patches.

`giPrefsVRefNum`
The volume reference number of preferences.

`giPrefsDirID`
The directory ID of the At Ease Items folder on the preferences volume.

`giUserLogInTime`
The time in seconds the user has been logged in.

`giUsingPrintQuotas`
`True` if the logged in user is using printer quotas.

`giUsingDiskQuotas`
`True` if the logged in user has disk quotas active.

`giInSystemAccess`
`True` if the system is in System Access, that is the owner is logged in.

`giUserFolderEnabled`
`True` if `FindFolder` is redirecting folders.

`giReserved8`
`giReserved9`
`giInLoginScreen`
`True` if no user has logged in, including the owner.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`Folders.h`

Constants

Create Folder Flags

Indicate whether a folder should be created, if it is not found.

```
enum {
    kCreateFolder = true,
    kDontCreateFolder = false
};
```

Constants
`kCreateFolder`
Specifies that the folder should be created, if it is not found.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kDontCreateFolder`
Specifies that the folder should not be created, if it is not found.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

Discussion
You can pass these flag constants in the `createFolder` parameter of the function `FSFindFolder` (page 966).

Folder Descriptor Classes

Specify how folder location information should be interpreted.

```
enum {
    kRelativeFolder = 'relf',
    kSpecialFolder = 'spcf'
};
typedef OSType FolderClass;
```

Constants

`kRelativeFolder`

Relative folders are located in terms of the folders in which they are nested, that is, their parent folders. This constant indicates that the folder location specified is the folder type of the parent folder, and the name specified is the name of the folder. Most folder descriptors are for relative folders.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSpecialFolder`

Special folders—such as the System Folder and the disk's root directory—are in set locations that are not determined relative to any other folder. This constant indicates that the folder is located algorithmically, according to the constant supplied for the folder location (`kBlessedFolder` or `kRootFolder`). Developers cannot create new folder descriptors of the `kSpecialFolder` class.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

Discussion

Constants of type `FolderClass` are used to specify how folder location information should be interpreted in the function `AddFolderDescriptor` (page 957) and the structure `FolderDesc` (page 977). The `FolderClass` constants are supported under Mac OS 8 and later.

Developers can only create new folder descriptors with a class of `kRelativeFolder`.

Folder Descriptor Flags

Specify various attributes of a folder.

```
enum {
    kCreateFolderAtBoot = 0x00000002,
    kCreateFolderAtBootBit = 1,
    kFolderCreatedInvisible = 0x00000004,
    kFolderCreatedInvisibleBit = 2,
    kFolderCreatedNameLocked = 0x00000008,
    kFolderCreatedNameLockedBit = 3,
    kFolderCreatedAdminPrivs = 0x00000010,
    kFolderCreatedAdminPrivsBit = 4
};enum {
    kFolderInUserFolder = 0x00000020,
    kFolderInUserFolderBit = 5,
    kFolderTrackedByAlias = 0x00000040,
    kFolderTrackedByAliasBit = 6,
    kFolderInRemoteUserFolderIfAvailable = 0x00000080,
    kFolderInRemoteUserFolderIfAvailableBit = 7,
    kFolderNeverMatchedInIdentifyFolder = 0x00000100,
    kFolderNeverMatchedInIdentifyFolderBit = 8,
    kFolderMustStayOnSameVolume = 0x00000200,
    kFolderMustStayOnSameVolumeBit = 9,
    kFolderManagerFolderInMacOS9FolderIfMacOSXIsInstalledMask =
0x00000400,
    kFolderManagerFolderInMacOS9FolderIfMacOSXIsInstalledBit = 10,
    kFolderInLocalOrRemoteUserFolder = kFolderInUserFolder |
kFolderInRemoteUserFolderIfAvailable
};
typedef UInt32 FolderDescFlags;
```

Constants

`kCreateFolderAtBoot`
If the bit specified by this mask is set, the folder is created during startup if needed.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kCreateFolderAtBootBit`
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kFolderCreatedInvisible`
If the bit specified by this mask is set, the folder created is invisible.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kFolderCreatedInvisibleBit`
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kFolderCreatedNameLocked`
If the bit specified by this mask is set, the name of the folder is locked when the folder is created.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kFolderCreatedNameLockedBit`
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kFolderCreatedAdminPrivs`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFolderCreatedAdminPrivsBit`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

Discussion
The `FolderDescFlags` enumeration defines masks your application can use in the `AddFolderDescriptor` (page 957) function and the `FolderDesc` (page 977) structure to specify various attributes of a folder. All other flag bits are reserved for future use. The `FolderDescFlags` constants are supported under Mac OS 8 and later.

Folder Descriptor Locations

Identify special folder locations.

```
enum {
    kBlessedFolder = 'blsf',
    kRootFolder = 'rotf'
};typedef OSType FolderLocation;
```

Constants
`kBlessedFolder`
Indicates that the folder location is the System Folder on the volume.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kRootFolder`
Indicates that the folder location is the root directory of the volume.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

Discussion
There are two special folder locations that you can specify in folder descriptors via the `FolderDesc` (page 977) structure and the `AddFolderDescriptor` (page 957) function. For folders whose class is `kSpecialFolder`, you can use the following constants to specify the location of the folder algorithmically. The `FolderLocation` constants are supported under Mac OS 8 and later.

kCurrentUserFolderLocation

```
enum {
    kCurrentUserFolderLocation = 'cusf'
};
```

Constants
`kCurrentUserFolderLocation`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

Folder Type Constants

Specify a type of folder on a particular volume.

```
enum {
    kSystemFolderType = 'macs',
    kDesktopFolderType = 'desk',
    kSystemDesktopFolderType = 'sdsk',
    kTrashFolderType = 'trsh',
    kSystemTrashFolderType = 'strs',
    kWhereToEmptyTrashFolderType = 'empt',
    kPrintMonitorDocsFolderType = 'prnt',
    kStartupFolderType = 'strt',
    kShutdownFolderType = 'shdf',
    kAppleMenuFolderType = 'amnu',
    kControlPanelFolderType = 'ctrl',
    kSystemControlPanelFolderType = 'sctl',
    kExtensionFolderType = 'extn',
    kFontsFolderType = 'font',
    kPreferencesFolderType = 'pref',
    kSystemPreferencesFolderType = 'sprf',
    kTemporaryFolderType = 'temp'
};
enum {
    kExtensionDisabledFolderType = 'extD',
    kControlPanelDisabledFolderType = 'ctrD',
    kSystemExtensionDisabledFolderType = 'macD',
    kStartupItemsDisabledFolderType = 'strD',
    kShutdownItemsDisabledFolderType = 'shdD',
    kApplicationsFolderType = 'apps',
    kDocumentsFolderType = 'docs'
};
enum {
    kVolumeRootFolderType = 'root',
    kChewableItemsFolderType = 'flnt',
    kApplicationSupportFolderType = 'asup',
    kTextEncodingsFolderType = 'ftex',
    kStationeryFolderType = 'odst',
    kOpenDocFolderType = 'odod',
    kOpenDocShellPlugInsFolderType = 'odsp',
    kEditorsFolderType = 'oded',
    kOpenDocEditorsFolderType = 'fodf',
    kOpenDocLibrariesFolderType = 'odlb',
    kGenEditorsFolderType = 'fedi',
    kHelpFolderType = 'fhlp',
    kInternetPlugInFolderType = 'fnet',
    kModemScriptsFolderType = 'fmod',
    kPrinterDescriptionFolderType = 'ppdf',
    kPrinterDriverFolderType = 'fprd',
    kScriptingAdditionsFolderType = 'fscr',
    kSharedLibrariesFolderType = 'flib',
    kVoicesFolderType = 'fvoc',
    kControlStripModulesFolderType = 'sdev',
    kAssistantsFolderType = 'astf',
    kUtilitiesFolderType = 'utif',
    kAppleExtrasFolderType = 'aexf',
    kContextualMenuItemsFolderType = 'cmnu',
    kMacOSReadMesFolderType = 'morf',
    kALMModulesFolderType = 'walk',
    kALMPreferencesFolderType = 'trip',
    kALMLocationsFolderType = 'fall',
    kColorSyncProfilesFolderType = 'prof',
```

```
    kThemesFolderType = 'thme',
    kFavoritesFolderType = 'favs',
    kInternetFolderType = 'intf',
    kAppearanceFolderType = 'appr',
    kSoundSetsFolderType = 'snds',
    kDesktopPicturesFolderType = 'dtpf',
    kInternetSearchSitesFolderType = 'issf',
    kFindSupportFolderType = 'fnds',
    kFindByContentFolderType = 'fbcf',
    kInstallerLogsFolderType = 'ilgf',
    kScriptsFolderType = 'scrf',
    kFolderActionsFolderType = 'fasf',
    kLauncherItemsFolderType = 'laun',
    kRecentApplicationsFolderType = 'rapp',
    kRecentDocumentsFolderType = 'rdoc',
    kRecentServersFolderType = 'rsvr',
    kSpeakableItemsFolderType = 'spki',
    kKeychainFolderType = 'kchn',
    kQuickTimeExtensionsFolderType = 'qtex',
    kDisplayExtensionsFolderType = 'dspl',
    kMultiprocessingFolderType = 'mpxf',
    kPrintingPlugInsFolderType = 'pplg'
};
typedef OSType FolderType;
```

Constants

`kSystemFolderType`
Specifies the System Folder.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kDesktopFolderType`
Specifies the Desktop Folder.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kSystemDesktopFolderType`
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kTrashFolderType`
Specifies the single-user Trash folder.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kSystemTrashFolderType`
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kWhereToEmptyTrashFolderType`
Specifies the shared Trash folder on a file server, this indicates the parent directory of all logged-on users' Trash subdirectories.
Available in Mac OS X v10.0 and later.
Declared in `Folders.h`.

`kPrintMonitorDocsFolderType`
Specifies the PrintMonitor Documents folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kStartupFolderType`
Specifies the Startup Items folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kShutdownFolderType`
Specifies the Shutdown Items folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kAppleMenuFolderType`
Specifies the Apple Menu Items folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kControlPanelFolderType`
Specifies the Control Panels folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSystemControlPanelFolderType`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kExtensionFolderType`
Specifies the Extensions folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFontsFolderType`
Specifies the Fonts folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kPreferencesFolderType`
Specifies the Preferences folder in the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSystemPreferencesFolderType`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kTemporaryFolderType`
Specifies the Temporary folder. This folder exists as an invisible folder at the volume root.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kExtensionDisabledFolderType`
Specifies the Extensions (Disabled) folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kControlPanelDisabledFolderType`
Specifies the Control Panels (Disabled) folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSystemExtensionDisabledFolderType`
Specifies the System Extensions (Disabled) folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kStartupItemsDisabledFolderType`
Specifies the Startup Items (Disabled) folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kShutdownItemsDisabledFolderType`
Specifies the Shutdown Items (Disabled) folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kApplicationsFolderType`
Specifies the Applications folder installed at the root level of the volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kDocumentsFolderType`
Specifies the Documents folder. This folder is created at the volume root. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kVolumeRootFolderType`
Specifies the root folder of a volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kChewableItemsFolderType`
Specifies the invisible folder on the system disk called "Cleanup at Startup" whose contents are deleted when the system is restarted, instead of merely being moved to the Trash. When the `FindFolder` function indicates this folder is available (by returning `noErr`), developers should usually use this folder for their temporary items, in preference to the Temporary Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kApplicationSupportFolderType`
Specifies the Application Support folder in the System Folder. This folder contains code and data files needed by third-party applications. These files should usually not be written to after they are installed. In general, files deleted from this folder remove functionality from an application, unlike files in the Preferences folder, which should be non-essential. One type of file that could be placed here would be plug-ins that the user might want to maintain separately from any application, such as for an image-processing application that has many "fourth-party" plug-ins that the user might want to upgrade separately from the host application. Another type of file that might belong in this folder would be application-specific data files that are not preferences, such as for a scanner application that needs to read description files for specific scanner models according to which are currently available on the SCSI bus or network. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kTextEncodingsFolderType`
Specifies the Text Encodings folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kStationeryFolderType`
Specifies the OpenDoc stationery folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kOpenDocFolderType`
Specifies the OpenDoc root folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kOpenDocShellPlugInsFolderType`
Specifies the OpenDoc shell plug-ins folder in the OpenDoc folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kEditorsFolderType`
Specifies the OpenDoc editors folder in the Mac OS folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kOpenDocEditorsFolderType`
Specifies the OpenDoc subfolder in the Editors folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kOpenDocLibrariesFolderType`
Specifies the OpenDoc libraries folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kGenEditorsFolderType`
Specifies a general editors folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kHelpFolderType`
Specifies the Help folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kInternetPlugInFolderType`
Specifies the Browser Plug-ins folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kModemScriptsFolderType`
Specifies the Modem Scripts folder in the Extensions folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kPrinterDescriptionFolderType`
Specifies the Printer Descriptions folder in the Extensions folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kPrinterDriverFolderType`
Specifies the printer drivers folder. This constant is not currently supported.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kScriptingAdditionsFolderType`
Specifies the Scripting Additions folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSharedLibrariesFolderType`
Specifies the general shared libraries folder. This constant is not currently supported.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kVoicesFolderType`
Specifies the Voices folder in the Extensions folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kControlStripModulesFolderType`
Specifies the Control Strip Modules folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kAssistantsFolderType`
Specifies the Assistants folder installed at the root level of the volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kUtilitiesFolderType`
Specifies the Utilities folder installed at the root level of the volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kAppleExtrasFolderType`
Specifies the Apple Extras folder installed at the root level of the volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kContextualMenuItemsFolderType`
Specifies the Contextual Menu Items folder in the System Folder. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kMacOSReadMesFolderType`
Specifies the Mac OS Read Me Files folder installed at the root level of the volume. Supported with Mac OS 8 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kALMModulesFolderType`
Specifies the Location Manager Modules folder in the Extensions Folder. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kALMPreferencesFolderType`
Specifies the Location Manager Prefs folder in the Preferences folder. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kALMLocationsFolderType`
Specifies the Locations folder in the Location Manager Prefs folder. Files containing configuration information for different locations are stored here. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kColorSyncProfilesFolderType`
Specifies the ColorSync Profiles folder in the System Folder. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kThemesFolderType`
Specifies the Theme Files folder in the Appearance folder. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFavoritesFolderType`
Specifies the Favorites folder in the System Folder. This folder is for storing Internet location files, aliases, and aliases to other frequently used items. Facilities for adding items into this folder are found in Contextual Menus, the Finder, Navigation Services, and others. Supported with Mac OS 8.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kInternetFolderType`
Specifies the Internet folder installed at the root level of the volume. This folder is a location for saving Internet-related applications, resources, and tools. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kAppearanceFolderType`
Specifies the Appearance folder in the System Folder. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSoundSetsFolderType`
Specifies the Sound Sets folder in the Appearance folder. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kDesktopPicturesFolderType`
Specifies the Desktop Pictures folder in the Appearance folder. This folder is used for storing desktop picture files. Files of type `'JPEG'` are auto-routed into this folder when dropped into the System Folder. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kInternetSearchSitesFolderType`
Specifies the Internet Search Sites folder in the System Folder. This folder contains Internet search site specification files used by the Find application when it accesses Internet search sites. Files of type `'issp'` are auto-routed to this folder. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFindSupportFolderType`
Specifies the Find folder in the Extensions folder. This folder contains files used by the Find application. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFindByContentFolderType`
Specifies the Find By Content folder installed at the root level of the volume. This folder is invisible and its use is private to Find By Content. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kInstallerLogsFolderType`
Specifies the Installer Logs folder installed at the root level of the volume. You can use this folder to save installer log files. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kScriptsFolderType`
Specifies the Scripts folder in the System Folder. This folder is for saving AppleScript scripts. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kFolderActionsFolderType`
Specifies the Folder Action Scripts folder in the Scripts folder. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kLauncherItemsFolderType`
Specifies the Launcher Items folder in the System Folder. Items in this folder appear in the Launcher control panel. Items included in folders with names beginning with a bullet (Option-8) character will appear as a separate panel in the Launcher window. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kRecentApplicationsFolderType`
Specifies the Recent Applications folder in the Apple Menu Items folder. Apple Menu Items saves aliases to recent applications here. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kRecentDocumentsFolderType`

Specifies the Recent Documents folder in the Apple Menu Items folder. Apple Menu Items saves aliases to recently opened documents here. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kRecentServersFolderType`

Specifies the Recent Servers folder in the Apple Menu Items folder. Apple Menu Items saves aliases to recently mounted servers here. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSpeakableItemsFolderType`

Specifies the Speakable Items folder. This folder is for storing scripts and items recognized by speech recognition. Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

kDomainTopLevelFolderType

```
enum {
    kDomainTopLevelFolderType = 'dtop',
    kDomainLibraryFolderType = 'dlib',
    kColorSyncFolderType = 'sync',
    kColorSyncCMMFolderType = 'ccmm',
    kColorSyncScriptingFolderType = 'cscr',
    kPrintersFolderType = 'impr',
    kSpeechFolderType = 'spch',
    kCarbonLibraryFolderType = 'carb',
    kDocumentationFolderType = 'info',
    kDeveloperDocsFolderType = 'ddoc',
    kDeveloperHelpFolderType = 'devh',
    kISSDownloadsFolderType = 'issd',
    kUserSpecificTmpFolderType = 'utmp',
    kCachedDataFolderType = 'cach',
    kFrameworksFolderType = 'fram',
    kPrivateFrameworksFolderType = 'pfrm',
    kClassicDesktopFolderType = 'sdsk',
    kDeveloperFolderType = 'devf',
    kSystemSoundsFolderType = 'ssnd',
    kComponentsFolderType = 'cmpd',
    kQuickTimeComponentsFolderType = 'wcmp',
    kCoreServicesFolderType = 'csrv',
    kPictureDocumentsFolderType = 'pdoc',
    kMovieDocumentsFolderType = 'mdoc',
    kMusicDocumentsFolderType = 'doc',
    kInternetSitesFolderType = 'site',

    kDirectoryServicesPlugInsFolderType = 'dplg',
    kInstallerReceiptsFolderType = 'rcpt',
    kFileSystemSupportFolderType = 'fsys',
    kAppleShareSupportFolderType = 'shar',
    kAppleShareAuthenticationFolderType = 'auth',
    kMIDIDriversFolderType = 'midi',
    kKeyboardLayoutsFolderType = 'klay',
    kIndexFilesFolderType = 'indx',
    kFindByContentIndexesFolderType = 'fbcx',
    kManagedItemsFolderType = 'mang',
    kBootTimeStartupItemsFolderType = 'empz'
};
```

kAppleshareAutomountServerAliasesFolderType

```
enum {
    kAppleshareAutomountServerAliasesFolderType = 'srvƒ',
    kPreMacOS91ApplicationsFolderType = 'åpps',
```

```
    kPreMacOS91InstallerLogsFolderType = 'îlgf',
    kPreMacOS91AssistantsFolderType = 'åstƒ',
    kPreMacOS91UtilitiesFolderType = 'ütiƒ',
    kPreMacOS91AppleExtrasFolderType = 'åexƒ',
    kPreMacOS91MacOSReadMesFolderType = 'orƒ',
    kPreMacOS91InternetFolderType = 'întƒ',
    kPreMacOS91AutomountedServersFolderType = 'ßrvƒ',
    kPreMacOS91StationeryFolderType = 'ødst'
};
```

kUsersFolderType

```
enum {
    kUsersFolderType = 'usrs',
    kCurrentUserFolderType = 'cusr',
    kCurrentUserRemoteFolderLocation = 'rusf',
    kCurrentUserRemoteFolderType = 'rusr',
    kSharedUserDataFolderType = 'sdat',
    kVolumeSettingsFolderType = 'vsfd'
};
```

kLocalesFolderType

```
enum {
    kLocalesFolderType = 'ƒloc',
    kFindByContentPluginsFolderType = 'fbcp'
};
```

Disk and Domain Constants

Identify the disk or domain in which to locate a folder.

```
enum {
    kOnSystemDisk = -32768L,
    kOnAppropriateDisk = -32767,
    kSystemDomain = -32766,
    kLocalDomain = -32765,
    kNetworkDomain = -32764,
    kUserDomain = -32763,
    kClassicDomain = -32762
};
enum {
    kLastDomainConstant = kUserDomain
};
```

Constants

`kOnSystemDisk`

Specifies the system disk.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kOnAppropriateDisk`
In most cases, the equivalent of `kOnSystemDisk`. On Mac OS X, use this constant instead of the constant `kOnSytemDisk` to indicate any disk.

Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kSystemDomain`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kLocalDomain`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kNetworkDomain`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kUserDomain`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kClassicDomain`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

`kLastDomainConstant`
Available in Mac OS X v10.0 and later.

Declared in `Folders.h`.

Discussion
You can pass this constant in the `vRefNum` parameter of `FSFindFolder` (page 966) to locate a folder on the startup disk.

Notification Options

Specify options for the `FolderManagerRegisterNotificationProc` function.

```
enum {
    kDoNotRemoveWhenCurrentApplicationQuitsBit = 0,
    kDoNotRemoveWheCurrentApplicationQuitsBit =
kDoNotRemoveWhenCurrentApplicationQuitsBit
};
```

Constants
`kDoNotRemoveWhenCurrentApplicationQuitsBit`
Tells the Folder Manager to not remove your notification function when the current application quits. Otherwise, a notification function registered within an application's context will be automatically removed when that application quits. Programs that register notifications at system startup should set this bit.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kDoNotRemoveWheCurrentApplicationQuitsBit`
Use `kDoNotRemoveWhenCurrentApplicationQuitsBit` instead.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `Folders.h`.

FSFindFolderExtended Flags

Specify additional options for folder searches performed with the `FSFindFolderExtended` function.

```
enum {
    kFindFolderExtendedFlagsDoNotFollowAliasesBit = 0,
    kFindFolderExtendedFlagsDoNotUseUserFolderBit = 1,
    kFindFolderExtendedFlagsUseOtherUserRecord = 0x01000000
};
```

Discussion
These are passed to `FSFindFolderExtended` (page 966) and `FindFolderExtended` (page 962) in the `flags` field.

FindFolderUserRedirectionGlobals Flags

Used in the `flags` field of the `FindFolderUserRedirectionGlobals` structure

```
enum {
    kFindFolderRedirectionFlagUseDistinctUserFoldersBit = 0,
    kFindFolderRedirectionFlagUseGivenVRefAndDirIDAsUserFolderBit
= 1,
    kFindFolderRedirectionFlagsUseGivenVRefNumAndDirIDAsRemoteUserFolderBit
= 2
};
typedef UInt32 RoutingFlags;
```

FindFolderUserRedirectionGlobals Structure Version

Represents the current version of the `FindFolderUserRedirectionGlobals` structure.

```
enum {
    kFolderManagerUserRedirectionGlobalsCurrentVersion = 1
};
```

Notification Messages

Define messages sent to your notification function.

```
enum {
    kFolderManagerNotificationMessageUserLogIn = 'log+',
    kFolderManagerNotificationMessagePreUserLogIn = 'logj',
    kFolderManagerNotificationMessageUserLogOut = 'log-',
    kFolderManagerNotificationMessagePostUserLogOut = 'logp',
    kFolderManagerNotificationDiscardCachedData = 'dche',
    kFolderManagerNotificationMessageLoginStartup = 'stup'
};
```

Constants

`kFolderManagerNotificationMessageUserLogIn`
Sent when a user has logged in. When you receive this message `FindFolder` will return the `vRefNum` and `dirID` of the user's redirected folders until the user logs out. This message can be used to load the new user's preferences.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kFolderManagerNotificationMessagePreUserLogIn`
Sent just prior to redirecting `FindFolder` to the user's folders. Calling `FindFolder` when receiving this notification will return the `vRefNum` and `dirID` of the system folders. This message can be used to update the owner's preference files prior to `FindFolder` being redirected.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kFolderManagerNotificationMessageUserLogOut`
Sent when a user has logged out. This is the last time `FindFolder` will return the user's folders; after this notification `FindFolder` will return the `vRefNum` and `dirID` of system folders. This message can be used to update a user's preference files during logout.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kFolderManagerNotificationMessagePostUserLogOut`
Sent just after `FindFolder` has been restored to return the `vRefNum` and `dirID` of system folders. This message can be used to load the owner's preferences.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kFolderManagerNotificationDiscardCachedData`
Sent by third-party software when the entire Folder Manager cache should be flushed.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

`kFolderManagerNotificationMessageLoginStartup`
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Folders.h`.

FolderManagerCallNotificationProcs Options

Used in the `options` parameter of `FolderManagerCallNotificationProcs`.

```
enum {
    kStopIfAnyNotificationProcReturnsErrorBit = 31
};
```

Result Codes

The most common result codes returned by Folder Manager are listed below.

Result Code	Value	Description
`badFolderDescErr`	-4270	Invalid folder Available in Mac OS X v10.0 and later.
`duplicateFolderDescErr`	-4271	Duplicate folders for a particular routing Available in Mac OS X v10.0 and later.
`noMoreFolderDescErr`	-4272	Available in Mac OS X v10.0 and later.
`invalidFolderTypeErr`	-4273	Invalid folder name Available in Mac OS X v10.0 and later.
`duplicateRoutingErr`	-4274	Same routing for two folders Available in Mac OS X v10.0 and later.
`routingNotFoundErr`	-4275	No routing set up for the folder passed in Available in Mac OS X v10.0 and later.
`badRoutingSizeErr`	-4276	Incorrect `descSize` field of the folder routing structure Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Folder Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Gestalt Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Gestalt.h

Overview

You can use the Gestalt Manager and other system software facilities to investigate the operating environment. You need to know about the operating environment if your application takes advantage of hardware or software that is not available on all Macintosh computers. You can also use the Gestalt Manager to inform the operating system that your software is present and to find out about other software registered with the Gestalt Manager.

Carbon supports the Gestalt Manager. However, the results returned by Gestalt functions in Mac OS X are relevant only to your application's context. In general, the `Gestalt` function returns a different result when called from a Carbon application running in Mac OS X than it returns when called from a Classic application in Mac OS X, because these are different environments. For example, Carbon does not use a ROM, so calling `Gestalt` from a Carbon application on a beige G3 Macintosh computer and passing the `ROMVersion` selector returns a different result than `Gestalt` returns for a Classic application on the same computer. In fact, `Gestalt` could conceivably return different results for the same call by two Carbon applications.

Because `Gestalt` operates on a per-context basis in Mac OS X, you can't use it to share information (through pointers or any other means) among applications.

The `ROMVersion` and `machineType` selectors are not supported in Carbon.

In versions of the Mac OS prior to Mac OS X, the `NewGestalt` and `ReplaceGestalt` functions make use of the system heap, so that new or replaced selectors are available to any process. In Mac OS X, however, there is no system heap, and the selectors are available only on a per-context basis.

Functions by Task

Getting and Setting Gestalt Selector Codes and Values

`Gestalt` (page 1005)
Obtains information about the operating environment.

`NewGestaltValue` (page 1008)
Installs a new `Gestalt` selector code and a value that `Gestalt` returns for that selector.

`SetGestaltValue` (page 1010)
Sets the value the function `Gestalt` will return for a specified selector code, installing the selector if it was not already installed.

`ReplaceGestaltValue` (page 1009)
Replaces the value that the function `Gestalt` returns for a specified selector code with the value provided to the function.

`DeleteGestaltValue` (page 1004)
Deletes a `Gestalt` selector code so that it is no longer recognized by `Gestalt`.

`NewGestalt` (page 1007) Deprecated in Mac OS X v10.3
Adds a selector code to those already recognized by `Gestalt`. (Deprecated. Use `NewGestaltValue` (page 1008) instead.)

`ReplaceGestalt` (page 1009) Deprecated in Mac OS X v10.3
Replaces the selector function associated with an existing selector code. (Deprecated. Use `NewGestaltValue` (page 1008) instead.)

Working With Universal Procedure Pointers for Gestalt Selector Functions

`NewSelectorFunctionUPP` (page 1008)
Creates a universal procedure pointer (UPP) to a selector callback function.

`DisposeSelectorFunctionUPP` (page 1005)
Disposes of a universal procedure pointer to a selector callback function.

`InvokeSelectorFunctionUPP` (page 1006)
Invokes a selector callback function.

Functions

DeleteGestaltValue

Deletes a `Gestalt` selector code so that it is no longer recognized by `Gestalt`.

```
OSErr DeleteGestaltValue (
   OSType selector
);
```

Parameters

selector
The selector code you want to delete. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

Return Value
A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion
After calling this function, subsequent query or replacement calls for the selector code will fail as if the selector had never been installed.

In Mac OS X, the selector is on a per-context basis. You cannot use this function to affect another process.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

DisposeSelectorFunctionUPP

Disposes of a universal procedure pointer to a selector callback function.

```
void DisposeSelectorFunctionUPP (
   SelectorFunctionUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer you want to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

Gestalt

Obtains information about the operating environment.

```
OSErr Gestalt (
   OSType selector,
   SInt32 *response
);
```

Parameters

selector

The selector code for the information you need. You can provide any of the four-character sequences defined in "Gestalt Manager Constants" (page 1012).

response

On input, `Gestalt` interprets this parameter as an address at which it is to place the result returned by the selector function. `Gestalt` ignores any information already at this address.

On return, a pointer to the requested information whose format depends on the selector code specified in the selector parameter. Note that the `Gestalt` function returns the response from all selectors in a long word, which occupies 4 bytes. When not all 4 bytes are needed, the significant information appears in the low-order byte or bytes.

Return Value
A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion
The Apple-defined selector codes fall into two categories: environmental selectors, which supply specific environmental information you can use to control the behavior of your application, and informational selectors, which can't supply information you can use to determine what hardware or software features are available. You can use one of the selector codes defined by Apple or a selector code defined by a third-party product.

Selectors with the suffix `Attr` return a 32-bit response value in which the individual bits represent specific attributes. The constants listed for these response values represent bit numbers.

Special Considerations

When passed one of the Apple-defined selector codes, the `Gestalt` function does not move or purge memory and therefore may be called even at interrupt time. However, selector functions associated with non-Apple selector codes might move or purge memory, and third-party software can alter the Apple-defined selector functions. Therefore, it is safest always to assume that `Gestalt` could move or purge memory.

Version Notes

The `ROMVersion` and `machineType` selectors are not supported in Carbon.

In general, the `Gestalt` function returns a different result when called from a Carbon application running in Mac OS X than it returns when called from a Classic application in Mac OS X, because these are different environments. For example, Carbon does not use a ROM, so calling `Gestalt` from a Carbon application on a beige G3 Macintosh computer and passing the `ROMVersion` selector returns a different result than Gestalt returns for a Classic application on the same computer.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QTCarbonShell
QTMetaData
SampleScannerApp
SoftVDigX
WhackedTV

Declared In

`Gestalt.h`

InvokeSelectorFunctionUPP

Invokes a selector callback function.

```
OSErr InvokeSelectorFunctionUPP (
   OSType selector,
   long *response,
   SelectorFunctionUPP userUPP
);
```

Parameters

selector

The selector code for the function you want to invoke. You can provide any of the four-character sequences defined in "Gestalt Manager Constants" (page 1012).

response

On ouput, the value associated with the selector code.

userUPP

A universal procedure pointer to the selector callback function you want to invoke.

Return Value

A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion
You should not need to call this function, as the operating system invokes your selecor callback for you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

NewGestalt

Adds a selector code to those already recognized by `Gestalt`. (Deprecated in Mac OS X v10.3. Use `NewGestaltValue` (page 1008) instead.)

```
OSErr NewGestalt (
   OSType selector,
   SelectorFunctionUPP gestaltFunction
);
```

Parameters

selector

The selector code you want to add. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

gestaltFunction

A universal procedure pointer (UPP) to the selector callback function that `Gestalt` executes when it receives the new selector code. See `SelectorFunctionProcPtr` (page 1011) for more information on the callback you need to provide.

Return Value
A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion
The `NewGestalt` function registers a specified selector code with the Gestalt Manager so that when the `Gestalt` function is called with that selector code, the specified selector function is executed. Before calling `NewGestalt`, you must define a selector function callback. See `SelectorFunctionProcPtr` (page 1011) for a description of how to define your selector function.

Registering with the Gestalt Manager is a way for software such as system extensions to make their presence known to potential users of their services.

Special Considerations

You should avoid using the `NewGestalt` function to add a selector code, which requires moving your selector function into the system heap. Applications do not have access to the system heap in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Gestalt.h`

NewGestaltValue

Installs a new `Gestalt` selector code and a value that `Gestalt` returns for that selector.

```
OSErr NewGestaltValue (
   OSType selector,
   SInt32 newValue
);
```

Parameters

selector

The selector code you want to add. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

newValue

The value to return for the new selector code.

Return Value

A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion

You call the function `NewGestaltValue` when the specified selector is not already installed and you don't want to override an existing value.

In Mac OS X, the new selector and value are on a per-context basis. That means they are available only to the application or other code that installs them. You cannot use this function to make information available to another process.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Gestalt.h`

NewSelectorFunctionUPP

Creates a universal procedure pointer (UPP) to a selector callback function.

```
SelectorFunctionUPP NewSelectorFunctionUPP (
   SelectorFunctionProcPtr userRoutine
);
```

Parameters

userRoutine

The address of the selector callback function.

Return Value

On return, a universal procedure pointer to the selector callback function. See the description of the `SelectorFunctionUPP` data type.

Discussion

You use the `NewSelectorFunctionUPP` function to create a UPP to pass to the `NewGestalt` or `ReplaceGestalt` functions.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

ReplaceGestalt

Replaces the selector function associated with an existing selector code. (Deprecated in Mac OS X v10.3. Use `NewGestaltValue` (page 1008) instead.)

```
OSErr ReplaceGestalt (
   OSType selector,
   SelectorFunctionUPP gestaltFunction,
   SelectorFunctionUPP *oldGestaltFunction
);
```

Parameters

selector

The selector code for the function you want to replace. You must provide the four-character sequence you provided previously for the function you are replacing.

gestaltFunction

A universal procedure pointer to the replacement selector function. You must obtain the value for this argument by calling the `NewGestaltSelectorFunctionUPP` function.

oldGestaltFunction

On output, a universal procedure pointer to the callback function previously associated with the specified selector. If the function `ReplaceGestalt` returns an error of any type, then the value of `oldGestaltFunction` is undefined.

Return Value
A result code. See "Gestalt Manager Result Codes" (page 1113).

Special Considerations

You should avoid using the `ReplaceGestalt` function to replace an existing selector callback function, which also requires your replacement function to reside in the system heap. Applications do not have access to the system heap in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Gestalt.h`

ReplaceGestaltValue

Replaces the value that the function `Gestalt` returns for a specified selector code with the value provided to the function.

```
OSErr ReplaceGestaltValue (
   OSType selector,
   SInt32 replacementValue
);
```

Parameters

selector

The selector code you want to add. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

replacementValue

The replacement `Gestalt` value for the selector code.

Return Value

A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion

You use the function `ReplaceGestaltValue` to replace an existing value. You should not call this function to introduce a value that doesn't already exist; instead call the function `NewGestaltValue` (page 1008).

In Mac OS X, the selector and replacement value are on a per-context basis. That means they are available only to the application or other code that installs them. You cannot use this function to make information available to another process.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Gestalt.h`

SetGestaltValue

Sets the value the function `Gestalt` will return for a specified selector code, installing the selector if it was not already installed.

```
OSErr SetGestaltValue (
   OSType selector,
   SInt32 newValue
);
```

Parameters

selector

The selector code you want to set. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

newValue

The new `Gestalt` value for the selector code.

Return Value

A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion

You use `SetGestaltValue` to establish a value for a selector, without regard to whether the selector was already installed.

In Mac OS X, the selector and new value are on a per-context basis. That means they are available only to the application or other code that installs them. You cannot use this function to make information available to another process.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

Callbacks

SelectorFunctionProcPtr

Defines a pointer to a selector callback function that returns information associated with your own selector code.

```
typedef OSErr (*SelectorFunctionProcPtr)
(
    OSType selector,
    long * response
);
```

If you name your function `MySelectorFunctionProc`, you would declare it like this:

```
OSErr SelectorFunctionProcPtr (
    OSType selector,
    long * response
);
```

Parameters

`selector`
The selector code that triggers the function. This should be a four-character sequence similar to those defined in "Gestalt Manager Constants" (page 1012).

`response`
On output, the information associated with the selector code.

Return Value
A result code. See "Gestalt Manager Result Codes" (page 1113).

Discussion
Your selector function places the requested information in the `response` parameter and returns a result code. If the information is not available, the selector function returns the appropriate error code, which the `Gestalt` function returns as its function result.

A selector function can call `Gestalt` or even other selector functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

Data Types

SelectorFunctionUPP

Defines a universal procedure pointer to a selector function callback.

```
typedef SelectorFunctionProcPtr SelectorFunctionUPP;
```

Discussion
You can obtain a `SelectorFunctionUPP` by calling the function `NewSelectorFunctionUPP` (page 1008). For more information, see `SelectorFunctionProcPtr` (page 1011).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Gestalt.h`

Constants

Addressing Mode Attribute Selectors

Specify feature availability information for the addressing mode of the operating system.

```
enum {
    gestaltAddressingModeAttr = 'addr',
    gestalt32BitAddressing = 0,
    gestalt32BitSysZone = 1,
    gestalt32BitCapable = 2
};
```

Constants

`gestaltAddressingModeAttr`
The `Gestalt` selector you pass to determine the addressing mode attributes that are present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt32BitAddressing`
If `true`, the operating system is using 32-bit addressing mode.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt32BitSysZone`
If `true`, there is a 32-bit compatible system zone.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt32BitCapable`
If `true`, Machine is 32-bit capable.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent on memory, your application should pass the selector `gestaltAddressingModeAttr` to the Gestalt function to determine the addressing mode attributes that are present.

Admin Attribute Selectors

Specify feature availability for Macintosh Manager adminstration software.

```
enum {
    gestaltAdminFeaturesFlagsAttr = 'fred',
    gestaltFinderUsesSpecialOpenFoldersFile = 0
};
```

Constants
`gestaltAdminFeaturesFlagsAttr`
The `Gestalt` selector you pass to determine the admin features that are present. This selector is typically used by the system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFinderUsesSpecialOpenFoldersFile`
Specifies that the Finder uses a special file to store the list of open folders.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

AFP Client Selectors

Specify version and feature availability information for the AFP client.

```
enum {
    gestaltAFPClient = 'afps',
    gestaltAFPClientVersionMask = 0x0000FFFF,
    gestaltAFPClient3_5 = 0x0001,
    gestaltAFPClient3_6 = 0x0002,
    gestaltAFPClient3_6_1 = 0x0003,
    gestaltAFPClient3_6_2 = 0x0004,
    gestaltAFPClient3_6_3 = 0x0005,
    gestaltAFPClient3_7 = 0x0006,
    gestaltAFPClient3_7_2 = 0x0007,
    gestaltAFPClient3_8 = 0x0008,
    gestaltAFPClient3_8_1 = 0x0009,
    gestaltAFPClient3_8_3 = 0x000A,
    gestaltAFPClient3_8_4 = 0x000B,
    gestaltAFPClientAttributeMask = 0xFFFF0000,
    gestaltAFPClientCfgRsrc = 16,
    gestaltAFPClientSupportsIP = 29,
    gestaltAFPClientVMUI = 30,
    gestaltAFPClientMultiReq = 31
};
```

Alias Manager Attribute Selectors

Specify feature availability information for the Alias Manager.

```
enum {
    gestaltAliasMgrAttr = 'alis',
    gestaltAliasMgrPresent = 0,
    gestaltAliasMgrSupportsRemoteAppletalk = 1,
    gestaltAliasMgrSupportsAOCEKeychain = 2,
    gestaltAliasMgrResolveAliasFileWithMountOptions = 3,
    gestaltAliasMgrFollowsAliasesWhenResolving = 4,
    gestaltAliasMgrSupportsExtendedCalls = 5,
    gestaltAliasMgrSupportsFSCalls = 6,
    gestaltAliasMgrPrefersPath = 7
};
```

Constants

`gestaltAliasMgrAttr`

The selector you pass to the `Gestalt` function to determine the Alias Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Appearance Manager Attribute Selectors

Specify feature availability information for the Appearance Manager.

```
enum {
    gestaltAppearanceAttr = 'appr',
    gestaltAppearanceExists = 0,
    gestaltAppearanceCompatMode = 1
};
```

Constants

`gestaltAppearanceAttr`

The `Gestalt` selector passed to determine whether the Appearance Manager is present. Produces a 32-bit value whose bits you should test to determine which Appearance Manager features are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppearanceExists`

If this bit is set, Appearance Manager functions are available. To determine which version of the Appearance Manager is installed, check for the presence of the `Gestalt` selector `gestaltAppearanceVersion`. If this bit is not set, Appearance Manager functions are not available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppearanceCompatMode`

If this bit is set, systemwide platinum appearance is off. When systemwide platinum appearance is off, the Appearance Manager does not auto-map standard System 7 definition functions to their Mac OS 8 equivalents (for those applications that have not called `RegisterAppearanceClient`). If this bit is not set, systemwide platinum appearance is on, and the Appearance Manager auto-maps standard System 7 definition functions to their Mac OS 8 equivalents for all applications.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

Before calling any functions dependent upon the Appearance Manager's presence, your application should pass the selector `gestaltAppearanceAttr` to the `Gestalt` function to determine whether the Appearance Manager is present. To determine which version of the Appearance Manager is installed, your application should check for the presence of the `Gestalt` selector `gestaltAppearanceVersion`.

Appearance Manager Version Selector

Specifies version information for the Appearance Manager.

```
enum {
    gestaltAppearanceVersion = 'apvr'
};
```

Constants

`gestaltAppearanceVersion`

The `Gestalt` selector passed to determine which version of the Appearance Manager is installed. If this selector exists, Appearance Manager 1.0.1 (or later) is installed. The version number of the currently installed Appearance Manager is returned in the low-order word of the result in binary code decimal format (for example, version 1.0.1 would be 0x0101). If this selector does not exist but `gestaltAppearanceAttr` does, Appearance Manager 1.0 is installed.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Apple Event Manager Attribute Selectors

Specify feature availability information for the Apple Event Manager.

```
enum {
    gestaltAppleEventsAttr = 'evnt',
    gestaltAppleEventsPresent = 0,
    gestaltScriptingSupport = 1,
    gestaltOSLInSystem = 2,
    gestaltSupportsApplicationURL = 4
};
```

Constants

`gestaltAppleEventsAttr`
A selector you pass to the `Gestalt` function. If the Apple Event Manager is not present, the `Gestalt` function returns an error value; otherwise, it returns `noErr` and supplies, in the `response` parameter, a 32-bit value whose bits specify which features of the Apple Event Manager are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppleEventsPresent`
A `Gestalt` attribute constant. If the bit specified by this constant is set in the `response` parameter value supplied by `Gestalt` for the `gestaltAppleEventsAttr` selector, the Apple Event Manager is present and installed in the system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltScriptingSupport`
A `Gestalt` attribute constant. If the bit specified by this constant is set in the `response` parameter value supplied by `Gestalt` for the `gestaltAppleEventsAttr` selector, the Open Scripting Architecture (OSA) is available to provide scripting support. The OSA is described in "Scripting Components".

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltOSLInSystem`
A `Gestalt` attribute constant. If the bit specified by this constant is set in the `response` parameter value supplied by `Gestalt` for the `gestaltAppleEventsAttr` selector, the Object Support Library (OSL) is part of the system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSupportsApplicationURL`
Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

AppleScript Attribute Selectors

Specify feature availability information for AppleScript.

```
enum {
    gestaltAppleScriptAttr = 'ascr',
    gestaltAppleScriptPresent = 0,
    gestaltAppleScriptPowerPCSupport = 1
};
```

Constants

`gestaltAppleScriptAttr`

A selector you pass to the `Gestalt` function. If AppleScript is not present, the `Gestalt` function returns an error value; otherwise, it returns `noErr` and supplies, in the `response` parameter, a 32-bit value whose bits specify which AppleScript features are available.

The only bit currently in use specifies whether AppleScript is present. You can test this bit with the constant `gestaltAppleScriptPresent`.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppleScriptPresent`

A `Gestalt` attribute constant. If the bit specified by this constant is set in the `response` parameter value supplied by `Gestalt` for the `gestaltAppleScriptAttr` selector, AppleScript is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppleScriptPowerPCSupport`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

AppleScript Version Selector

Specifies version information for AppleScript.

```
enum {
    gestaltAppleScriptVersion = 'ascv'
};
```

Constants

`gestaltAppleScriptVersion`

A selector you pass to the `Gestalt` function. If AppleScript is not present, the `Gestalt` function returns an error value; otherwise, it returns `noErr` and supplies, in the `response` parameter, a 32-bit AppleScript version number.

The low word of the 32-bit AppleScript version number specifies the current AppleScript version, while the high word specifies a compatibility version. For example, for AppleScript 1.3.7, which shipped with Mac OS 8.6, the value returned in the `response` parameter, viewed as a hex number, is 0x01100137. The low word, 0x0137, refers to the current AppleScript version. The high word, 0x0110, refers to the compatibility version number—scripts written for AppleScript versions 1.1.0 and later will run with AppleScript version 1.3.7.

The Version Notes section provides additional information about AppleScript versions and features.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Version Notes
For System 7.0 and 7.1, AppleScript and the Apple Event Manager were optional installs. Starting with System 7.5, they are part of a standard install, so if you've already checked for the presence of System 7.5 or later, you'll know that the Apple Event Manager is available, though AppleScript could be disabled using the Extensions Manager.

If you need features that are only available starting with a specific version of AppleScript, call `Gestalt` with the `gestaltAppleScriptVersion` selector to obtain the version number, then determine whether it is greater than or equal to the version your application requires.

AppleTalk Driver Version Selector

Specifies version information for the AppleTalk driver.

```
enum {
    gestaltATalkVersion = 'atkv'
};
```

Constants

`gestaltATalkVersion`

The version number of the AppleTalk driver, in the format introduced with AppleTalk version 56. The version is stored in the high 3 bytes of the return value.

Byte 3 contains the major revision number, byte 2 contains the minor revision number, and byte 1 contains a constant that represents the release stage.

For example, if you call the `Gestalt` function with the 'atkv' selector when AppleTalk version 57 is loaded, you receive the long integer response value $39008000.

Byte 0 always contains 0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

AppleTalk Version Selector

Specifies version information for AppleTalk.

```
enum {
    gestaltAppleTalkVersion = 'atlk'
};
```

Constants

`gestaltAppleTalkVersion`

The version number of the AppleTalk driver (in particular, the .MPP driver) currently installed. The version number is placed into the low-order byte of the result; ignore the three high-order bytes. If an AppleTalk driver is not currently open, the `response` parameter is 0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

ATSUI Attribute Selectors

Specify feature availability for Apple Type Services for Unicode Imaging.

```
enum {
    gestaltATSUFeatures = 'uisf',
    gestaltATSUTrackingFeature = 0x00000001,
    gestaltATSUMemoryFeature = 0x00000001,
    gestaltATSUFallbacksFeature = 0x00000001,
    gestaltATSUGlyphBoundsFeature = 0x00000001,
    gestaltATSULineControlFeature = 0x00000001,
    gestaltATSULayoutCreateAndCopyFeature = 0x00000001,
    gestaltATSULayoutCacheClearFeature = 0x00000001,
    gestaltATSUTextLocatorUsageFeature = 0x00000002,
    gestaltATSULowLevelOrigFeatures = 0x00000004,
    gestaltATSUFallbacksObjFeatures = 0x00000008,
    gestaltATSUIgnoreLeadingFeature = 0x00000008,
    gestaltATSUByCharacterClusterFeature = 0x00000010,
    gestaltATSUAscentDescentControlsFeature = 0x00000010,
    gestaltATSUHighlightInactiveTextFeature = 0x00000010,
    gestaltATSUPositionToCursorFeature = 0x00000010,
    gestaltATSUBatchBreakLinesFeature = 0x00000010,
    gestaltATSUTabSupportFeature = 0x00000010,
    gestaltATSUDirectAccess = 0x00000010,
    gestaltATSUDecimalTabFeature  = 0x00000020,
    gestaltATSUBiDiCursorPositionFeature = 0x00000020,
    gestaltATSUNearestCharLineBreakFeature = 0x00000020,
    gestaltATSUHighlightColorControlFeature = 0x00000020,
    gestaltATSUUnderlineOptionsStyleFeature = 0x00000020,
    gestaltATSUStrikeThroughStyleFeature = 0x00000020,
    gestaltATSUDropShadowStyleFeature = 0x00000020
};
```

Constants

`gestaltATSUFeatures`

Specifies the ATSUI features available on the user's system. You pass this selector to the `Gestalt` function. On return, the `Gestalt` function passes back a value that represents the features available in the version of ATSUI installed on the user's system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltATSUTrackingFeature`

If the bit specified by this mask constant is set, the functions `ATSUCountFontTracking` and `ATSUGetIndFontTracking` are available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSUMemoryFeature`

If the bit specified by this mask is set, the functions `ATSUCreateMemorySetting`, `ATSUSetCurrentMemorySetting`, `ATSUGetCurrentMemorySetting`, and `ATSUDisposeMemorySetting` are available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSUFallbacksFeature`

If the bit specified by this mask is set, the functions `ATSUSetFontFallbacks` and `ATSUGetFontFallbacks` are available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSUGlyphBoundsFeature`
If the bit specified by this mask is set, the function `ATSUGetGlyphBounds` is available.

Available beginning with ATSU 1.1.

Declared in `Gestalt.h`.

`gestaltATSULineControlFeature`
If the bit specified by this mask is set, the functions `ATSUCopyLineControls`, `ATSUSetLineControls`, `ATSUGetLineControl`, `ATSUGetAllLineControls`, and `ATSUClearLineControls` are available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSULayoutCreateAndCopyFeature`
If the bit specified by this mask is set, the function `ATSUCreateAndCopyTextLayout` is available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSULayoutCacheClearFeature`
If the bit specified by this mask is set, the function `ATSUClearLayoutCache` is available.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSUTextLocatorUsageFeature`
If the bit specified by this mask is set, the text-break locator attribute is available for both style and text layout objects.

Available beginning with ATSUI 1.2.

Declared in `Gestalt.h`.

`gestaltATSULowLevelOrigFeatures`
If the bit specified by this mask is set, the low-level features introduced in ATSUI version 2.0 are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltATSUFallbacksObjFeatures`
If the bit specified by this mask is set, `ATSUFontFallbacks` objects are available.

Available beginning with ATSUI version 2.3.

Declared in `Gestalt.h`.

`gestaltATSUIgnoreLeadingFeature`
If the bit specified by this mask is set, the line layout option (`kATSIgnoreFontLeadingTag`) to ignore the font leading value is available.

Available beginning with ATSUI version 2.3.

Declared in `Gestalt.h`.

`gestaltATSUByCharacterClusterFeature`
If the bit specified by this mask is set, ATSUI cursor movement types are available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUAscentDescentControlsFeature`
If the bit specified by this mask is set, ascent and descent controls (`kATSUDescentTag` and `kATSUAscentTag`) are available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUHighlightInactiveTextFeature`
If the bit specified by this mask is set, the highlight inactive text feature is available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUPositionToCursorFeature`
If the bit specified by this mask is set, the position-to-cursor feature is available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUBatchBreakLinesFeature`
If the bit specified by this mask is set, the `ATSUBatchBreakLines` function is available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUTabSupportFeature`
If the bit specified by this mask is set, support for tabs is available.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUDirectAccess`
If the bit specified by this mask is set, ATSU direct-access functions are available. These functions let you access glyph information directly.

Available beginning with ATSUI version 2.4.

Declared in `Gestalt.h`.

`gestaltATSUDecimalTabFeature`
If the bit specified by this mask is set, your application can set a decimal tab character.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUBiDiCursorPositionFeature`
If the bit specified by this mask is set, support for bidirectional cursor positioning is available.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUNearestCharLineBreakFeature`
If the bit specified by this mask is set, the nearest character line break feature is available.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUHighlightColorControlFeature`
If the bit specified by this mask is set, your application can control highlight color.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUUnderlineOptionsStyleFeature`
If the bit specified by this mask is set, underline options are available.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUStrikeThroughStyleFeature`
If the bit specified by this mask is set, strike through styles are available.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

`gestaltATSUDropShadowStyleFeature`
If the bit specified by this mask is set, drop shadow features are available.

Available beginning with ATSUI version 2.5.

Declared in `Gestalt.h`.

Discussion
You can pass the `gestaltATSUFeature` selector to the `Gestalt` function to obtain a value that specifies which ATSUI features are available on the user's system.

You can pass the `gestaltATSUVersion` selector to the `Gestalt` function to determine which version of ATSUI is installed on the user's system. See "ATSUI Version Selectors" (page 1022) for more information

ATSUI Version Selectors

Specify version information for Apple Type Service for Unicode Imaging.

```
enum {
    gestaltATSUVersion = 'uisv',
    gestaltOriginalATSUVersion = (1 << 16),
    gestaltATSUUpdate1 = (2 << 16),
    gestaltATSUUpdate2 = (3 << 16),
    gestaltATSUUpdate3 = (4 << 16),
    gestaltATSUUpdate4 = (5 << 16),
    gestaltATSUUpdate5 = (6 << 16),
    gestaltATSUUpdate6 = (7 << 16),
    gestaltATSUUpdate7 = (8 << 16)
};
```

Constants
`gestaltATSUVersion`
Specifies the version of ATSUI installed on the user's system. You pass this selector to the `Gestalt` function. On return, the `Gestalt` function passes back a value that represents the version of ATSUI installed on the user's system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltOriginalATSUVersion`
Indicates that version 1.0 of ATSUI is installed on the user's system.

Available beginning with ATSUI 1.0.

Declared in `Gestalt.h`.

`gestaltATSUUpdate1`
Indicates that version 1.1 of ATSUI is installed on the user's system.

Available beginning with ATSUI 1.1.

Declared in `Gestalt.h`.

`gestaltATSUUpdate2`
Indicates that version 1.2 of ATSUI is installed on the user's system.

Available beginning with ATSUI 1.2.

Declared in `Gestalt.h`.

`gestaltATSUUpdate3`
Indicates that version 2.0 of ATSUI is installed on the user's system.

Available beginning with ATSUI 2.0.

Declared in `Gestalt.h`.

`gestaltATSUUpdate4`
Indicates that ATSUI for a version of Mac OS X from 10.0.1 through 10.0.4 is installed on the user's system.

Available beginning with Mac OS X version 10.0.1.

Declared in `Gestalt.h`.

`gestaltATSUUpdate5`
Indicates that version 2.3 of ATSUI is installed on the user's system. Available beginning with ATSUI 2.3, in Mac OS X version 10.1.

Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

`gestaltATSUUpdate6`
Indicates that version 2.4 of ATSUI is installed on the user's system. Available beginning with ATSUI 2.4, in Mac OS X version 10.2.

Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

`gestaltATSUUpdate7`
Indicates that version 2.5 of ATSUI is installed on the user's system. Available beginning with ATSUI 2.5, in Mac OS X version 10.3.

Available in Mac OS X v10.3 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any functions dependent upon ATSUI, you should pass the `gestaltATSUVersion` selector to the `Gestalt` function to determine which version of ATSUI is available.

You can pass the `gestaltATSUFeatures` selector to the `Gestalt` function to determine which features of ATSUI are available. See "ATSUI Attribute Selectors" (page 1018) for more information.

ATA Manager Attribute Selectors

Specify feature availability information for the ATA Manager.

```
enum {
    gestaltATAAttr = 'ata ',
    gestaltATAPresent = 0
};
```

AUX Version Selector

Specifies version information for A/UX.

```
enum {
    gestaltAUXVersion = 'a/ux'
};
```

Constants

`gestaltAUXVersion`

The version of A/UX if it is currently executing. The result is placed into the low-order word of the response parameter. If A/UX is not executing, the `Gestalt` function returns `gestaltUnknownErr`.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

AVL Tree Attribute Selectors

Specify feature availability information for AVL tree routines.

```
enum {
    gestaltAVLTreeAttr = 'tree',
    gestaltAVLTreePresentBit = 0,
    gestaltAVLTreeSupportsHandleBasedTreeBit = 1,
    gestaltAVLTreeSupportsTreeLockingBit = 2
};
```

Bus Clock Version Selector

Specifies version information for the bus clock speed.

```
enum {
    gestaltBusClkSpeed = 'bclk'
};
```

Carbon Version Selector

Specifies version information for Carbon.

```
enum {
    gestaltCarbonVersion = 'cbon'
};
```

Classic Compatibility Attribute Selectors

Specify feature availability for the Classic environment.

```
enum {
    gestaltMacOSCompatibilityBoxAttr = 'bbox',
    gestaltMacOSCompatibilityBoxPresent = 0,
    gestaltMacOSCompatibilityBoxHasSerial = 1,
    gestaltMacOSCompatibilityBoxless = 2
};
```

CloseView Attribute Selectors

Specify feature availability information for CloseView.

```
enum {
    gestaltCloseViewAttr = 'BSDa',
    gestaltCloseViewEnabled = 0,
    gestaltCloseViewDisplayMgrFriendly = 1
};
```

Code Fragment Manager Attribute Selectors

Specify feature availability information for the Code Fragment Manager.

```
enum {
    gestaltCFMAttr = 'cfrg',
    gestaltCFMPresent = 0,
    gestaltCFMPresentMask = 0x0001,
    gestaltCFM99Present = 2,
    gestaltCFM99PresentMask = 0x0004
};
```

Collection Manager Version Selector

Specify version information for the Collection manager.

```
enum {
    gestaltCollectionMgrVersion = 'cltn'
};
```

Constants

`gestaltCollectionMgrVersion`
Collection Manager version.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Color Picker Version Selectors

Specify version information for the Color Picker.

```
enum {
    gestaltColorPickerVersion = 'cpkr',
    gestaltColorPicker = 'cpkr'
};
```

Discussion
To test for the availability and version of the Color Picker Manager, use the `Gestalt` function with the selector defined by this enumerator.

If the `Gestalt` function returns a value of 00000200, version 2.0 of the Color Picker Manager is available. If the `Gestalt` function returns a value of 00000100, version 1.0 (that is, the original Color Picker Package) is available.

ColorSync Manager Attribute Selectors

Specify feature availability information for the ColorSync Manager.

```
enum {
    gestaltColorMatchingAttr = 'cmta',
    gestaltHighLevelMatching = 0,
    gestaltColorMatchingLibLoaded = 1
};
```

Constants

`gestaltColorMatchingAttr`
The selector for obtaining version information. Use when calling the `Gestalt` function to check for particular ColorSync Manager features.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHighLevelMatching`
This constant is provided for backward compatibility only. Bit 0 of the `Gestalt` response value is always set if ColorSync is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorMatchingLibLoaded`
This constant is provided for backward compatibility only. Bit 1 of the `Gestalt` response value is always set on a Power Macintosh machine if ColorSync is present. It is always cleared on a 68K machine if ColorSync is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
These constants were added to ColorSync version 2.0 to aid in the transition from 68K to PowerPC systems. They are not recommended for new applications and are not guaranteed to be carried forward in future versions of ColorSync. However, they are still supported as of version 2.5 for backward compatibility. If you call the `Gestalt` function passing the selector `gestaltColorMatchingAttr`, you can test the bit fields of

the returned value with the `gestaltColorMatchingLibLoaded` constant to determine if the ColorSync Manager shared libraries are loaded, or with the `gestaltHighLevelMatching` constant to determine if the ColorSync QuickDraw-specific functions are present.

ColorSync Manager Version Selectors

Specify version information for the ColorSync Manager.

```
enum {
    gestaltColorMatchingVersion = 'cmtc',
    gestaltColorSync10 = 0x0100,
    gestaltColorSync11 = 0x0110,
    gestaltColorSync104 = 0x0104,
    gestaltColorSync105 = 0x0105,
    gestaltColorSync20 = 0x0200,
    gestaltColorSync21 = 0x0210,
    gestaltColorSync211 = 0x0211,
    gestaltColorSync212 = 0x0212,
    gestaltColorSync213 = 0x0213,
    gestaltColorSync25 = 0x0250,
    gestaltColorSync26 = 0x0260,
    gestaltColorSync261 = 0x0261,
    gestaltColorSync30 = 0x0300
};
```

Constants

`gestaltColorMatchingVersion`
The selector for obtaining version information. Use when calling the `Gestalt` function to determine whether the ColorSync Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync10`
A `Gestalt` response value of `gestaltColorSync10` indicates version 1.0 of the ColorSync Manager is present. This version supports general purpose color matching only and does not provide QuickDraw-specific matching functions.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync11`
A `Gestalt` response value of `gestaltColorSync11` indicates version 1.0.3 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync104`
A `Gestalt` response value of `gestaltColorSync104` indicates version 1.4 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync105`
A `Gestalt` response value of `gestaltColorSync105` indicates version 1.5 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync20`
A `Gestalt` response value of `gestaltColorSync20` indicates version 2.0 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync21`
A `Gestalt` response value of `gestaltColorSync21` indicates version 2.1 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync211`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync212`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync213`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync25`
A `Gestalt` response value of `gestaltColorSync25` indicates version 2.5 of the ColorSync Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync26`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync261`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltColorSync30`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
These constants were added to ColorSync version 2.0 to aid in the transition from 68K to PowerPC systems. They are not recommended for new applications and are not guaranteed to be carried forward in future versions of ColorSync. However, they are still supported as of version 2.5 for backward compatibility. If you call the `Gestalt` function passing the selector `gestaltColorMatchingAttr`, you can test the bit fields of

the returned value with the `gestaltColorMatchingLibLoaded` constant to determine if the ColorSync Manager shared libraries are loaded, or with the `gestaltHighLevelMatching` constant to determine if the ColorSync QuickDraw-specific functions are present.

Communications Toolbox Version Selector

Specifies version information for the Communications Toolbox.

```
enum {
    gestaltCTBVersion = 'ctbv'
};
```

Constants

`gestaltCTBVersion`

The version number of the Communications Toolbox (in the low-order word of the return value).

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Communication Resource Manager Attribute Selectors

Specify version and feature availability information for the Communications Resource Manager.

```
enum {
    gestaltCRMAttr = 'crm ',
    gestaltCRMPresent = 0,
    gestaltCRMPersistentFix = 1,
    gestaltCRMToolRsrcCalls = 2
};
```

Component Manager Version Selectors

Specify version information for the Coomponent Manager.

```
enum {
    gestaltComponentMgr = 'cpnt',
    gestaltComponentPlatform = 'copl'
};
```

Constants

`gestaltComponentMgr`

The `Gestalt` selector you pass to determine what version of the Component Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

To determine the version of the current Component Manager, your application should pass the selector `gestaltComponentMgr` to the `Gestalt` function.

Computer Model Selectors

Specify computer models.

```
enum {
    gestaltMachineType = 'mach',
    gestaltClassic = 1,
    gestaltMacXL = 2,
    gestaltMac512KE = 3,
    gestaltMacPlus = 4,
    gestaltMacSE = 5,
    gestaltMacII = 6,
    gestaltMacIIx = 7,
    gestaltMacIIcx = 8,
    gestaltMacSE030 = 9,
    gestaltPortable = 10,
    gestaltMacIIci = 11,
    gestaltPowerMac8100_120 = 12,
    gestaltMacIIfx = 13,
    gestaltMacClassic = 17,
    gestaltMacIIsi = 18,
    gestaltMacLC = 19,
    gestaltMacQuadra900 = 20,
    gestaltPowerBook170 = 21,
    gestaltMacQuadra700 = 22,
    gestaltClassicII = 23,
    gestaltPowerBook100 = 24,
    gestaltPowerBook140 = 25,
    gestaltMacQuadra950 = 26,
    gestaltMacLCIII = 27,
    gestaltPerforma450 = gestaltMacLCIII,
    gestaltPowerBookDuo210 = 29,
    gestaltMacCentris650 = 30,
    gestaltPowerBookDuo230 = 32,
    gestaltPowerBook180 = 33,
    gestaltPowerBook160 = 34,
    gestaltMacQuadra800 = 35,
    gestaltMacQuadra650 = 36,
    gestaltMacLCII = 37,
    gestaltPowerBookDuo250 = 38,
    gestaltAWS9150_80 = 39,
    gestaltPowerMac8100_110 = 40,
    gestaltAWS8150_110 = gestaltPowerMac8100_110,
    gestaltPowerMac5200 = 41,
    gestaltPowerMac5260 = gestaltPowerMac5200,
    gestaltPerforma5300 = gestaltPowerMac5200,
    gestaltPowerMac6200 = 42,
    gestaltPerforma6300 = gestaltPowerMac6200,
    gestaltMacIIvi = 44,
    gestaltMacIIvm = 45,
    gestaltPerforma600 = gestaltMacIIvm,
    gestaltPowerMac7100_80 = 47,
    gestaltMacIIvx = 48,
    gestaltMacColorClassic = 49,
    gestaltPerforma250 = gestaltMacColorClassic,
    gestaltPowerBook165c = 50,
    gestaltMacCentris610 = 52,
    gestaltMacQuadra610 = 53,
    gestaltPowerBook145 = 54,
    gestaltPowerMac8100_100 = 55,
    gestaltMacLC520 = 56,
    gestaltAWS9150_120 = 57,
```

```

    gestaltPowerBookDuo270c = 77,
    gestaltMacQuadra840AV = 78,
    gestaltPerforma550 = 80,
    gestaltPowerBook165 = 84,
    gestaltPowerBook190 = 85,
    gestaltMacTV = 88,
    gestaltMacLC475 = 89,
    gestaltPerforma47x = gestaltMacLC475,
    gestaltMacLC575 = 92,
    gestaltMacQuadra605 = 94,
    gestaltMacQuadra630 = 98,
    gestaltMacLC580 = 99,
    gestaltPerforma580 = gestaltMacLC580,
    gestaltPowerMac6100_66 = 100,
    gestaltAWS6150_66 = gestaltPowerMac6100_66,
    gestaltPowerBookDuo280 = 102,
    gestaltPowerBookDuo280c = 103,
    gestaltPowerMacLC475 = 104,
    gestaltPowerMacPerforma47x = gestaltPowerMacLC475,
    gestaltPowerMacLC575 = 105,
    gestaltPowerMacPerforma57x = gestaltPowerMacLC575,
    gestaltPowerMacQuadra630 = 106,
    gestaltPowerMacLC630 = gestaltPowerMacQuadra630,
    gestaltPowerMacPerforma63x = gestaltPowerMacQuadra630,
    gestaltPowerMac7200 = 108,
    gestaltPowerMac7300 = 109,
    gestaltPowerMac7100_66 = 112,
    gestaltPowerBook150 = 115,
    gestaltPowerMacQuadra700 = 116,
    gestaltPowerMacQuadra900 = 117,
    gestaltPowerMacQuadra950 = 118,
    gestaltPowerMacCentris610 = 119,
    gestaltPowerMacCentris650 = 120,
    gestaltPowerMacQuadra610 = 121,
    gestaltPowerMacQuadra650 = 122,
```

```
    gestaltPowerMacQuadra800 = 123,
    gestaltPowerBookDuo2300 = 124,
    gestaltPowerBook500PPCUpgrade = 126,
    gestaltPowerBook5300 = 128,
    gestaltPowerBook1400 = 310,
    gestaltPowerBook3400 = 306,
    gestaltPowerBook2400 = 307,
    gestaltPowerBookG3Series = 312,
    gestaltPowerBookG3 = 313,
    gestaltPowerBookG3Series2 = 314,
    gestaltPowerMacNewWorld = 406,
    gestaltPowerMacG3 = 510,
    gestaltPowerMac5500 = 512,
    gestalt20thAnniversary = gestaltPowerMac5500,
    gestaltPowerMac6500 = 513,
    gestaltPowerMac4400_160 = 514,
    gestaltPowerMac4400 = 515,
    gestaltMacOSCompatibility = 1206
};
```

Discussion
To obtain a string containing the machine's name, you can pass the returned value to the `GetIndString` procedure as an index into the resource of type `'STR#'` in the System file having the resource ID defined by the constant `kMachineNameStrID`.

Computer Name Selector

Specifes user-visiblity information for the computer name.

```
enum {
    gestaltUserVisibleMachineName = 'mnam'
};
```

Connection Manager Attribute Selectors

Specify feature availability information for the Connection Manager.

```
enum {
    gestaltConnMgrAttr = 'conn',
    gestaltConnMgrPresent = 0,
    gestaltConnMgrCMSearchFix = 1,
    gestaltConnMgrErrorString = 2,
    gestaltConnMgrMultiAsyncIO = 3
};
```

Constants

`gestaltConnMgrAttr`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltConnMgrPresent`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltConnMgrCMSearchFix`
The `gestaltConnMgrCMSearchFix` bit flag indicates that the fix is present that allows the `CMAddSearch` function to work over the `mAttn` channel.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltConnMgrErrorString`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltConnMgrMultiAsyncIO`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Control Manager Attribute Selectors

Specify feature availability information for the Control Manager.

```
enum {
    gestaltControlMgrAttr = 'cntl',
    gestaltControlMgrPresent = (1L << 0),
    gestaltControlMgrPresentBit = 0,
    gestaltControlMsgPresentMask = (1L << gestaltControlMgrPresentBit)
};
```

Constants

`gestaltControlMgrAttr`
The `Gestalt` selector passed to determine what features of the Control Manager are present. This selector is available with Mac OS 8.5 and later. The `Gestalt` function produces a 32-bit value whose bits you should test to determine what Control Manager functionality is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltControlMgrPresent`
If the bit specified by this mask is set, the Control Manager functionality for Appearance Manager 1.1 is available. This bit is set for Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltControlMgrPresentBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltControlMsgPresentMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

Before calling any functions dependent upon the Control Manager, your application should pass the selector `gestaltControlMgrAttr` to the `Gestalt` function to determine which Control Manager functions are available.

Control Manager Version Selector

Specifies version information for the Control Manager.

```
enum {
    gestaltControlMgrVersion = 'cmvr'
};
```

Constants

`gestaltControlMgrVersion`
Available in Mac OS X v10.1 and later.
Declared in `Gestalt.h`.

Control Strip Attribute Selectors

Specify feature availability for the Control Strip.

```
enum {
    gestaltControlStripAttr = 'sdev',
    gestaltControlStripExists = 0,
    gestaltControlStripVersionFixed = 1,
    gestaltControlStripUserFont = 2,
    gestaltControlStripUserHotKey = 3
};
```

Control Strip Version Selector

Specifies version information for the Control Strip.

```
enum {
    gestaltControlStripVersion = 'csvr'
};
```

Constants

`gestaltControlStripVersion`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

CPU Selectors for Apollo

Specify version information for Apollo CPUs.

```
enum {
    gestaltCPUApollo = 0x0111,
    gestaltCPU750FX = 0x0120
};
```

CPU Selectors for Intel and Pentium

Specify version information for Intel and Pentium CPUs.

```
enum {
    gestaltCPU486 = 'i486',
    gestaltCPUPentium = 'i586',
    gestaltCPUPentiumPro = 'i5pr',
    gestaltCPUPentiumII = 'i5ii',
    gestaltCPUX86 = 'ixxx'
};
```

Data Access Manager Attribute Selectors

Specify feature availability information for the Data Access Manager.

```
enum {
    gestaltDBAccessMgrAttr = 'dbac',
    gestaltDBAccessMgrPresent = 0
};
```

Desktop Pictures Attribute Selectors

Specify feature availability information for Desktop Pictures.

```
enum {
    gestaltDesktopPicturesAttr = 'dkpx',
    gestaltDesktopPicturesInstalled = 0,
    gestaltDesktopPicturesDisplayed = 1
};
```

Desktop Printing Attribute Selector

Specify feature availablity information for all desktop printer.

```
enum {
    gestaltDTPInfo = 'dtpx'
};
```

Desktop Printing Driver Attribute Selectors

Specify feature availability for third-party desktop printing drivers.

```
enum {
    gestaltDTPFeatures = 'dtpf',
    kDTPThirdPartySupported = 0x00000004
};
```

Dialog Manager Attribute Selectors

Specify feature availability for the Dialog Manager.

```
enum {
    gestaltDITLExtAttr = 'ditl',
    gestaltDITLExtPresent = 0,
    gestaltDITLExtSupportsIctb = 1
};
```

Constants

`gestaltDITLExtAttr`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltDITLExtPresent`
If this flag bit is `TRUE`, then the Dialog Manager extensions included in System 7 are available.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltDITLExtSupportsIctb`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Dictionary Manager Attribute Selectors

Specify feature availability information for the Dictionary Manager.

```
enum {
    gestaltDictionaryMgrAttr = 'dict',
    gestaltDictionaryMgrPresent = 0
};
```

Dialog Manager Selectors for Mac OS 8.5

Specify version and feature availability information for the Dialog Manager in Mac OS 8.5.

```
enum {
    gestaltDialogMgrAttr = 'dlog',
    gestaltDialogMgrPresent = (1L << 0),
    gestaltDialogMgrPresentBit = 0,
    gestaltDialogMgrHasAquaAlertBit = 2,
    gestaltDialogMgrPresentMask = (1L << gestaltDialogMgrPresentBit),
    gestaltDialogMgrHasAquaAlertMask = (1L << gestaltDialogMgrHasAquaAlertBit),
    gestaltDialogMsgPresentMask = gestaltDialogMgrPresentMask
};
```

Constants

`gestaltDialogMgrAttr`
The `Gestalt` selector passed to determine what features of the Dialog Manager are present. This selector is available with Mac OS 8.5 and later. Passing `gestaltDialogManagerAttr` produces a 32-bit value whose bits you should test to determine what Dialog Manager functionality is available.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltDialogMgrPresent`
If the bit specified by this mask is set, the Dialog Manager functionality for Appearance Manager 1.1 is available. This bit is set for Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDialogMgrPresentBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDialogMgrHasAquaAlertBit`
Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

`gestaltDialogMgrPresentMask`
Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

`gestaltDialogMgrHasAquaAlertMask`
Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

`gestaltDialogMsgPresentMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any Dialog Manager functions, your application should pass the selector `gestaltDialogManagerAttr` to the `Gestalt` function to determine which Dialog Manager functions are available.

Digital Signature Version Selector

Specifies version information for digital signatures.

```
enum {
    gestaltDigitalSignatureVersion = 'dsig'
};
```

Direct IO Attribute Selector

Specifies availability of direct input/ouput support by the file system.

```
enum {
    gestaltFSSupportsDirectIO = 11
};
```

Disk Cache Size Selector

Specifies size information for the disk cache buffer.

```
enum {
    gestaltDiskCacheSize = 'dcsz'
};
```

Constants

`gestaltDiskCacheSize`

A selector that you pass to the `Gestalt` function. If the function returns `noErr`, the `response` parameter contains the size of the disk cache's buffer. See the Gestalt Manager Reference for more information on the `Gestalt` function.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Display Manager Attribute Selectors

Specify feature availability for the Display Manager.

```
enum {
    gestaltDisplayMgrAttr = 'dply',
    gestaltDisplayMgrPresent = 0,
    gestaltDisplayMgrCanSwitchMirrored = 2,
    gestaltDisplayMgrSetDepthNotifies = 3,
    gestaltDisplayMgrCanConfirm = 4,
    gestaltDisplayMgrColorSyncAware = 5,
    gestaltDisplayMgrGeneratesProfiles = 6,
    gestaltDisplayMgrSleepNotifies = 7
};
```

Constants

`gestaltDisplayMgrAttr`

The `Gestalt` selector you pass to determine which Display Manager attributes are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrPresent`

If `true`, the Display Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrCanSwitchMirrored`

If `true`, the Display Manager can switch modes on mirrored displays.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrSetDepthNotifies`

If `true`, and you have registered for notification and you will be notified of depth mode changes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrCanConfirm`
Not yet supported. Most commonly comes up for display modes that are not marked `kModeSafe`. There is currently no system support for trying an unsafe mode and then restoring if the user does not confirm. When this is supported, this bit will be set.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrColorSyncAware`
If `true`, Display Manager supports profiles for displays.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrGeneratesProfiles`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDisplayMgrSleepNotifies`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon the Display Manager, your application should pass the selector `gestaltDisplayMgrAttr` to the `Gestalt` function to determine the Display Manager attributes that are present.

Display Manager Version Selector

Specifies version information for the Display Manager.

```
enum {
    gestaltDisplayMgrVers = 'dplv'
};
```

Constants
`gestaltDisplayMgrVers`
The `Gestalt` selector you pass to determine what version of the Display Manager is present. For example, a Gestalt result may be 0x00020500, which means that the Display Manager version 2.5 is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
To determine the version of the current Display Manager, your application should pass the selector `gestaltDisplayMgrVers` to the `Gestalt` function.

Drag Manager Attribute Selectors

Specify feature availability information for the Drag Manager.

```
enum {
    gestaltDragMgrAttr = 'drag',
    gestaltDragMgrPresent = 0,
    gestaltDragMgrFloatingWind = 1,
    gestaltPPCDragLibPresent = 2,
    gestaltDragMgrHasImageSupport = 3,
    gestaltCanStartDragInFloatWindow = 4,
    gestaltSetDragImageUpdates = 5
};
```

Constants

`gestaltDragMgrAttr`
The Gestalt selector passed to determine what features of the Drag Manager are present. Passing the `gestaltDragMgrAttr` constant produces a 32-bit value whose bits you should test to determine what Drag Manager functionality is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDragMgrPresent`
If the bit specified by this mask is set, the Drag Manager functions are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDragMgrFloatingWind`
If the bit specified by this mask is set, the Drag Manager floating window support functions are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCDragLibPresent`
If the bit specified by this mask is set, the Drag Manager PPC Drag Library functions are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDragMgrHasImageSupport`
If the bit specified by this mask is set, the Drag Manager image support functions are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltCanStartDragInFloatWindow`
If the bit specified by this mask is set, the Drag Manager can start a drag in a floating window.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSetDragImageUpdates`
Available in Mac OS X v10.1 and later.

Declared in `Gestalt.h`.

Draw Sprocket Version Selectors

Specifies version information for Draw Sprocket.

```
enum {
    gestaltDrawSprocketVersion = 'dspv'
};
```

Easy Access Selectors

Specify version and feature availability information for Easy Access.

```
enum {
    gestaltEasyAccessAttr = 'easy',
    gestaltEasyAccessOff = 0,
    gestaltEasyAccessOn = 1,
    gestaltEasyAccessSticky = 2,
    gestaltEasyAccessLocked = 3
};
```

Edition Manager Attribute Selectors

Specify feature availability for the Edition Manager.

```
enum {
    gestaltEditionMgrAttr = 'edtn',
    gestaltEditionMgrPresent = 0,
    gestaltEditionMgrTranslationAware = 1
};
```

Extension Table Version Selector

Specifies version information for the extension table.

```
enum {
    gestaltExtensionTableVersion = 'etbl'
};
```

File Mapping Attribute Selectors

Specify feature availability for file mapping.

```
enum {
    gestaltFileMappingAttr = 'flmp',
    gestaltFileMappingPresent = 0,
    gestaltFileMappingMultipleFilesFix = 1
};
```

File System Attribute Selectors

Specify feature availability for the file system.

```
enum {
    gestaltFSAttr = 'fs  ',
    gestaltFullExtFSDispatching = 0,
    gestaltHasFSSpecCalls = 1,
    gestaltHasFileSystemManager = 2,
    gestaltFSMDoesDynamicLoad = 3,
    gestaltFSSupports4GBVols = 4,
    gestaltFSSupports2TBVols = 5,
    gestaltHasExtendedDiskInit = 6,
    gestaltDTMgrSupportsFSM = 7,
    gestaltFSNoMFSVols = 8,
    gestaltFSSupportsHFSPlusVols = 9,
    gestaltFSIncompatibleDFA82 = 10
};
```

Constants

`gestaltFSAttr`

A selector you pass to the `Gestalt` function. If the Gestalt function returns `noErr`, the `response` parameter contains a 32-bit value specifying the features of the file system.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFullExtFSDispatching`

If this bit is set in the `response` parameter, all of the functions selected through the `_HFSDispatch` trap are available to external file systems. If this bit is clear, the File Manager checks the selector passed to `_HFSDispatch` and ensures that it is valid; if the selector is invalid, the result code `paramErr` is returned to the caller. If this bit is set, no such validity checking is performed. See the *Guide to the File System Manager* for more information on external file systems.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasFSSpecCalls`

If this bit is set in the `response` parameter, the operating environment provides the file system specification (`FSSpec`) versions of the basic file-manipulation functions, as well as the `FSMakeFSSpec` function.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasFileSystemManager`

If this bit is set in the `response` parameter, the File System Manager is present. See the *Guide to the File System Manager* for more information about the File System Manager.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSMDoesDynamicLoad`

If this bit is set in the `response` parameter, the File System Manager supports dynamic loading of external file system code resources.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSSupports4GBVols`

If this bit is set in the `response` parameter, the file system supports 4 gigabyte volumes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSSupports2TBVols`
If this bit is set in the `response` parameter, the file system supports 2 terabyte volumes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasExtendedDiskInit`
If this bit is set in the `response` parameter, the extended Disk Initialization Package functions are present. These are the `DIXFormat`, `DIXZero`, or `DIReformat` functions. See the *Guide to the File System Manager* for more information about the Disk Initialization Package interfaces.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDTMgrSupportsFSM`
If this bit is set in the `response` parameter, the desktop database supports File System Manager-based foreign file systems.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSNoMFSVols`
If this bit is set in the `response` parameter, the file system does not support MFS volumes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSSupportsHFSPlusVols`
If this bit is set in the `response` parameter, the file system supports HFS Plus volumes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSIncompatibleDFA82`
If this bit is set in the `response` parameter, VCB and FCB structures are changed; DFA 8.2 is incompatible.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

File System Attribute Selectors for Mac OS 9

Specify feature availability for the file system for features introduced in Mac OS 9.

```
enum {
    gestaltHasHFSPlusAPIs = 12,
    gestaltMustUseFCBAccessors = 13,
    gestaltFSUsesPOSIXPathsForConversion = 14,
    gestaltFSSupportsExclusiveLocks = 15,
    gestaltFSSupportsHardLinkDetection = 16
};
```

Constants

`gestaltHasHFSPlusAPIs`
If this bit is set in the `response` parameter, the File Manager supports the HFS Plus APIs. Individual file systems may or may not implement the HFS Plus APIs. However, if this bit is set, the File Manager will emulate the HFS Plus APIs for file systems that do not implement them. Call the functions `PBHGetVolParmsSync` or `PBHGetVolParmsAsync` to determine whether the HFS Plus APIs are directly supported on a given volume.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMustUseFCBAccessors`
If this bit is set in the `response` parameter, the File Manager no longer supports the low memory globals `FCBSPtr` and `FSFCBLen`. All access to file or fork control blocks must use the File System Manager utility functions instead.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSUsesPOSIXPathsForConversion`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFSSupportsExclusiveLocks`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

`gestaltFSSupportsHardLinkDetection`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

Discussion

Use these constants with the gestalt selector `gestaltFSAttr`, described in "File System Attribute Selectors" (page 1042).

File System Manager Version Selector

Specifies version information for the File System Manager.

```
enum {
    gestaltFSMVersion = 'fsm '
};
```

Constants

`gestaltFSMVersion`

Pass this selector to the `Gestalt` function to determine the version of the HFS External File Systems Manager (FSM).

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

File System Transport Manager Attribute Selectors

Specify feature availability for the File System Transport Manager

```
enum {
    gestaltFXfrMgrAttr = 'fxfr',
    gestaltFXfrMgrPresent = 0,
    gestaltFXfrMgrMultiFile = 1,
    gestaltFXfrMgrErrorString = 2,
    gestaltFXfrMgrAsync = 3
};
```

Constants

`gestaltFXfrMgrAttr`

The selector you pass to the `Gestalt` function to determine the File Transfer Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Find By Content State Selectors

Specify state information for Find By Content.

```
enum {
    gestaltFBCIndexingState = 'fbci',
    gestaltFBCindexingSafe = 0,
    gestaltFBCindexingCritical = 1
};
```

Find By Content Version Selectors

Specify version information for Find By Content.

```
enum {
    gestaltFBCVersion = 'fbcv',
    gestaltFBCCurrentVersion = 0x0011,
    gestaltOSXFBCCurrentVersion = 0x0100
};
```

Find Folder Redirection Attribute Selector

Specifies feature availability information for Find Folder.

```
enum {
    gestaltFindFolderRedirectionAttr = 'fole'
};
```

Finder Attribute Selectors

Specify feature availability for the Finder.

```
enum {
    gestaltFinderAttr = 'fndr',
    gestaltFinderDropEvent = 0,
    gestaltFinderMagicPlacement = 1,
    gestaltFinderCallsAEProcess = 2,
    gestaltOSLCompliantFinder = 3,
    gestaltFinderSupports4GBVolumes = 4,
    gestaltFinderHasClippings = 6,
    gestaltFinderFullDragManagerSupport = 7,
    gestaltFinderFloppyRootComments = 8,
    gestaltFinderLargeAndNotSavedFlavorsOK = 9,
    gestaltFinderUsesExtensibleFolderManager = 10,
    gestaltFinderUnderstandsRedirectedDesktopFolder = 11
};
```

Floppy Driver Attribute Selectors

Specify feature availability information for the floppy disk drive.

```
enum {
    gestaltFloppyAttr = 'flpy',
    gestaltFloppyIsMFMOnly = 0,
    gestaltFloppyIsManualEject = 1,
    gestaltFloppyUsesDiskInPlace = 2
};
```

Font Manager Attribute Selectors

Specify feature availability information for the Font Manager.

```
enum {
    gestaltFontMgrAttr = 'font',
    gestaltOutlineFonts = 0
};
```

Constants

`gestaltFontMgrAttr`
The `Gestalt` selector you pass to determine which Font Manager attributes are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltOutlineFonts`
If `true`, outline fonts are supported.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

Before calling any function dependent upon the Font Manager, your application should pass the selector `gestaltDisplayMgrAttr` to the `Gestalt` function to determine the Font Manager attributes that are present.

Folder Manager Attribute Selectors

Specify feature availability information for the Folder Manager.

```
enum {
    gestaltFindFolderAttr = 'fold',
    gestaltFindFolderPresent = 0,
    gestaltFolderDescSupport = 1,
    gestaltFolderMgrFollowsAliasesWhenResolving = 2,
    gestaltFolderMgrSupportsExtendedCalls = 3,
    gestaltFolderMgrSupportsDomains = 4,
    gestaltFolderMgrSupportsFSCalls = 5
};
```

Constants

`gestaltFindFolderAttr`
The selector you pass to the `Gestalt` function to determine the `FindFolder` function attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFindFolderPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFolderDescSupport`
If this bit is set, the extended Folder Manager functionality supporting folder descriptors and routings is available. This bit is set for versions of the Mac OS starting with Mac OS 8.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFolderMgrFollowsAliasesWhenResolving`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFolderMgrSupportsExtendedCalls`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFolderMgrSupportsDomains`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltFolderMgrSupportsFSCalls`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any Folder Manager functions, your application should pass the selector `gestaltFindFolderAttr` to the `Gestalt` function to determine which Folder Manager functions are available.

FPU Type Selectors

Specify version and availability information for the type of floating-point unit installed.

```
enum {
    gestaltFPUType = 'fpu ',
    gestaltNoFPU = 0,
    gestalt68881 = 1,
    gestalt68882 = 2,
    gestalt68040FPU = 3
};
```

Constants
`gestaltFPUType`
A constant that represents the type of floating-point unit currently installed, if any.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltNoFPU`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68881`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68882`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68040FPU`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Gestalt Manager Version Selectors

Specify Gestalt Manager version information.

```
enum {
    gestaltVersion = 'vers',
    gestaltValueImplementedVers = 5
};
```

Constants

`gestaltVersion`

The selector you pass to the function `Gestalt` (page 1005) to determine the version of the Gestalt Manager. The function passes back the version in the low-order word of the response.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltValueImplementedVers`

The first version of the Gestalt Manager that implements this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Hardware Attribute Attribute Selectors

Specify feature availability information for hardware.

```
enum {
    gestaltHardwareAttr = 'hdwr',
    gestaltHasVIA1 = 0,
    gestaltHasVIA2 = 1,
    gestaltHasASC = 3,
    gestaltHasSCC = 4,
    gestaltHasSCSI = 7,
    gestaltHasSoftPowerOff = 19,
    gestaltHasSCSI961 = 21,
    gestaltHasSCSI962 = 22,
    gestaltHasUniversalROM = 24,
    gestaltHasEnhancedLtalk = 30
};
```

Constants

`gestaltHardwareAttr`

The selector you pass to the Gestalt function to determine low-level hardware configuration attributes.

Never infer the existence of certain hardware or software features from the responses that `Gestalt` returns when you pass it this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasVIA1`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasVIA2`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasASC`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSCC`
The `gestaltHasSCC` bit is normally returned as 0 on the Macintosh IIfx and Macintosh Quadra 900 computers, which have intelligent I/O processors that isolate the hardware and make direct access to the SCC impossible. However, if the user has used the Compatibility Switch control panel to enable compatibility mode, `gestaltHasSCC` is set.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSCSI`
The `gestaltHasSCSI` bit means the machine is equipped with a SCSI implementation based on the 53C80 chip, which was introduced in the Macintosh Plus. This bit is 0 on computers with a different SCSI implementation.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSoftPowerOff`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSCSI961`
This bit is set if the machine has a SCSI implementation based on the 53C96 chip installed on an internal bus.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSCSI962`
This bit is set if the machine has a SCSI implementation based on the 53C96 chip installed on an external bus.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasUniversalROM`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasEnhancedLtalk`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Hardware Icon Selector

Specifies icon family resource ID information for the computer hardware.

```
enum {
    gestaltMachineIcon = 'micn'
};
```

Constants

`gestaltMachineIcon`
The selector you pass to the `Gestalt` function to determine the icon family resource ID for the current type of Macintosh.

Never infer the existence of certain hardware or software features from the responses that `Gestalt` returns when you pass it this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Hardware Vendor Selectors

Specify hardware vendor information.

```
enum {
    gestaltHardwareVendorCode = 'hrad',
    gestaltHardwareVendorApple = 'Appl'
};
```

Help Manager Attribute Selectors

Specify feature availability for the Apple Help Manager.

```
enum {
    gestaltHelpMgrAttr = 'help',
    gestaltHelpMgrPresent = 0,
    gestaltHelpMgrExtensions = 1,
    gestaltAppleGuideIsDebug = 30,
    gestaltAppleGuidePresent = 31
};
```

Constants

`gestaltHelpMgrAttr`
The selector you pass to the `Gestalt` function to determine the Help Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHelpMgrPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHelpMgrExtensions`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppleGuideIsDebug`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAppleGuidePresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Icon Services Attribute Selectors

Specify feature availability for Icon Services.

```
enum {
    gestaltIconUtilitiesAttr = 'icon',
    gestaltIconUtilitiesPresent = 0,
    gestaltIconUtilitiesHas48PixelIcons = 1,
    gestaltIconUtilitiesHas32BitIcons = 2,
    gestaltIconUtilitiesHas8BitDeepMasks = 3,
    gestaltIconUtilitiesHasIconServices = 4
};
```

Constants

`gestaltIconUtilitiesAttr`
The `Gestalt` selector passed to determine which features of Icon Services are present. The `Gestalt` function produces a 32-bit value whose bits you should test to determine which Icon Services features are available.

Note: available in System 7.0, despite gestalt.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIconUtilitiesPresent`
True if icon utilities are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIconUtilitiesHas48PixelIcons`
True if 48x48 icons are supported by IconUtilities.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIconUtilitiesHas32BitIcons`
True if 32-bit deep icons are supported.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIconUtilitiesHas8BitDeepMasks`
True if 8-bit deep masks are supported.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIconUtilitiesHasIconServices`
True if IconServices is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any Icon Services functions, your application should pass the selector `gestaltIconUtilitiesAttr` to the `Gestalt` function.

Image Compression Manager Version Selector

Specifies the version of the Image Compression Manager.

```
enum {
    gestaltCompressionMgr = 'icmp'
};
```

Constants
`gestaltCompressionMgr`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Intel Architecture Selector

Specifies the Intel architecture.

```
enum {
    gestaltIntel = 10
};
```

Internal Display Location Selector

Specifies the slot number information for the internal display location.

```
enum {
    gestaltInternalDisplay = 'idsp'
};
```

Keyboard Selectors

Specify keyboard information.

```
enum {
    gestaltKeyboardType = 'kbd ',
    gestaltMacKbd = 1,
    gestaltMacAndPad = 2,
    gestaltMacPlusKbd = 3,
    gestaltExtADBKbd = 4,
    gestaltStdADBKbd = 5,
    gestaltPrtblADBKbd = 6,
    gestaltPrtblISOKbd = 7,
    gestaltStdISOADBKbd = 8,
    gestaltExtISOADBKbd = 9,
    gestaltADBKbdII = 10,
    gestaltADBISOKbdII = 11,
    gestaltPwrBookADBKbd = 12,
    gestaltPwrBookISOADBKbd = 13,
    gestaltAppleAdjustKeypad = 14,
    gestaltAppleAdjustADBKbd = 15,
    gestaltAppleAdjustISOKbd = 16,
    gestaltJapanAdjustADBKbd = 17,
    gestaltPwrBkExtISOKbd = 20,
    gestaltPwrBkExtJISKbd = 21,
    gestaltPwrBkExtADBKbd = 24,
    gestaltPS2Keyboard = 27,
    gestaltPwrBkSubDomKbd = 28,
    gestaltPwrBkSubISOKbd = 29,
    gestaltPwrBkSubJISKbd = 30,
    gestaltPwrBkEKDomKbd = 195,
    gestaltPwrBkEKISOKbd = 196,
    gestaltPwrBkEKJISKbd = 197,
    gestaltUSBCosmoANSIKbd = 198,
    gestaltUSBCosmoISOKbd = 199,
    gestaltUSBCosmoJISKbd = 200,
    gestaltPwrBk99JISKbd = 201,
    gestaltUSBAndyANSIKbd = 204,
    gestaltUSBAndyISOKbd = 205,
    gestaltUSBAndyJISKbd = 206
};
```

Constants

`gestaltKeyboardType`

The selector you pass to the `Gestalt` function to determine the type of the keyboard.

If the Apple Desktop Bus (ADB) is in use, there may be multiple keyboards or other ADB devices attached to the machine. The `gestaltKeyboardType` selector identifies only the type of the keyboard on which the last keystroke occurred.

You cannot use this selector to find out what ADB devices are connected. For that, you can use the Apple Desktop Bus Manager. Note that the ADB keyboard types described by `Gestalt` do not necessarily map directly to ADB device handler IDs.

Future support for the `gestaltKeyboardType` selector is not guaranteed. To determine the type of the keyboard last touched without using `Gestalt`, check the system global variable `KbdType`.

If the Gestalt Manager does not recognize the keyboard type, it returns an error.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Keyboard Selectors for Laptops

Specify laptop keyboard information.

```
enum {
    gestaltPortable2001ANSIKbd = 202,
    gestaltPortable2001ISOKbd = 203,
    gestaltPortable2001JISKbd = 207
};
```

Logical Page Size Selector

Specifies logical page size information.

```
enum {
    gestaltLogicalPageSize = 'pgsz'
};
```

Constants

`gestaltLogicalPageSize`

The logical page size. This value is defined only on machines with the MC68010, MC68020, MC68030, or MC68040 microprocessors. On a machine with the MC68000, the `Gestalt` function returns an error when called with this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Logical RAM Size Selector

Specifies logical randon-access memory size information.

```
enum {
    gestaltLogicalRAMSize = 'lram'
};
```

Constants

`gestaltLogicalRAMSize`

The amount of logical memory available. This value is the same as that returned by `gestaltPhysicalRAMSize` when virtual memory is not installed. On some machines, however, this value might be less than the value returned by `gestaltPhysicalRAMSize` because some RAM may be used by the video display and the Operating System.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Low Memory Size Selector

Specifies information about the size of the low-memory area.

```
enum {
    gestaltLowMemorySize = 'lmem'
};
```

Constants

`gestaltLowMemorySize`

The size (in bytes) of the low-memory area. The low-memory area is used for vectors, global variables, and dispatch tables

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Machine Name String ID

Defines a machine name string ID.

```
enum {
    kMachineNameStrID = -16395
};
```

Mailer Version Selector

Specifies version information for the OCE standard mailer.

```
enum {
    gestaltSMPMailerVersion = 'malr'
};
```

Mailer Send LetterVersion Selector

Specifies version information for the OCE standard mailer's send letter.

```
enum {
    gestaltSMPSPSendLetterVersion = 'spsl'
};
```

Media Bay Selectors

Specify information about media bay availability.

```
enum {
    gestaltMediaBay = 'mbeh',
    gestaltMBLegacy = 0,
    gestaltMBSingleBay = 1,
    gestaltMBMultipleBays = 2
};
```

Memory Attribute Selectors

Specify feature availability information for memory.

```
enum {
    gestaltOSAttr = 'os  ',
    gestaltSysZoneGrowable = 0,
    gestaltLaunchCanReturn = 1,
    gestaltLaunchFullFileSpec = 2,
    gestaltLaunchControl = 3,
    gestaltTempMemSupport = 4,
    gestaltRealTempMemory = 5,
    gestaltTempMemTracked = 6,
    gestaltIPCSupport = 7,
    gestaltSysDebuggerSupport = 8,
    gestaltNativeProcessMgrBit = 19,
    gestaltAltivecRegistersSwappedCorrectlyBit = 20
};
```

Constants

`gestaltOSAttr`

The `Gestalt` selector you pass to determine general Operating System attributes, such as whether temporary memory handles are real handles. The low-order bits of the response parameter are interpreted as bit flags. A flag is set to 1 to indicate that the corresponding feature is available. Currently, the following bits are significant.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSysZoneGrowable`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltLaunchCanReturn`

If this bit is set, the `_Launch` trap macro can return to the caller. The `_Launch` trap macro in system software version 7.0 (and in earlier versions running MultiFinder) gives your application the option to continue running after it launches another application. In earlier versions of system software not running MultiFinder, the `_Launch` trap macro forces the launching application to quit.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltLaunchFullFileSpec`

If this bit is set, the `launchControlFlags` field supports control flags in addition to the `launchContinue` flag, and if the `_Launch` trap can process the `launchAppSpec`, `launchProcessSN`, `launchPreferredSize`, `launchMinimumSize`, `launchAvailableSize`, and `launchAppParameters` fields in the launch parameter block.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltLaunchControl`

If this bit is set, the Process Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTempMemSupport`

If `true`, there is temporary memory support.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltRealTempMemory`
If `true`, temporary memory handles are real.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTempMemTracked`
If `true`, temporary memory handles are tracked.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltIPCSupport`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSysDebuggerSupport`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltNativeProcessMgrBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltAltivecRegistersSwappedCorrectlyBit`
Available in Mac OS X v10.2 and later.
Declared in `Gestalt.h`.

Memory Mapping Attribute Selectors

Specify feature availibility information for memory mapping.

```
enum {
    gestaltMemoryMapAttr = 'mmap',
    gestaltMemoryMapSparse = 0
};
```

Menu Manager Selectors in Mac OS 8.5

Specify version and feature availability information for the Menu Manager in Mac OS 8.5

```
enum {
    gestaltMenuMgrAttr = 'menu',
    gestaltMenuMgrPresent = (1L << 0),
    gestaltMenuMgrPresentBit = 0,
    gestaltMenuMgrAquaLayoutBit = 1,
    gestaltMenuMgrMultipleItemsWithCommandIDBit = 2,
    gestaltMenuMgrRetainsIconRefBit = 3,
    gestaltMenuMgrSendsMenuBoundsToDefProcBit = 4,
    gestaltMenuMgrMoreThanFiveMenusDeepBit = 5,
    gestaltMenuMgrPresentMask = (1L << gestaltMenuMgrPresentBit),
    gestaltMenuMgrAquaLayoutMask = (1L << gestaltMenuMgrAquaLayoutBit),
    gestaltMenuMgrMultipleItemsWithCommandIDMask = (1L <<
gestaltMenuMgrMultipleItemsWithCommandIDBit),
    gestaltMenuMgrRetainsIconRefMask = (1L << gestaltMenuMgrRetainsIconRefBit),
    gestaltMenuMgrSendsMenuBoundsToDefProcMask = (1L <<
gestaltMenuMgrSendsMenuBoundsToDefProcBit),
    gestaltMenuMgrMoreThanFiveMenusDeepMask = (1L <<
gestaltMenuMgrMoreThanFiveMenusDeepBit)
};
```

Constants

`gestaltMenuMgrAttr`
The `Gestalt` selector passed to determine what features of the Menu Manager are present. This selector is available with Mac OS 8.5 and later. Passing `gestaltMenuMgrAttr` produces a 32-bit value whose bits you should test to determine what Menu Manager functionality is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrPresent`
If the bit specified by this mask is set, the Menu Manager functionality for Appearance Manager 1.1 is available. This bit is set for Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrPresentBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrAquaLayoutBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrMultipleItemsWithCommandIDBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrRetainsIconRefBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrSendsMenuBoundsToDefProcBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrMoreThanFiveMenusDeepBit`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrPresentMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrAquaLayoutMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrMultipleItemsWithCommandIDMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrRetainsIconRefMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrSendsMenuBoundsToDefProcMask`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMenuMgrMoreThanFiveMenusDeepMask`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any Menu Manager functions, your application should pass the selector `gestaltMenuMgrAttr` to the `Gestalt` function to determine which Menu Manager functions are available.

Message Manager Version Selector

Specify version information for the Message Manager.

```
enum {
    gestaltMessageMgrVersion = 'mess'
};
```

Miscellaneous Attribute Selectors

Specify feature availability information for miscellaneous pieces of the operating system or the hardware configuration.

```
enum {
    gestaltMiscAttr = 'misc',
    gestaltScrollingThrottle = 0,
    gestaltSquareMenuBar = 2
};
```

Constants

`gestaltMiscAttr`
The selector you pass to the `Gestalt` function to determine information about miscellaneous pieces of the Operating System or hardware configuration.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltScrollingThrottle`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSquareMenuBar`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Mixed Mode Manager Selectors

Specify version and feature availability information for the Mixed Mode Manager.

```
enum {
    gestaltMixedModeAttr = 'mixd',
    gestaltMixedModePowerPC = 0,
    gestaltPowerPCAware = 0,
    gestaltMixedModeCFM68K = 1,
    gestaltMixedModeCFM68KHasTrap = 2,
    gestaltMixedModeCFM68KHasState = 3
};
```

Constants

`gestaltMixedModeAttr`
The Gestalt selector you pass to determine what version of Mixed Mode Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMixedModePowerPC`
True if Mixed Mode supports PowerPC ABI calling conventions

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPowerPCAware`
Old name for `gestaltMixedModePowerPC`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMixedModeCFM68K`
: True if Mixed Mode supports CFM-68K calling conventions

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMixedModeCFM68KHasTrap`
: True if CFM-68K Mixed Mode implements `_MixedModeDispatch` (versions 1.0.1 and prior did not)

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMixedModeCFM68KHasState`
: True if CFM-68K Mixed Mode exports Save/RestoreMixedModeState

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon Mixed Mode Manager, your application should pass the selector `gestaltMixedModeAttr` to the `Gestalt` function to determine the Mixed Mode Manager attributes that are present.

Mixed Mode Manager Version Selector

Specifies version information for the Mixed Mode Manager.

```
enum {
    gestaltMixedModeVersion = 'mixd'
};
```

Constants
`gestaltMixedModeVersion`
: The selector you pass to the `Gestalt` function to determine the version of Mixed Mode Manager.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

MMU Type Selectors

Specify information about the type of MMU installed.

```
enum {
    gestaltMMUType = 'mmu ',
    gestaltNoMMU = 0,
    gestaltAMU = 1,
    gestalt68851 = 2,
    gestalt68030MMU = 3,
    gestalt68040MMU = 4,
    gestaltEMMU1 = 5
};
```

Constants

`gestaltMMUType`
The selector you pass to the `Gestalt` function to determine the type of MMU currently installed.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltNoMMU`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltAMU`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt68851`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt68030MMU`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt68040MMU`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltEMMU1`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Multiple Users State Selector

Specifies information about the multiple user state.

```
enum {
    gestaltMultipleUsersState = 'mfdr'
};
```

Name-Binding Protocol Attribute Selectors

Specify feature availiability information for the standard name-binding protocol.

```
enum {
    gestaltStdNBPAttr = 'nlup',
    gestaltStdNBPPresent = 0,
    gestaltStdNBPSupportsAutoPosition = 1
};
```

Constants

`gestaltStdNBPAttr`
The selector you pass to the `Gestalt` function to determine information about the StandardNBP (Name-Binding Protocol) function.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStdNBPPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStdNBPSupportsAutoPosition`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Name Registry Version Selector

Specifies the version of the name registry.

```
enum {
    gestaltNameRegistryVersion = 'nreg'
};
```

Constants

`gestaltNameRegistryVersion`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Native CPU Selectors

Specify the native CPU type or family.

```
enum {
    gestaltNativeCPUtype = 'cput',
    gestaltNativeCPUfamily = 'cpuf',
    gestaltCPU68000 = 0,
    gestaltCPU68010 = 1,
    gestaltCPU68020 = 2,
    gestaltCPU68030 = 3,
    gestaltCPU68040 = 4,
    gestaltCPU601 = 0x0101,
    gestaltCPU603 = 0x0103,
    gestaltCPU604 = 0x0104,
    gestaltCPU603e = 0x0106,
    gestaltCPU603ev = 0x0107,
    gestaltCPU750 = 0x0108,
    gestaltCPU604e = 0x0109,
    gestaltCPU604ev = 0x010A,
    gestaltCPUG4 = 0x010C,
    gestaltCPUG47450 = 0x0110
};
```

Constants

`gestaltNativeCPUtype`
The selector you pass to the `Gestalt` function to determine the native CPU type.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltNativeCPUfamily`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU68000`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU68010`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU68020`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU68030`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU68040`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU601`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU603`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU604`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU603e`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU603ev`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU750`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU604e`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPU604ev`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPUG4`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltCPUG47450`
Available in Mac OS X v10.2 and later.
Declared in `Gestalt.h`.

Discussion
The use of these selectors is no longer recommended. You can use the `gestaltSysArchitecture` (page 1098) selector to determine whether your application is running on a PowerPC or Intel-based Macintosh. If you are trying to determine whether you can use a particular processor feature, you should check directly for that feature using a BSD library function such as `sysctl` or `sysctlbyname`. For more information, see *Mac OS X Man Pages*.

Notification Manager Attribute Selectors

Specify feature availability information for the Notification Manager.

```
enum {
    gestaltNotificationMgrAttr = 'nmgr',
    gestaltNotificationPresent = 0
};
```

Constants
`gestaltNotificationMgrAttr`
.The Gestalt selector which you pass to the `Gestalt` function to determine Notification Manager attributes.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltNotificationPresent`
True if the Notification Manager exists.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

NuBus Location Selector

Specifies information about the NuBus slot connector locations.

```
enum {
    gestaltNuBusConnectors = 'sltc'
};
```

Constants

`gestaltNuBusConnectors`
A bitmap that describes the NuBus slot connector locations. On a Macintosh II, for example, the return value would have bits 9 through 14 set, indicating that 6 NuBus slots are present, at locations 9 through 14.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

NuBus Slot Count Selector

Specifies information about the number of NuBus slots.

```
enum {
    gestaltNuBusSlotCount = 'nubs'
};
```

OCE Toolbox Attribute Selectors

Specify feature availability for the OCE Toolbox.

```
enum {
    gestaltOCEToolboxAttr = 'oceu',
    gestaltOCETBPresent = 0x01,
    gestaltOCETBAvailable = 0x02,
    gestaltOCESFServerAvailable = 0x04,
    gestaltOCETBNativeGlueAvailable = 0x10
};
```

OCE Toolbox Version Selectors

Specify version information for the OCE Toolbox.

```
enum {
    gestaltOCEToolboxVersion = 'ocet',
    gestaltOCETB = 0x0102,
    gestaltSFServer = 0x0100
};
```

Open Firmware Selector

Specifies version information for Open Firmware.

```
enum {
    gestaltOpenFirmwareInfo = 'opfw'
};
```

Open Firmware Safe Selectors

Specify feature availability for Open Firmware safe features.

```
enum {
    gestaltSafeOFAttr = 'safe',
    gestaltVMZerosPagesBit = 0,
    gestaltInitHeapZerosOutHeapsBit = 1,
    gestaltNewHandleReturnsZeroedMemoryBit = 2,
    gestaltNewPtrReturnsZeroedMemoryBit = 3,
    gestaltFileAllocationZeroedBlocksBit = 4
};
```

Open Transport Selectors

Specify version and feature availability information for Open Transport.

```
enum {
    gestaltOpenTpt = 'otan',
    gestaltOpenTptPresentMask = 0x00000001,
    gestaltOpenTptLoadedMask = 0x00000002,
    gestaltOpenTptAppleTalkPresentMask = 0x00000004,
    gestaltOpenTptAppleTalkLoadedMask = 0x00000008,
    gestaltOpenTptTCPPresentMask = 0x00000010,
    gestaltOpenTptTCPLoadedMask = 0x00000020,
    gestaltOpenTptIPXSPXPresentMask = 0x00000040,
    gestaltOpenTptIPXSPXLoadedMask = 0x00000080,
    gestaltOpenTptPresentBit = 0,
    gestaltOpenTptLoadedBit = 1,
    gestaltOpenTptAppleTalkPresentBit = 2,
    gestaltOpenTptAppleTalkLoadedBit = 3,
    gestaltOpenTptTCPPresentBit = 4,
    gestaltOpenTptTCPLoadedBit = 5,
    gestaltOpenTptIPXSPXPresentBit = 6,
    gestaltOpenTptIPXSPXLoadedBit = 7
};
```

Open Transport Network Setup Selectors

Specify feature availability and setup information for Open Transport networking.

```
enum {
    gestaltOpenTptNetworkSetup = 'otcf',
    gestaltOpenTptNetworkSetupLegacyImport = 0,
    gestaltOpenTptNetworkSetupLegacyExport = 1,
    gestaltOpenTptNetworkSetupSupportsMultihoming = 2
};
```

Open Transport Network Version Selector

Specifies the version of the Open Transport network setup.

```
enum {
    gestaltOpenTptNetworkSetupVersion = 'otcv'
};
```

Open Transport Remote Access Selectors

Specify feature availabiliy for Open Transport remote access.

```
enum {
    gestaltOpenTptRemoteAccess = 'otra',
    gestaltOpenTptRemoteAccessPresent = 0,
    gestaltOpenTptRemoteAccessLoaded = 1,
    gestaltOpenTptRemoteAccessClientOnly = 2,
    gestaltOpenTptRemoteAccessPServer = 3,
    gestaltOpenTptRemoteAccessMPServer = 4,
    gestaltOpenTptPPPPresent = 5,
    gestaltOpenTptARAPPresent = 6
};
```

Opent Transport Remote Access Version Selector

Specifies version information for Open Transport remote access.

```
enum {
    gestaltOpenTptRemoteAccessVersion = 'otrv'
};
```

Open Transport Version Selector

Specifies version information for Open Transport.

```
enum {
    gestaltOpenTptVersions = 'otvr'
};
```

OS Trap Table Selector

Specifies base address information for the operating system trap dispatch table.

```
enum {
    gestaltOSTable = 'ostt'
};
```

Constants

`gestaltOSTable`

The selector you pass to the `Gestalt` function to determine the base address of the operating system trap dispatch table.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Parity Checking Attribute Selectors

Specify feature availability for parity checking.

```
enum {
    gestaltParityAttr = 'prty',
    gestaltHasParityCapability = 0,
    gestaltParityEnabled = 1
};
```

Constants

`gestaltParityAttr`
The selector you pass to the `Gestalt` function to determine information about the machine's parity-checking features.

Note that parity is not considered to be enabled unless all installed memory is parity RAM.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasParityCapability`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltParityEnabled`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

PC Compatibility Card Selectors

Specify version and feature availability information for a PC-compatibility card.

```
enum {
    gestaltPCCard = 'pccd',
    gestaltCardServicesPresent = 0,
    gestaltPCCardFamilyPresent = 1,
    gestaltPCCardHasPowerControl = 2,
    gestaltPCCardSupportsCardBus = 3
};
```

PC Exchange Attribute Selectors

Specify feature availability information for PC Exchange.

```
enum {
    gestaltPCXAttr = 'pcxg',
    gestaltPCXHas8and16BitFAT = 0,
    gestaltPCXHasProDOS = 1,
    gestaltPCXNewUI = 2,
    gestaltPCXUseICMapping = 3
};
```

Constants

`gestaltPCXAttr`
The selector you pass to the `Gestalt` function to determine the PC Exchange attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPCXHas8and16BitFAT`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPCXHasProDOS`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPCXNewUI`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPCXUseICMapping`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Physical RAM Size Selector

Specifies information about the size of the physical RAM.

```
enum {
    gestaltPhysicalRAMSize = 'ram '
};
```

Constants

`gestaltPhysicalRAMSize`
The selector you pass to the `Gestalt` function to determine the number of bytes of physical RAM currently installed.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Pop-up Control Selector

Specify feature availability for pop-up controls.

```
enum {
    gestaltPopupAttr = 'pop!',
    gestaltPopupPresent = 0
};
```

Constants

`gestaltPopupAttr`
The selector you pass to the `Gestalt` function to determine the attribute of the pop-up control definition.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPopupPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Power Manager Attribute Selectors

Specify feature availability for the Power Manager.

```
enum {
    gestaltPowerMgrAttr = 'powr',
    gestaltPMgrExists = 0,
    gestaltPMgrCPUIdle = 1,
    gestaltPMgrSCC = 2,
    gestaltPMgrSound = 3,
    gestaltPMgrDispatchExists = 4,
    gestaltPMgrSupportsAVPowerStateAtSleepWake = 5
};
```

Constants

`gestaltPowerMgrAttr`
The `Gestalt` selector you pass to determine which Power Manager capabilities are available.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrExists`
If true, the Power Manager is present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrCPUIdle`
If true the CPU is capable of going into a low–power-consumption state.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrSCC`
If true, it is possible to stop the SCC clock, thus effectively turning off the serial ports.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrSound`
If true, it is possible to turn off power to the sound circuits.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrDispatchExists`
If true, Dispatch is present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPMgrSupportsAVPowerStateAtSleepWake`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Power Manager Version Selector

Specifies version information for the Power Manager.

```
enum {
    gestaltPowerMgrVers = 'pwrv'
};
```

PowerPC Attribute Selectors

Specify feature availability for PowerPC processors.

```
enum {
    gestaltPowerPCProcessorFeatures = 'ppcf',
    gestaltPowerPCHasGraphicsInstructions = 0,
    gestaltPowerPCHasSTFIWXInstruction = 1,
    gestaltPowerPCHasSquareRootInstructions = 2,
    gestaltPowerPCHasDCBAInstruction = 3,
    gestaltPowerPCHasVectorInstructions = 4,
    gestaltPowerPCHasDataStreams = 5
};
```

PowerPC Toolbox Attribute Selectors

Specify feature availability for the PowerPC Toolbox.

```
enum {
    gestaltPPCToolboxAttr = 'ppc ',
    gestaltPPCToolboxPresent = 0x0000,
    gestaltPPCSupportsRealTime = 0x1000,
    gestaltPPCSupportsIncoming = 0x0001,
    gestaltPPCSupportsOutGoing = 0x0002,
    gestaltPPCSupportsTCP_IP = 0x0004,
    gestaltPPCSupportsIncomingAppleTalk = 0x0010,
    gestaltPPCSupportsIncomingTCP_IP = 0x0020,
    gestaltPPCSupportsOutgoingAppleTalk = 0x0100,
    gestaltPPCSupportsOutgoingTCP_IP = 0x0200
};
```

Constants

`gestaltPPCToolboxAttr`
The selector you pass to the Gestalt function to determine the Program-to-Program Communication (PPC) Toolbox attributes. Note that these constants are defined as masks, not bit numbers.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCToolboxPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsRealTime`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsIncoming`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsOutGoing`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsTCP_IP`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsIncomingAppleTalk`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsIncomingTCP_IP`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsOutgoingAppleTalk`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPPCSupportsOutgoingTCP_IP`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Preemptive Function Atrribute Selectors

Specify feature availability information for preemptive system software functions.

```
enum {
    gestaltMPCallableAPIsAttr = 'mpsc',
    gestaltMPFileManager = 0,
    gestaltMPDeviceManager = 1,
    gestaltMPTrapCalls = 2
};
```

Constants

`gestaltMPCallableAPIsAttr`
The Gestalt selector passed to determine the availability of preemptive system software functions. The `Gestalt` function produces a 32-bit value that you should test to determine which what type of preemptive calls are allowed.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMPFileManager`
If this bit is set, you can call preemptively safe File Manager functions.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMPDeviceManager`
If this bit is set, you can call preemptively safe Device Manager function.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMPTrapCalls`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any Mac OS system software functions from a preemptive task , you should call the `Gestalt` function with the `gestaltMPCallableAPIsAttr` selector set to determine which preemptively safe system calls are allowed.

Note that for functions that are shared between managers (for example, `PBCloseSync`), you should check the bit that is appropriate for the manager you want to call.

Version Notes
Introduced with Multiprocessing Services 2.1

Processor Clock Speed Selector

Specifies information about processor clock speed.

```
enum {
    gestaltProcClkSpeed = 'pclk'
};
```

Processor Type Selector

Specifies information about the type of microprocessor.

```
enum {
    gestaltProcessorType = 'proc',
    gestalt68000 = 1,
    gestalt68010 = 2,
    gestalt68020 = 3,
    gestalt68030 = 4,
    gestalt68040 = 5
};
```

Constants
`gestaltProcessorType`
The selector you pass to the `Gestalt` function to determine the type of microprocessor currently running.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68000`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68010`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68020`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt68030`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestalt68040`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Quadra Redefinitions

Specifies alternate names for MacQuadra constants.

```
enum {
    gestaltQuadra605 = gestaltMacQuadra605,
    gestaltQuadra610 = gestaltMacQuadra610,
    gestaltQuadra630 = gestaltMacQuadra630,
    gestaltQuadra650 = gestaltMacQuadra650,
    gestaltQuadra660AV = gestaltMacQuadra660AV,
    gestaltQuadra700 = gestaltMacQuadra700,
    gestaltQuadra800 = gestaltMacQuadra800,
    gestaltQuadra840AV = gestaltMacQuadra840AV,
    gestaltQuadra900 = gestaltMacQuadra900,
    gestaltQuadra950 = gestaltMacQuadra950
};
```

QuickDraw 3D Attribute Selectors

Specify feature availability information for QuickDraw 3D.

```
enum {
    gestaltQD3D = 'qd3d',
    gestaltQD3DPresent = 0
};
```

Quick Draw 3D Old Attribute Selectors

Specify old feature availability information for QuickDraw 3D.

```
enum {
    gestaltQD3DNotPresent = (0 << gestaltQD3DPresent),
    gestaltQD3DAvailable = (1 << gestaltQD3DPresent)
};
```

Quick Draw 3D Version Selector

Specifies version information for QuickDraw 3D.

```
enum {
    gestaltQD3DVersion = 'q3v '
};
```

QuickDraw 3D Viewer Attribute Selectors

Specify feature availablity information for QuickDraw 3D Viewer.

```
enum {
    gestaltQD3DViewer = 'q3vc',
    gestaltQD3DViewerPresent = 0
};
```

QuickDraw Attribute Selectors

Specify feature availability information for QuickDraw.

```
enum {
    gestaltQuickdrawFeatures = 'qdrw',
    gestaltHasColor = 0,
    gestaltHasDeepGWorlds = 1,
    gestaltHasDirectPixMaps = 2,
    gestaltHasGrayishTextOr = 3,
    gestaltSupportsMirroring = 4,
    gestaltQDHasLongRowBytes = 5
};
```

Constants

`gestaltQuickdrawFeatures`
The selector you pass to the `Gestalt` function to determine the QuickDraw features.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasColor`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasDeepGWorlds`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasDirectPixMaps`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasGrayishTextOr`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSupportsMirroring`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltQDHasLongRowBytes`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

QuickDraw Version Selectors

Specify version information for QuickDraw.

```
enum {
    gestaltQuickdrawVersion = 'qd  ',
    gestaltOriginalQD = 0x0000,
    gestalt8BitQD = 0x0100,
    gestalt32BitQD = 0x0200,
    gestalt32BitQD11 = 0x0201,
    gestalt32BitQD12 = 0x0220,
    gestalt32BitQD13 = 0x0230,
    gestaltAllegroQD = 0x0250,
    gestaltMacOSXQD = 0x0300
};
```

Constants

`gestaltQuickdrawVersion`
The Gestalt selector you pass to determine what version of QuickDraw is present. For QuickDraw Text, the Gestalt selector you pass to determine what version of QuickDraw Text is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltOriginalQD`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt8BitQD`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt32BitQD`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt32BitQD11`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt32BitQD12`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt32BitQD13`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAllegroQD`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMacOSXQD`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
The version of QuickDraw is encoded as a revision number in the low-order word of the return value. The high-order byte represents the major revision number, and the low-order byte represents the minor revision number. For example, version 1.3 of 32-Bit QuickDraw represents QuickDraw revision 2.3; its response value is $0230.

Values having a major revision number of 1 or 2 indicate that Color QuickDraw is available, in either the 8-bit or 32-bit version. These results do not, however, indicate whether a color monitor is attached to the system. You must use high-level QuickDraw functions to obtain that information.

QuickDraw GX Overall Version Selector

Specifies version information for the overall version of QuickDraw GX.

```
enum {
    gestaltGXVersion = 'qdgx'
};
```

QuickDraw GX Printing Version Selector

Specifies version information for QuickDraw GX printing.

```
enum {
    gestaltGXPrintingMgrVersion = 'pmgr'
};
```

QuickDraw GX Version Selectors

Specify version information for QuickDraw GX.

```
enum {
    gestaltGraphicsVersion = 'grfx',
    gestaltCurrentGraphicsVersion = 0x00010200
};
```

Constants
`gestaltGraphicsVersion`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltCurrentGraphicsVersion`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

QuickDraw GX Attribute Selectors

Specify feature availability information for QuickDraw GX.

```
enum {
    gestaltGraphicsAttr = 'gfxa',
    gestaltGraphicsIsDebugging = 0x00000001,
    gestaltGraphicsIsLoaded = 0x00000002,
    gestaltGraphicsIsPowerPC = 0x00000004
};
```

QuickDraw 3D Viewer Old Selectors

Specify old feature availability information for QuickDraw 3D.

```
enum {
    gestaltQD3DViewerNotPresent = (0 << gestaltQD3DViewerPresent),
    gestaltQD3DViewerAvailable = (1 << gestaltQD3DViewerPresent)
};
```

QuickDraw Text Attribute Selectors

Specify feature availability information for QuickDraw Text.

```
enum {
    gestaltQDTextFeatures = 'qdtf',
    gestaltWSIISupport = 0,
    gestaltSbitFontSupport = 1,
    gestaltAntiAliasedTextAvailable = 2,
    gestaltOFA2available = 3,
    gestaltCreatesAliasFontRsrc = 4,
    gestaltNativeType1FontSupport = 5,
    gestaltCanUseCGTextRendering = 6
};
```

Constants

`gestaltQDTextFeatures`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltWSIISupport`
WSII support is included.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSbitFontSupport`
sbit-only fonts are supported.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltAntiAliasedTextAvailable`
Capable of antialiased text.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltOFA2available`
OFA2 is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltCreatesAliasFontRsrc`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltNativeType1FontSupport`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltCanUseCGTextRendering`
Available in Mac OS X v10.2 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon QuickDraw Text, your application should pass the selector `gestaltQDTextFeatures` to the Gestalt function to determine the QuickDraw Text attributes that are present.

QuickDraw Text Version Selectors

Specify version information for QuickDraw Text.

```
enum {
    gestaltQDTextVersion = 'qdtx',
    gestaltOriginalQDText = 0x0000,
    gestaltAllegroQDText = 0x0100,
    gestaltMacOSXQDText = 0x0200
};
```

Constants
`gestaltQDTextVersion`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltOriginalQDText`
This is the original version of QuickDraw Text, used through Mac OS 8.1.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltAllegroQDText`
This is the version of QuickDraw Text used with Mac OS 8.2 and up.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMacOSXQDText`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
To determine the version of the current QuickDraw Text, your application should pass the selector `gestaltQuickdrawVersion` to the Gestalt function.

QuickTime VR Feature Selectors

Specify feature availability information for QuickTime VR.

```
enum {
    gestaltQTVRMgrAttr = 'qtvr',
    gestaltQTVRMgrPresent = 0,
    gestaltQTVRObjMoviesPresent = 1,
    gestaltQTVRCylinderPanosPresent = 2,
    gestaltQTVRCubicPanosPresent = 3
};
```

QuickTime VR Version Selector

Specifies version information for QuickTime VR.

```
enum {
    gestaltQTVRMgrVers = 'qtvv'
};
```

QuickTime Attribute Selectors

Specify feature availability information for QuickTime.

```
enum {
    gestaltQuickTimeFeatures = 'qtrs',
    gestaltPPCQuickTimeLibPresent = 0
};
```

QuickTime Version Selectors

Specify version information for QuickTime.

```
enum {
    gestaltQuickTimeVersion = 'qtim',
    gestaltQuickTime = 'qtim'
};
```

Constants

`gestaltQuickTimeVersion`
The selector you pass to the `Gestalt` function to determine the QuickTime version.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltQuickTime`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

QuickTime Conferencing Information Selector

Specifies information about QuickTime conferencing.

```
enum {
    gestaltQuickTimeConferencingInfo = 'qtci'
};
```

Constants

`gestaltQuickTimeConferencingInfo`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

QuickTime Conferencing Selector

Specifies availability information for QuickTime conferencing.

```
enum {
    gestaltQuickTimeConferencing = 'mtlk'
};
```

QuickTime Streaming Attribute Selector

Specify feature availability information for QuickTime streaming.

```
enum {
    gestaltQuickTimeStreamingFeatures = 'qtsf'
};
```

QuickTime Streaming Version Selector

Specifies version information for QuickTime streaming.

```
enum {
    gestaltQuickTimeStreamingVersion = 'qtst'
};
```

RBV Address Selector

Specifies information about the RBV base address.

```
enum {
    gestaltRBVAddr = 'rbv '
};
```

Realtime Manager Attribute Selectors

Specify feature availability information for the Realtime Manager.

```
enum {
    gestaltRealtimeMgrAttr = 'rtmr',
    gestaltRealtimeMgrPresent = 0
};
```

Constants

`gestaltRealtimeMgrAttr`
The selector you pass to the `Gestalt` function to determine the Realtime Manager attributes.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltRealtimeMgrPresent`
(description forthcoming)
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Resource Manager Bug Fixes Attribute Selectors

Specify feature availability information for Resource Manager bug fixes.

```
enum {
    gestaltResourceMgrBugFixesAttrs = 'rmbg',
    gestaltRMForceSysHeapRolledIn = 0,
    gestaltRMFakeAppleMenuItemsRolledIn = 1,
    gestaltSanityCheckResourceFiles = 2,
    gestaltSupportsFSpResourceFileAlreadyOpenBit = 3,
    gestaltRMSupportsFSCalls = 4,
    gestaltRMTypeIndexOrderingReverse = 8
};
```

Resource Manager Attribute Selectors

Specify feature availability information for the Resource Manager.

```
enum {
    gestaltResourceMgrAttr = 'rsrc',
    gestaltPartialRsrcs = 0,
    gestaltHasResourceOverrides = 1
};
```

Constants

`gestaltResourceMgrAttr`
The `Gestalt` selector you pass to determine which Resource Manager attributes are present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPartialRsrcs`
If `true`, partial resources exist.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasResourceOverrides`

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon the Resource Manager, your application should pass the selector `gestaltResourceMgrAttr` to the `Gestalt` function to determine the Resource Manager attributes that are present.

ROM Size Selector

Specifies information about ROM size information.

```
enum {
    gestaltROMSize = 'rom '
};
```

Constants
`gestaltROMSize`

The selector you pass to the `Gestalt` function to determine the size of the installed ROM, in bytes. The value is returned in only one word.

You should not infer the existence of certain hardware or software features from the responses that Gestalt returns when you pass it this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

ROM Version Selector

Specifies ROM version information.

```
enum {
    gestaltROMVersion = 'romv'
};
```

Constants
`gestaltROMVersion`

This selector is NOT supported in Carbon.

The selector you pass to the `Gestalt` function to determine the version number of the installed ROM (in the low-order word of the return value).

Never infer the existence of certain hardware or software features from the responses that `Gestalt` returns when you pass it this selector.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

SCC Read Address Selector

Specifies information about the base address for reading SCC.

```
enum {
    gestaltSCCReadAddr = 'sccr'
};
```

SCC Write Address Selector

Specifies information about the base address for writing SCC.

```
enum {
    gestaltSCCWriteAddr = 'sccw'
};
```

SCSI Manager Attribute Selectors

Specify feature availability information for the SCSI Manager.

```
enum {
    gestaltSCSI = 'scsi',
    gestaltAsyncSCSI = 0,
    gestaltAsyncSCSIINROM = 1,
    gestaltSCSISlotBoot = 2,
    gestaltSCSIPollSIH = 3
};
```

Scrap Manager Selectors

Specify version and feature availability information for the Scrap Manager.

```
enum {
    gestaltScrapMgrAttr = 'scra',
    gestaltScrapMgrTranslationAware = 0
};
```

Constants

`gestaltScrapMgrAttr`
The `Gestalt` selector you pass to determine which Scrap Manager attributes are present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltScrapMgrTranslationAware`
If `true`, the Scrap Manager supports Translation Manager.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Discussion

Before calling any function dependent upon the Scrap Manager, your application should pass the selector `gestaltScrapMgrAttr` to the `Gestalt` function to determine the Scrap Manager attributes that are present.

Screen Capture Selectors

Specifies location information for screen capture.

```
enum {
    gestaltScreenCaptureMain = 'pic1',
    gestaltScreenCaptureDir = 'pic2'
};
```

Script Manager Version Selector

Specifies version information for the Script Manager.

```
enum {
    gestaltScriptMgrVersion = 'scri'
};
```

Constants

`gestaltScriptMgrVersion`

The selector you pass to the `Gestalt` function to determine the version number of the Script Manager (in the low-order word of the return value).

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Script Systems Count Selector

Specifies information about the number of active script systems.

```
enum {
    gestaltScriptCount = 'scr#'
};
```

Constants

`gestaltScriptCount`

The selector you pass to the Gestalt function to determine the number of script systems currently active.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Serial Hardware Attribute Selectors

Specify serial hardware attributes.

```
enum {
    gestaltSerialAttr = 'ser ',
    gestaltHasGPIaToDCDa = 0,
    gestaltHasGPIaToRTxCa = 1,
    gestaltHasGPIbToDCDb = 2,
    gestaltHidePortA = 3,
    gestaltHidePortB = 4,
    gestaltPortADisabled = 5,
    gestaltPortBDisabled = 6
};
```

Constants

`gestaltSerialAttr`
The selector you pass to the `Gestalt` function to determine the serial hardware attributes of the machine, such as whether or not the GPIa line is connected and can be used for external clocking.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasGPIaToDCDa`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasGPIaToRTxCa`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasGPIbToDCDb`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHidePortA`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHidePortB`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPortADisabled`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPortBDisabled`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Serial Port Arbitrator Attribute Selectors

Specify feature availability information for serial port arbitration.

```
enum {
    gestaltArbitorAttr = 'arb ',
    gestaltSerialArbitrationExists = 0
};
```

Settings Manager Attribute Selectors

Specify feature availability information for the Settings Manager.

```
enum {
    gestaltALMAttr = 'trip',
    gestaltALMPresent = 0,
    gestaltALMHasSFGroup = 1,
    gestaltALMHasCFMSupport = 2,
    gestaltALMHasRescanNotifiers = 3
};
```

Discussion
See also "Settings Manager Version Selector" (page 1091).

Settings Manager Location Selector

Specifies location information for the Settings Manager.

```
enum {
    gestaltALMHasSFLocation = gestaltALMHasSFGroup
};
```

Settings Manager Version Selector

Specifies version information for the Settings Manager.

```
enum {
    gestaltALMVers = 'walk'
};
```

Shutdown Attribute Selectors

Specify shutdown attributes.

```
enum {
    gestaltShutdownAttributes = 'shut',
    gestaltShutdownHassdOnBootVolUnmount = 0
};
```

Single Window Mode Selectors

Specify single-window modes.

```
enum {
    gestaltHasSingleWindowModeBit = 8,
    gestaltHasSingleWindowModeMask = (1L << gestaltHasSingleWindowModeBit)
};
```

Slot Attribute Selectors

Specify feature availablity for slots.

```
enum {
    gestaltSlotAttr = 'slot',
    gestaltSlotMgrExists = 0,
    gestaltNuBusPresent = 1,
    gestaltSESlotPresent = 2,
    gestaltSE30SlotPresent = 3,
    gestaltPortableSlotPresent = 4
};
```

Constants

`gestaltSlotAttr`
The selector you pass to the `Gestalt` function to determine the Slot Manager attributes.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSlotMgrExists`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltNuBusPresent`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSESlotPresent`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSE30SlotPresent`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltPortableSlotPresent`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Slot Number Selector

Specifies information about the first physical slot in the computer.

```
enum {
    gestaltFirstSlotNumber = 'slt1'
};
```

Constants

`gestaltFirstSlotNumber`
The first physical slot.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Software Vendor Codes

Specify codes for software vendors.

```
enum {
    gestaltSoftwareVendorCode = 'srad',
    gestaltSoftwareVendorApple = 'Appl',
    gestaltSoftwareVendorLicensee = 'Lcns'
};
```

Sound Manager Attribute Selectors

Specify feature availability information for the Sound Manager.

```
enum {
    gestaltSoundAttr = 'snd ',
    gestaltStereoCapability = 0,
    gestaltStereoMixing = 1,
    gestaltSoundIOMgrPresent = 3,
    gestaltBuiltInSoundInput = 4,
    gestaltHasSoundInputDevice = 5,
    gestaltPlayAndRecord = 6,
    gestalt16BitSoundIO = 7,
    gestaltStereoInput = 8,
    gestaltLineLevelInput = 9,
    gestaltSndPlayDoubleBuffer = 10,
    gestaltMultiChannels = 11,
    gestalt16BitAudioSupport = 12
};
```

Constants

`gestaltSoundAttr`
The Gestalt selector which you pass to the `Gestalt` function.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStereoCapability`
Set if the built-in sound hardware is able to produce stereo sounds.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStereoMixing`
Set if the built-in sound hardware mixes both left and right channels of stereo sound into a single audio signal for the internal speaker.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSoundIOMgrPresent`
Set if the Sound Input Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltBuiltInSoundInput`
Set if a built-in sound input device is available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasSoundInputDevice`
Set if a sound input device is available. This device can be either built-in or external.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPlayAndRecord`
Set if the built-in sound hardware is able to play and record sounds simultaneously. If this bit is clear, the built-in sound hardware can either play or record, but not do both at once. This bit is valid only if the `gestaltBuiltInSoundInput` bit is set, and it applies only to any built-in sound input and output hardware.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt16BitSoundIO`
Set if the built-in sound hardware is able to play and record 16-bit samples. This indicates that built-in hardware necessary to handle 16-bit data is available.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStereoInput`
Set if the built-in sound hardware can record stereo sounds.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltLineLevelInput`
Set if the built-in sound input port requires line level input.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSndPlayDoubleBuffer`
Set if the Sound Manager supports the play-from-disk functions.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltMultiChannels`
Set if the Sound Manager supports multiple channels of sound.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt16BitAudioSupport`
Set if the Sound Manager can handle 16-bit audio data. This indicates that software necessary to handle 16-bit data is available.

This bit is not defined for versions of the Sound Manager prior to version 3.0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
You can pass the `gestaltSoundAttr` selector to the `Gestalt` function to determine information about the sound input capabilities of a Macintosh computer.

The `Gestalt` function returns information by setting or clearing bits in the `response` parameter. The bits relevant to the Sound Input Manager are defined by constants.

Speech Manager Attribute Selectors

Specify feature availability information for the Speech Manager.

```
enum {
    gestaltSpeechAttr = 'ttsc',
    gestaltSpeechMgrPresent = 0,
    gestaltSpeechHasPPCGlue = 1
};
```

Constants
`gestaltSpeechAttr`
The selector you pass to the `Gestalt` function to determine the Speech Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSpeechMgrPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSpeechHasPPCGlue`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Speech Recognition Version Selector

Specifies version information for the Speech Recognition Manager.

```
enum {
    gestaltSpeechRecognitionVersion = 'srtb'
};
```

Speech Recognition Manager Attribute Selectors

Specify feature availability information for the Speech Recognition Manager.

```
enum {
    gestaltSpeechRecognitionAttr = 'srta',
    gestaltDesktopSpeechRecognition = 1,
    gestaltTelephoneSpeechRecognition = 2
};
```

Constants

`gestaltSpeechRecognitionAttr`
The selector which you pass to the `Gestalt` function to determine the Speech Recognition Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltDesktopSpeechRecognition`
If this bit is set, the Speech Recognition Manager supports the desktop microphone.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTelephoneSpeechRecognition`
If this bit is set, the Speech Recognition Manager supports telephone input. In versions 1.5 and earlier, this bit is always 0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

You can pass the `gestaltSpeechRecognitionAttr` selector to the `Gestalt` function to get the attributes of the Speech Recognition Manager. `Gestalt` returns information to you by returning a long word in the `response` parameter. The returned values are defined by these constants.

Standard Directory Find Panel Selector

Specifies version information for the standard directory find panel.

```
enum {
    gestaltSDPFindVersion = 'dfnd'
};
```

Standard Directory Prompt Panel Selector

Specifies version information for the standard directory prompt panel.

```
enum {
    gestaltSDPPromptVersion = 'prpv'
};
```

Standard Directory Version Selector

Specifies version information for the standard directory.

```
enum {
    gestaltSDPStandardDirectoryVersion = 'sdvr'
};
```

Startup Disk Attribute Selectors

Specify feature availability information for the startup disk.

```
enum {
    gestaltSplitOSAttr = 'spos',
    gestaltSplitOSBootDriveIsNetworkVolume = 0,
    gestaltSplitOSAware = 1,
    gestaltSplitOSEnablerVolumeIsDifferentFromBootVolume = 2,
    gestaltSplitOSMachineNameSetToNetworkNameTemp = 3,
    gestaltSplitOSMachineNameStartupDiskIsNonPersistent = 5
};
```

Standard File Attribute Selectors

Specify feature availabity information for Standard File.

```
enum {
    gestaltStandardFileAttr = 'stdf',
    gestaltStandardFile58 = 0,
    gestaltStandardFileTranslationAware = 1,
    gestaltStandardFileHasColorIcons = 2,
    gestaltStandardFileUseGenericIcons = 3,
    gestaltStandardFileHasDynamicVolumeAllocation = 4
};
```

Constants

`gestaltStandardFileAttr`

The selector you pass to the Gestalt function to determine the Standard File Package attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStandardFile58`

If the `gestaltStandardFile58` flag bit is set, you can call the four new procedures—`StandardPutFile`, `StandardGetFile`, `CustomPutFile`, and `CustomGetFile`—introduced with System 7. (The name of the constant reflects the enabling of selectors 5 through 8 on the trap macro that handles the Standard File Package.)

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStandardFileTranslationAware`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStandardFileHasColorIcons`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStandardFileUseGenericIcons`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltStandardFileHasDynamicVolumeAllocation`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

System Architecture Selectors

Specify the native system architecture.

```
enum {
    gestaltSysArchitecture = 'sysa',
    gestalt68k = 1,
    gestaltPowerPC = 2,
    gestaltIntel = 10
};
```

Constants

`gestaltSysArchitecture`
The selector you pass to the `Gestalt` function to determine the native system architecture.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestalt68k`
If the `Gestalt` function returns `gestalt68k`, the system is a MC680x0 Macintosh.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltPowerPC`
If the `Gestalt` function returns `gestaltPowerPC`, the system is a PowerPC Macintosh.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltIntel`
If the `Gestalt` function returns `gestaltIntel`, the system is is an Intel-based Macintosh.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

System Update Version Selector

Specifies version information for system updates.

```
enum {
    gestaltSystemUpdateVersion = 'sysu'
};
```

System Version Selectors

Specifies version information for the operating system.

```
enum {
    gestaltSystemVersion = 'sysv'
    gestaltSystemVersionMajor = 'sys1',
    gestaltSystemVersionMinor = 'sys2',
    gestaltSystemVersionBugFix = 'sys3'
};
```

Constants

`gestaltSystemVersion`

The selector you pass to the `Gestalt` function to determine the version number of the currently active System file. For systems prior to Mac OS X, the version is represented as four hexadecimal digits in the low-order word of the return value. For example, if your application is running in version 7.0.1, then `Gestalt` returns the value 0x0701. Ignore the high-order word of the returned value. For Mac OS X versions, the representation is as shown in Table 18-1.

Table 18-1 The representation of Mac OS X versions by the Gestalt Manager

Mac OS X Version	Representation
10.0	0x1000
10.1	0x1010
10.2	0x1020
10.3	0x1030
10.4	0x1040

If the values of the minor or bug fix revision are larger than 9, then `gestaltSystemVersion` will substitute the value 9 for them. For example, Mac OS X 10.3.15 will be returned as 0x1039, and Mac OS X 10.10.5 will return 0x1095.

Never infer the existence of certain hardware or software features from the responses that `Gestalt` returns when you pass it this selector.

In Mac OS X v10.4 and later, a better way to get system version information is to use the selectors `gestaltSystemVersionMajor`, `gestaltSystemVersionMinor`, and `gestaltSystemVersionBugFix`, which are listed below. These selectors don't have arbitrary limits on the values returned.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSystemVersionMajor`
The major system version number. For example, in 10.4.12, this would be the decimal value 10.

Available in Mac OS X v10.3 and later.

Declared in `Gestalt.h`.

`gestaltSystemVersionMinor`
The minor system version number. For example, in 10.4.12, this would be the decimal value 4.

Available in Mac OS X v10.3 and later.

Declared in `Gestalt.h`.

`gestaltSystemVersionBugFix`
The bug fix version number. For example, in 10.4.12, this would be the decimal value 12.

Available in Mac OS X v10.3 and later.

Declared in `Gestalt.h`.

Telephone Manager Attribute Selectors

Specify feature availability information for the Telephone Manager.

```
enum {
    gestaltTeleMgrAttr = 'tele',
    gestaltTeleMgrPresent = 0,
    gestaltTeleMgrPowerPCSupport = 1,
    gestaltTeleMgrSoundStreams = 2,
    gestaltTeleMgrAutoAnswer = 3,
    gestaltTeleMgrIndHandset = 4,
    gestaltTeleMgrSilenceDetect = 5,
    gestaltTeleMgrNewTELNewSupport = 6
};
```

Terminal Manager Attribute Selectors

Specify feature availability information for the Terminal Manager.

```
enum {
    gestaltTermMgrAttr = 'term',
    gestaltTermMgrPresent = 0,
    gestaltTermMgrErrorString = 2
};
```

Constants

`gestaltTermMgrAttr`
The selector you pass to the `Gestalt` function to determine the Terminal Manager attributes.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTermMgrPresent`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTermMgrErrorString`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

TextEdit Attribute Selectors

Specify feature availability information for TextEdit.

```
enum {
    gestaltTEAttr = 'teat',
    gestaltTEHasGetHiliteRgn = 0,
    gestaltTESupportsInlineInput = 1,
    gestaltTESupportsTextObjects = 2,
    gestaltTEHasWhiteBackground = 3
};
```

Constants

`gestaltTEAttr`
The `Gestalt` selector you pass to determine whichTextEdit attributes are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTEHasGetHiliteRgn`
If true, TextEdit has `TEGetHiliteRgn`.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTESupportsInlineInput`
If `true`, TextEdit does Inline Input.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTESupportsTextObjects`
If `true`, TextEdit does Text Objects.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTEHasWhiteBackground`
If `true`, TextEdit supports overriding the `TERec`' data structure background field to white.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon TextEdit, your application should pass the selector `gestaltTEAttr` to the `Gestalt` function to determine the TextEdit attributes that are present.

TextEdit Version Selectors

Specify version information for TextEdit.

```
enum {
    gestaltTextEditVersion = 'te  ',
    gestaltTE1 = 1,
    gestaltTE2 = 2,
    gestaltTE3 = 3,
    gestaltTE4 = 4,
    gestaltTE5 = 5
};
```

Constants

`gestaltTextEditVersion`
The `Gestalt` selector you pass to determine what version of TextEdit is present.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTE1`
The version of TextEdit found in Mac IIci ROM.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTE2`
The version of TextEdit shipped with 6.0.4 Script Systems on Mac IIci (Script bug fixes for Mac IIci).
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTE3`
The version of TextEdit shipped with 6.0.4 Script Systems (all but Mac IIci).
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTE4`
The version of TextEdit shipped in System 7.0.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltTE5`
`TextWidthHook` is available in TextEdit.
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

Discussion

To determine the version of the current TextEdit, your application should pass the selector `gestalt` TextEditVersion to the `Gestalt` function.

Text Services Manager Attribute Selectors

Specify feature availability information for the Text Services Manager.

```
enum {
    gestaltTSMgrAttr = 'tsma',
    gestaltTSMDisplayMgrAwareBit = 0,
    gestaltTSMdoesTSMTEBit = 1
};
```

Text Services Manager Version Selectors

Specifies version information for the Text Services Manager.

```
enum {
    gestaltTSMgrVersion = 'tsmv',
    gestaltTSMgr15 = 0x0150,
    gestaltTSMgr20 = 0x0200
};
```

Constants

`gestaltTSMgrVersion`
The selector you pass to the `Gestalt` function to determine the version of the Text Services Manager.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTSMgr15`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTSMgr20`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Thread Manager Attribute Selectors

Specify feature availability information for the Thread Manager.

```
enum {
    gestaltThreadMgrAttr = 'thds',
    gestaltThreadMgrPresent = 0,
    gestaltSpecificMatchSupport = 1,
    gestaltThreadsLibraryPresent = 2
};
```

Constants

`gestaltThreadMgrAttr`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltThreadMgrPresent`
This bit is set if the Thread Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltSpecificMatchSupport`
: This bit is set if the Thread Manager supports the allocation of threads based on an exact match with the requested stack size. If this bit is not set, the Thread Manager allocates threads based on the closest match to the requested stack size.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

`gestaltThreadsLibraryPresent`
: This bit is set if the native version of the threads library has been loaded.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

Discussion
Before calling any function dependent upon the Thread Manager, your application should pass the selector `gestaltThreadMgrAttr` to the `Gestalt` function to determine the Thread Manager attributes that are present.

Time Manager Version Selectors

Specify version information for the Time Manager.

```
enum {
    gestaltTimeMgrVersion = 'tmgr',
    gestaltStandardTimeMgr = 1,
    gestaltRevisedTimeMgr = 2,
    gestaltExtendedTimeMgr = 3,
    gestaltNativeTimeMgr = 4
};
```

Constants
`gestaltTimeMgrVersion`
: The Gestalt selector you pass to determine what version of the Time Manager is present.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

`gestaltStandardTimeMgr`
: If this bit is set, the original Time Manager is present.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

`gestaltRevisedTimeMgr`
: If this bit is set, the revised Time Manager is present.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

`gestaltExtendedTimeMgr`
: If this bit is set, the extended Time Manager is present.

  Available in Mac OS X v10.0 and later.

  Declared in `Gestalt.h`.

`gestaltNativeTimeMgr`
If this bit is set, the native Time Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion
To determine the version of the current Time Manager, your application should pass the selector `gestaltTimeMgrVersion` to the `Gestalt` function.

Toolbox Trap Table Selector

Specifes base address information for the Toolbox trap dispatch table.

```
enum {
    gestaltToolboxTable = 'tbtt'
};
```

Constants
`gestaltToolboxTable`
The selector you pass to the `Gestalt` function to determine the base address of the Toolbox trap dispatch table.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Toolbox Trap Table (Second Half) Selector

Specifies address information for the second half of the Toolbox trap table.

```
enum {
    gestaltExtToolboxTable = 'xttt'
};
```

Constants
`gestaltExtToolboxTable`
The base address of the second half of the Toolbox trap table if the table is discontiguous. If the table is contiguous, this selector returns 0.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Translation Manager Attribute Selectors

Specify feature availability information for the Translation Manager.

```
enum {
    gestaltTranslationAttr = 'xlat',
    gestaltTranslationMgrExists = 0,
    gestaltTranslationMgrHintOrder = 1,
    gestaltTranslationPPCAvail = 2,
    gestaltTranslationGetPathAPIAvail = 3
};
```

Constants

`gestaltTranslationAttr`
The `Gestalt` selector you pass to determine which Translation Manager attributes are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTranslationMgrExists`
If `true`, the Translation Manager is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTranslationMgrHintOrder`
In earlier versions of the Translation Manager, the scrap hints in the `DoTranslateScrapProcPtr` function were reversed. In later versions, this was fixed. If this bit is true, this bug fix is in effect.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTranslationPPCAvail`
If `true`, the PowerPC Translation Library is available, and you can call the Translation Manager from native PowerPC code.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltTranslationGetPathAPIAvail`
If true, the functions `GetFileTranslationPath` and `GetPathTranslationDialog` are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

Before calling any function dependent upon the Translation Manager your application should pass the selector `gestaltTranslationAttr` to the `Gestalt` function to determine the Translation Manager attributes that are present.

TSME Version Selector

Specifies version information for the Text Services Manager integrated with TextEdit.

```
enum {
    gestaltTE6 = 6
};
```

TSMTE Attribute Selectors

Specify feature availability information for TSMTE.

```
enum {
    gestaltTSMTEAttr = 'tmTE',
    gestaltTSMTEPresent = 0,
    gestaltTSMTE = 0
};
```

TSMTE Version Selectors

Specify version information for TSMTE.

```
enum {
    gestaltTSMTEVersion = 'tmTV',
    gestaltTSMTE1 = 0x0100,
    gestaltTSMTE15 = 0x0150,
    gestaltTSMTE152 = 0x0152
};
```

TV Tuner Attribute Selectors

Specifies feature availabilty information for the TV tuner.

```
enum {
    gestaltTVAttr = 'tv  ',
    gestaltHasTVTuner = 0,
    gestaltHasSoundFader = 1,
    gestaltHasHWClosedCaptioning = 2,
    gestaltHasIRRemote = 3,
    gestaltHasVidDecoderScaler = 4,
    gestaltHasStereoDecoder = 5,
    gestaltHasSerialFader = 6,
    gestaltHasFMTuner = 7,
    gestaltHasSystemIRFunction = 8,
    gestaltIRDisabled = 9,
    gestaltINeedIRPowerOffConfirm = 10,
    gestaltHasZoomedVideo = 11
};
```

UDF Selector

Specifes support information for communication between implementations of UDF .

```
enum {
    gestaltUDFSupport = 'kudf'
};
```

USB Attribute Selectors

Specifies feature availability information for USB.

```
enum {
    gestaltUSBAttr = 'usb ',
    gestaltUSBPresent = 0,
    gestaltUSBHasIsoch = 1
};
```

USB Printer Sharing Version Selectors

Specify version information for USB printer sharing.

```
enum {
    gestaltUSBPrinterSharingVersion = 'zak ',
    gestaltUSBPrinterSharingVersionMask = 0x0000FFFF,
    gestaltUSBPrinterSharingAttr = 'zak ',
    gestaltUSBPrinterSharingAttrMask = 0xFFFF0000,
    gestaltUSBPrinterSharingAttrRunning = 0x80000000,
    gestaltUSBPrinterSharingAttrBooted = 0x40000000
};
```

USB Version Selector

Specifies version information for USB.

```
enum {
    gestaltUSBVersion = 'usbv'
};
```

VIA1 Base Address Selector

Specifies base address information for VIA 1.

```
enum {
    gestaltVIA1Addr = 'via1'
};
```

VIA2 Base Address Selector

Specifies base address information for VIA 2.

```
enum {
    gestaltVIA2Addr = 'via2'
};
```

Virtual Memory Manager Attribute Selectors

Specify feature availability information for the Virtual Memory Manager.

```
enum {
    gestaltVMAttr = 'vm  ',
    gestaltVMPresent = 0,
    gestaltVMHasLockMemoryForOutput = 1,
    gestaltVMFilemappingOn = 3,
    gestaltVMHasPagingControl = 4
};
```

Constants

`gestaltVMAttr`
The `Gestalt` selector you pass to determine the virtual memory attributes that are present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltVMPresent`
If `true`, virtual memory is present.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltVMHasLockMemoryForOutput`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltVMFilemappingOn`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltVMHasPagingControl`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

Discussion

Before calling any function dependent on memory, your application should pass the selector `gestaltVMAttr` to the `Gestalt` function to determine the virtual memory attributes that are present.

Virtual Memory Backing Store Selector

Specifes file reference number information for the VM backing store.

```
enum {
    gestaltVMBackingStoreFileRefNum = 'vmbs'
};
```

Virtual Memory Information Type Selectors

Specifes information about the VM type.

```
enum {
    gestaltVMInfoType = 'vmin',
    gestaltVMInfoSizeStorageType = 0,
    gestaltVMInfoSizeType = 1,
    gestaltVMInfoSimpleType = 2,
    gestaltVMInfoNoneType = 3
};
```

Win32 Attribute Selectors

Specify feature availability information for Win32.

```
enum {
    gestaltX86Features = 'x86f',
    gestaltX86HasFPU = 0,
    gestaltX86HasVME = 1,
    gestaltX86HasDE = 2,
    gestaltX86HasPSE = 3,
    gestaltX86HasTSC = 4,
    gestaltX86HasMSR = 5,
    gestaltX86HasPAE = 6,
    gestaltX86HasMCE = 7,
    gestaltX86HasCX8 = 8,
    gestaltX86HasAPIC = 9,
    gestaltX86Reserved10 = 10,
    gestaltX86HasSEP = 11,
    gestaltX86HasMTRR = 12,
    gestaltX86HasPGE = 13,
    gestaltX86HasMCA = 14,
    gestaltX86HasCMOV = 15,
    gestaltX86HasPAT = 16,
    gestaltX86HasPSE36 = 17,
    gestaltX86HasMMX = 23,
    gestaltX86HasFXSR = 24
};
```

Window Manager Attribute Selectors

Specify feature availability information for the Window Manager.

```
enum {
    gestaltWindowMgrAttr = 'wind',
    gestaltWindowMgrPresent = (1L << 0),
    gestaltWindowMgrPresentBit = 0,
    gestaltExtendedWindowAttributes = 1,
    gestaltExtendedWindowAttributesBit = 1,
    gestaltHasFloatingWindows = 2,
    gestaltHasFloatingWindowsBit = 2,
    gestaltHasWindowBuffering = 3,
    gestaltHasWindowBufferingBit = 3,
    gestaltWindowLiveResizeBit = 4,
    gestaltWindowMinimizeToDockBit = 5,
    gestaltHasWindowShadowsBit = 6,
    gestaltSheetsAreWindowModalBit = 7,
    gestaltFrontWindowMayBeHiddenBit = 8,
    gestaltWindowMgrPresentMask = (1L << gestaltWindowMgrPresentBit),
   gestaltExtendedWindowAttributesMask = (1L << gestaltExtendedWindowAttributesBit),
    gestaltHasFloatingWindowsMask = (1L << gestaltHasFloatingWindowsBit),
    gestaltHasWindowBufferingMask = (1L << gestaltHasWindowBufferingBit),
    gestaltWindowLiveResizeMask = (1L << gestaltWindowLiveResizeBit),
    gestaltWindowMinimizeToDockMask = (1L << gestaltWindowMinimizeToDockBit),
    gestaltHasWindowShadowsMask = (1L << gestaltHasWindowShadowsBit),
    gestaltSheetsAreWindowModalMask = (1L << gestaltSheetsAreWindowModalBit),
    gestaltFrontWindowMayBeHiddenMask = (1L << gestaltFrontWindowMayBeHiddenBit)
};
```

Constants

`gestaltWindowMgrAttr`
The `Gestalt` selector passed to determine what features of the Window Manager are present. This selector is available with Mac OS 8.5 and later. The `Gestalt` function produces a 32-bit value whose bits you should test to determine which Window Manager features are available.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltWindowMgrPresent`
If the bit specified by this mask is set, the Window Manager functionality for Appearance Manager 1.1 is available. This bit is set for Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltWindowMgrPresentBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltExtendedWindowAttributes`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltExtendedWindowAttributesBit`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasFloatingWindows`
Available in Mac OS X v10.0 and later.

Declared in `Gestalt.h`.

`gestaltHasFloatingWindowsBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasWindowBuffering`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasWindowBufferingBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltWindowLiveResizeBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltWindowMinimizeToDockBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasWindowShadowsBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSheetsAreWindowModalBit`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltFrontWindowMayBeHiddenBit`
Available in Mac OS X v10.2 and later.
Declared in `Gestalt.h`.

`gestaltWindowMgrPresentMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltExtendedWindowAttributesMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasFloatingWindowsMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasWindowBufferingMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltWindowLiveResizeMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltWindowMinimizeToDockMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltHasWindowShadowsMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltSheetsAreWindowModalMask`
Available in Mac OS X v10.0 and later.
Declared in `Gestalt.h`.

`gestaltFrontWindowMayBeHiddenMask`
Available in Mac OS X v10.2 and later.
Declared in `Gestalt.h`.

Discussion
Before calling any functions dependent on the Window Manager, your application should pass the selector `gestaltWindowMgrAttr` to the `Gestalt` function to determine which Window Manager functions are available.

WorldScriptII Version Selectors

Specify version information for WorldScript II.

```
enum {
    gestaltWorldScriptIIVersion = 'doub',
    gestaltWorldScriptIIAttr = 'wsat',
    gestaltWSIICanPrintWithoutPrGeneralBit = 0
};
```

Result Codes

The most common result codes returned by the Gestalt Manager are listed below.

Result Code	Value	Description
`gestaltUnknownErr`	-5550	Specifies an unknown error. Available in Mac OS X v10.0 and later.
`gestaltUndefSelectorErr`	-5551	Specifies an undefined selector was passed to the Gestalt Manager. Available in Mac OS X v10.0 and later.
`gestaltDupSelectorErr`	-5552	Specifies you tried to add an entry that already existed. Available in Mac OS X v10.0 and later.
`gestaltLocationErr`	-5553	Specifies the gestalt function ptr was not in the system heap. Available in Mac OS X v10.0 and later.

Keychain Manager Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	KeychainCore.h KeychainHI.h

Overview

The Keychain Manager is an API that provides a uniform way for your application to handle passwords for multiple users, multiple databases, or any situation in which a user must enter single or multiple passwords. You can use the Keychain Manager to provide secure storage for a user's passwords, cryptographic keys, and digital certificates.

This document, which describes KeychainLib 2.0, is relevant to you if your application needs to create and manage passwords and other secure data.

Important: Keychain Manager is being phased out and replaced by Keychain Services. Any new development should use Keychain Services. See Keychain Services Reference.

Carbon fully supports the Keychain Manager.

Functions by Task

Getting Information About the Keychain Manager

`KCGetKeychainManagerVersion` (page 1154)
Determines the version of the Keychain Manager installed on the user's system.

Creating and Disposing of Keychain References

`KCMakeKCRefFromAlias` (page 1159)
Creates a keychain reference from a keychain alias.

`KCMakeAliasFromKCRef` (page 1158)
Creates an alias to a keychain reference.

`KCReleaseKeychain` (page 1162)
Disposes of the memory associated with a keychain reference.

KCMakeKCRefFromFSSpec (page 1159) Deprecated in Mac OS X v10.5
Creates a keychain reference from a file specification record.

Managing Keychains

KCCreateKeychain (page 1134)
Creates an empty keychain.

kccreatekeychain (page 1135)

KCSetDefaultKeychain (page 1166)
Sets the default keychain.

KCGetDefaultKeychain (page 1152)
Obtains the default keychain.

KCGetStatus (page 1156)
Determines the permissions that are set in a keychain.

KCGetKeychainName (page 1155)
Determines the name of a keychain.

kcgetkeychainname (page 1155)

KCCountKeychains (page 1133)
Determines the number of available keychains.

KCGetIndKeychain (page 1152)
Obtains the reference to an indexed keychain.

Storing and Retrieving Passwords

KCAddAppleSharePassword (page 1120)
Adds a new AppleShare server password to the default keychain.

kcaddapplesharepassword (page 1122)

KCFindAppleSharePassword (page 1136)
Finds the first AppleShare password in the default keychain that matches the specified parameters.

kcfindapplesharepassword (page 1138)

KCAddInternetPassword (page 1126)
Adds a new Internet server password to the default keychain.

kcaddinternetpassword (page 1127)

KCAddInternetPasswordWithPath (page 1128)
Adds a new Internet server password with a specified path to the default keychain.

kcaddinternetpasswordwithpath (page 1129)

`KCFindInternetPassword` (page 1142)
Finds the first Internet password in the default keychain that matches the specified parameters.
`kcfindinternetpassword` (page 1144)

`KCFindInternetPasswordWithPath` (page 1145)
Finds the first Internet password in the default keychain that matches the specified parameters, including path information.
`kcfindinternetpasswordwithpath` (page 1147)

`KCAddGenericPassword` (page 1124)
Adds a new generic password to the default keychain.
`kcaddgenericpassword` (page 1125)

`KCFindGenericPassword` (page 1140)
Finds the first generic password in the default keychain matching the specified parameters.
`kcfindgenericpassword` (page 1142)

Creating and Disposing of Keychain Item References

`KCNewItem` (page 1160)
Creates a reference to a keychain item.
`KCReleaseItem` (page 1161)
Disposes of the memory occupied by a keychain item reference.

Manipulating Keychain Items

`KCAddItem` (page 1130)
Adds a password or other keychain item to the default keychain.
`KCDeleteItem` (page 1136)
Deletes a password or other keychain item from the default keychain.
`KCUpdateItem` (page 1169)
Updates a password or other keychain item.
`KCCopyItem` (page 1132)
Copies a password or other keychain item from one keychain to another.
`KCGetKeychain` (page 1153)
Determines the location of a password or other keychain item.

Setting and Obtaining Keychain Item Data

`KCSetAttribute` (page 1164)
Sets or edits keychain item data using a keychain item attribute structure.

`KCGetAttribute` (page 1149)
Determines keychain item data using a keychain item attribute structure.

`KCSetData` (page 1165)
Sets or edits keychain item data.

`KCGetData` (page 1151)
Determines keychain item data.

Searching for Keychain Items

`KCFindFirstItem` (page 1139)
Finds the first keychain item in a specified keychain that matches specified attributes.

`KCFindNextItem` (page 1148)
Finds the next keychain item matching the previously specified search criteria.

`KCReleaseSearch` (page 1162)
Disposes of the memory occupied by a search criteria reference.

Managing User Interaction

`KCLock` (page 1157)
Locks a keychain.

`KCUnlock` (page 1167)
Displays a dialog box that prompts the user for a password before unlocking a keychain.

`kcunlock` (page 1169)

`KCChangeSettings` (page 1131)
Displays a dialog box enabling the user to change the name, password, or settings of a keychain.

`KCSetInteractionAllowed` (page 1167)
Enables or disables Keychain Manager functions that display a user interface.

`KCIsInteractionAllowed` (page 1157)
Indicates whether Keychain Manager functions that display a user interaction will do so.

Registering Your Keychain Event Callback Function

`KCAddCallback` (page 1123)
Registers your keychain event callback function.

`KCRemoveCallback` (page 1163)
Unregisters your keychain event callback function.

Working With Your Keychain Manager Callback Function

`NewKCCallbackUPP` (page 1170)
Creates a UPP to your keychain event callback.

`InvokeKCCallbackUPP` (page 1119)
Invokes your keychain event callback.

`DisposeKCCallbackUPP` (page 1119)
Disposes of a UPP to your keychain event callback.

Unsupported Functions

`KCChooseCertificate` (page 1132)
Displays a list of certificates that the user can choose from.

`KCFindX509Certificates` (page 1149)
Finds the certificates in a keychain that match specified search criteria.

Functions

DisposeKCCallbackUPP

Disposes of a UPP to your keychain event callback.

Not recommended

```
void DisposeKCCallbackUPP (
   KCCallbackUPP userUPP
);
```

Parameters

userUPP
A Universal Procedure Pointer (UPP) to your keychain event callback function.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion
When you are finished with a UPP to your keychain event callback function, you should dispose of it by calling the `DisposeKCCallbackUPP` function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In
`KeychainCore.h`

InvokeKCCallbackUPP

Invokes your keychain event callback.

Not recommended

```
OSStatus InvokeKCCallbackUPP (
   KCEvent keychainEvent,
   KCCallbackInfo *info,
   void *userContext,
   KCCallbackUPP userUPP
);
```

Parameters

keychainEvent

The keychain events you want your application to receive. See "Keychain Events Constants" (page 1180) for a description of possible values. The Keychain Manager tests the bitmask you pass in the `eventMask` parameter of the function `KCAddCallback` (page 1123) to determine which events to pass to your callback function. See "Keychain Events Mask" (page 1182) for a description of this bitmask.

info

A pointer to a structure of type `KCCallbackInfo` (page 1173) that provides information about the keychain event to your callback function. The Keychain Manager passes a pointer to this structure in the `info` parameter of your callback function.

userContext

A pointer to application-defined storage. The Keychain Manager passes this value in the `userContext` parameter of your callback function. Your application can use this to associate any particular call of the `InvokeKCCallbackUPP` function with any particular call of the keychain event callback function.

userUPP

A Universal Procedure Pointer to your keychain event callback function. For information on how to create a keychain event callback function, see `KCCallbackProcPtr` (page 1171).

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion

You should not need to use the function `InvokeKCCallbackUPP`, as the system calls your `KCAddCallback` (page 1123) callback function for you.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In

`KeychainCore.h`

KCAddAppleSharePassword

Adds a new AppleShare server password to the default keychain.

Not recommended

```
OSStatus KCAddAppleSharePassword (
   AFPServerSignature *serverSignature,
   StringPtr serverAddress,
   StringPtr serverName,
   StringPtr volumeName,
   StringPtr accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverSignature

A pointer to a 16-byte Apple File Protocol server signature block. Pass a value of type `AFPServerSignature` (page 1172). Pass `NULL` to match any server signature. The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverAddress

A pointer to a Pascal string containing the server address, which may be specified as an AppleTalk zone name, a DNS domain name (in the format "xxx.yyy.zzz"), or an IP address (in the format "111.222.333.444"). The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverName

A pointer to a Pascal string containing the server name.

volumeName

A pointer to a Pascal string containing the volume name.

accountName

A pointer to a Pascal string containing the account name.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCAddAppleSharePassword`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion

The `KCAddAppleSharePassword` function adds a new AppleShare server password to the default keychain that is uniquely identified by the `serverName`, `volumeName`, and `accountName` parameters, and a location specified either by the `serverAddress` or `serverSignature` parameters. The `KCAddAppleSharePassword` function optionally returns a reference to the newly added item.

Most applications do not need to store AppleShare password data, as this is handled transparently by the AppleShare client software. To be compatible with the AppleShare client, you should store a fully-specified File Manager structure `AFPXVolMountInfo` as the password data.

The `KCAddAppleSharePassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddapplesharepassword` to add an AppleShare server password to the default keychain. `kcaddapplesharepassword` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddapplesharepassword` function provides the same functionality as `KCAddAppleSharePassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCAddAppleSharePassword`, since `kcaddapplesharepassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

It is recommended that you use internet passwords instead of AppleShare passwords. Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

kcaddapplesharepassword

Not recommended

```
OSStatus kcaddapplesharepassword (
   AFPServerSignature *serverSignature,
   const char *serverAddress,
   const char *serverName,
   const char *volumeName,
   const char *accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddAppleSharePassword` (page 1120) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

It is recommended that you use internet passwords instead of AppleShare passwords. Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddCallback

Registers your keychain event callback function.

Not recommended

```
OSStatus KCAddCallback (
   KCCallbackUPP callbackProc,
   KCEventMask eventMask,
   void *userContext
);
```

Parameters

`callbackProc`

A Universal Procedure Pointer (UPP) to your keychain event callback function, described in `KCCallbackProcPtr` (page 1171). You indicate the type of keychain events you want to receive by passing a bitmask of the desired events in the `eventMask` parameter. To create a UPP to your callback function, call the function `NewKCCallbackUPP` (page 1170).

`eventMask`

A bitmask indicating the keychain events that your application wishes to be notified of. See "Keychain Events Mask" (page 1182) for a description of this bitmask. The Keychain Manager tests this mask to determine the keychain events that you wish to receive, and passes these events in the `keychainEvent` parameter of your callback function. See "Keychain Events Constants" (page 1180) for a description of these events.

`userContext`

A pointer to application-defined storage that will be passed to your callback function. Your application can use this to associate any particular call of the `KCAddCallback` function with any particular call of your keychain event callback function.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCDuplicateCallback` indicates that your callback function is already registered.

Discussion
You can register your callback function by passing a UPP to it in the `callbackProc` parameter of the `KCAddCallback` function. Once you have done so, the Keychain Manager calls the function `InvokeKCCallbackUPP` (page 1119) when the keychain event specified in the `eventMask` parameter occurs. In turn, the function `InvokeKCCallbackUPP` (page 1119) passes the keychain event, information about the event, and application-defined storage to your keychain event callback function.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddCallback` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCAddGenericPassword

Adds a new generic password to the default keychain.

Not recommended

```
OSStatus KCAddGenericPassword (
   StringPtr serviceName,
   StringPtr accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serviceName
A pointer to a Pascal string containing an application-defined service name.

accountName
A pointer to a Pascal string containing an application-defined account name.

passwordLength
The length of the password data to be stored

passwordData
A pointer to the buffer that holds the returned password data. Before calling the `KCAddGenericPassword` function, allocate enough memory for the buffer to hold the data you want to store.

item
On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion
The `KCAddGenericPassword` function adds a new generic password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName`, which are application-defined strings. The `KCAddGenericPassword` function optionally returns a reference to the newly added item.

You can use the `KCAddGenericPassword` function to add passwords for accounts other than Internet or AppleShare. For example, you might add passwords for your database or scheduling programs.

You can also call the function `kcaddgenericpassword` to add a new generic password to the default keychain. The difference between the two functions is that the `kcaddgenericpassword` function takes a pointer to a C string instead of a Pascal string in the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

The `KCAddGenericPassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddgenericpassword` function provides the same functionality as the function `KCAddGenericPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCAddGenericPassword` function, since the `kcaddgenericpassword` function is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddGenericPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

kcaddgenericpassword

Not recommended

```
OSStatus kcaddgenericpassword (
   const char *serviceName,
   const char *accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddGenericPassword` (page 1124) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddGenericPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddInternetPassword

Adds a new Internet server password to the default keychain.

Not recommended

```
OSStatus KCAddInternetPassword (
   StringPtr serverName,
   StringPtr securityDomain,
   StringPtr accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name.

securityDomain

A pointer to a Pascal string containing the security domain. This parameter is optional, as not all protocols will require it.

accountName

A pointer to a Pascal string containing the account name.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1180), to specify any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1191) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to specify any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1176) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to specify any authentication scheme.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer that holds the returned password data. Before calling the `KCAddInternetPasswordWithPath` function, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion
The `KCAddInternetPassword` function adds a new Internet server password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName` (you cannot pass `NULL` for both parameters). In addition, some protocols may require an optional value in the `securityDomain` parameter when authentication is requested. `KCAddInternetPassword` optionally returns a reference to the newly added item.

The `KCAddInternetPassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddinternetpassword` to add a new Internet server password to the default keychain. The `kcaddinternetpassword` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddinternetpassword` function provides the same functionality as `KCAddInternetPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCAddInternetPassword`, since `kcaddinternetpassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

kcaddinternetpassword

Not recommended

```
OSStatus kcaddinternetpassword (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddInternetPassword` (page 1126) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In

`KeychainHI.h`

KCAddInternetPasswordWithPath

Adds a new Internet server password with a specified path to the default keychain.

Not recommended

```
OSStatus KCAddInternetPasswordWithPath (
   StringPtr serverName,
   StringPtr securityDomain,
   StringPtr accountName,
   StringPtr path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name.

securityDomain

A pointer to a Pascal string containing the security domain. This parameter is optional, as not all protocols will require it.

accountName

A pointer to a Pascal string containing the account name.

path

A pointer to a Pascal string containing additional information that specifies a file or directory on the server specified by the `serverName` parameter. In a typical URL, path information begins directly after the first slash ("/") character following the server name. This parameter is optional.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1180), to specify any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1191) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to specify any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1176) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to specify any authentication scheme.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCAddInternetPasswordWithPath`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion

The `KCAddInternetPasswordWithPath` function enables you to specify path information when adding a new Internet server password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName` (you cannot pass `NULL` for both parameters). In addition, some protocols may require an optional `securityDomain` when authentication is requested. `KCAddInternetPasswordWithPath` optionally returns a reference to the newly added item.

The `KCAddInternetPasswordWithPath` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddinternetpasswordwithpath` to add a new Internet server password to the default keychain. The function `kcaddinternetpasswordwithpath` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes

Available beginning with KeychainLib 2.0. In KeychainLib 1.0, the `kcaddinternetpasswordwithpath` function provides the same functionality as the `KCAddInternetPasswordWithPath` function, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCAddInternetPasswordWithPath` function, since the function `kcaddinternetpasswordwithpath` is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In

`KeychainHI.h`

kcaddinternetpasswordwithpath

Not recommended

```
OSStatus kcaddinternetpasswordwithpath (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   const char *path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddInternetPasswordWithPath` (page 1128) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddItem

Adds a password or other keychain item to the default keychain.

Not recommended

```
OSStatus KCAddItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item you wish to add. If you pass an existing item in the keychain, the item is updated. If you pass an item that has not been previously added to the keychain and an identical item already exists in the keychain, `KCAddItem` returns the result code `errKCDuplicateItem`.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCDuplicateItem` indicates that you tried to add a new item that already exists in the keychain.

Discussion
You can use the `KCAddItem` function to add a password or other keychain item to the permanent data store of the default keychain. If you want to add a password to a keychain other than the default, call the function `KCSetDefaultKeychain` (page 1166) to change the default keychain. The `KCAddItem` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

When you use Keychain Services to create an item, it is always added to the specified keychain at creation time.

Declared In
`KeychainHI.h`

KCChangeSettings

Displays a dialog box enabling the user to change the name, password, or settings of a keychain.

Not recommended

```
OSStatus KCChangeSettings (
   KCRef keychain
);
```

Parameters

keychain
A reference to an unlocked keychain. Pass in `NULL` to specify the default keychain.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errUserCanceled` indicates that the user pressed the Cancel button in the Change Settings dialog box. The result code `errKCNoDefaultKeychain` indicates that the default keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Discussion
Typically, your application should not call the `KCChangeSettings` function. You would only call the `KCChangeSettings` function in response to a user's request to change keychain settings, name, or password. Note that you cannot change a keychain passphrase directly. You must call the `KCChangeSettings` function and allow the user to change it.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetSettings` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCChooseCertificate

Displays a list of certificates that the user can choose from.

Unsupported

```
OSStatus KCChooseCertificate (
    CFArrayRef items,
    KCItemRef *certificate,
    CFArrayRef policyOIDs,
    KCVerifyStopOn stopOn
);
```

Parameters

items

An array of certificate references.

certificate

If the `items` array only contains one certificate, on return, a pointer to that certificate. In this case, no user interface is displayed.

policyOIDs

An array of trust policy options used for Macintosh file signing. To obtain a pointer to this array, call the function `SecMacGetDefaultPolicyOIDs`.

stopOn

The criteria to use in selecting the certificates to display. See "Certificate Verification Criteria" (page 1179) for a description of this mask.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `userCanceledErr` indicates that the user pressed the Cancel button in the user interface.

Discussion

The `KCChooseCertificate` function displays a list of the certificates from which the user can choose. If only one certificate matches the criteria, the reference is passed back in the `certificate` parameter and no user interface is presented.

Version Notes

Available beginning with KeychainLib 2.0.

Carbon Porting Notes

This function is obsolete. There is currently no replacement.

Declared In

`KeychainHI.h`

KCCopyItem

Copies a password or other keychain item from one keychain to another.

Not recommended

```
OSStatus KCCopyItem (
   KCItemRef item,
   KCRef destKeychain,
   KCItemRef *copy
);
```

Parameters

item

A reference to the keychain item you wish to copy.

destKeychain

A reference to the keychain into which the item is to be copied.

copy

A pointer to a reference to the new copied keychain item.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCReadOnly` indicates that the destination keychain is read only. The result code `errKCNoSuchClass` indicates that the item has an invalid keychain item class. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid.

Discussion

You can use the `KCCopyItem` function to copy a keychain item from one keychain to another. The `KCCopyItem` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item to be copied is currently locked.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyContent` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCCountKeychains

Determines the number of available keychains.

Not recommended

```
UInt16 KCCountKeychains (
   void
);
```

Parameters

Return Value

The number of available keychains. This includes all keychains in the Keychains folder, as well as any other keychains known to the Keychain Manager.

Discussion
This function reports the number of keychains known to the Keychain Manager. These keychains are created by the function `KCCreateKeychain` (page 1134).

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopySearchList` function in Keychain Services followed by a call to `CFArrayGetCount` instead.

Declared In
`KeychainCore.h`

KCCreateKeychain

Creates an empty keychain.

Not recommended

```
OSStatus KCCreateKeychain (
   StringPtr password,
   KCRef *keychain
);
```

Parameters

password

A pointer to a Pascal string representing the password string which will be used to protect the new keychain. If you pass `NULL`, the Keychain Setup dialog box will be displayed to obtain it.

keychain

A pointer to a reference to the keychain you wish to create. You create a keychain reference by calling the function `KCMakeKCRefFromFSSpec` (page 1159) or `KCMakeKCRefFromAlias` (page 1159). If you pass a pointer to a keychain reference, the user will not need to be prompted for a name and location; in all other cases, `KCCreateKeychain` will interactively request this information from the user. If you pass a pointer to a `NULL` keychain reference, the Keychain Manager allocates the memory for the keychain reference and returns it in this parameter. Pass a `NULL` pointer if you do not need a reference returned.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `userCanceledErr` indicates that the user pressed the Cancel button in the create keychain. The result code `errKCDuplicateKeychain` indicates that the user tried to create a keychain which already exists. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid. Additional errors may be returned if the keychain could not be created (for example, a file system or network error may be returned if there is no write access to the storage media).

Discussion
The `KCCreateKeychain` function creates an empty keychain. The `keychain` and `password` parameters are optional. If user interaction to create a keychain is posted, the newly-created keychain is automatically unlocked after creation.

You can also call the function `kccreatekeychain` to create an empty keychain. The function `kccreatekeychain` requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `password` parameter.

Special Considerations

It is recommended that the `KCCreateKeychain` function not be explicitly called by applications. Instead, you should call one of the add functions in "Storing and Retrieving Passwords" (page 1116) to add a password to the default keychain. If a default keychain does not exist, it is created automatically.

When you are finished with a keychain, you must deallocate its memory by calling the function `KCReleaseKeychain` (page 1162).

Version Notes

Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kccreatekeychain` function provides the same functionality as `KCCreateKeychain`. In KeychainLib 2.0, you should use `KCCreateKeychain`, since `kccreatekeychain` is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCreate` function in Keychain Services instead.

Declared In

`KeychainHI.h`

kccreatekeychain

Not recommended

```
OSStatus kccreatekeychain (
   const char *password,
   KCRef *keychain
);
```

Discussion

This function is available for convenience only and may be removed. Use the function `KCCreateKeychain` (page 1134) instead.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCreate` function in Keychain Services instead.

Declared In

`KeychainHI.h`

KCDeleteItem

Deletes a password or other keychain item from the default keychain.

Not recommended

```
OSStatus KCDeleteItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item you wish to delete. If you pass an item that has not been previously added to the keychain, the function `KCDeleteItem` does nothing and returns `noErr`.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid.

Discussion

You can use the `KCDeleteItem` function to delete a keychain item from the permanent data store of the default keychain. The `KCDeleteItem` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Special Considerations

The `KCDeleteItem` function does not dispose the memory occupied by the item reference. To do so, call the function `KCReleaseItem` (page 1161) when you are finished with an item.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemDelete` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCFindAppleSharePassword

Finds the first AppleShare password in the default keychain that matches the specified parameters.

Not recommended

```
OSStatus KCFindAppleSharePassword (
   AFPServerSignature *serverSignature,
   ConstStringPtr serverAddress,
   ConstStringPtr serverName,
   ConstStringPtr volumeName,
   ConstStringPtr accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverSignature

A pointer to a 16-byte Apple File Protocol server signature block. Pass a value of type `AFPServerSignature` (page 1172). Pass `NULL` to match any server signature. The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverAddress

A pointer to a Pascal string containing the server address, which may be specified as an AppleTalk zone name, a DNS domain name (in the format "xxx.yyy.zzz"), or an IP address (in the format "111.222.333.444"). The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverName

A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

volumeName

A pointer to a Pascal string containing the volume name. Pass `NULL` to match any volume name.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCFindAppleSharePassword`, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by `passwordData` is smaller than the actual length of the data, `KCFindAppleSharePassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling `KCFindAppleSharePassword` again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCFindAppleSharePassword` again.

Discussion
The `KCFindAppleSharePassword` function finds the first AppleShare password item which matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise `KCFindAppleSharePassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindAppleSharePassword` function again. The `KCFindAppleSharePassword` function optionally returns a reference to the found item.

The `KCFindAppleSharePassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindapplesharepassword` to find the first AppleShare server password matching specified attributes. `kcfindapplesharepassword` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindapplesharepassword` function provides the same functionality as `KCFindAppleSharePassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCFindAppleSharePassword`, since `kcfindapplesharepassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by the `SecKeychainSearchCopyNext` function instead.

Declared In
`KeychainCore.h`

kcfindapplesharepassword
Not recommended

```
OSStatus kcfindapplesharepassword (
   AFPServerSignature *serverSignature,
   const char *serverAddress,
   const char *serverName,
   const char *volumeName,
   const char *accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCFindAppleSharePassword` (page 1136) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by the `SecKeychainSearchCopyNext` function instead.

Declared In
`KeychainCore.h`

KCFindFirstItem

Finds the first keychain item in a specified keychain that matches specified attributes.

Not recommended

```
OSStatus KCFindFirstItem (
   KCRef keychain,
   const KCAttributeList *attrList,
   KCSearchRef *search,
   KCItemRef *item
);
```

Parameters

keychain
A reference to the keychain that you wish to search. If you pass a locked keychain, the Unlock Keychain dialog box is displayed. If you pass `NULL`, the `KCFindFirstItem` function searches all unlocked keychains.

attrList
A pointer to a list of 0 or more structures containing information about the keychain item attributes to be matched. Pass `NULL` to match any attribute.

search
On return, a pointer to a reference to the current search criteria.

item
On return, a pointer to the first matching keychain item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCItemNotFound` indicates that no matching keychain item was found. The result code `errKCNoSuchAttr` indicates that the specified attribute is undefined for this item class.

Discussion
The `KCFindFirstItem` function returns a reference to the first keychain item in a keychain that matches a list of attributes. The `KCFindFirstItem` function also returns a reference to the search criteria used. You should pass the returned search criteria in the `searchRef` parameter of the function `KCFindNextItem` (page 1148).

The `KCFindFirstItem` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item you are searching for is currently locked.

Special Considerations

When you are completely finished with a search, you should the functions `KCReleaseItem` (page 1161) and `KCReleaseSearch` (page 1162) to release the memory occupied by the keychain item and search criteria reference.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by a call to `SecKeychainSearchCopyNext` instead.

Declared In
`KeychainCore.h`

KCFindGenericPassword

Finds the first generic password in the default keychain matching the specified parameters.

Not recommended

```
OSStatus KCFindGenericPassword (
   ConstStringPtr serviceName,
   ConstStringPtr accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

`serviceName`

A pointer to a Pascal string containing an application-defined service name. Pass `NULL` to match any service name.

accountName

A pointer to a Pascal string containing an application-defined account name. Pass `NULL` to match any account name.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to the buffer that holds the returned password data. Before calling the `KCFindGenericPassword` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the `KCFindGenericPassword` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindGenericPassword` function again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindGenericPassword` again.

Discussion

The `KCFindGenericPassword` function finds the first generic password item which matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindGenericPassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindGenericPassword` again. The `KCFindGenericPassword` function optionally returns a reference to the found item.

The `KCFindGenericPassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindgenericpassword` to find the first generic password matching specified attributes. The `kcfindgenericpassword` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes

Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindgenericpassword` function provides the same functionality as the function `KCFindGenericPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCFindGenericPassword` function, since the `kcfindgenericpassword` function is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindGenericPassword` function in Keychain Services instead.

Declared In

`KeychainCore.h`

kcfindgenericpassword

Not recommended

```
OSStatus kcfindgenericpassword (
   const char *serviceName,
   const char *accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion

This function is available for convenience only and may be removed. Use the function `KCFindGenericPassword` (page 1140) instead.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindGenericPassword` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCFindInternetPassword

Finds the first Internet password in the default keychain that matches the specified parameters.

Not recommended

```
OSStatus KCFindInternetPassword (
   ConstStringPtr serverName,
   ConstStringPtr securityDomain,
   ConstStringPtr accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

securityDomain

A pointer to a Pascal string containing the security domain. Pass `NULL` to match any domain.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1180), to match any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1191) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to match any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1176) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to match any authentication scheme.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to the buffer that holds the returned password data. Before calling the `KCFindInternetPassword` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the `KCFindInternetPassword` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindInternetPassword` function again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPassword` again.

Discussion
The `KCFindInternetPassword` function finds the first Internet password item that matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindInternetPassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPassword` again. The `KCFindInternetPassword` function optionally returns a reference to the found item.

The `KCFindInternetPassword` function automatically calls the function `KCUnlock` (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindinternetpassword` to find the first Internet password item matching specified attributes. The `kcfindinternetpassword` function requires that you pass a pointer to a C string instead of a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindinternetpassword` function provides the same functionality as the function `KCFindInternetPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCFindInternetPassword` function, since `kcfindinternetpassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes
Use the `SecKeychainFindInternetPassword` function in Keychain Services instead.

Declared In
`KeychainCore.h`

kcfindinternetpassword
Not recommended

```
OSStatus kcfindinternetpassword (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCFindInternetPassword` (page 1142) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindInternetPassword` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCFindInternetPasswordWithPath

Finds the first Internet password in the default keychain that matches the specified parameters, including path information.

Not recommended

```
OSStatus KCFindInternetPasswordWithPath (
   ConstStringPtr serverName,
   ConstStringPtr securityDomain,
   ConstStringPtr accountName,
   ConstStringPtr path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverName
A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

securityDomain
A pointer to a Pascal string containing the security domain. Pass `NULL` to match any domain.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

path

A pointer to a Pascal string containing additional information that specifies a file or directory on the server specified by the `serverName` parameter. In a typical URL, path information begins directly after the first slash ("/") character following the server name. This parameter is optional.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1180), to match any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1191) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to match any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1176) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1180), to match any authentication scheme.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling the `KCFindInternetPasswordWithPath` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the function `KCFindInternetPasswordWithPath` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPasswordWithPath` again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPasswordWithPath` again.

Discussion

The `KCFindInternetPasswordWithPath` function finds the first Internet password item which matches the attributes you provide, including path information. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindInternetPasswordWithPath` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindInternetPasswordWithPath` function again. The `KCFindInternetPasswordWithPath` function optionally returns a reference to the found item.

The KCFindInternetPasswordWithPath function automatically calls the function KCUnlock (page 1167) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function kcfindinternetpasswordwithpath to find the first Internet password item matching specified attributes. The function kcfindinternetpasswordwithpath requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the serverAddress, serverName, volumeName, accountName, and passwordData parameters.

Version Notes
Available beginning with KeychainLib 2.0. In KeychainLib 1.0, the kcfindinternetpassword function provides the same functionality as the function KCFindInternetPassword, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use KCFindInternetPassword, since kcfindinternetpassword is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainFindInternetPassword function in Keychain Services instead.

Declared In
KeychainCore.h

kcfindinternetpasswordwithpath

Not recommended

```
OSStatus kcfindinternetpasswordwithpath (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   const char *path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function KCFindInternetPasswordWithPath (page 1145) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainFindInternetPassword function in Keychain Services instead.

Declared In
KeychainCore.h

KCFindNextItem

Finds the next keychain item matching the previously specified search criteria.

Not recommended

```
OSStatus KCFindNextItem (
   KCSearchRef search,
   KCItemRef *item
);
```

Parameters

search

A reference to the previously-specified search criteria. Pass the reference passed back in the searchRef parameter of the function KCFindFirstItem (page 1139).

item

On return, a pointer to the next matching keychain item, if any.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code errKCNoDefaultKeychain indicates that no default keychain could be found. The result code errKCItemNotFound indicates that no matching keychain item was found. The result code errKCInvalidSearchRef indicates that the specified search reference was invalid.

Discussion
The KCFindNextItem function finds the next keychain item matching the search criteria previously specified by a call to the function KCFindFirstItem (page 1139). The KCFindNextItem function returns a reference to the matching item, if any. The KCFindNextItem function automatically calls the function KCUnlock (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item you are searching for is currently locked.

Special Considerations

When you are completely finished with a search, you should use the functions KCReleaseItem (page 1161) and KCReleaseSearch (page 1162) to release the keychain item and search criteria reference.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainSearchCopyNext function in Keychain Services instead.

Declared In
KeychainCore.h

KCFindX509Certificates

Finds the certificates in a keychain that match specified search criteria.

Unsupported

```
OSStatus KCFindX509Certificates (
    KCRef keychain,
    CFStringRef name,
    CFStringRef emailAddress,
    KCCertSearchOptions options,
    CFMutableArrayRef *certificateItems
);
```

Parameters

keychain
A reference to the keychain you want to search. If the keychain is locked, the Unlock Keychain dialog box is automatically displayed.

name
A pointer to a C string containing the certificate owner's common name.

emailAddress
A pointer to a C string containing the certificate owner's email address.

options
The search criteria you wish to use. See "Certificate Search Options" (page 1177) for a description of this mask.

certificateItems
On return, a pointer to a list of the matching certificates. Pass `NULL` if you don't want to obtain these references.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that a default keychain was not found. The result code `errKCBufferTooSmall` indicates that the certificate data was too large for the supplied buffer. In this case, you should allocate a new buffer of sufficient size before calling `KCFindX509Certificates` again. The result code `errKCItemNotFound` indicates that no matching certificate was found.

Version Notes

Available beginning with KeychainLib 2.0.

Carbon Porting Notes

This function is obsolete. There is currently no replacement.

Declared In

`KeychainHI.h`

KCGetAttribute

Determines keychain item data using a keychain item attribute structure.

Not recommended

```
OSStatus KCGetAttribute (
   KCItemRef item,
   KCAttribute *attr,
   UInt32 *actualLength
);
```

Parameters

item

A reference to the keychain item whose attribute data you wish to determine.

attr

A pointer to a structure of type `KCAttribute` (page 1172). Before calling the `KCGetAttribute` function, fill in the `tag`, `length`, and `data` fields (the `data` field should contain a pointer to a buffer of sufficient length for the type of data to be returned). On return, the `KCGetAttribute` function passes back the requested data in the `data` field.

actualLength

On return, a pointer to the actual length of the attribute data. This may be more than the length you allocated in the length field of the attribute structure.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCNoSuchAttr` indicates that you tried to set an attribute which is undefined for this item class. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCGetAttribute` again.

Discussion

You can call the function `KCGetAttribute` or the function `KCGetData` (page 1151) to obtain keychain item data. The difference between the functions is that the function `KCGetData` (page 1151) requires that you pass the length of the data and a pointer to that data as separate parameters rather than fields in a keychain item attribute structure.

If the keychain that contains the item is locked, before calling the `KCGetAttribute` function you should call the function `KCUnlock` (page 1167) to prompt the user to unlock the keychain.

You can determine any of the standard item attributes identified by the following tag constants: `kClassKCItemAttr`, `kCreationDateKCItemAttr`, `kModDateKCItemAttr`, `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kScriptCodeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can determine, depending upon the type of keychain item whose data you wish to obtain. See "Keychain Item Attribute Tag Constants" (page 1184) for more information.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyAttributesAndData` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCGetData

Determines keychain item data.

Not recommended

```
OSStatus KCGetData (
   KCItemRef item,
   UInt32 maxLength,
   void *data,
   UInt32 *actualLength
);
```

Parameters

item

A reference to the keychain item whose data you wish to determine.

maxLength

The length of the data buffer pointed to by the `data` parameter.

data

A pointer to the buffer that holds the returned data. Before calling the `KCGetData` function, allocate enough memory for the buffer to hold the data you want to store. On return, a pointer to the attribute data you requested.

actualLength

On return, a pointer to the actual length of the data being retrieved. If the buffer pointed to by the `data` parameter is smaller than the actual length of the data, the `KCGetData` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling `KCGetData` again.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCGetData` again. The result code `errKCDataNotModifiable` indicates that the data is not available for this item.

Discussion

You can call the function `KCGetData` or the function `KCGetAttribute` (page 1149) to obtain keychain item data. The difference between the functions is that the function `KCGetAttribute` (page 1149) requires that you pass the length of the data and a pointer to that data as fields in a keychain item attribute structure rather than as separate parameters.

If the keychain that contains the item is locked, before calling the function `KCGetData` you should call the function `KCUnlock` (page 1167) to prompt the user to unlock the keychain. You cannot call the `KCGetData` function for a private key.

You can determine any of the standard item attributes identified by the following tag constants: `kClassKCItemAttr`, `kCreationDateKCItemAttr`, `kModDateKCItemAttr`, `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kScriptCodeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can determine, depending upon the type of keychain item whose data you wish to obtain. See "Keychain Item Attribute Tag Constants" (page 1184) for more information.

Version Notes

Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetDefaultKeychain

Obtains the default keychain.

Not recommended

```
OSStatus KCGetDefaultKeychain (
   KCRef *keychain
);
```

Parameters

keychain

On return, a pointer to default keychain reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoDefaultKeychain` indicates that there is no default keychain.

Discussion
You can determine the name of the default keychain by passing the returned keychain reference to the function `KCGetKeychainName` (page 1155).

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopyDefault` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetIndKeychain

Obtains the reference to an indexed keychain.

Not recommended

```
OSStatus KCGetIndKeychain (
   UInt16 index,
   KCRef *keychain
);
```

Parameters

index

An index of the list of available keychains. Pass a value between 1 and the number returned by the function `KCCountKeychains` (page 1133).

keychain

On return, pointer to the keychain reference corresponding to the index in the `index` parameter.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoSuchKeychain` indicates that the index value is out of range.

Discussion

To guarantee correct operation, you should call the function `KCCountKeychains` (page 1133) once before calling `KCGetIndKeychain`.

Special Considerations

The memory that the keychain reference occupies must be released by calling the function `KCReleaseKeychain` (page 1162) when you are finished with it.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopySearchList` function in Keychain Services followed by a call to `CFArrayGetValueAtIndex` instead.

Declared In

`KeychainCore.h`

KCGetKeychain

Determines the location of a password or other keychain item.

Not recommended

```
OSStatus KCGetKeychain (
   KCItemRef item,
   KCRef *keychain
);
```

Parameters

item

A reference to the keychain item whose keychain location you wish to determine. If you pass a reference to a keychain item whose keychain is locked, the `KCGetKeychain` function returns the result code `errKCInvalidItemRef`.

keychain
On return, a pointer to the keychain containing the specified item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidItemRef` indicates that the keychain item reference was invalid.

Discussion
The `KCGetKeychain` function determines the location of a keychain item in an unlocked keychain. It does not search locked keychains. Calling the `KCGetKeychain` function displays the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Special Considerations

The keychain reference returned by `KCGetKeychain` should be released by calling the function `KCReleaseItem` (page 1161).

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyKeychain` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetKeychainManagerVersion

Determines the version of the Keychain Manager installed on the user's system.

Not Recommended

```
OSStatus KCGetKeychainManagerVersion (
   UInt32 *returnVers
);
```

Parameters
returnVers
On return, a pointer to the version number of the Keychain Manager installed on the current system.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion
Your application can call the `KCGetKeychainManagerVersion` function to find out which version of the Keychain Manager is installed on the user's system.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetVersion` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCGetKeychainName

Determines the name of a keychain.

Not recommended

```
OSStatus KCGetKeychainName (
   KCRef keychain,
   StringPtr keychainName
);
```

Parameters

keychain

A reference to the keychain whose name you wish to obtain.

keychainName

A pointer to a Pascal string. On return, this string contains the name of the keychain.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidKeychain` indicates that the keychain is invalid.

Discussion

You can also call the function `kcgetkeychainname` to obtain the name of a keychain. `kcgetkeychainname` requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `keychainName` parameter.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services instead.

Declared In

`KeychainCore.h`

kcgetkeychainname

Not recommended

```
OSStatus kcgetkeychainname (
   KCRef keychain,
   char *keychainName
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCGetKeychainName` (page 1155) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetStatus

Determines the permissions that are set in a keychain.

Not recommended

```
OSStatus KCGetStatus (
   KCRef keychain,
   UInt32 *keychainStatus
);
```

Parameters

keychain

A pointer to the keychain reference whose permissions you wish to determine. Pass `NULL` to obtain the status of the default keychain.

keychainStatus

On return, a pointer to a bitmask that you can test to determine the permissions that are set in a keychain. See "Keychain Status Constants" (page 1193) for a description of this mask.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoSuchKeychain` indicates that the specified keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetStatus` function in Keychain Services instead.

Declared In
KeychainCore.h

KCIsInteractionAllowed

Indicates whether Keychain Manager functions that display a user interaction will do so.

Not recommended

```
Boolean KCIsInteractionAllowed (
   void
);
```

Parameters

Return Value
A Boolean value indicating whether user interaction is permitted. If true, user interaction is allowed, and Keychain Manager functions that display a user interface can do so as appropriate.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainGetUserInteractionAllowed function in Keychain Services instead.

Declared In
KeychainCore.h

KCLock

Locks a keychain.

Not recommended

```
OSStatus KCLock (
   KCRef keychain
);
```

Parameters

keychain

A reference to the keychain to lock. Pass NULL to lock all unlocked keychains.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code errKCNoSuchKeychain indicates that specified keychain could not be found. The result code errKCInvalidKeychain indicates that the specified keychain is invalid.

Discussion
Your application should not call the KCLock function unless you are responding to a user's request to lock a keychain. In general, you should leave the keychain unlocked so that the user does not have to unlock it again in another application.

Version Notes
The function `KCLock` replaces the function `KCLockKeychain`, which was available in KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainLock` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCMakeAliasFromKCRef

Creates an alias to a keychain reference.

Not Recommended

```
OSStatus KCMakeAliasFromKCRef (
   KCRef keychain,
   AliasHandle *keychainAlias
);
```

Parameters

keychain

A reference to the keychain for which you want to create an alias.

keychainAlias

On return, a pointer to an alias handle to the file referred to by the keychain reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion
You may wish to call the `KCMakeAliasFromKCRef` function to determine the location of a keychain.

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1162) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services followed by calls to the function `FSPathMakeRef` and `FSNewAlias` instead.

Declared In
`KeychainCore.h`

KCMakeKCRefFromAlias

Creates a keychain reference from a keychain alias.

Not Recommended

```
OSStatus KCMakeKCRefFromAlias (
   AliasHandle keychainAlias,
   KCRef *keychain
);
```

Parameters

keychainAlias

A handle to an alias record of the keychain file. Since the keychain is a file, an alias can be made to the keychain file.

keychain

On return, a pointer to a reference to the keychain specified by the alias in the `keychainAlias` parameter.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194).

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1162) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainOpen` function in Keychain Services instead. If the keychain doesn't exist, use the `SecKeychainCreate` function in Keychain Services.

Declared In

`KeychainCore.h`

KCMakeKCRefFromFSSpec

Creates a keychain reference from a file specification record. (Deprecated in Mac OS X v10.5.)

Not Recommended

```
OSStatus KCMakeKCRefFromFSSpec (
   FSSpec *keychainFSSpec,
   KCRef *keychain
);
```

Parameters

keychainFSSpec

A pointer to a keychain file specification record.

keychain

On return, a pointer to a reference to the keychain specified by the file in the `keychainFSSpec` parameter.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1162) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Carbon Porting Notes

Use the `SecKeychainOpen` function in Keychain Services instead. If the keychain doesn't exist, use the `SecKeychainCreate` function in Keychain Services.

Declared In
`KeychainCore.h`

KCNewItem

Creates a reference to a keychain item.

Not recommended

```
OSStatus KCNewItem (
   KCItemClass itemClass,
   OSType itemCreator,
   UInt32 length,
   const void *data,
   KCItemRef *item
);
```

Parameters

itemClass

The type of keychain item that you wish to create. See "Keychain Item Type Constants" (page 1190) for a description of possible values and a description of the `KCItemClass` data type.

itemCreator

The creator code of the application that owns this item.

length

The length of the data to be stored in this item.

data

A pointer to a buffer containing the data to be stored in this item. Before calling `KCNewItem`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the newly-created item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The Memory Manager result code `memFullErr` indicates that you did not allocate enough memory in the current heap to create the item.

Discussion
After calling the `KCNewItem` function, you should call the function `KCAddItem` (page 1130) if you wish to permanently store a password or other keychain item. Note that a copy of the data buffer pointed to by the `data` parameter is stored in the newly-created item.

Special Considerations

When you are done with a keychain item, you should call the function `KCReleaseItem` (page 1161) to release its memory. You should not use the item after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCreateFromContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCReleaseItem

Disposes of the memory occupied by a keychain item reference.

Not recommended

```
OSStatus KCReleaseItem (
   KCItemRef *item
);
```

Parameters

item

A pointer to a keychain item reference. Pass the keychain item reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion
You should call the `KCReleaseItem` function to release the memory occupied by a keychain item reference when you are finished with it.

Version Notes
Available beginning with KeychainLib 1.0

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In
`KeychainCore.h`

KCReleaseKeychain

Disposes of the memory associated with a keychain reference.

Not recommended

```
OSStatus KCReleaseKeychain (
   KCRef *keychain
);
```

Parameters

keychain

A pointer to a keychain reference. Pass the keychain reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion
You should call the `KCReleaseKeychain` function to release the memory occupied by a keychain reference when you are finished with it. You should not use the reference after it has been released.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In
`KeychainCore.h`

KCReleaseSearch

Disposes of the memory occupied by a search criteria reference.

Not recommended

```
OSStatus KCReleaseSearch (
   KCSearchRef *search
);
```

Parameters

search

A pointer to a search criteria reference. Pass the search criteria reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidSearchRef` indicates that the specified search reference was invalid.

Discussion

You should call the `KCReleaseSearch` function to release the memory occupied by a search criteria reference when you are completely finished with a search performed by calling the functions `KCFindFirstItem` (page 1139) or `KCFindNextItem` (page 1148).

Version Notes

Available beginning with KeychainLib 1.0

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In

`KeychainCore.h`

KCRemoveCallback

Unregisters your keychain event callback function.

Not recommended

```
OSStatus KCRemoveCallback (
   KCCallbackUPP callbackProc
);
```

Parameters

callbackProc

A Universal Procedure Pointer (UPP) to your keychain event callback function that was previously registered with the function `KCAddCallback` (page 1123).

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidCallback` indicates that the callback function was not previously registered.

Discussion

After you pass a UPP to your keychain event callback function to the `KCRemoveCallback` function, it will no longer be called by the Keychain Manager.

Special Considerations

After calling `KCRemoveCallback`, you should call the function `DisposeKCCallbackUPP` (page 1119) to dispose of the UPP to your callback function.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainRemoveCalllback` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCSetAttribute

Sets or edits keychain item data using a keychain item attribute structure.

Not recommended

```
OSStatus KCSetAttribute (
   KCItemRef item,
   KCAttribute *attr
);
```

Parameters

item

A reference to the keychain item whose data you wish to set or edit.

attr

A pointer to a structure of type `KCAttribute` (page 1172) containing keychain item data you want to set. Before calling the function `KCSetAttribute`, fill in the `tag`, `length`, and `data` fields of this structure with the tag identifying the attribute you wish to modify or set, the length of the attribute data you wish to set, and a pointer to that data, respectively.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidItemRef` indicates that the keychain item reference was invalid. The result code `errKCNoSuchAttr` indicates that the item attribute you wish to set is undefined for the specified item. The result code `errKCDataTooLarge` indicates that more data was supplied than is allowed for this attribute.

Discussion

You can call the `KCSetAttribute` function or the function `KCSetData` (page 1165) to set or modify keychain item data. The difference between the functions is that the `KCSetData` (page 1165) function requires that you pass the length of the data and a pointer to that data as separate parameters rather than fields in a keychain item attribute structure.

If the keychain that contains the item is locked, before calling the `KCSetAttribute` function you should call the function `KCUnlock` (page 1167) to prompt the user to unlock the keychain. The keychain must permit read/write access in order to modify keychain item data.

You can only set or modify standard item attributes identified by the tag constants `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kTypeKCItemAttr`, and `kCustomIconKCItemAttr`. In addition, each class of keychain item has attributes specific to that class which may be set or modified. See "Keychain Item Attribute Tag Constants" (page 1184) for more information.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyAttributesAndData` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCSetData

Sets or edits keychain item data.

Not recommended

```
OSStatus KCSetData (
   KCItemRef item,
   UInt32 length,
   const void *data
);
```

Parameters

item
A reference to the keychain item whose data you wish to set.

length
The length of the data buffer pointed to by the `data` parameter.

data
A pointer to a buffer containing the data to be stored in this item. Before calling the `KCSetData` function, allocate enough memory for the buffer to hold the data you want to store.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCDataTooLarge` indicates that the data was too large for the supplied buffer. The result code `errKCDataNotModifiable` indicates that the data cannot be set for this item.

Discussion
You can call the function `KCSetData` or the function `KCSetAttribute` (page 1164) to set or modify keychain item data. The difference between the functions is that the function `KCSetAttribute` (page 1164) requires that you pass the length of the data buffer as a field in a keychain item attribute structure rather than as a separate parameter.

If the keychain that contains the item is locked, before calling the `KCSetData` function you should call the function `KCUnlock` (page 1167) to prompt the user to unlock the keychain. The keychain must permit read/write access in order to modify keychain item data.

You can set or edit any of the standard item attributes identified by the following tag constants: `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kTypeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can set, depending upon the type of keychain item whose data you are manipulating. See "Keychain Item Attribute Tag Constants" (page 1184) for more information.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCSetDefaultKeychain

Sets the default keychain.

Not recommended

```
OSStatus KCSetDefaultKeychain (
   KCRef keychain
);
```

Parameters

keychain

A reference to the keychain you wish to make the default.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code `errKCNoSuchKeychain` indicates that the specified keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Discussion
In most cases, your application should not need to set the default keychain, because this is a choice normally made by the user. You should call the `KCSetDefaultKeychain` function to change where a password or other keychain items are added.

The `KCSetDefaultKeychain` function sets the default keychain regardless of whether the keychain is currently locked.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetDefault` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCSetInteractionAllowed

Enables or disables Keychain Manager functions that display a user interface.

Not recommended

```
OSStatus KCSetInteractionAllowed (
   Boolean state
);
```

Parameters

state

A flag that indicates whether the Keychain Manager will display a user interface. If you pass `true`, user interaction is allowed. This is the default value. If `false`, Keychain Manager functions that normally display a user interface will instead return an error.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194).

Discussion

The `KCSetInteractionAllowed` function enables you to control whether the functions `KCLock` (page 1157), `KCUnlock` (page 1167), and `KCChangeSettings` (page 1131) display a user interface. Note that failure to re-enable user interaction will affect other clients of the Keychain Manager. By default, user interaction is permitted.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetUserInteractionAllowed` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCUnlock

Displays a dialog box that prompts the user for a password before unlocking a keychain.

Not recommended

```
OSStatus KCUnlock (
   KCRef keychain,
   StringPtr password
);
```

Parameters

keychain

A reference to the keychain to unlock. Pass `NULL` to specify the default keychain. If you pass `NULL` and the default keychain is currently locked, the keychain will appear as the default choice. If you pass a locked keychain, the function `KCUnlock` displays the Unlock Keychain dialog box and the keychain appears as the chosen menu item in the keychain popup menu. If the default keychain is currently unlocked, the Unlock Keychain dialog box is not displayed and the `KCUnlock` function returns `noErr`.

password

A pointer to a Pascal string representing the password string for this keychain. Pass `NULL` if the user password is unknown. In this case, The `KCUnlock` function displays the Unlock Keychain dialog box, and the authentication user interface associated with the keychain about to be unlocked. If you specify an invalid password, you will not be able to unlock the keychain with a specified password until the machine is rebooted. In this case, the `KCUnlock` function returns `errKCInteractionRequired`.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). The result code `noErr` does not guarantee that the specified keychain is unlocked, because the user can select any available keychain and unlock it. The result code `userCanceledErr` indicates that the user pressed the Cancel button in the Unlock Keychain dialog box. The result code `errKCAuthFailed` indicates that authentication failed because of too many unsuccessful retries. The result code `errKCInteractionRequired` indicates that user interaction is required to unlock the keychain. In this case, you will not be able to unlock the keychain with that password until the machine is rebooted.

Discussion

In most cases, your application does not need to call the `KCUnlock` function directly, since most Keychain Manager functions that require an unlocked keychain call `KCUnlock` automatically. If your application needs to verify that a keychain is unlocked, call the function `KCGetStatus` (page 1156).

You can also call the function `kcunlock` to display a user interface prompting the user to unlock a keychain. The `kcunlock` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `password` parameter.

Special Considerations

It is recommended that the `KCUnlock` function not be explicitly called by applications. Most functions that require an unlocked keychain call the `KCUnlock` function for you.

The memory that the keychain reference occupies must be released by calling the function `KCReleaseKeychain` (page 1162) when you are finished with it.

Version Notes

The `KCUnlock` function replaces the function `KCUnlockKeychain`, which was available in KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainUnlock` function in Keychain Services instead.

Declared In
KeychainHI.h

kcunlock

Not recommended

```
OSStatus kcunlock (
   KCRef keychain,
   const char *password
);
```

Discussion
This function is available for convenience only and may be removed. Use the function KCUnlock (page 1167) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainUnlock function in Keychain Services instead.

Declared In
KeychainHI.h

KCUpdateItem

Updates a password or other keychain item.

Not recommended

```
OSStatus KCUpdateItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item whose data you wish to update. If you pass an item that has not been previously added to the keychain, the KCUpdateItem function does nothing and returns noErr.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1194). The result code errKCNoDefaultKeychain indicates that no default keychain could be found. The result code errKCInvalidItemRef indicates that the specified keychain item reference was invalid.

Discussion
You can use the KCUpdateItem function to update a password or other keychain item in a keychain's permanent data store after changing its data. The function KCUpdateItem automatically calls the function KCUnlock (page 1167) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

NewKCCallbackUPP

Creates a UPP to your keychain event callback.

Not recommended

```
KCCallbackUPP NewKCCallbackUPP (
   KCCallbackProcPtr userRoutine
);
```

Parameters

`userRoutine`

A pointer to your keychain event callback function. For information on how to create a keychain event callback, see `KCCallbackProcPtr` (page 1171).

Return Value
A UPP to your callback function. You can register your callback function by passing this UPP in the `callbackProc` parameter of the function `KCAddCallback` (page 1123). See the description of the `KCCallbackUPP` data type.

Discussion
The `NewKCCallbackUPP` function creates a pointer to your keychain event callback function. You pass a pointer to your callback function in the `callbackProc` parameter of the function `KCAddCallback` (page 1123) if you want your application to receive data transfer events.

Special Considerations

When you are finished with a UPP to your keychain event callback function, you should dispose of it by calling the function `DisposeKCCallbackUPP` (page 1119).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In
`KeychainCore.h`

Callbacks

KCCallbackProcPtr

Defines a pointer to your keychain event callback that handles user keychain access events.

```
typedef OSStatus (*KCCallbackProcPtr)
(
        KCEvent keychainEvent,
        KCCallbackInfo * info,
        void * userContext
);
```

If you name your function `MyKCCallbackProc`, you would declare it like this:

```
OSStatus MyKCCallbackProc (
        KCEvent keychainEvent,
        KCCallbackInfo * info,
        void * userContext
);
```

Parameters

keychainEvent

The keychain event that your application wishes to be notified of. See "Keychain Events Constants" (page 1180) for a description of possible values. The type of event that can trigger your callback depends on the bitmask you passed in the `eventMask` parameter of the function `KCAddCallback` (page 1123). For more information, see the discussion.

info

A pointer to a structure of type `KCCallbackInfo` (page 1173). On return, the structure contains information about the keychain event that occurred. The Keychain Manager passes this information to your callback function via the `info` parameter of the function `InvokeKCCallbackUPP` (page 1119).

userContext

A pointer to application-defined storage that your application previously passed to the function `KCAddCallback` (page 1123). You can use this value to perform operations such as tracking which instance of a function is operating.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1194). Your keychain event callback function should process the keychain event and return `noErr`.

Discussion

Your keychain event callback function handles those keychain events that you indicate. In order to be notified of these events, you must pass a UPP to your notification callback function in the `callbackProc` parameter of `KCAddCallback` (page 1123). You indicate the type of data transfer events you want to receive via a bitmask in the `eventMask` parameter. When you no longer wish to receive notification of keychain events, you should call the function `KCRemoveCallback` (page 1163) to dispose of the UPP to your keychain event callback function.

Carbon Porting Notes

Use the `SecKeychainCallback` function in Keychain Services instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

Data Types

AFPServerSignature

Represents a 16-byte Apple File Protocol server signature block.

```
typedef UInt8 AFPServerSignature[16];
```

Discussion
The `AFPServerSignature` type represents a 16-byte Apple File Protocol server signature block. You can pass a value of this type in the serverSignature parameter of the functions `KCAddAppleSharePassword` (page 1120) and `KCFindAppleSharePassword` (page 1136) to represent an Apple File Protocol server signature. You can use a value of this type with the keychain item attribute constant `kSignatureKCItemAttr` to specify an Apple File Protocol server signature.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttribute

Contains information about a keychain item attribute.

```
typedef SecKeychainAttribute KCAttribute;
```

Discussion
The `KCAttribute` type represents a structure containing information about the attribute of a keychain item. It contains a tag that identifies a particular keychain item attribute value, the length of the attribute value, and a pointer to the attribute value. You can modify attribute data for a keychain item attribute by passing a pointer to this structure in the `attr` parameter of the function `KCSetAttribute` (page 1164). The function `KCGetAttribute` (page 1149) passes back a pointer to this structure in the `attr` parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttributeList

Lists attributes in a keychain item.

```
typedef SecKeychainAttributeList KCAttributeList;
```

Discussion
The `KCAttributeList` type represents a list of structures containing information about the attributes in a keychain item. You pass a pointer to this list of 0 or more structures in the `attrList` parameter of the function `KCFindFirstItem` (page 1139) to indicate the attributes to be matched.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttrType

Identifies a keychain item attribute value.

```
typedef SecKeychainAttrType KCAttrType;
```

Discussion
The `KCAttrType` type represents a tag that identifies a keychain item attribute value. You can use this value in the `tag` field of the structure `KCAttribute` (page 1172) to identify the keychain item attribute value you wish to set or obtain. See `Keychain Item Attribute Tag Constants` (page 1184) for a description of the Apple-defined tag constants and the data types of the values they identify. Your application can create application-defined tags of type `KCAttrType`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCCallbackInfo

Contains information about a keychain event.

```
struct KCCallbackInfo {
    UInt32 version;
    KCItemRef item;
    long processID[2];
    long event[4];
    KCRef keychain;
};
typedef struct KCCallbackInfo KCCallbackInfo;
```

Fields

`version`
The version of this structure.

`item`
A reference to the keychain item in which the event occurred. If the event did not involve an item, this field is not valid.

`processID`
: A 64-bit quantity containing the process serial number of the process in which the event occurred. This is not available on Mac OS X.

`event`
: The keychain event that occurred. If the event is a system event as indicated by the constant `kSystemKCEvent`, the Keychain client can process events. If the event is not a system event, this field is not valid. This is not available on Mac OS X.

`keychain`
: A reference to the keychain in which the event occurred. If the event did not involve a keychain, this field is not valid.

Discussion
The `KCCallbackInfo` type represents a structure that contains information about the keychain event of which your application wants to be notified. The Keychain Manager passes a pointer to this structure in the `info` parameter of your callback function via the function `InvokeKCCallbackUPP` (page 1119), which invokes your callback function. For information on how to write a keychain event callback function, see `KCCallbackProcPtr` (page 1171).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCCallbackUPP

Defines a data type for the `KCCallbackProcPtr` callback pointer.

```
typedef KCCallbackProcPtr KCCallbackUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCItemRef

Represents a reference to a keychain item.

```
typedef SecKeychainItemRef KCItemRef;
```

Discussion
The `KCItemRef` type represents a reference to an opaque structure that identifies a keychain item. You should call the function `KCNewItem` (page 1160) to create a keychain item reference. The function `KCReleaseItem` (page 1161) disposes of a keychain item reference when no longer needed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCPublicKeyHash

Represents a 20-byte public key hash.

```
typedef UInt8 KCPublicKeyHash[20];
```

Discussion
The `KCPublicKeyHash` type represents a hash of a public key. You can use the constant `kPublicKeyHashKCItemAttr`, described in `Keychain Item Attribute Tag Constants` (page 1184), to set or retrieve a certificate attribute value of this type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCRef

Represents a reference to a keychain.

```
typedef SecKeychainRef KCRef;
```

Discussion
The `KCRef` type represents a reference to an opaque structure that identifies a keychain. You should call the function `KCMakeKCRefFromFSSpec` (page 1159) or `KCMakeKCRefFromAlias` (page 1159) to create a keychain reference. The function `KCReleaseKeychain` (page 1162) disposes of a keychain reference when no longer needed. You pass a reference of this type to Keychain Manager functions that operate on a keychain in some way.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCSearchRef

Represents a reference to the current search criteria.

```
typedef SecKeychainSearchRef KCSearchRef;
```

Discussion
The `KCSearchRef` type represents a reference to an opaque structure that identifies the current search criteria. The function `KCFindFirstItem` (page 1139) passes back a reference of this type in the `search` parameter for subsequent calls to the function `KCFindNextItem` (page 1148). You must release this reference when you are finished with a search by calling the function `KCReleaseSearch` (page 1162).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCStatus

Identifies a mask that you can use in determining the permissions that are set in a keychain.

```
typedef SecKeychainStatus KCStatus;
```

Discussion
The `KCStatus` enumeration defines masks your application can use to determine the read and write permissions for a keychain. The function `KCGetStatus` (page 1156) passes back this mask in the `status` parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

Constants

Authentication Type Constants

Represent the type of authentication to use in storing and retrieving Internet passwords.

```
enum {
    kKCAuthTypeNTLM = 'ntlm',
    kKCAuthTypeMSN = 'msna',
    kKCAuthTypeDPA = 'dpaa',
    kKCAuthTypeRPA = 'rpaa',
    kKCAuthTypeHTTPDigest = 'httd',
    kKCAuthTypeDefault = 'dflt'
};
typedef FourCharCode KCAuthType;
```

Constants

`kKCAuthTypeNTLM`
Specifies Windows NT LAN Manager authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeMSN`
Specifies Microsoft Network authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeDPA`
Specifies Distributed Password authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeRPA`
Specifies Remote Password authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCAuthTypeHTTPDigest`
Specifies HTTP Digest Access authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCAuthTypeDefault`
Specifies default authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCAuthType` enumeration defines constants you can use to identify the type of authentication to use in storing and retrieving Internet passwords. You can pass a constant of this type in the `authType` parameter of the functions `KCAddInternetPassword` (page 1126), `KCAddInternetPasswordWithPath` (page 1128), `KCFindInternetPassword` (page 1142), and `KCFindInternetPasswordWithPath` (page 1145).

Certificate Search Options

Represent a mask that specifies the search criteria to use when finding certificates.

```
typedef UInt32 KCCertSearchOptions;
enum {
    kCertSearchShift = 0,
    kCertSearchSigningIgnored = 0,
    kCertSearchSigningAllowed = 1 << (kCertSearchShift + 0),
    kCertSearchSigningDisallowed = 1 << (kCertSearchShift + 1),
    kCertSearchSigningMask = ((kCertSearchSigningAllowed) |
        (kCertSearchSigningDisallowed)),
    kCertSearchVerifyIgnored = 0,
    kCertSearchVerifyAllowed = 1 << (kCertSearchShift + 2),
    kCertSearchVerifyDisallowed = 1 << (kCertSearchShift + 3),
    kCertSearchVerifyMask = ((kCertSearchVerifyAllowed) |
        (kCertSearchVerifyDisallowed)),
    kCertSearchEncryptIgnored = 0,
    kCertSearchEncryptAllowed = 1 << (kCertSearchShift + 4),
    kCertSearchEncryptDisallowed = 1 << (kCertSearchShift + 5),
    kCertSearchEncryptMask = ((kCertSearchEncryptAllowed) |
        (kCertSearchEncryptDisallowed)),
    kCertSearchDecryptIgnored = 0,
    kCertSearchDecryptAllowed = 1 << (kCertSearchShift + 6),
    kCertSearchDecryptDisallowed = 1 << (kCertSearchShift + 7),
    kCertSearchDecryptMask = ((kCertSearchDecryptAllowed) |
        (kCertSearchDecryptDisallowed)),
    kCertSearchWrapIgnored = 0,
    kCertSearchWrapAllowed = 1 << (kCertSearchShift + 8),
    kCertSearchWrapDisallowed = 1 << (kCertSearchShift + 9),
    kCertSearchWrapMask = ((kCertSearchWrapAllowed) |
        (kCertSearchWrapDisallowed)),
    kCertSearchUnwrapIgnored = 0,
    kCertSearchUnwrapAllowed = 1 << (kCertSearchShift + 10),
    kCertSearchUnwrapDisallowed = 1 << (kCertSearchShift + 11),
    kCertSearchUnwrapMask = ((kCertSearchUnwrapAllowed) |
        (kCertSearchUnwrapDisallowed)),
    kCertSearchPrivKeyRequired = 1 << (kCertSearchShift + 12),
    kCertSearchAny = 0
};
```

Discussion
The `KCCertSearchOptions` enumeration defines masks that you can use in the `options` parameter of the function `KCFindX509Certificates` (page 1149).

Certificate Usage Options

Represent a mask that specifies the usage options when adding certificates.

```
typedef UInt32 KCCertAddOptions;
enum {
    kSecOptionReserved = 0x000000FF,
    kCertUsageShift = 8,
    kCertUsageSigningAdd         = 1 << (kCertUsageShift + 0),
    kCertUsageSigningAskAndAdd = 1 << (kCertUsageShift + 1),
```

```
    kCertUsageVerifyAdd = 1 << (kCertUsageShift + 2),
