    kCertUsageVerifyAskAndAdd = 1 << (kCertUsageShift + 3),
    kCertUsageEncryptAdd = 1 <<(kCertUsageShift + 4),
    kCertUsageEncryptAskAndAdd = 1 << (kCertUsageShift + 5),
    kCertUsageDecryptAdd = 1 << (kCertUsageShift + 6),
    kCertUsageDecryptAskAndAdd = 1 << (kCertUsageShift + 7),
    kCertUsageKeyExchAdd = 1 << (kCertUsageShift + 8),
    kCertUsageKeyExchAskAndAdd = 1 << (kCertUsageShift + 9),
    kCertUsageRootAdd = 1 << (kCertUsageShift + 10),
    kCertUsageRootAskAndAdd = 1 << (kCertUsageShift + 11),
    kCertUsageSSLAdd = 1 << (kCertUsageShift + 12),
    kCertUsageSSLAskAndAdd = 1 << (kCertUsageShift + 13),
    kCertUsageAllAdd = 0x7FFFFF00
};
```

Certificate Verification Criteria

Identify the verification criteria for use when displaying certificates to the user.

```
typedef UInt16 KCVerifyStopOn;
enum {
    kPolicyKCStopOn = 0,
    kNoneKCStopOn = 1,
    kFirstPassKCStopOn = 2,
    kFirstFailKCStopOn = 3
};
```

Constants

`kPolicyKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1132) should use the trust policy options currently in effect.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kNoneKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1132) completes after examining all available certificates.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kFirstPassKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1132) when one certificate meeting the verification criteria is found.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kFirstFailKCStopOn`
Specifies that the function `KCChooseCertificate` (page 1132) completes when one certificate that fails to meet the verification criteria is found.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCVerifyStopOn` enumeration defines constants your application can use to identify the verification criteria to use in selecting certificates. You can pass a constant of this type in the `stopOn` parameter of the function `KCChooseCertificate` (page 1132).

Default Internet Port Constant

Represent the internet ports available.

```
enum {
    kAnyPort = 0
};
```

Constants

`kAnyPort`
Indicates that any Internet port can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

Default Internet Protocol And Authentication Type Constants

Represent the internet protocols and authentication types available.

```
enum {
    kAnyProtocol = 0,
    kAnyAuthType = 0
};
```

Constants

`kAnyProtocol`
Indicates that any Internet protocol can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

`kAnyAuthType`
Indicates that any Internet authentication type can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

Keychain Events Constants

Identify keychain events.

```
typedef UInt16 KCEvent;
enum {
    kIdleKCEvent = 0,
    kLockKCEvent = 1,
    kUnlockKCEvent = 2,
    kAddKCEvent = 3,
    kDeleteKCEvent = 4,
    kUpdateKCEvent = 5,
    kPasswordChangedKCEvent = 6,
    kSystemKCEvent = 8,
    kDefaultChangedKCEvent = 9,
    kDataAccessKCEvent = 10,
    kKeychainListChangedKCEvent = 11
};
```

Constants

`kIdleKCEvent`
Indicates a `NULL` event.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kLockKCEvent`
Indicates that the keychain was locked.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kUnlockKCEvent`
Indicates that the keychain was unlocked.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kAddKCEvent`
Indicates that an item was added to a keychain.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kDeleteKCEvent`
Indicates that an item was deleted from a keychain.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kUpdateKCEvent`
Indicates that a keychain item was updated.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kPasswordChangedKCEvent`
Indicates that the identity of the keychain was changed.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kSystemKCEvent`
Indicates that the keychain client can process events.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDefaultChangedKCEvent`
Indicates that the default keychain has changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDataAccessKCEvent`
Indicates that a process has called the function `KCGetData` (page 1151) to access a keychain item's data.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKeychainListChangedKCEvent`
Indicates that the list of keychains has changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCEvent` enumeration defines constants that identify the Keychain-related events your callback function wishes to receive. The Keychain Manager tests a mask that you pass in the `eventMask` parameter of the function `KCAddCallback` (page 1123) to determine the data transfer events your notification callback function wishes to receive. It passes these events in the `keychainEvent` parameter of the function `InvokeKCCallbackUPP` (page 1119). For a description of the Keychain-related event masks, see `Keychain Events Mask` (page 1182).

Keychain Events Mask

Identify a mask that you can use to set the keychain events you wish to receive.

```
typedef UInt16 KCEventMask;
enum {
    kIdleKCEventMask = 1 << kIdleKCEvent,
    kLockKCEventMask = 1 << kLockKCEvent,
    kUnlockKCEventMask = 1 << kUnlockKCEvent,
    kAddKCEventMask = 1 << kAddKCEvent,
    kDeleteKCEventMask = 1 << kDeleteKCEvent,
    kUpdateKCEventMask = 1 << kUpdateKCEvent,
    kPasswordChangedKCEventMask = 1 << kPasswordChangedKCEvent,
    kSystemEventKCEventMask = 1 << kSystemKCEvent,
    kDefaultChangedKCEventMask = 1 << kDefaultChangedKCEvent,
    kDataAccessKCEventMask = 1 << kDataAccessKCEvent,
    kEveryKCEventMask = 0xFFFF
};
```

Constants
`kIdleKCEventMask`
If the bit specified by this mask is set, your callback function will be invoked during a `NULL` event.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kLockKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain is locked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUnlockKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain is unlocked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAddKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when an item is added to the keychain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDeleteKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when an item is removed from the keychain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUpdateKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when a keychain item is updated.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPasswordChangedKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain identity is changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSystemEventKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain client processes an event.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDefaultChangedKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the default keychain is changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDataAccessKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when a process calls the function `KCGetData` (page 1151).

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEveryKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when any of the above Keychain-related events occur.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion

The `KCEventMask` enumeration defines masks your application can use to set Keychain event bits. You pass this mask in the `eventMask` parameter of the function `KCAddCallback` (page 1123), thereby defining the Keychain-related events to which your callback will respond. The Keychain Manager uses this mask to test which events your callback function will handle. It passes these events in the `keychainEvent` parameter of the function `InvokeKCCallbackUPP` (page 1119). For a description of Keychain-related events, see `Keychain Events Constants` (page 1180).

Keychain Item Attribute Tag Constants

Represent tags that identify keychain item attribute values.

```
enum {
    kClassKCItemAttr = 'clas',
    kCreationDateKCItemAttr = 'cdat',
    kModDateKCItemAttr = 'mdat',
    kDescriptionKCItemAttr = 'desc',
    kCommentKCItemAttr = 'icmt',
    kCreatorKCItemAttr = 'crtr',
    kTypeKCItemAttr = 'type',
    kScriptCodeKCItemAttr = 'scrp',
    kLabelKCItemAttr = 'labl',
    kInvisibleKCItemAttr = 'invi',
    kNegativeKCItemAttr = 'nega',
    kCustomIconKCItemAttr = 'cusi',
    kAccountKCItemAttr = 'acct',
    kServiceKCItemAttr = 'svce',
    kGenericKCItemAttr = 'gena',
    kSecurityDomainKCItemAttr = 'sdmn',
    kServerKCItemAttr = 'srvr',
    kAuthTypeKCItemAttr = 'atyp',
    kPortKCItemAttr = 'port',
    kPathKCItemAttr = 'path',
    kVolumeKCItemAttr = 'vlme',
    kAddressKCItemAttr = 'addr',
    kSignatureKCItemAttr = 'ssig',
    kProtocolKCItemAttr = 'ptcl',
    kSubjectKCItemAttr = 'subj',
    kCommonNameKCItemAttr = 'cn  ',
    kIssuerKCItemAttr = 'issu',
    kSerialNumberKCItemAttr = 'snbr',
    kEMailKCItemAttr = 'mail',
    kPublicKeyHashKCItemAttr = 'hpky',
    kIssuerURLKCItemAttr = 'iurl',
    kEncryptKCItemAttr = 'encr',
    kDecryptKCItemAttr = 'decr',
    kSignKCItemAttr = 'sign',
    kVerifyKCItemAttr = 'veri',
    kWrapKCItemAttr = 'wrap',
    kUnwrapKCItemAttr = 'unwr',
    kStartDateKCItemAttr = 'sdat',
    kEndDateKCItemAttr = 'edat'
};
typedef FourCharCode KCItemAttr;
```

Constants

`kClassKCItemAttr`

Identifies the class attribute. You use this tag to set or get a value of type `KCItemClass` that indicates whether the item is an AppleShare, Internet, or generic password, or a certificate. See "KCPublicKeyHash" (page 1175) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCreationDateKCItemAttr`

Identifies the creation date attribute. You use this tag to set or get a value of type `UInt32` that indicates the date the item was created.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kModDateKCItemAttr`
Identifies the modification date attribute. You use this tag to set or get a value of type `UInt32` that indicates the last time the item was updated.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDescriptionKCItemAttr`
Identifies the description attribute. You use this tag to set or get a value of type `string` that represents a user-visible string describing this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCommentKCItemAttr`
Identifies the comment attribute. You use this tag to set or get a value of type `string` that represents a user-editable string containing comments for this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCreatorKCItemAttr`
Identifies the creator attribute. You use this tag to set or get a value of type `OSType` that represents the item's creator.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kTypeKCItemAttr`
Identifies the type attribute. You use this tag to set or get a value of type `OSType` that represents the item's type.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kScriptCodeKCItemAttr`
Identifies the script code attribute. You use this tag to set or get a value of type `ScriptCode` that represents the script code for all strings.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kLabelKCItemAttr`
Identifies the label attribute. You use this tag to set or get a value of type `string` that represents a user-editable string containing the label for this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kInvisibleKCItemAttr`
Identifies the invisible attribute. You use this tag to set or get a value of type `Boolean` that indicates whether the item is invisible.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kNegativeKCItemAttr`

Identifies the negative attribute. You use this tag to set or get a value of type `Boolean` that indicates whether there is a valid password associated with this keychain item. This is useful if your application doesn't want a password for some particular service to be stored in the keychain, but prefers that it always be entered by the user. The item (typically invisible and with zero-length data) acts as a placeholder to say “don't use me.”

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCustomIconKCItemAttr`

Identifies the custom icon attribute. You use this tag to set or get a value of type `Boolean` that indicates whether the item has an application-specific icon. To do this, you must also set the attribute value identified by the tag kTypeKCItemAttr to a file type for which there is a corresponding icon in the desktop database, and set the attribute value identified by the tag `kCreatorKCItemAttr` to an appropriate application creator type. If a custom icon corresponding to the item's type and creator can be found in the desktop database, it will be displayed by Keychain Access. Otherwise, default icons are used.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAccountKCItemAttr`

Identifies the account attribute. You use this tag to set or get a value of type `Str63` that represents the user account. It also applies to generic and AppleShare passwords.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kServiceKCItemAttr`

Identifies the service attribute for a generic password. You use this tag to set or get a value of type `Str63` that represents the service.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kGenericKCItemAttr`

Identifies the generic attribute for a generic password. You use this tag to set or get a value of untyped bytes that represents a user-defined attribute.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSecurityDomainKCItemAttr`

Identifies the security domain attribute for an internet password. You use this tag to set or get a value of type `Str63` that represents the Internet security domain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kServerKCItemAttr`

Identifies the server attribute for an internet password. You use this tag to set or get a value of type `string` that represents the Internet server's domain name or IP address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAuthTypeKCItemAttr`
Identifies the authentication type attribute for an internet password. You use this tag to set or get a value of type `KCAuthType` that represents the Internet authentication scheme.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPortKCItemAttr`
Identifies the port attribute for an internet password. You use this tag to set or get a value of type `UInt16` that represents the Internet port.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPathKCItemAttr`
Identifies the path attribute for an internet password. You use this tag to set or get a value of type `Str255` that represents the path.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kVolumeKCItemAttr`
Identifies the volume attribute for an AppleShare password. You use this tag to set or get a value of type `Str63` that represents the AppleShare volume.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAddressKCItemAttr`
Identifies the address attribute for an AppleShare password. You use this tag to set or get a value of type `string` that represents the zone name, or the IP or domain name that represents the server address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSignatureKCItemAttr`
Identifies the server signature attribute for an AppleShare password. You use this tag to set or get a value of type `KCPublicKeyHash` (page 1175) that represents the server signature block.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kProtocolKCItemAttr`
Identifies the protocol attribute for an AppleShare or internet password. You use this tag to set or get a value of type `KCProtocolType` that represents the Internet protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSubjectKCItemAttr`
Identifies the subject attribute for a certificate. You use this tag to set or get `DER`-encoded data that represents the subject distinguished name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCommonNameKCItemAttr`
Identifies the common name attribute for a certificate. You use this tag to set or get a `UTF8`-encoded string that represents the common name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kIssuerKCItemAttr`
Identifies the issuer attribute for a certificate. You use this tag to set or get a `DER`-encoded data that represents the issuer distinguished name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSerialNumberKCItemAttr`
Identifies the serial number attribute for a certificate. You use this tag to set or get a `DER`-encoded data that represents the serial number.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEMailKCItemAttr`
Identifies the email attribute for a certificate. You use this tag to set or get an `ASCII`-encoded string that represents the issuer's email address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPublicKeyHashKCItemAttr`
Identifies the public key hash attribute for a certificate. You use this tag to set or get a value of type `KCPublicKeyHash` (page 1175) that represents the hash of the public key.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kIssuerURLKCItemAttr`
Identifies the issuer URL attribute for a certificate. You use this tag to set or get an `ASCII`-encoded string that represents the URL of the certificate issuer.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEncryptKCItemAttr`
Identifies the encrypt attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can encrypt.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDecryptKCItemAttr`
Identifies the decrypt attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can decrypt.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSignKCItemAttr`
Identifies the sign attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can sign.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kVerifyKCItemAttr`
Identifies the verify attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can verify.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kWrapKCItemAttr`
Identifies the wrap attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can wrap.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUnwrapKCItemAttr`
Identifies the unwrap attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can unwrap.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kStartDateKCItemAttr`
Identifies the start date attribute for a certificate or key. You use this tag to set or get a value of type `UInt32` that indicates the start date.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEndDateKCItemAttr`
Identifies the end date attribute for a certificate or key. You use this tag to set or get a value of type `UInt32` that indicates the end date.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCItemAttr` enumeration defines the Apple-defined tag constants that identify keychain item attribute values. Your application can use one of these tags in the `tag` field of the structure `KCAttribute` (page 1172) to identify the keychain item attribute value you wish to set or retrieve. Your application can create application-defined tags of type `KCAttrType` (page 1173).

Keychain Item Type Constants

Identify the type of keychain item.

```
enum {
    kCertificateKCItemClass = 'cert',
    kAppleSharePasswordKCItemClass = 'ashp',
    kInternetPasswordKCItemClass = 'inet',
    kGenericPasswordKCItemClass = 'genp'
};
typedef FourCharCode KCItemClass;
```

Constants

`kCertificateKCItemClass`
Specifies that the item is a digital certificate.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kAppleSharePasswordKCItemClass`
Specifies that the item is an AppleShare password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kInternetPasswordKCItemClass`
Specifies that the item is an Internet password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kGenericPasswordKCItemClass`
Specifies that the item is a generic password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

Discussion

The `KCItemClass` enumeration defines constants your application can use to specify the type of the keychain item you wish to create, dispose, add, delete, update, copy, or locate. You pass a constant of this type to the functions `KCNewItem` (page 1160), `KCReleaseItem` (page 1161), `KCAddItem` (page 1130), `KCDeleteItem` (page 1136), `KCUpdateItem` (page 1169), `KCCopyItem` (page 1132), and `KCGetKeychain` (page 1153). You can also use these constants with the tag constant `kClassKCItemAttr`, described in `Keychain Item Attribute Tag Constants` (page 1184).

Keychain Protocol Type Constants

Identify the protocol to use in storing and retrieving Internet passwords.

```
enum {
    kKCProtocolTypeFTP = 'ftp ',
    kKCProtocolTypeFTPAccount = 'ftpa',
    kKCProtocolTypeHTTP = 'http',
    kKCProtocolTypeIRC = 'irc ',
    kKCProtocolTypeNNTP = 'nntp',
    kKCProtocolTypePOP3 = 'pop3',
    kKCProtocolTypeSMTP = 'smtp',
    kKCProtocolTypeSOCKS = 'sox ',
    kKCProtocolTypeIMAP = 'imap',
    kKCProtocolTypeLDAP = 'ldap',
    kKCProtocolTypeAppleTalk = 'atlk',
    kKCProtocolTypeAFP = 'afp ',
    kKCProtocolTypeTelnet = 'teln'
};
typedef FourCharCode KCProtocolType;
```

Constants

`kKCProtocolTypeFTP`
Specifies the File Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeFTPAccount`
Specifies the File Transfer Protocol Account.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeHTTP`
Specifies the HyperText Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeIRC`
Specifies the Internet Relay Channel Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeNNTP`
Specifies the Network News Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypePOP3`
Specifies the Post Office 3 Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeSMTP`
Specifies the Simple Mail Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeSOCKS`
Specifies the Secure Proxy Server Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeIMAP`
Specifies the Internet Message Access Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeLDAP`
Specifies the Lightweight Directory Access Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeAppleTalk`
Specifies the AppleTalk Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeAFP`
Specifies the AppleTalk File Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeTelnet`
Specifies the Telnet Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCProtocolType` enumeration defines constants you can use to identify the type of authentication to use in storing and retrieving Internet passwords. You can pass a constant of this type in the `protocol` parameter of the functions `KCAddInternetPassword` (page 1126), `KCAddInternetPasswordWithPath` (page 1128), `KCFindInternetPassword` (page 1142), and `KCFindInternetPasswordWithPath` (page 1145).

Keychain Status Constants

Identify the keychain status.

```
enum {
    kUnlockStateKCStatus = 1,
    kRdPermKCStatus = 2,
    kWrPermKCStatus = 4
};
```

Constants
`kUnlockStateKCStatus`
If the bit specified by this mask is set (bit 0), the keychain is unlocked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kRdPermKCStatus`
If the bit specified by this mask is set (bit 1), the keychain is unlocked with read permission.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kWrPermKCStatus`
If the bit specified by this mask is set (bit 2), the keychain is unlocked with write permission.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

Result Codes

The most common result codes returned by Keychain Manager are listed below.

Result Code	Value	Description
`errKCNotAvailable`	-25291	Indicates that the Keychain Manager was not loaded. Available in Mac OS X v10.0 and later.
`errKCReadOnly`	-25292	Returned by the function `KCCopyItem` to indicate that the keychain file is read-only and cannot be edited. Available in Mac OS X v10.0 and later.
`errKCAuthFailed`	-25293	Returned by the function `KCUnlock` to indicate that the authentication failed (too many unsuccessful retries). Available in Mac OS X v10.0 and later.
`errKCNoSuchKeychain`	-25294	Returned by the functions `KCUnlock`, `KCSetDefaultKeychain`, `KCGetStatus`, and `KCGetIndKeychain` to indicate that the specified keychain was not found. Available in Mac OS X v10.0 and later.
`errKCInvalidKeychain`	-25295	Returned by the functions `KCUnlock`, `KCSetDefaultKeychain`, `KCGetStatus`, `KCGetKeychainName`, `KCChangeSettings`, and `KCCreateKeychain` to indicate that the keychain is not valid. Available in Mac OS X v10.0 and later.
`errKCDuplicateKeychain`	-25296	Returned by the function `KCCreateKeychain` to indicate that your application tried to create a keychain that already exists. Available in Mac OS X v10.0 and later.
`errKCDuplicateCallback`	-25297	Returned by the function `KCAddCallback` to indicate that your callback function was already registered. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errKCInvalidCallback	-25298	Returned by the function KCRemoveCallback to indicate that the callback function was not previously registered. Available in Mac OS X v10.0 and later.
errKCDuplicateItem	-25299	Returned by the functions KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, and KCAddItem to indicate that you tried to add an existing keychain item to the keychain. Available in Mac OS X v10.0 and later.
errKCItemNotFound	-25300	Returned by the functions KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCFindNextItem, and KCFindFirstItem to indicate that no matching item was found. Available in Mac OS X v10.0 and later.
errKCBufferTooSmall	-25301	Returned by the functions KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCGetAttribute, KCGetData, and KCFindX509Certificates to indicate that the buffer was not large enough to contain the password data. Available in Mac OS X v10.0 and later.
errKCDataTooLarge	-25302	Returned by the functions KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, KCSetAttribute, and KCSetData to indicate that the data is too large. Available in Mac OS X v10.0 and later.
errKCNoSuchAttr	-25303	Returned by the functions KCSetAttribute, KCGetAttribute, and KCFindFirstItem to indicate that no such attribute exists. Available in Mac OS X v10.0 and later.
errKCInvalidItemRef	-25304	Returned by the functions KCSetAttribute, KCGetAttribute, KCSetData, KCGetData, KCAddItem, KCDeleteItem, KCUpdateItem, KCCopyItem, and KCGetKeychain to indicate that the keychain item reference is invalid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errKCInvalidSearchRef	-25305	Returned by the functions KCFindNextItem and KCReleaseSearch to indicate that the specified search reference is invalid. Available in Mac OS X v10.0 and later.
errKCNoSuchClass	-25306	Returned by the function KCCopyItem to indicate that the item class does not exist. Available in Mac OS X v10.0 and later.
errKCNoDefaultKeychain	-25307	Returned by the functions KCChangeSettings, KCSetDefaultKeychain, KCGetDefaultKeychain, KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCCopyItem, KCAddItem, KCDeleteItem, KCUpdateItem, KCFindNextItem, KCFindFirstItem, and KCFindX509Certificates to indicate that there is no default keychain. Available in Mac OS X v10.0 and later.
errKCInteractionNotAllowed	-25308	Returned by the functions KCCreateKeychain, KCChangeSettings, KCUnlock, and KCGetData (the latter two only when the Unlock Dialog and Allow Access dialog boxes are needed) to indicate that there is no start-up keychain. Available in Mac OS X v10.0 and later.
errKCReadOnlyAttr	-25309	Returned by the function KCSetAttribute to indicate that the keychain item attribute is read-only. Available in Mac OS X v10.0 and later.
errKCWrongKCVersion	-25310	Indicates that the wrong version of Keychain Manager is installed to perform this operation. Available in Mac OS X v10.0 and later.
errKCKeySizeNotAllowed	-25311	Indicates that the key size is illegal. Available in Mac OS X v10.0 and later.
errKCNoStorageModule	-25312	Returned by functions that prompts the loading of the Keychain Manager to indicate that the storage module is not found. Available in Mac OS X v10.0 and later.
errKCNoCertificateModule	-25313	Returned when a function is required for a certificate and the certificate module is not found. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`errKCNoPolicyModule`	-25314	Returned when a function is required for a trust policy and the policy module is not found. Available in Mac OS X v10.0 and later.
`errKCInteractionRequired`	-25315	Returned by the function `KCUnlock` to indicate that user interaction is required for this operation. Available in Mac OS X v10.0 and later.
`errKCDataNotAvailable`	-25316	Indicates that the requested data is not available. Available in Mac OS X v10.0 and later.
`errKCDataNotModifiable`	-25317	Returned by the functions `KCSetData` and `KCGetData` to indicate that the data cannot be modified. Available in Mac OS X v10.0 and later.
`errKCCreateChainFailed`	-25318	Returned by the functions `KCChooseCertificate` and `KCFindX509Certificates` to indicate that the attempt to create a new keychain failed. Available in Mac OS X v10.0 and later.

Launch Services Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	LSInfo.h LSOpen.h
Companion guide	Launch Services Programming Guide

Overview

Mac OS X Launch Services is an API that enables a running application to open other applications or their document files in a way similar to the Finder or the Dock. Using Launch Services, an application can perform such tasks as:

- Open (**launch** or activate) another application
- Open a document or a URL (uniform resource locator) in another application
- Identify the preferred application for opening a given document or URL
- Register information about the kinds of document files and URLs an application is capable of opening
- Obtain appropriate information for displaying a file or URL on the screen, such as its icon, display name, and kind string
- Maintain and update the contents of the Recent Items menu

Although most of these services are normally performed by the Finder, other applications may also find them useful for purposes such as opening email attachments, following URLs embedded in a document, running helper applications, or opening embedded document components that were created by another application or require it for viewing or editing.

Many of Launch Services' capabilities were formerly provided by the Desktop Manager. With the advent of Mac OS X application bundles, however, the Desktop Manager has lost its usefulness, since it is not knowledgeable about bundled applications and simply ignores them. Similarly, Launch Services' facilities for dealing with URLs were formerly implemented through the Internet Config API. Launch Services replaces and supersedes the Desktop Manager and Internet Config with a new API providing similar functionality, but designed to operate properly in the Mac OS X environment.

Launch Services was created specifically to avoid the common need for applications to ask the Finder to open an application, document, or URL for them. In the past, opening such items in a way similar to the Finder required knowledge of several APIs, including the Desktop Manager, File Manager, Translation Manager, Internet Config, Process Manager, and Apple Event Manager. The Finder also had implicit knowledge of the desktop database and other information not available elsewhere for determining the correct application with which to open a given document.

Launch Services removes this specialized knowledge from the Finder and isolates it in a single, straightforward API available to any application. The Mac OS X Finder itself uses Launch Services to open applications, documents, and URLs at the user's request. Since the Finder does no additional processing beyond calling Launch Services, any client using Launch Services for these purposes is guaranteed to behave identically to the Finder itself.

Before reading this document, you should be familiar with the related document, *Launch Services Programming Guide*, which presents a conceptual overview of Launch Services and its operations.

Functions by Task

This section describes the functions defined in the Launch Services API.

Locating an Application

The functions described in this section locate the preferred application for opening a given item or family of items or the application matching a given set of defining characteristics, or test whether an application can open a designated item.

`LSGetApplicationForItem` (page 1219)
: Locates the preferred application for opening an item designated by file-system reference.

`LSGetApplicationForURL` (page 1220)
: Locates the preferred application for opening an item designated by URL.

`LSGetApplicationForInfo` (page 1218)
: Locates the preferred application for opening items with a specified file type, creator signature, filename extension, or any combination of these characteristics.

`LSCopyApplicationForMIMEType` (page 1206)
: Locates the preferred application for opening items with a specified MIME type.

`LSCopyApplicationURLsForURL` (page 1207)
: Locates all known applications suitable for opening an item designated by URL.

`LSCanRefAcceptItem` (page 1203)
: Tests whether an application can accept (open) an item designated by file-system reference.

`LSCanURLAcceptURL` (page 1204)
: Tests whether an application can accept (open) an item designated by URL.

`LSFindApplicationForInfo` (page 1217)
: Locates an application with a specified creator signature, bundle ID, filename, or any combination of these characteristics.

Opening Items

The functions described in this section open a designated item or collection of items, or launch or activate a designated application.

`LSOpenApplication` (page 1223)
: Launches the specified application.

`LSOpenItemsWithRole` (page 1229)
Opens items specified as an array of values of type `FSRef` with a specified role.

`LSOpenURLsWithRole` (page 1230)
Opens one or more URLs with the specified roles.

`LSOpenFSRef` (page 1228)
Opens an item designated by file-system reference, in the default manner in its preferred application.

`LSOpenFromRefSpec` (page 1225)
Opens one or more items designated by file-system reference, in either their preferred applications or a designated application.

`LSOpenCFURLRef` (page 1224)
Opens an item designated by URL, in the default manner in its preferred application.

`LSOpenFromURLSpec` (page 1226)
Opens one or more items designated by URL, in either their preferred applications or a designated application.

Obtaining Information About an Item

The functions described in this section obtain requested information about an item.

`LSCopyItemInfoForRef` (page 1212)
Obtains requested information about an item designated by file-system reference.

`LSCopyItemInfoForURL` (page 1213)
Obtains requested information about an item designated by URL.

`LSCopyDisplayNameForRef` (page 1209)
Obtains the display name for an item designated by file-system reference.

`LSCopyDisplayNameForURL` (page 1210)
Obtains the display name for an item designated by URL.

`LSCopyKindStringForRef` (page 1214)
Obtains the kind string for an item designated by file-system reference.

`LSCopyKindStringForURL` (page 1216)
Obtains the kind string for an item designated by URL.

`LSCopyKindStringForTypeInfo` (page 1215)
Obtains a kind string for items with a specified file type, creator signature, filename extension, or any combination of these characteristics.

`LSCopyKindStringForMIMEType` (page 1213)
Obtains the kind string for a specified MIME type.

`LSCopyItemAttribute` (page 1210)
Obtains the value of an item's attribute.

`LSCopyItemAttributes` (page 1211)
Obtains multiple item attribute values as a dictionary.

Getting and Setting Filename Extension Information

The functions described in this section obtain information about an item's filename extension, or control whether the extension should be hidden or shown on the screen.

`LSGetExtensionInfo` (page 1221)
Obtains the starting index of the extension within a filename.

`LSSetExtensionHiddenForRef` (page 1234)
Specifies whether the filename extension for an item designated by file-system reference should be hidden or shown.

`LSSetExtensionHiddenForURL` (page 1235)
Specifies whether the filename extension for an item designated by URL should be hidden or shown.

Registering an Application

The functions described in this section register an application in the Launch Services database.

`LSRegisterFSRef` (page 1231)
Registers an application, designated by file-system reference, in the Launch Services database.

`LSRegisterURL` (page 1232)
Registers an application, designated by URL, in the Launch Services database.

Working With Role Handlers

The functions described in this section get and set application bundle identifiers for handlers of specified content types and URL schemes.

`LSCopyAllRoleHandlersForContentType` (page 1205)
Returns an array of application bundle identifiers for applications capable of handling a specified content type with the specified roles.

`LSCopyDefaultRoleHandlerForContentType` (page 1208)
Returns the application bundle identifier of the user's preferred default handler for the specified content type with the specified role.

`LSSetDefaultRoleHandlerForContentType` (page 1233)
Sets the user's preferred default handler for the specified content type in the specified roles.

`LSGetHandlerOptionsForContentType` (page 1222)
Gets the handler options for the specified content type.

`LSSetHandlerOptionsForContentType` (page 1235)
Sets the handler option for the specified content type.

`LSCopyAllHandlersForURLScheme` (page 1205)
Returns an array of application bundle identifiers for applications capable of handling the specified URL scheme.

`LSCopyDefaultHandlerForURLScheme` (page 1207)
Returns the application bundle identifier of the user's preferred default handler for the specified URL scheme.

`LSSetDefaultHandlerForURLScheme` (page 1232)
Sets the user's preferred default handler for the specified URL scheme.

Functions No Longer Used

The functions described in this section are no longer used.

`LSInit` (page 1222) Deprecated in Mac OS X v10.3
(Deprecated. Formerly used to initialize Launch Services; now does nothing.)

`LSTerm` (page 1236) Deprecated in Mac OS X v10.3
(Deprecated. Formerly used to terminate Launch Services; now does nothing.)

Functions

LSCanRefAcceptItem

Tests whether an application can accept (open) an item designated by file-system reference.

```
OSStatus LSCanRefAcceptItem (
   const FSRef *inItemFSRef,
   const FSRef *inTargetRef,
   LSRolesMask inRoleMask,
   LSAcceptanceFlags inFlags,
   Boolean *outAcceptsItem
);
```

Parameters

inItemFSRef
A pointer to a file-system reference designating the source item (the item to test for acceptance by the target application); see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inTargetFSRef
A pointer to a file-system reference designating the target application; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inRolesMask
A bit mask specifying the target application's desired role or roles with respect to the source item; see "Roles Mask" (page 1241) for a description of this mask. If the role is unimportant, pass `kLSRolesAll`.

inFlags
Flags specifying behavior to observe during the acceptance test; see "Acceptance Flags" (page 1248) for a description of these flags.

outAcceptsItem
A pointer to a Boolean value that, on return, will indicate whether the target application can accept the source item with at least one of the specified roles.

Return Value

A result code; see "Launch Services Result Codes" (page 1251).

Version Notes

Thread-safe since Mac OS version 10.2.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QTCarbonShell

Declared In
`LSInfo.h`

LSCanURLAcceptURL

Tests whether an application can accept (open) an item designated by URL.

```
OSStatus LSCanURLAcceptURL (
   CFURLRef inItemURL,
   CFURLRef inTargetURL,
   LSRolesMask inRoleMask,
   LSAcceptanceFlags inFlags,
   Boolean *outAcceptsItem
);
```

Parameters

inItemURL

A Core Foundation URL reference designating the source item (the item to test for acceptance by the target application); see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

inTargetURL

A Core Foundation URL reference designating the target application; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to an application file or application bundle.

inRolesMask

A bit mask specifying the target application's desired role or roles with respect to the source item; see "Roles Mask" (page 1241) for a description of this mask. This parameter applies only to URLs with a scheme component of `file`, and is ignored for all other schemes. If the role is unimportant, pass `kLSRolesAll`.

inFlags

Flags specifying behavior to observe during the acceptance test; see "Acceptance Flags" (page 1248) for a description of these flags.

outAcceptsItem

A pointer to a Boolean value that, on return, will indicate whether the target application can accept the source item with at least one of the specified roles.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
If the item URL's scheme is `file` (designating either a file or a directory), the acceptance test is based on the designated item's filename extension, file type, and creator signature, along with the role specified by the `inRolesMask` parameter; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`).

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSCopyAllHandlersForURLScheme

Returns an array of application bundle identifiers for applications capable of handling the specified URL scheme.

```
CFArrayRef LSCopyAllHandlersForURLScheme (
   CFStringRef inURLScheme
);
```

Parameters

inURLScheme

The URL scheme for which the application bundle identifiers are to be returned.

Return Value

An array containing the application bundle identifiers for applications capable of handling the URL scheme specified by `inURLScheme`, or `NULL` if no handlers are available.

Discussion

This function returns all of the application bundle identifiers that are capable of handling the specified URL scheme.

URL handling capability is determined according to the value of the `CFBundleURLTypes` key in an application's `Info.plist`. For information on the `CFBundleURLTypes` key, see the section "CFBundleURLTypes" in *Mac OS X Runtime Configuration Guidelines*.

Version Notes

Thread-safe since Mac OS X v10.4.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`LSInfo.h`

LSCopyAllRoleHandlersForContentType

Returns an array of application bundle identifiers for applications capable of handling a specified content type with the specified roles.

```
CFArrayRef LSCopyAllRoleHandlersForContentType (
   CFStringRef inContentType,
   LSRolesMask inRole
);
```

Parameters

inContentType

The content type. The content type is a uniform type identifier (UTI).

inRole

The role. Pass `kLSRolesAll` if any role is acceptable. For additional possible values, see "Roles Mask" (page 1241).

Return Value

The application bundle identifiers for applications capable of handling the specified content type in the specified roles, or `NULL` if no handlers are available.

Discussion
This function returns all of the application bundle identifiers that are capable of handling the specified content type in the specified roles.

The `CFBundleDocumentTypes` key in an application's `Info.plist` can be used to set an application's content handling capabilities. The `LSItemContentTypes` key is particularly useful because it supports the use of UTIs in document claims. For information on the `CFBundleDocumentTypes` key, see the section "CFBundleDocumentTypes" in *Mac OS X Runtime Configuration Guidelines*.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSCopyApplicationForMIMEType

Locates the preferred application for opening items with a specified MIME type.

```
OSStatus LSCopyApplicationForMIMEType (
   CFStringRef inMIMEType,
   LSRolesMask inRoleMask,
   CFURLRef *outAppURL
);
```

Parameters

inMIMEType
A Core Foundation string object specifying the MIME type to consider; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. Comparison of MIME types is case-insensitive.

inRolesMask
A bit mask specifying the application's desired role or roles with respect to items with the specified MIME type; see "Roles Mask" (page 1241) for a description of this mask. If the role is unimportant, pass `kLSRolesAll`.

outAppURL
A pointer to a Core Foundation URL reference that, on return, will identify the preferred application for items with the specified MIME type; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. You are responsible for releasing the URL reference object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251). If no application suitable for opening items with the specified MIME type is found in the Launch Services database, the function will return the result code `kLSApplicationNotFoundErr`.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`LSInfo.h`

LSCopyApplicationURLsForURL

Locates all known applications suitable for opening an item designated by URL.

```
CFArrayRef LSCopyApplicationURLsForURL (
   CFURLRef inURL,
   LSRolesMask inRoleMask
);
```

Parameters

inURL

A Core Foundation URL reference designating the item for which all suitable applications are requested; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

inRolesMask

A bit mask specifying the applications' desired role or roles with respect to the designated item; see "Roles Mask" (page 1241) for a description of this mask. This parameter applies only to URLs with a scheme component of `file`, and is ignored for all other schemes. If the role is unimportant, pass `kLSRolesAll`.

Return Value
An array of Core Foundation URL references, one for each application that can open the designated item with at least one of the specified roles. You are responsible for releasing the array object. If no suitable applications are found in the Launch Services database, the function will return `NULL`

Discussion
If the item URL's scheme is `file` (designating either a file or a directory), the selection of suitable applications is based on the designated item's filename extension, file type, and creator signature, along with the role specified by the `inRolesMask` parameter; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`).

Version Notes
Thread-safe since Mac OS version 10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`LSInfo.h`

LSCopyDefaultHandlerForURLScheme

Returns the application bundle identifier of the user's preferred default handler for the specified URL scheme.

```
CFStringRef LSCopyDefaultHandlerForURLScheme (
   CFStringRef inURLScheme
);
```

Parameters

inURLScheme

The URL scheme for which the application bundle identifier is to be returned.

Return Value

The application bundle identifier of the specified URL scheme.

Discussion

This function returns the user's currently preferred default handler for the specified URL scheme.

URL handling capability is determined according to the value of the `CFBundleURLTypes` key in an application's `Info.plist`. For information on the `CFBundleURLTypes` key, see the section "CFBundleURLTypes" in *Mac OS X Runtime Configuration Guidelines*.

Version Notes

Thread-safe since Mac OS X v10.4.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`LSInfo.h`

LSCopyDefaultRoleHandlerForContentType

Returns the application bundle identifier of the user's preferred default handler for the specified content type with the specified role.

```
CFStringRef LSCopyDefaultRoleHandlerForContentType (
   CFStringRef inContentType,
   LSRolesMask inRole
);
```

Parameters

inContentType

The content type. The content type is a uniform type identifier (UTI).

inRole

The role. Pass `kLSRolesAll` if any role is acceptable. For additional possible values, see "Roles Mask" (page 1241).

Return Value

The application bundle identifier of the default handler for the specified content type in the specified roles, or `NULL` if no handler is available.

Discussion

This function returns the user's currently preferred default handler for the specified content type. Say, for example, that `LSSetDefaultRoleHandlerForContentType` (page 1233) has been used to set "com.Apple.TextEdit" for the "public.xml" content type. When a file whose content type is "public.xml" is double-clicked, TextEdit will be launched to open the file. If you call `LSCopyDefaultRoleHandlerForContentType (CFSTR("public.xml"), kLSRolesAll)`, the string `com.apple.TextEdit` is returned.

The `CFBundleDocumentTypes` key in an application's `Info.plist` can be used to set an application's content handling capabilities. The `LSItemContentTypes` key is particularly useful because it supports the use of UTIs in document claims. For information on the `CFBundleDocumentTypes` key, see the section "CFBundleDocumentTypes" in *Mac OS X Runtime Configuration Guidelines*.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSCopyDisplayNameForRef

Obtains the display name for an item designated by file-system reference.

```
OSStatus LSCopyDisplayNameForRef (
   const FSRef *inRef,
   CFStringRef *outDisplayName
);
```

Parameters

`inRef`

A pointer to a file-system reference designating the item whose display name is requested; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

`outDisplayName`

A pointer to a Core Foundation string object that, on return, will contain the item's display name; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The item's display name is returned in the form in which it will appear on the user's screen; it may be localized (for applications and folders), and it excludes the filename extension if the extension is set to be hidden and the Finder preference to always show extensions is not enabled.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.1 and later.

Related Sample Code
QTMetaData

Declared In
`LSInfo.h`

LSCopyDisplayNameForURL

Obtains the display name for an item designated by URL.

```
OSStatus LSCopyDisplayNameForURL (
   CFURLRef inURL,
   CFStringRef *outDisplayName
);
```

Parameters

inFileURL

A Core Foundation URL reference designating the item whose display name is requested; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to either a file or a directory.

outDisplayName

A pointer to a Core Foundation string object that, on return, will contain the item's display name; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value

A result code; see "Launch Services Result Codes" (page 1251).

Discussion

The item's display name is returned in the form in which it will appear on the user's screen; it may be localized (for applications and folders), and it excludes the filename extension if the extension is set to be hidden and the Finder preference to always show extensions is not enabled.

Version Notes

Thread-safe since Mac OS version 10.2.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`LSInfo.h`

LSCopyItemAttribute

Obtains the value of an item's attribute.

```
OSStatus LSCopyItemAttribute (
   const FSRef *inItem,
   LSRolesMask inRoles,
   CFStringRef inAttributeName,
   CFTypeRef *outValue
);
```

Parameters

inItem

The `FSRef` of the item to query.

inRoles

The roles. When obtaining attributes related to document binding (such as `kLSItemRoleHandlerDisplayName`), at least one of the roles must be provided by the application selected. Pass `kLSRolesAll` if any role is acceptable.

inAttributeName

The name of the attribute to copy. For possible values, see "Item Attribute Constants" (page 1245).

outValue

A pointer to a `CFTypeRef`. On return, the `CFTypeRef` is set to the copied attribute value (a CF object), or is `NULL` if an error occurs. The type of the returned object varies depending on the attribute that is requested.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSCopyItemAttributes

Obtains multiple item attribute values as a dictionary.

```
OSStatus LSCopyItemAttributes (
   const FSRef *inItem,
   LSRolesMask inRoles,
   CFArrayRef inAttributeNames,
   CFDictionaryRef *outValues
);
```

Parameters

inItem

The `FSRef` of the item to query.

inRoles

The roles. When obtaining attributes related to document binding (such as `kLSItemRoleHandlerDisplayName`), at least one of the roles must be provided by the application selected. Pass `kLSRolesAll` if any role is acceptable.

inAttributeNames

A `CFArrayRef` for an array containing the attribute names to copy. For possible values, see "Item Attribute Constants" (page 1245).

outValues

On return, a pointer a `CFDictionaryRef` for a dictionary whose keys are the attribute names specified by the `inAttributeNames` parameter and whose values are the attribute's values. The `CFTypeID` of each value in the dictionary varies by attribute. See "Item Attribute Constants" (page 1245) for the data type of each value. If the item does not have a specified attribute, the key for the attribute is not in the dictionary.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSCopyItemInfoForRef

Obtains requested information about an item designated by file-system reference.

```
OSStatus LSCopyItemInfoForRef (
   const FSRef *inItemRef,
   LSRequestedInfo inWhichInfo,
   LSItemInfoRecord *outItemInfo
);
```

Parameters

inItemRef

A pointer to a file-system reference designating the item about which information is requested; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inWhichInfo

Flags specifying what information to obtain; see "Requested-Information Flags" (page 1244) for a description of these flags.

outItemInfo

A pointer to an item-information record that, on return, will contain the requested information; see LSItemInfoRecord (page 1240) for a description of this structure.

If you request the item's filename extension (field `extension` of the item-information record, requested by flag `kLSRequestExtension`), you are responsible for releasing the Core Foundation string object in which the extension is returned.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The information obtained about an item can include its filename extension, file type, creator signature, and various item-information flags (indicating, for example, whether the item is an application, or whether it has a hidden extension); see "Item-Information Flags" (page 1246) for a description of these flags.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

`LSInfo.h`

LSCopyItemInfoForURL

Obtains requested information about an item designated by URL.

```
OSStatus LSCopyItemInfoForURL (
   CFURLRef inURL,
   LSRequestedInfo inWhichInfo,
   LSItemInfoRecord *outItemInfo
);
```

Parameters

inFileURL

A Core Foundation URL reference designating the item about which information is requested; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to either a file or a directory.

inWhichInfo

Flags specifying what information to obtain; see "Requested-Information Flags" (page 1244) for a description of these flags.

outItemInfo

A pointer to an item-information record that, on return, will contain the requested information; see LSItemInfoRecord (page 1240) for a description of this structure.

If you request the item's filename extension (field `extension` of the item-information record, requested by flag `kLSRequestExtension`), you are responsible for releasing the Core Foundation string object in which the extension is returned.

Return Value

A result code; see "Launch Services Result Codes" (page 1251).

Discussion

The information obtained about an item can include its filename extension, file type, creator signature, and various item-information flags (indicating, for example, whether the item is an application, or whether it has a hidden extension); see "Item-Information Flags" (page 1246) for a description of these flags.

Version Notes

Thread-safe since Mac OS version 10.2.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonCocoa_PictureCursor

Declared In

`LSInfo.h`

LSCopyKindStringForMIMEType

Obtains the kind string for a specified MIME type.

```
OSStatus LSCopyKindStringForMIMEType (
   CFStringRef inMIMEType,
   CFStringRef *outKindString
);
```

Parameters

inMIMEType

A Core Foundation string object specifying the MIME type whose kind string is requested; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. Comparison of MIME types is case-insensitive.

outKindString

A pointer to a Core Foundation string object that, on return, will contain the kind string for the specified MIME type; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The kind string (which may be localized) is obtained from the preferred application for opening items of the specified the MIME type, if one is found in the Launch Services database; otherwise, a more generic kind string is chosen.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`LSInfo.h`

LSCopyKindStringForRef

Obtains the kind string for an item designated by file-system reference.

```
OSStatus LSCopyKindStringForRef (
   const FSRef *inFSRef,
   CFStringRef *outKindString
);
```

Parameters

inFSRef

A pointer to a file-system reference designating the item whose kind string is requested; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

outKindString

A pointer to a Core Foundation string object that, on return, will contain the item's kind string; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The kind string (which may be localized) is obtained from the item's preferred application, if one is found in the Launch Services database; otherwise, a more generic kind string is chosen. For example, the kind string might be `FrameMaker Document`, or just `Document` if the item is a document for which no application is found.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSCopyKindStringForTypeInfo

Obtains a kind string for items with a specified file type, creator signature, filename extension, or any combination of these characteristics.

```
OSStatus LSCopyKindStringForTypeInfo (
   OSType inType,
   OSType inCreator,
   CFStringRef inExtension,
   CFStringRef *outKindString
);
```

Parameters

inType

The file type to consider. Comparison of file types is case-sensitive. Pass `kLSUnknownType` if the items' file type is unimportant.

inCreator

The creator signature to consider. Comparison of creator signatures is case-sensitive. Pass `kLSUnknownCreator` if the items' creator signature is unimportant.

inExtension

A Core Foundation string object specifying the filename extension to consider; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. Comparison of filename extensions is case-insensitive. Pass `NULL` if the items' filename extension is unimportant.

outKindString

A pointer to a Core Foundation string object that, on return, will contain the requested kind string; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function obtains the kind string that most closely describes items having the specified characteristics. It is useful when you want to display the kind string for a document you do not yet have (such as an email attachment).

You can request any combination of one, two, or all three of the characteristics specified by the *inType*, *inCreator*, and *inExtension* parameters; at least one of these characteristics must be supplied. The kind string (which may be localized) is obtained from the preferred application for opening such items, if one is found in the Launch Services database; otherwise, a more generic kind string is chosen. For example, the kind string might be `FrameMaker Document`, or just `Document` if no suitable application is found.

Note that since the choice of a preferred application is subject to any document binding preferences the user may have set, the kind string will not necessarily be obtained from the default application that matches the specified creator signature (if any), but may instead be taken from a user-specified application that overrides the default. For example, if the user has specified that files of type `'PDF '` and creator `'ACRO'` should be opened in the Preview application rather than in Acrobat, the kind string for this combination of characteristics will be that defined for `'PDF '` files by Preview and not by Acrobat.

Version Notes
Thread-safe since Mac OS version 10.2

Availability
Available in Mac OS X v10.2 and later.

Declared In
`LSInfo.h`

LSCopyKindStringForURL

Obtains the kind string for an item designated by URL.

```
OSStatus LSCopyKindStringForURL (
   CFURLRef inURL,
   CFStringRef *outKindString
);
```

Parameters

inURL

A Core Foundation URL reference designating the item whose kind string is requested; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

outKindString

A pointer to a Core Foundation string object that, on return, will contain the item's kind string; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. You are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The kind string (which may be localized) is obtained from the item's preferred application, if one is found in the Launch Services database; otherwise, a more generic kind string is chosen. For example, the kind string might be `FrameMaker Document`, or just `Document` if the item is a document for which no application is found. If the item URL's scheme is `file` (designating either a file or a directory), the selection of the preferred application is based on the designated item's filename extension, file type, and creator signature; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`).

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSFindApplicationForInfo

Locates an application with a specified creator signature, bundle ID, filename, or any combination of these characteristics.

```
OSStatus LSFindApplicationForInfo (
   OSType inCreator,
   CFStringRef inBundleID,
   CFStringRef inName,
   FSRef *outAppRef,
   CFURLRef *outAppURL
);
```

Parameters

inCreator

The creator signature to consider. Comparison of creator signatures is case-sensitive. Pass `kLSUnknownCreator` if the application's creator signature is unimportant.

inBundleID

A Core Foundation string object specifying the bundle ID to consider; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. Comparison of bundle IDs is case-insensitive. Pass `NULL` if the application's bundle ID is unimportant.

inName

A Core Foundation string object specifying the filename to consider; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. The string must include any extension (such as `'.app'`) that is part of the filename. Comparison of filenames is case-insensitive. Pass `NULL` if the application's filename is unimportant.

outAppRef

A pointer to a file-system reference that, on return, will identify the requested application; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Pass `NULL` if you are not interested in identifying the application in this form; however, this parameter and `outAppURL` cannot both be `NULL`.

outAppURL

A pointer to a Core Foundation URL reference that, on return, will identify the requested application; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. Pass `NULL` if you are not interested in identifying the application in this form; however, this parameter and `outAppRef` cannot both be `NULL`.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251). If no suitable application is found in the Launch Services database, the function will return the result code `kLSApplicationNotFoundErr`.

Discussion
You can request any combination of one, two, or all three of the characteristics specified by the *inCreator*, *inBundleID*, and *inName* parameters; at least one of these characteristics must be supplied. If more than one application is found matching the specified characteristics, Launch Services chooses one in the same manner as when locating the preferred application for opening an item.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSGetApplicationForInfo

Locates the preferred application for opening items with a specified file type, creator signature, filename extension, or any combination of these characteristics.

```
OSStatus LSGetApplicationForInfo (
   OSType inType,
   OSType inCreator,
   CFStringRef inExtension,
   LSRolesMask inRoleMask,
   FSRef *outAppRef,
   CFURLRef *outAppURL
);
```

Parameters

inType
The file type to consider. Comparison of file types is case-sensitive. Pass `kLSUnknownType` if the items' file type is unimportant.

inCreator
The creator signature to consider. Comparison of creator signatures is case-sensitive. Pass `kLSUnknownCreator` if the items' creator signature is unimportant.

inExtension
A Core Foundation string object specifying the filename extension to consider; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type. Comparison of filename extensions is case-insensitive. Pass `NULL` if the items' filename extension is unimportant.

inRolesMask
A bit mask specifying the application's desired role or roles with respect to items with the specified characteristics; see "Roles Mask" (page 1241) for a description of this mask. If the role is unimportant, pass `kLSRolesAll`.

outAppRef
A pointer to a file-system reference that, on return, will identify the preferred application for opening items with the specified characteristics; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppURL` cannot both be `NULL`.

outAppURL

A pointer to a Core Foundation URL reference that, on return, will identify the preferred application for items with the specified characteristics; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppRef` cannot both be `NULL`.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251). If no application suitable for opening items with the specified characteristics is found in the Launch Services database, the function will return the result code `kLSApplicationNotFoundErr`.

Discussion
You can request any combination of one, two, or all three of the characteristics specified by the *inType*, *inCreator*, and *inExtension* parameters; at least one of these characteristics must be supplied. Note that since the choice of a preferred application is subject to any document binding preferences the user may have set, the application chosen will not necessarily be the default application that matches the input characteristics, but may instead be a user-specified application that overrides the default.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSGetApplicationForItem

Locates the preferred application for opening an item designated by file-system reference.

```
OSStatus LSGetApplicationForItem (
   const FSRef *inItemRef,
   LSRolesMask inRoleMask,
   FSRef *outAppRef,
   CFURLRef *outAppURL
);
```

Parameters

inItemRef

A pointer to a file-system reference designating the item whose preferred application is requested; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inRolesMask

A bit mask specifying the application's desired role or roles with respect to the designated item; see "Roles Mask" (page 1241) for a description of this mask. If the role is unimportant, pass `kLSRolesAll`.

outAppRef

A pointer to a file-system reference that, on return, will identify the item's preferred application; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppURL` cannot both be `NULL`.

outAppURL

A pointer to a Core Foundation URL reference that, on return, will identify the item's preferred application; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppRef` cannot both be `NULL`.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value

A result code; see "Launch Services Result Codes" (page 1251). If no application suitable for opening the item is found in the Launch Services database, the function will return the result code `kLSApplicationNotFoundErr`.

Version Notes

Thread-safe since Mac OS version 10.2.

Availability

Available in Mac OS X v10.0 and later.

`LSInfo.h`

LSGetApplicationForURL

Locates the preferred application for opening an item designated by URL.

```
OSStatus LSGetApplicationForURL (
   CFURLRef inURL,
   LSRolesMask inRoleMask,
   FSRef *outAppRef,
   CFURLRef *outAppURL
);
```

Parameters

inURL

A Core Foundation URL reference designating the item whose preferred application is requested; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

inRolesMask

A bit mask specifying the application's desired role or roles with respect to the designated item; see "Roles Mask" (page 1241) for a description of this mask. This parameter applies only to URLs with a scheme component of `file`, and is ignored for all other schemes. If the role is unimportant, pass `kLSRolesAll`.

outAppRef

A pointer to a file-system reference that, on return, will identify the item's preferred application; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppURL` cannot both be `NULL`.

outAppURL

A pointer to a Core Foundation URL reference that, on return, will identify the item's preferred application; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. Pass `NULL` if you are not interested in identifying the preferred application in this form; however, this parameter and `outAppRef` cannot both be `NULL`.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251). If no application suitable for opening the item is found in the Launch Services database, the function will return the result code `kLSApplicationNotFoundErr`.

Discussion
If the item URL's scheme is `file` (designating either a file or a directory), the selection of the preferred application is based on the designated item's filename extension, file type, and creator signature, along with the role specified by the `inRolesMask` parameter; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`).

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSInfo.h`

LSGetExtensionInfo

Obtains the starting index of the extension within a filename.

```
OSStatus LSGetExtensionInfo (
   UniCharCount inNameLen,
   const UniChar inNameBuffer[],
   UniCharCount *outExtStartIndex
);
```

Parameters
inNameLen

The number of characters in the filename specified by the *inNameBuffer* parameter.

inNameBuffer

The buffer containing the filename's Unicode characters.

outExtStartIndex

A pointer to a value of type `UniCharCount` that, on return, will give the starting index of the extension within the filename. If the name does not contain a valid extension (one with no spaces in it), the value on return will be `kLSInvalidExtensionIndex`.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The starting index is the number of Unicode characters from the start of the filename buffer to the first character of the extension (not including the period).

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.1 and later.

Related Sample Code
QTCarbonShell

Declared In
`LSInfo.h`

LSGetHandlerOptionsForContentType

Gets the handler options for the specified content type.

```
LSHandlerOptions LSGetHandlerOptionsForContentType (
   CFStringRef inContentType
);
```

Parameters

inContentType
The content type for which the handler options are to be obtained. The content type is a uniform type identifier (UTI).

Return Value
The handler option that is set for the specified content type. For possible values, see "Handler Option Constants" (page 1249).

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSInit

(Deprecated in Mac OS X v10.3. Formerly used to initialize Launch Services; now does nothing.)

Not recommended.

```
OSStatus LSInit (
   LSInitializeFlags inFlags
);
```

Discussion
Calling this function was formerly required in order to initialize Launch Services; it is no longer needed, however, because Launch Services is now initialized automatically the first time one of its functions is called. `LSInit` now does nothing at all.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

Declared In
`LSInfo.h`

LSOpenApplication

Launches the specified application.

```
OSStatus LSOpenApplication (
   const LSApplicationParameters *appParams,
   ProcessSerialNumber *outPSN
);
```

Parameters

`inAppParams`
A `LSApplicationParameters` (page 1237) structure specifying the application to launch and its launch parameters. This parameter cannot be `NULL`.

`outPSN`
On input, a pointer to a value of type `ProcessSerialNumber` that, on return, contains the process serial number (PSN) of the application specified by `inAppParams`, or `NULL` if you don't want to receive the PSN.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The `LSOpenApplication` launches one application. This function is an updated alternative to the Process Manager's `LaunchApplication` function. Launch arguments are specified in the `inAppParams` argument, which must be supplied. If the application is already running in the current session, it is made the front process (unless the `kLSLaunchNewInstance` flag is used, which always causes a new process to be created).

If `outPSN` is not `NULL`, on return, the structure it points to contains the PSN of the launched (or activated) process. Note that for asynchronous launches, the application may not have finished launching when this function returns.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
LSOpen.h

LSOpenCFURLRef

Opens an item designated by URL, in the default manner in its preferred application.

```
OSStatus LSOpenCFURLRef (
   CFURLRef inURL,
   CFURLRef *outLaunchedURL
);
```

Parameters

inURL

A Core Foundation URL reference designating the item to open; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

outLaunchedURL

A pointer to a Core Foundation URL reference that, on return, will identify the application launched. Pass `NULL` if this information is unimportant.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
The designated item is opened in the default manner, as if it had been opened with the `LSOpenFromURLSpec` function with a launch specification specifying the launch flag `kLSLaunchDefaults`: that is, asynchronously, starting the Classic emulation environment if necessary, and with the remaining launch parameters taken from the application's information property list. For greater control, call `LSOpenFromURLSpec` directly. See `"Launch Flags"` (page 1242) for more information about launch flags.

If the item URL's scheme is `file` (designating either a file or a directory), the selection of the preferred application is based on the designated item's filename extension, file type, and creator signature; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`). The application is launched or activated, as required, and sent an appropriate Apple event depending on the circumstances:

- If the URL's scheme is `file` and it designates a document, the document's preferred application is launched (or activated if it is already running).
  - If the application claims to accept `file` URLs, it is sent a `'GURL'` ("get URL") Apple event containing the item's URL.
  - If the application does not claim to accept `file` URLs, it is sent an `'odoc'` ("open document") Apple event identifying the document to open.
- If the URL's scheme is `file` and it designates an application:
  - If the application is not already running, it is launched and sent an `'oapp'` ("open application") Apple event.
  - If the application is already running, it is activated and sent an `'rapp'` ("reopen application") Apple event.

- If the URL has a scheme other than `file`, the scheme's preferred application is launched (or activated if it is already running) and sent a `'GURL'` ("get URL") Apple event containing the item's URL.

As of Mac OS X v10.4 and later, `LSOpenURLsWithRole` (page 1230) is the preferred way of opening a URL.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSOpen.h`

LSOpenFromRefSpec

Opens one or more items designated by file-system reference, in either their preferred applications or a designated application.

```
OSStatus LSOpenFromRefSpec (
   const LSLaunchFSRefSpec *inLaunchSpec,
   FSRef *outLaunchedRef
);
```

Parameters

`inLaunchSpec`
A pointer to a file-based launch specification indicating what to open and how to launch the relevant application or applications; see LSLaunchFSRefSpec (page 1237) for a description of this structure.

`outLaunchedRef`
A pointer to a file-system reference that, on return, will identify the application launched; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Pass `NULL` if this information is unimportant. If more than one application is launched, the one identified will be the one corresponding to the first item designated in the launch specification.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function affords greater control of how items are opened or applications launched than is possible with the `LSOpenFSRef` function. For instance, you can use it to open multiple items in a single call, in either the same or different applications; open documents for printing rather than for simple viewing or editing; or force a document to open in an application other than its own preferred application.

The launch specification supplied for the `inLaunchSpec` parameter may designate an application to launch, items to open, or both. The relevant application or applications are launched or activated, as required, and sent an appropriate Apple event depending on the circumstances:

- If the launch specification designates both items to open and an application with which to open them, the designated application is used to open all of the items. The application is launched (or activated if it is already running) and sent an `'odoc'` ("open document") Apple event containing the list of items to open; if the items are to be printed, the Apple event is `'pdoc'` ("print document") instead.

  Note: When both an application and a list of items are supplied, the designated application is asked to open all of the items, whether or not it claims the ability to do so. Launch Services does not report an error if the application is unable to open one or more of the items; any error processing is the application's responsibility.

- If the launch specification designates items to open but not an application with which to open them, each item is opened in its own preferred application. Each application is launched or activated and sent an `'odoc'` or `'pdoc'` Apple event, as described for the preceding case. (If two or more of the items have the same preferred application, the application receives a single `'odoc'` or `'pdoc'` event listing all of the relevant items.)
- If the launch specification designates only an application to launch (or if one or more of the items to open are applications):
  - If the application is not already running, it is launched and sent an `'oapp'` ("open application") Apple event.
  - If the application is already running, it is activated and sent an `'rapp'` ("reopen application") Apple event.

As of Mac OS X v10.4 and later, `LSOpenItemsWithRole` (page 1229) is the preferred way of opening items.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSOpen.h`

LSOpenFromURLSpec

Opens one or more items designated by URL, in either their preferred applications or a designated application.

```
OSStatus LSOpenFromURLSpec (
   const LSLaunchURLSpec *inLaunchSpec,
   CFURLRef *outLaunchedURL
);
```

Parameters

inLaunchSpec

A pointer to a URL-based launch specification indicating what to open and how to launch the relevant application or applications; see LSLaunchURLSpec (page 1238) for a description of this structure.

outLaunchedURL

A pointer to a Core Foundation URL reference that, on return, will identify the application launched; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. Pass `NULL` if this information is unimportant. If more than one application is launched, the one identified will be the one corresponding to the first item designated in the launch specification.

Despite the absence of the word `Copy` in its name, this function retains the URL reference object on your behalf; you are responsible for releasing this object.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function affords greater control of how items are opened or applications launched than is possible with the `LSOpenCFURLRef` function. For instance, you can use it to open multiple items in a single call, in either the same or different applications; open documents for printing rather than for simple viewing or editing; or force a document to open in an application other than its own preferred application.

The launch specification supplied for the `inLaunchSpec` parameter may designate an application to launch, items to open, or both. The relevant application or applications are launched or activated, as required, and sent an appropriate Apple event depending on the circumstances:

- If the launch specification designates both items to open and an application with which to open them, the designated application is used to open all of the items. The application is launched (or activated if it is already running) and sent one or more Apple events:
  - If one or more of the item URLs have scheme `file` and designate documents to open, and if the application claims to accept `file` URLs, it is sent a `'GURL'` ("get URL") Apple event for each such URL.
  - If one or more of the item URLs have scheme `file` and designate documents to open, and if the application does not claim to accept `file` URLs, it is sent a single `'odoc'` ("open document") Apple event containing the list of items to open; if the items are to be printed, the Apple event is `'pdoc'` ("print document") instead.
  - For each item URL with a scheme other than `file`, the application is sent a `'GURL'` ("get URL") Apple event containing the item's URL.

Note: When both an application and a list of items are supplied, the designated application is asked to open all of the items, whether or not it claims the ability to do so. Launch Services does not report an error if the application is unable to open one or more of the items; any error processing is the application's responsibility.

- If the launch specification designates items to open but not an application with which to open them, each item is opened in its own preferred application. Each application is launched or activated and sent one or more Apple events, as described for the preceding case. (If two or more of the items have the same preferred application, the application receives a single `'odoc'` or `'pdoc'` event listing all of the relevant items.)
- If the launch specification designates only an application to launch (or if one or more of the items to open are `file` URLs designating applications):
  - If the application is not already running, it is launched and sent an `'oapp'` ("open application") Apple event.

- If the application is already running, it is activated and sent an `'rapp'` (“reopen application”) Apple event.

As of Mac OS X v10.4 and later, `LSOpenURLsWithRole` (page 1230) is the preferred way of opening URLs.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSOpen.h`

LSOpenFSRef

Opens an item designated by file-system reference, in the default manner in its preferred application.

```
OSStatus LSOpenFSRef (
   const FSRef *inRef,
   FSRef *outLaunchedRef
);
```

Parameters

inRef
A pointer to a file-system reference designating the item to open; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

outLaunchedRef
A pointer to a file-system reference that, on return, will identify the application launched. Pass `NULL` if this information is unimportant.

Return Value
A result code; see “Launch Services Result Codes” (page 1251).

Discussion
The designated item is opened in the default manner, as if it had been opened with the `LSOpenFromRefSpec` function with a launch specification specifying the launch flag `kLSLaunchDefaults`: that is, asynchronously, starting the Classic emulation environment if necessary, and with the remaining launch parameters taken from the application’s information property list. For greater control, call `LSOpenFromRefSpec` directly. See `“Launch Flags”` (page 1242) for more information about launch flags.

The application is launched or activated, as required, and sent an appropriate Apple event depending on the circumstances:

- If the item is a document, its preferred application is launched (or activated if it is already running) and sent an `'odoc'` (“open document”) Apple event.
- If the item is an application that is not already running, it is launched and sent an `'oapp'` (“open application”) Apple event.
- If the item is an application that is already running, it is activated and sent an `'rapp'` (“reopen application”) Apple event.

As of Mac OS X v10.4 and later, `LSOpenItemsWithRole` (page 1229) is the preferred way of opening an item.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LSOpen.h`

LSOpenItemsWithRole

Opens items specified as an array of values of type `FSRef` with a specified role.

```
OSStatus LSOpenItemsWithRole (
   const FSRef *inItems,
   CFIndex inItemCount,
   LSRolesMask inRole,
   const AEKeyDesc *inAEParam,
   const LSApplicationParameters *inAppParams,
   ProcessSerialNumber *outPSNs,
   CFIndex inMaxPSNCount
);
```

Parameters

inItems
An array of values of type `FSRef`.

inItemCount
The number of items specified in `inItems`.

inRole
A value of type `LSRolesMask` specifying one or more roles. If the role doesn't matter, use `kLSRolesAll`. For possible values, see "Roles Mask" (page 1241). If the `inAppParams` parameter is not `NULL`, this parameter is ignored.

inAEParam
An `AEKeyDesc` that is to be attached to the Apple Event(s) generated by Launch Services with the specified `AEKeyword`. This parameter can be `NULL`.

inAppParams
An `LSApplicationParameters` (page 1237) structure specifying the application to launch and its launch parameters, in which case the `inRole` parameter is ignored. This parameter can be `NULL`, in which case an application is selected that can handle each input item in at least one of the roles specified by the `inRole` parameter.

outPSNs
On input, a pointer to a caller-allocated buffer or `NULL` if you don't want to receive process serial number (PSN) information. If not `NULL` on input, on return, the buffer contains at each index the PSN that was used to open the item at the same index of the input item array (`inItems`).

inMaxPSNCount
The maximum number of PSNs that the buffer pointed to by `outPSNs` can hold.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function opens the specified items with the specified role. You can optionally specify the application and launch parameters in the `inAppParams` parameter. If an application is specified in the `inAppParams` parameter, the `inRole` parameter is ignored and the application is launched (if necessary).

Each application (regardless of whether it is launched or already running) receives an `'odoc'` Apple Event specifying the items that are to be opened.

If the `inItems` array contains any applications, this function launches them only if the `kLSRolesShell` bit is set in the `inRoles` parameter to indicate that the operating system should use the application itself as the execution shell of the new process.

If not `NULL`, the `outPSNs` buffer is filled with the PSN that was used to open each item at the same index of the `inItems` array. The PSN capacity of the output buffer is specified by `inMaxPSNCount`.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSOpen.h`

LSOpenURLsWithRole

Opens one or more URLs with the specified roles.

```
OSStatus LSOpenURLsWithRole (
   CFArrayRef inURLs,
   LSRolesMask inRole,
   const AEKeyDesc *inAEParam,
   const LSApplicationParameters *inAppParams,
   ProcessSerialNumber *outPSNs,
   CFIndex inMaxPSNCount
);
```

Parameters

inURLs
An array of values of type `CFURLRef`.

inRole
A value of type `LSRolesMask` specifying one or more roles. If the role doesn't matter, use `kLSRolesAll`. For possible values, see "Roles Mask" (page 1241). This parameter is ignored if the `inAppParams` parameter is not `NULL`.

inAEParam
A value of type `AEKeyDesc` that is to be attached to the Apple Event(s) generated by Launch Services with the specified `AEKeyword`. This parameter can be `NULL`.

inAppParams
An `LSApplicationParameters` (page 1237) structure specifying the application to launch and its launch parameters, in which case the `inRole` parameter is ignored. This parameter can be `NULL`, in which case an application is selected that can handle each input URL in at least one of the roles specified by the `inRole` parameter.

outPSNs

On input, a pointer to a caller-allocated buffer or `NULL` if you don't want to receive process serial number (PSN) information. If not `NULL` on input, on return, the buffer contains at each index the PSN that was used to open the URL at the same index of the input URL array (`inURLs`).

inMaxPSNCount

The maximum number of PSNs that the buffer pointed to by `outPSNs` can hold.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function opens the URLs specified by `inURLs` with the roles specified by `inRole`.

Each launched application receives one or more `'GURL'` Apple Events specifying the URLs to be opened. You can also pass file URLs, which are interpreted as file system items and opened in the manner of `LSOpenItemsWithRole` (page 1229) (that is, a handler is selected based on the item's filesystem metadata).If `inURLs` contains any application URLs, this function launches them only if the `kLSRolesShell` bit is set in the `inRoles` parameter, in which case the application is its own shell.If not `NULL`, the `outPSNs` buffer is filled with the process serial numbers that were used to open each URL at the same index of the input URL array specified by the `inURLs` parameter. The PSN capacity of the output buffer is specified by `inMaxPSNCount`.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSOpen.h`

LSRegisterFSRef

Registers an application, designated by file-system reference, in the Launch Services database.

```
OSStatus LSRegisterFSRef (
   const FSRef *inRef,
   Boolean inUpdate
);
```

Parameters

inRef

A pointer to a file-system reference designating the application to be registered; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inUpdate

A Boolean value specifying whether Launch Services should update existing information registered for the application, if any. If this parameter is `false`, the application will not be registered if it has already been registered previously and its current modification date has not changed from when it was last registered; if the parameter is `true`, the application's registered information will be updated even if its modification date has not changed.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function adds the designated application and its document and URL claims (if any) to the Launch Services database, making the application a candidate for document and URL binding.

Version Notes
Thread-safe since Mac OS version 10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`LSInfo.h`

LSRegisterURL

Registers an application, designated by URL, in the Launch Services database.

```
OSStatus LSRegisterURL (
   CFURLRef inURL,
   Boolean inUpdate
);
```

Parameters

inFileURL

A Core Foundation URL reference designating the application to be registered; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to an application file or application bundle.

inUpdate

A Boolean value specifying whether Launch Services should update existing information registered for the application, if any. If this parameter is `false`, the application will not be registered if it has already been registered previously and its current modification date has not changed from when it was last registered; if the parameter is `true`, the application's registered information will be updated even if its modification date has not changed.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
This function adds the designated application and its document and URL claims (if any) to the Launch Services database, making the application a candidate for document and URL binding.

Version Notes
Thread-safe since Mac OS version 10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`LSInfo.h`

LSSetDefaultHandlerForURLScheme

Sets the user's preferred default handler for the specified URL scheme.

```
OSStatus LSSetDefaultHandlerForURLScheme (
   CFStringRef inURLScheme,
   CFStringRef inHandlerBundleID
);
```

Parameters

inURLScheme

The URL scheme for which the handler is to be set.

inHandlerBundleID

The application bundle identifier that is to be set as the handler for the URL scheme specified by `inURLScheme`.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
Call `LSCopyDefaultHandlerForURLScheme` (page 1207) to get the current setting of the user's preferred default handler for a specified content type.

URL handling capability is determined according to the value of the `CFBundleURLTypes` key in an application's `Info.plist`. For information on the `CFBundleURLTypes` key, see the section "CFBundleURLTypes" in *Mac OS X Runtime Configuration Guidelines*.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSSetDefaultRoleHandlerForContentType

Sets the user's preferred default handler for the specified content type in the specified roles.

```
OSStatus LSSetDefaultRoleHandlerForContentType (
   CFStringRef inContentType,
   LSRolesMask inRole,
   CFStringRef inHandlerBundleID
);
```

Parameters

inContentType

The content type for which the default role handler is being set. The content type is a uniform type identifier (UTI).

inRole

The roles for which the default role handler is being set. Pass `kLSRolesAll` to specify all roles. For additional possible values, see "Roles Mask" (page 1241).

inHandlerBundleID

The application bundle identifier that is to be set as the default handler for the specified content type and roles.

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Discussion
Call `LSCopyDefaultRoleHandlerForContentType` (page 1208) to get the current setting of the user's preferred default handler for a specified content type.

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSSetExtensionHiddenForRef

Specifies whether the filename extension for an item designated by file-system reference should be hidden or shown.

```
OSStatus LSSetExtensionHiddenForRef (
   const FSRef *inRef,
   Boolean inHide
);
```

Parameters

inRef

A pointer to a file-system reference designating the item whose filename extension is to be hidden or shown; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type.

inHide

A Boolean value specifying whether the filename extension should be hidden (`true`) or shown (`false`).

Return Value
A result code; see "Launch Services Result Codes" (page 1251). The function will return the result code `kLSCannotSetInfoErr` if:

- The extension is not valid (contains spaces)
- The extension is not active (is not claimed by an application registered with Launch Services)
- Hiding the extension would make the filename appear to have an active but incorrect extension (for example, in the filename `Photo.jpeg.scpt`, where hiding the extension would make an AppleScript file appear to be a JPEG file)

Discussion
This function sets the necessary file-system state controlling whether the filename extension should be hidden in the display name of the item designated by the `inRef` parameter. To determine whether an item's extension is currently hidden, you can use the `LSCopyItemInfoForRef` function.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`LSInfo.h`

LSSetExtensionHiddenForURL

Specifies whether the filename extension for an item designated by URL should be hidden or shown.

```
OSStatus LSSetExtensionHiddenForURL (
   CFURLRef inURL,
   Boolean inHide
);
```

Parameters

`inFileURL`

A Core Foundation URL reference designating the item whose filename extension is to be hidden or shown; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to either a file or a directory.

`inHide`

A Boolean value specifying whether the extension should be hidden (`true`) or shown (`false`).

Return Value
A result code; see "Launch Services Result Codes" (page 1251). The function will return the result code `kLSCannotSetInfoErr` if:

- The extension is not valid (contains spaces)
- The extension is not active (is not claimed by an application registered with Launch Services)
- Hiding the extension would make the filename appear to have an active but incorrect extension (for example, in the filename `Photo.jpeg.scpt`, where hiding the extension would make an AppleScript file appear to be a JPEG file)

Discussion
This function sets the necessary file-system state controlling whether the filename extension should be hidden in the display name of the item designated by the `inFileURL` parameter. To determine whether an item's extension is currently hidden, you can use the `LSCopyItemInfoForURL` function.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`LSInfo.h`

LSSetHandlerOptionsForContentType

Sets the handler option for the specified content type.

```
OSStatus LSSetHandlerOptionsForContentType (
   CFStringRef inContentType,
   LSHandlerOptions inOptions
);
```

Parameters

inContentType

The content type for which the handler options are to be set. The content type is a uniform type identifier (UTI).

inOptions

The handler options to set. For possible values, see "Handler Option Constants" (page 1249).

Return Value
A result code; see "Launch Services Result Codes" (page 1251).

Version Notes
Thread-safe since Mac OS X v10.4.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`LSInfo.h`

LSTerm

(Deprecated in Mac OS X v10.3. Formerly used to terminate Launch Services; now does nothing.)

Not recommended.

```
OSStatus LSTerm (
   void
);
```

Discussion
Calling this function was formerly required in order to terminate Launch Services; however, it is no longer needed and so should not be called. It now does nothing at all.

Version Notes
Thread-safe since Mac OS version 10.2.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.

Declared In
`LSInfo.h`

Data Types

This section describes the data types defined in the Launch Services API.

LSApplicationParameters

Specifies the application, launch flags, and additional parameters that control how an application is launched.

```
struct LSApplicationParameters {
    CFIndex version;
    LSLaunchFlags flags;
    const FSRef * application;
    void * asyncLaunchRefCon;
    CFDictionaryRef environment;
    CFArrayRef argv;
    AppleEvent * initialEvent
};
typedef struct LSApplicationParameters LSApplicationParameters;
```

Fields

`version`
The version of the structure. The value of this field must be `0`.

`flags`
Launch flags. For possible values, see "Launch Flags" (page 1242).

`application`
The `FSRef` of the application to open.

`asyncLaunchRefCon`
The client `refCon` that is to appear in subsequent launch notifications.

`environment`
A dictionary of `CFStringRef` keys and values for environment variables to set in the launched process. The value of this field can be `NULL`.

`argv`
An array of values of type `CFStringRef` that specify the arguments that are to be passed to `main()` in the launched process. The value of this field can be `NULL`. This field is ignored in Mac OS X v10.4.

`initialEvent`
The first Apple Event to send to the launched process. The value of this field can be `NULL`.

Discussion

This structure is passed as a parameter to `LSOpenApplication` (page 1223), `LSOpenItemsWithRole` (page 1229), and `LSOpenURLsWithRole` (page 1230).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`LSOpen.h`

LSLaunchFSRefSpec

Specifies, by file-system reference, an application to launch, items to open, or both, along with related information.

```
struct LSLaunchFSRefSpec {
    const FSRef *appRef;
    UInt32 numDocs;
    const FSRef *itemRefs;
    const AEDesc *passThruParams;
    LSLaunchFlags launchFlags;
    void *asyncRefCon;
};
typedef struct LSLaunchFSRefSpec LSLaunchFSRefSpec;
```

Fields

`appRef`

A pointer to a file-system reference designating the application to launch; see the *File Manager Reference* in the Carbon File Management Documentation for a description of the `FSRef` data type. Set this field to `NULL` to request that each item in the `itemRefs` array be opened in its own preferred application.

`numDocs`

The number of elements in the array specified by the `itemRefs` field. The value of this field can be `0`, in which case the application designated by `appRef` is launched without opening any items.

`itemRefs`

An array of file-system references designating the item or items to open. If the value of `numDocs` is `0`, this field is ignored and can be set to `NULL`.

`passThruParams`

A pointer to an Apple event descriptor that is passed untouched as an optional parameter, with keyword `keyAEPropData` (`'prdt'`), in the Apple event sent to each application launched or activated (whether individual preferred applications or the application designated by `appRef`). See the *Apple Event Manager Reference* in the Carbon Interapplication Communication Documentation for a description of the `AEDesc` data type. The value of this field can be `NULL`.

`launchFlags`

Launch flags specifying how to launch each application (including whether to print or merely open documents); see "Launch Flags" (page 1242) for a description of these flags.

`asyncRefCon`

A pointer to an arbitrary application-defined value, passed in the Carbon event notifying you of an application's launch or termination (if you have registered for such notification). The value of this field can be `NULL`.

Discussion

This data type defines a file-based launch specification designating, by file-system reference, an application to launch, items to open, or both. To request that items be opened in a particular application, set `appRef`, `numDocs`, and `itemRefs` accordingly. To request that each designated item be opened in its own preferred application, set *`appRef`* to `NULL`. To request that a particular application be launched without opening any documents, set *`appRef`* accordingly and set `numDocs` to `0`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`LSOpen.h`

LSLaunchURLSpec

Specifies, by URL, an application to launch, items to open, or both, along with related information.

```
struct LSLaunchURLSpec {
    CFURLRef appURL;
    CFArrayRef itemURLs;
    const AEDesc *passThruParams;
    LSLaunchFlags launchFlags;
    void *asyncRefCon;
};
typedef struct LSLaunchURLSpec LSLaunchURLSpec;
```

Fields

`appURL`

A Core Foundation URL reference designating the application to launch; see the *CFURL Reference* in the Core Foundation Reference Documentation for a description of the `CFURLRef` data type. The URL must have scheme `file` and contain a valid path to an application file or application bundle. Set this field to `NULL` to request that each item in the `itemURLs` array be opened in its own preferred application.

`itemURLs`

A reference to an array of Core Foundation URL references designating the item or items to open; see the *CFArray Reference* in the Core Foundation Reference Documentation for a description of the `CFArrayRef` data type. The value of this field can be `NULL`, in which case the application designated by `appURL` will be launched without opening any items.

`passThruParams`

A pointer to an Apple event descriptor that is passed untouched as an optional parameter, with keyword `keyAEPropData` (`'prdt'`), in the Apple event sent to each application launched or activated (whether individual preferred applications or the application designated by `appURL`). See the *Apple Event Manager Reference* in the Carbon Interapplication Communication Documentation for a description of the `AEDesc` data type. The value of this field can be `NULL`.

`launchFlags`

Launch flags specifying how to launch each application (including whether to print or merely open documents); see "Launch Flags" (page 1242) for a description of these flags.

`asyncRefCon`

A pointer to an arbitrary application-defined value, passed in the Carbon event notifying you of an application's launch or termination (if you have registered for such notification). The value of this field can be `NULL`.

Discussion

This data type defines a URL-based launch specification designating, by URL, an application to launch, items to open, or both. To request that items be opened in a particular application, set *`appURL`* and `itemURLs` accordingly. To request that each designated item be opened in its own preferred application, set *`appURL`* to `NULL`. If the item URL's scheme is `file` (designating either a file or a directory), the selection of the preferred application is based on the designated item's filename extension, file type, and creator signature; otherwise, it is based on the URL scheme (such as `http`, `ftp`, or `mailto`). To request that a particular application be launched without opening any document, set *`appURL`* accordingly and set `itemURLs` to `NULL`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`LSOpen.h`

LSItemInfoRecord

Contains requested information about an item.

```
struct LSItemInfoRecord {
    LSItemInfoFlags flags;
    OSType filetype;
    OSType creator;
    CFStringRef extension;
    CFStringRef iconFileName;
    LSKindID kindID;
};
typedef struct LSItemInfoRecord LSItemInfoRecord;
```

Fields

`flags`
: Item-information flags specifying information about the item; see "Item-Information Flags" (page 1246) for a description of these flags.

`filetype`
: The item's file type.

`creator`
: The item's creator signature.

`extension`
: A Core Foundation string object specifying the item's filename extension; see the *CFString Reference* in the Core Foundation Reference Documentation for a description of the `CFStringRef` data type.

`iconFileName`
: No longer used.

`kindID`
: No longer used.

Discussion

This data type defines an item-information record used by the `LSCopyItemInfoForRef` and `LSCopyItemInfoForURL` functions to return requested information about an item.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`LSInfo.h`

LSKindID

Data type of the `kindID` field of an item-information record (`LSItemInfoRecord`); no longer used.

```
typedef UInt32 LSKindID;
```

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`LSInfo.h`

Constants

This section describes the constants defined in the Launch Services API.

Roles Mask

Specify the desired role or roles for an application to claim with respect to an item or family of items.

```
typedef OptionBits LSRolesMask;enum {
    kLSRolesNone = 0x00000001,
    kLSRolesViewer = 0x00000002,
    kLSRolesEditor = 0x00000004,
    kLSRolesShell = 0x00000008,
    kLSRolesAll = 0xFFFFFFFF
};
```

Constants

`kLSRolesNone`

Requests the role `None` (the application cannot open the item, but provides an icon and a kind string for it).

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRolesViewer`

Requests the role `Viewer` (the application can read and present the item, but cannot manipulate or save it).

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRolesEditor`

Requests the role `Editor` (the application can read, present, manipulate, and save the item).

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRolesShell`

Requests the role `Shell` (the application can execute the item).

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSRolesAll`

Accepts any role with respect to the item.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

Discussion

This bit mask is passed to functions that find the preferred application for a given item or family of items (`LSGetApplicationForItem`, `LSGetApplicationForURL`, `LSGetApplicationForInfo`), or that determine whether a given application can open a designated item (`LSCanRefAcceptItem`, `LSCanURLAcceptURL`), to specify the application's desired role or roles with respect to the item. For example, to request only an editor application, specify `kLSRolesEditor`; if either an editor or a viewer application is acceptable, specify `kLSRolesEditor | kLSRolesViewer`.

Launch Flags

Specify how to launch an application.

```
typedef OptionBits LSLaunchFlags;enum {
    kLSLaunchDefaults = 0x00000001,
    kLSLaunchAndPrint = 0x00000002,
    kLSLaunchReserved2 = 0x00000004,
    kLSLaunchReserved3 = 0x00000008,
    kLSLaunchReserved4 = 0x00000010,
    kLSLaunchReserved5 = 0x00000020,
    kLSLaunchAndDisplayErrors = 0x00000040,
    kLSLaunchInhibitBGOnly = 0x00000080,
    kLSLaunchDontAddToRecents = 0x00000100,
    kLSLaunchDontSwitch = 0x00000200,
    kLSLaunchNoParams = 0x00000800,
    kLSLaunchAsync = 0x00010000,
    kLSLaunchStartClassic = 0x00020000,
    kLSLaunchInClassic = 0x00040000,
    kLSLaunchNewInstance = 0x00080000,
    kLSLaunchAndHide = 0x00100000,
    kLSLaunchAndHideOthers = 0x00200000,
    kLSLaunchHasUntrustedContents = 0x00400000
};
```

Constants

`kLSLaunchDefaults`

Requests launching in the default manner (as if the only flags set were `kLSLaunchNoParams`, `kLSLaunchAsync`, and `kLSLaunchStartClassic`).

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchAndPrint`

Requests that documents opened in the application be printed.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchReserved2`

Reserved for future use.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchReserved3`

Reserved for future use.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchReserved4`

Reserved for future use.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchReserved5`
Reserved for future use.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchAndDisplayErrors`
Requests that launch and open failures be displayed in the UI.
Available in Mac OS X v10.4 and later.
Declared in `LSOpen.h`.

`kLSLaunchInhibitBGOnly`
Requests that the launch be made to fail if the application is background-only.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchDontAddToRecents`
Requests that the application or documents not be added to the Finder's Recent Items menu.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchDontSwitch`
Requests that the application be launched without being brought to the foreground.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchNoParams`
Requests that the application's information property list be used to determine the launch parameters.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchAsync`
Requests that the application be launched asynchronously: that is, the Launch Services function launching it return control immediately, without waiting for it to complete its launch sequence (indicated visually to the user when the application's icon stops "bouncing" in the Dock).
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchStartClassic`
Requests that the Classic emulation environment be started up if the application requires it. If this flag is not set and the application requires the Classic environment, the launch will fail.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchInClassic`
Requests that the application be forced to launch in the Classic emulation environment.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchNewInstance`
Requests that a new instance of the application be started, even if one is already running.
Available in Mac OS X v10.0 and later.
Declared in `LSOpen.h`.

`kLSLaunchAndHide`
Requests that the application be hidden as soon as it completes its launch sequence.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchAndHideOthers`
Requests that other applications be hidden as soon as the opened application completes its launch sequence.

Available in Mac OS X v10.0 and later.

Declared in `LSOpen.h`.

`kLSLaunchHasUntrustedContents`
Requests that the items to be launched should be marked as untrusted.

Available in Mac OS X v10.4 and later.

Declared in `LSOpen.h`.

Discussion
They are passed in a launch specification structure (`LSLaunchFSRefSpec` to the `LSOpenFromRefSpec` function or `LSLaunchURLSpec` to the `LSOpenFromURLSpec` function), to control the manner in which applications are launched.

Requested-Information Flags

Specify what information to obtain about an item.

```
typedef OptionBits LSRequestedInfo;enum {
    kLSRequestExtension = 0x00000001,
    kLSRequestTypeCreator = 0x00000002,
    kLSRequestBasicFlagsOnly = 0x00000004,
    kLSRequestAppTypeFlags = 0x00000008,
    kLSRequestAllFlags = 0x00000010,
    kLSRequestIconAndKind = 0x00000020,
    kLSRequestExtensionFlagsOnly = 0x00000040,
    kLSRequestAllInfo = 0xFFFFFFFF
};
```

Constants
`kLSRequestExtension`
Requests the item's filename extension.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestTypeCreator`
Requests the item's file type and creator signature.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestBasicFlagsOnly`
Requests all item-information flags that are not application-specific: that is, all except `kLSItemInfoIsNativeApp` through `kLSItemInfoAppIsScriptable`.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestAppTypeFlags`
Requests all application-specific item-information flags: that is, `kLSItemInfoIsNativeApp` through `kLSItemInfoAppIsScriptable`.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestAllFlags`
Requests all item-information flags.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestIconAndKind`
Not used.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSRequestExtensionFlagsOnly`
Requests only the `kLSItemInfoExtensionIsHidden` item-information flag.

Available in Mac OS X v10.1 and later.

Declared in `LSInfo.h`.

`kLSRequestAllInfo`
Requests all available item information.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

Discussion
These flags are passed to the `LSCopyItemInfoForRef` and `LSCopyItemInfoForURL` functions to specify the type of information to be obtained in an item-information record; see LSItemInfoRecord (page 1240) for a description of this structure.

Item Attribute Constants

Constants used to retrieve item attributes.

```
const CFStringRef kLSItemContentType;
const CFStringRef kLSItemFileType;
const CFStringRef kLSItemFileCreator;
const CFStringRef kLSItemExtension;
const CFStringRef kLSItemDisplayName
const CFStringRef kLSItemDisplayKind;
const CFStringRef kLSItemRoleHandlerDisplayName;
const CFStringRef kLSItemIsInvisible;
const CFStringRef kLSItemExtensionIsHidden;
```

Constants
`kLSItemContentType`
The item's content type identifier, which is a uniform type identifier string. The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemFileType`
The item's file type (OSType). The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemFileCreator`
The item's file creator (OSType). The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemExtension`
The item's filename extension. The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemDisplayName`
The item's name as displayed to the user. The display name reflects localization and extension hiding that may be in effect. The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemDisplayKind`
The localized kind string describing the item's type. The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemRoleHandlerDisplayName`
The display name of the application that is set to handle this item, subject to the role mask. The value type of this attribute is `CFStringRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemIsInvisible`
A value of `kCFBooleanTrue` if the item is normally hidden from users; otherwise, `kCFBooleanFalse`. The value type of this attribute is `CFBooleanRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSItemExtensionIsHidden`
A value of `kCFBooleanTrue` if the item's extension is set to be hidden; otherwise, `kCFBooleanFalse`. The value type of this attribute is `CFBooleanRef`.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

Item-Information Flags

Provide information about an item.

```
typedef OptionBits LSItemInfoFlags;enum {
    kLSItemInfoIsPlainFile = 0x00000001,
    kLSItemInfoIsPackage = 0x00000002,
    kLSItemInfoIsApplication = 0x00000004,
    kLSItemInfoIsContainer = 0x00000008,
    kLSItemInfoIsAliasFile = 0x00000010,
    kLSItemInfoIsSymlink = 0x00000020,
    kLSItemInfoIsInvisible = 0x00000040,
    kLSItemInfoIsNativeApp = 0x00000080,
    kLSItemInfoIsClassicApp = 0x00000100,
    kLSItemInfoAppPrefersNative = 0x00000200,
    kLSItemInfoAppPrefersClassic = 0x00000400,
    kLSItemInfoAppIsScriptable = 0x00000800,
    kLSItemInfoIsVolume = 0x00001000,
    kLSItemInfoExtensionIsHidden = 0x00100000
};
```

Constants

`kLSItemInfoIsPlainFile`
Item is a data file (and not, for example, a directory, volume, or UNIX symbolic link).
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsPackage`
Item is a packaged directory.
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsApplication`
Item is a single-file or packaged application.
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsContainer`
Item is a directory (includes packages) or volume.
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsAliasFile`
Item is an alias file (includes symbolic links).
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsSymlink`
Item is a UNIX symbolic link.
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsInvisible`
Item is invisible, because either its name begins with a period or its `isInvisible` Finder flag is set.
Available in Mac OS X v10.0 and later.
Declared in `LSInfo.h`.

`kLSItemInfoIsNativeApp`
Item is an application that can run natively in Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoIsClassicApp`
Item is an application that cannot run natively and must be launched in the Classic emulation environment.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoAppPrefersNative`
Item is an application that can run either natively or in the Classic emulation environment, but prefers to be launched natively. This flag is valid only when `kLSItemInfoIsNativeApp` is set.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoAppPrefersClassic`
Item is an application that can run either natively or in the Classic emulation environment, but prefers to be launched in the Classic environment. This flag is valid only when `kLSItemInfoIsNativeApp` is set.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoAppIsScriptable`
Item is an application that can be scripted.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoIsVolume`
Item is the root directory of a volume or mount point.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSItemInfoExtensionIsHidden`
Item has a hidden filename extension.

Available in Mac OS X v10.1 and later.

Declared in `LSInfo.h`.

Discussion
These flags are set in an item-information record to provide information about an item; see LSItemInfoRecord (page 1240) for a description of this structure.

Acceptance Flags

Specify behavior to observe when testing whether an application can accept (open) an item.

```
typedef OptionBits LSAcceptanceFlags;enum {
    kLSAcceptDefault = 0x00000001,
    kLSAcceptAllowLoginUI = 0x00000002
};
```

Constants

`kLSAcceptDefault`

Requests the default behavior (as opposed to the behavior specified by the `kLSAcceptAllowLoginUI` flag).

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSAcceptAllowLoginUI`

Requests that the user interface to log in be presented if necessary. If `LSCanRefAcceptItem` or `LSCanURLAcceptURL` is called during a drag-and-drop operation, showing a server login dialog would be an inappropriate user experience. If the target designated in the function call is an alias to an application, Launch Services needs to resolve the alias to ascertain what file types the application can open; however, if the application is on a server that needs to be authenticated, Launch Services will by default fail to resolve the alias, to avoid having to present the login interface. To override this default behavior by allowing the server login interface, set the `kLSAcceptAllowLoginUI` flag.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

Discussion

These flags are passed to the functions `LSCanRefAcceptItem` and `LSCanURLAcceptURL`.

Handler Option Constants

Specify the options for controlling how content handlers are selected.

```
typedef OptionBits LSHandlerOptions;enum {
    kLSHandlerOptionsDefault = 0,
    kLSHandlerOptionsIgnoreCreator = 1
};
```

Constants

`kLSHandlerOptionsDefault`

When set, causes Launch Services to use a content item's creator (when available) to select a handler. This is the default setting.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

`kLSHandlerOptionsIgnoreCreator`

When set, causes Launch Services to ignore the content item's creator when selecting a role handler for the specified content type.

Available in Mac OS X v10.4 and later.

Declared in `LSInfo.h`.

Invalid Extension Index

Represents an invalid filename extension index.

```
enum {
    kLSInvalidExtensionIndex = 0xFFFFFFFF
};
```

Constants

`kLSInvalidExtensionIndex`

The value obtained by the `LSGetExtensionInfo` function if the filename does not contain a valid extension.

Available in Mac OS X v10.1 through Mac OS X v10.4.

Declared in `LSInfo.h`.

Unknown Type or Creator

Represent an unknown file type or creator.

```
enum {
    kLSUnknownType = 0,
    kLSUnknownCreator = 0
};
```

Constants

`kLSUnknownType`

The value to supply as the file type (for example, to the `LSGetApplicationForInfo` function) if no file type information is available.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSUnknownCreator`

The value to supply as the creator signature if no file creator information is available.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

Constants No Longer Used

The following constants are no longer used.

```
typedef OptionBits LSInitializeFlags;enum {
    kLSInitializeDefaults = 0x00000001
};enum {
    kLSUnknownKindID = 0
};enum {
    kLSMinCatInfoBitmap = (kFSCatInfoNodeFlags | kFSCatInfoParentDirID
| kFSCatInfoFinderInfo | kFSCatInfoFinderXInfo)
};
```

Constants

`kLSInitializeDefaults`

Formerly passed to the `LSInit` function, which is no longer used.

Available in Mac OS X v10.0 and later.

Declared in `LSInfo.h`.

`kLSUnknownKindID`

A possible value of the `kindID` field of an item-information record, which is no longer used.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `LSInfo.h`.

`kLSMinCatInfoBitmap`

A minimal catalog information bitmap; no longer used.

Available in Mac OS X v10.1 and later.

Declared in `LSInfo.h`.

Result Codes

The table below lists the most common result codes returned by Launch Services functions.

Result Code	Value	Description
`kLSAppInTrashErr`	-10660	The application cannot be run because it is inside a Trash folder. Available in Mac OS X v10.3 and later.
`kLSUnknownErr`	-10810	An unknown error has occurred. Available in Mac OS X v10.0 and later.
`kLSNotAnApplicationErr`	-10811	The item to be registered is not an application. Available in Mac OS X v10.0 and later.
`kLSNotInitializedErr`	-10812	Formerly returned by `LSInit` on initialization failure; no longer used. Available in Mac OS X v10.0 and later.
`kLSDataUnavailableErr`	-10813	Data of the desired type is not available (for example, there is no kind string). Available in Mac OS X v10.0 and later.
`kLSApplicationNotFoundErr`	-10814	No application in the Launch Services database matches the input criteria. Available in Mac OS X v10.0 and later.
`kLSUnknownTypeErr`	-10815	Not currently used. Available in Mac OS X v10.0 and later.
`kLSDataTooOldErr`	-10816	Not currently used. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kLSDataErr	-10817	Data is structured improperly (for example, an item's information property list is malformed). Not used in Mac OS X v10.4. Available in Mac OS X v10.0 and later.
kLSLaunchInProgressErr	-10818	A launch of the application is already in progress. Available in Mac OS X v10.0 and later.
kLSNotRegisteredErr	-10819	Not currently used. Available in Mac OS X v10.0 and later.
kLSAppDoesNotClaimTypeErr	-10820	Not currently used. Available in Mac OS X v10.0 and later.
kLSAppDoesNotSupportSchemeWarning	-10821	Not currently used. Available in Mac OS X v10.0 and later.
kLSServerCommunicationErr	-10822	There is a problem communicating with the server process that maintains the Launch Services database. Available in Mac OS X v10.0 and later.
kLSCannotSetInfoErr	-10823	The filename extension to be hidden cannot be hidden. Available in Mac OS X v10.1 and later.
kLSNoRegistrationInfoErr	-10824	Not currently used. Available in Mac OS X v10.3 and later.
kLSIncompatibleSystemVersionErr	-10825	The application to be launched cannot run on the current Mac OS version. Available in Mac OS X v10.3 and later.
kLSNoLaunchPermissionErr	-10826	The user does not have permission to launch the application (on a managed network). Available in Mac OS X v10.3 and later.
kLSNoExecutableErr	-10827	The executable file is missing or has an unusable format. Available in Mac OS X v10.3 and later.
kLSNoClassicEnvironmentErr	-10828	The Classic emulation environment was required but is not available. Available in Mac OS X v10.3 and later.

Result Code	Value	Description
kLSMultipleSessionsNotSupportedErr	-10829	The application to be launched cannot run simultaneously in two different user sessions. Available in Mac OS X v10.3 and later.

Locale Utilities Reference

Framework: CoreServices/CoreServices.h

Declared in MacLocales.h

Overview

Unicode operations such as collation and text boundary determination can be affected by the conventions of a particular language or region. You can use Locale Utilities to specify language-specific or region-specific information for locale-sensitive Unicode operations. The Locale Utilities provide support for obtaining available locales, obtaining localized locale names, and converting among locale data formats.

Carbon supports the Locales Utilities.

Functions by Task

Obtaining Available Locales

`LocaleOperationGetLocales` (page 1263)
Obtains the list of available locale-and-variant combinations for a given class of operation.

`LocaleOperationCountLocales` (page 1261)
Obtains the total count of locale-and-variant combinations available for a given class of operation.

Obtaining Localized Locale Names

`LocaleGetName` (page 1258)
Obtains the localized name for a locale and/or operation variant, based on the requested language for the localized name.

`LocaleGetIndName` (page 1257)
Obtains a localized name for a locale and/or operation variant, based on an index into the list of all available localized names.

`LocaleCountNames` (page 1256)
Obtains the total count of all available localized names for a locale and/or operation variant.

`LocaleOperationGetName` (page 1264)
Obtains the localized name for an operation class, based on the requested language for the localized name.

`LocaleOperationGetIndName` (page 1262)
Obtains a localized name for an operation class, based on an index into the list of all available localized names.

`LocaleOperationCountNames` (page 1261)
Obtains the total count of all available localized names for an operation class.

`LocaleGetRegionLanguageName` (page 1260) Deprecated in Mac OS X v10.5
Obtains the localized language name for a region.

Converting Among Locale Data Formats

`LocaleRefFromLangOrRegionCode` (page 1265)
Converts a Mac OS language or region code to a locale reference.

`LocaleRefFromLocaleString` (page 1266)
Converts a string containing locale data to a locale reference.

`LocaleRefGetPartString` (page 1267)
Converts a locale reference to a string containing locale data.

`LocaleStringToLangAndRegionCodes` (page 1268)
Converts a string containing locale data to Mac OS language and region codes.

Functions

LocaleCountNames

Obtains the total count of all available localized names for a locale and/or operation variant.

```
OSStatus LocaleCountNames (
   LocaleRef locale,
   LocaleOperationVariant opVariant,
   LocaleNameMask nameMask,
   ItemCount *nameCount
);
```

Parameters

locale
A `LocaleRef` value identifying the locale for which you are requesting a localized name.

opVariant
A `LocaleOperationVariant` value identifying the operation variant for which you are requesting a localized name. Pass 0 to obtain the default operation variant.

nameMask
A `LocaleNameMask` value specifying the parts of the name that you are requesting: the name of the locale alone, the name of the operation variant alone, or the name for the combination of the two.

nameCount
A pointer to an `ItemCount` value. On return, the value is set to the total count of all available localized names for the locale and/or operation variant.

Return Value
A result code. The `LocaleCountNames` function can return `paramErr` if `nameCount` is `NULL`.

Discussion
This function provides a count of all available localized names for a given locale, operation variant, or locale-and-variant combination, for use in the function `LocaleGetIndName` (page 1257). You must call this function prior to calling `LocaleGetIndName`.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`MacLocales.h`

LocaleGetIndName

Obtains a localized name for a locale and/or operation variant, based on an index into the list of all available localized names.

```
OSStatus LocaleGetIndName (
   LocaleRef locale,
   LocaleOperationVariant opVariant,
   LocaleNameMask nameMask,
   ItemCount nameIndex,
   UniCharCount maxNameLen,
   UniCharCount *actualNameLen,
   UniChar displayName[],
   LocaleRef *displayLocale
);
```

Parameters

`locale`
A `LocaleRef` value identifying the locale for which you are requesting a localized name.

`opVariant`
A `LocaleOperationVariant` value identifying the operation variant for which you are requesting a localized name. Pass 0 to obtain the default operation variant.

`nameMask`
A `LocaleNameMask` value specifying the parts of the name that you are requesting: the name of the locale alone, the name of the operation variant alone, or the name for the combination of the two.

`nameIndex`
An `ItemCount` index value identifying an entry in the list of available localized names. You can obtain a count of all available localized names from the `nameCount` parameter of the function `LocaleCountNames` (page 1256). Note that index values must be in the range from 0 to `nameCount` -1. To create a list of all available localized names that correspond to the locale and operation variant you request, you can call the `LocaleGetIndName` function starting with an index value of 0, then increment the index value with each successive call to `LocaleGetIndName`, continuing to `nameCount`-1.

maxNameLen

A UniCharCount value specifying the length of the UniChar array being passed in the displayName parameter. An array of 32 characters is typically adequate if you request just a single name (that is, the name for a locale or an operation variant), or 64 characters if you request both names.

actualNameLen

A pointer to a UniCharCount value. On return, the value contains the actual length of the name produced in the displayName parameter.

displayName

An array of UniChar values. On return, the array contains the requested name as localized for a particular display locale.

displayLocale

A pointer to a LocaleRef value. On return, the value indicates the language of the name produced in the displayName parameter.

Return Value

A result code. If the value specified in the maxNameLen parameter is too small for the requested string, LocaleGetIndName returns kLocalesBufferTooSmallErr (-30001).

Discussion

The LocaleGetIndName function obtains a localized name for a locale, operation variant, or locale-and-variant combination. LocaleGetIndName produces the name based on a requested locale, an operation variant, and an index into the count of all available localized names for the locale and/or operation variant. The language for the obtained name is produced on return.

You can use repeated calls to the LocaleGetIndName function to create a list of all available localized names (that is, the names from all available display locales), that correspond to a given locale and operation variant. Alternately, for a particular locale, operation variant, or locale-and-variant combination, the function LocaleGetName (page 1258) obtains the corresponding name as localized for a particular display locale.

Note that, in some languages, the name for a language or locale may have several different grammatical forms, where the correct form depends on the usage or context. For example, Swedish uses different forms of a language name depending on whether the name is applied to a collation order, to text break rules, or to keyboard layouts. However, the Locale Utilities functions only return one form of a language or locale name—typically that name which would be used for the language name alone. Therefore, this name may not be the correct form for some usages in some languages.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

MacLocales.h

LocaleGetName

Obtains the localized name for a locale and/or operation variant, based on the requested language for the localized name.

```
OSStatus LocaleGetName (
   LocaleRef locale,
   LocaleOperationVariant opVariant,
   LocaleNameMask nameMask,
   LocaleRef displayLocale,
   UniCharCount maxNameLen,
   UniCharCount *actualNameLen,
   UniChar displayName[]
);
```

Parameters

locale

A `LocaleRef` value identifying the locale for which you are requesting a localized name.

opVariant

A `LocaleOperationVariant` value identifying the operation variant for which you are requesting a localized name. Pass 0 to obtain the default operation variant.

nameMask

A `LocaleNameMask` value specifying the parts of the name that you are requesting: the name of the locale alone, the name of the operation variant alone, or the name for the combination of the two.

displayLocale

A `LocaleRef` value indicating the requested language for the name produced in the `displayName` parameter. If `LocaleGetName` cannot find a name in the requested language, it produces a name in the default display locale.

maxNameLen

A `UniCharCount` value specifying the length of the `UniChar` array being passed in the `displayName` parameter. An array of 32 characters is typically adequate if you request just a single name (that is, the name for a locale or an operation variant), or 64 characters if you request both names.

actualNameLen

A pointer to a `UniCharCount` value. On return, the value contains the actual length of the name produced in the `displayName` parameter.

displayName

An array of `UniChar` values. On return, the array contains the requested name as localized for a particular display locale.

Return Value

A result code. If `LocaleGetName` cannot find a name that matches the language specified in the `displayLocale` parameter, it returns `kLocalesDefaultDisplayStatus` (-30029). If the value specified in the `maxNameLen` parameter is too small for the requested string, `LocaleGetName` returns `kLocalesBufferTooSmallErr` (-30001).

Discussion

For a particular locale, operation variant, or locale-and-variant combination, the `LocaleGetName` function obtains the corresponding name as localized for a particular display locale. Alternately, you can use repeated calls to the function `LocaleGetIndName` (page 1257) to iterate through all of the available display locales to create a list of the corresponding names as localized in each of the display locales.

Note that, in some languages, the name for a language or locale may have several different grammatical forms, where the correct form depends on the usage or context. For example, Swedish uses different forms of a language name depending on whether the name is applied to a collation order, to text break rules, or to keyboard layouts. However, the Locale Utilities functions only return one form of a language or locale name—typically that name which would be used for the language name alone. Therefore, this name may not be the correct form for some usages in some languages.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleGetRegionLanguageName

Obtains the localized language name for a region. (Deprecated in Mac OS X v10.5.)

```
OSStatus LocaleGetRegionLanguageName (
   RegionCode region,
   Str255 languageName
);
```

Parameters

region

A Mac OS `RegionCode` value, specifying the region for which you are requesting a localized language name.

languageName

A Pascal string. On return, the string contains the name of the language corresponding to the region specified in the `region` parameter. The language name is produced in its own language and in the appropriate Mac OS encoding for that region.

Return Value

A result code. The `LocaleGetRegionLanguageName` function returns `paramErr` if `languageName` is `NULL` or if `region` is invalid (

Discussion

For a particular Mac OS region code, the `LocaleGetRegionLanguageName` function returns the name of the corresponding language in that language and in the non-Unicode Mac OS text encoding used for that region.

Note that, in some languages, the name for a language or locale may have several different grammatical forms, where the correct form depends on the usage or context. For example, Swedish uses different forms of a language name depending on whether the name is applied to a collation order, to text break rules, or to keyboard layouts. However, the Locale Utilities functions only return one form of a language or locale name—typically that name which would be used for the language name alone. Therefore, this name may not be the correct form for some usages in some languages.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacLocales.h

LocaleOperationCountLocales

Obtains the total count of locale-and-variant combinations available for a given class of operation.

```
OSStatus LocaleOperationCountLocales (
   LocaleOperationClass opClass,
   ItemCount *localeCount
);
```

Parameters

opClass

A LocaleOperationClass value identifying the operation class for which you are requesting availability information.

localeCount

A pointer to an ItemCount value. On return, the value is set to the total count of all available locale-and-variant combinations for the specified class of operation.

Return Value
A result code. The LocaleOperationCountLocales function returns paramErr if the opClass parameter is 0 or if the localeCount parameter is NULL.

Discussion
The LocaleOperationCountLocales function counts the total number of locale-and-variant combinations available for a given operation class. You should call LocaleOperationCountLocales before the function LocaleOperationGetLocales (page 1263) in order to determine how much memory to allocate for the list LocaleOperationGetLocales produces.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
MacLocales.h

LocaleOperationCountNames

Obtains the total count of all available localized names for an operation class.

```
OSStatus LocaleOperationCountNames (
   LocaleOperationClass opClass,
   ItemCount *nameCount
);
```

Parameters

opClass

A LocaleOperationClass value identifying the operation class for which you are requesting a localized name.

nameCount

A pointer to an `ItemCount` value. On return, the value is set to the total count of all available localized names for the operation class.

Return Value

A result code. The `LocaleOperationCountNames` function returns `paramErr` if `nameCount` is `NULL`.

Discussion

This function provides a count of all available localized names for a given operation class, for use in the function `LocaleOperationGetIndName` (page 1262). You must call this function prior to calling `LocaleOperationGetIndName`.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleOperationGetIndName

Obtains a localized name for an operation class, based on an index into the list of all available localized names.

```
OSStatus LocaleOperationGetIndName (
   LocaleOperationClass opClass,
   ItemCount nameIndex,
   UniCharCount maxNameLen,
   UniCharCount *actualNameLen,
   UniChar displayName[],
   LocaleRef *displayLocale
);
```

Parameters

opClass

A `LocaleOperationClass` value identifying the operation class for which you are requesting a localized name.

nameIndex

An `ItemCount` index value identifying an entry in the list of available localized names. You can obtain a count of all available localized names from the `nameCount` parameter of the function `LocaleOperationCountNames` (page 1261). Note that index values must be in the range from 0 to `nameCount` -1. To create a list of all available localized names that correspond to the requested operation class, you can call the `LocaleOperationGetIndName` function starting with an index value of 0, then increment the index value with each successive call to `LocaleOperationGetIndName`, continuing to `nameCount`-1.

maxNameLen

A `UniCharCount` value specifying the length of the `UniChar` array being passed in the `displayName` parameter.

actualNameLen
A pointer to a `UniCharCount` value. On return, the value contains the actual length of the name produced in the `displayName` parameter.

displayName
An array of `UniChar` values. On return, the array contains the requested name as localized for a particular display locale.

displayLocale
A pointer to a `LocaleRef` value. On return, the value indicates the language of the name produced in the `displayName` parameter.

Return Value
A result code. If the value specified in the `maxNameLen` parameter is too small for the requested string, `LocaleOperationGetIndName` returns `kLocalesBufferTooSmallErr` (-30001).

Discussion
The `LocaleOperationGetIndName` function obtains a localized name for an operation class based on an index into the count of all available localized names for the operation class. The language for the obtained name is produced on return.

You can use repeated calls to the `LocaleOperationGetIndName` function to create a list of all available localized names (that is, the names from all available display locales), that correspond to a given operation class. Alternately, for a particular operation class, the function `LocaleOperationGetName` (page 1264) obtains the corresponding name as localized for a particular display locale.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`MacLocales.h`

LocaleOperationGetLocales

Obtains the list of available locale-and-variant combinations for a given class of operation.

```
OSStatus LocaleOperationGetLocales (
   LocaleOperationClass opClass,
   ItemCount maxLocaleCount,
   ItemCount *actualLocaleCount,
   LocaleAndVariant localeVariantList[]
);
```

Parameters

opClass
A `LocaleOperationClass` value identifying the operation class for which you are requesting availability information.

maxLocaleCount

An `ItemCount` value specifying the size of the array passed in the `localeVariantList` parameter. To determine how much memory to allocate for the list, you can call the function `LocaleOperationCountLocales` (page 1261). `LocaleOperationCountLocales` produces a count of the locale-and-variant combinations available for a given operation class in its `localeCount` parameter.

actualLocaleCount

A pointer to an `ItemCount` value. On return, the value contains the actual length of the list produced in the `localeVariantList` parameter.

localeVariantList

An array of `LocaleAndVariant` values. On return, the array contains a list of the available combinations of locale and operation variant for a specified operation class. The `LocaleAndVariant.opVariant` field may be 0 for entries that do not have a specific operation variant.

Return Value

A result code. If the value specified in the `maxLocaleCount` parameter is too small for the complete list, `LocaleOperationGetLocales` returns `kLocalesBufferTooSmallErr` (-30001). The function returns `paramErr` if `opClass` is 0 or if either the `actualLocaleCount` or `localeVariantList` parameter is `NULL`.

Discussion

The `LocaleOperationGetLocales` function provides a list of all the combinations of locales and operation variants that are available for a given class of operations, such as collation.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleOperationGetName

Obtains the localized name for an operation class, based on the requested language for the localized name.

```
OSStatus LocaleOperationGetName (
   LocaleOperationClass opClass,
   LocaleRef displayLocale,
   UniCharCount maxNameLen,
   UniCharCount *actualNameLen,
   UniChar displayName[]
);
```

Parameters

opClass

A `LocaleOperationClass` value identifying the operation class for which you are requesting a localized name.

displayLocale

A `LocaleRef` value indicating the requested language for the name produced in the `displayName` parameter. If `LocaleOperationGetName` cannot find a name in the requested language, it produces a name in the default display locale.

maxNameLen

A UniCharCount value specifying the length of the UniChar array being passed in the displayName parameter. An array of 64 characters is typically adequate.

actualNameLen

A pointer to a UniCharCount value. On return, the value contains the actual length of the name produced in the displayName parameter.

displayName

An array of UniChar values. On return, the array contains the requested name as localized for a particular display locale.

Return Value

A result code. If LocaleOperationGetName cannot find a name that matches the language specified in the displayLocale parameter, it returns kLocalesDefaultDisplayStatus (-30029). If the value specified in the maxNameLen parameter is too small for the requested string, LocaleOperationGetName returns kLocalesBufferTooSmallErr (-30001).

Discussion

For a particular operation class, the LocaleOperationGetName function obtains the corresponding name as localized for a particular display locale. Alternately, you can use repeated calls to the function LocaleOperationGetIndName (page 1262) to iterate through all of the available display locales to create a list of the corresponding names as localized in each of the display locales.

Special Considerations

This function can move memory in Carbon and Mac OS 9.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

MacLocales.h

LocaleRefFromLangOrRegionCode

Converts a Mac OS language or region code to a locale reference.

```
OSStatus LocaleRefFromLangOrRegionCode (
   LangCode lang,
   RegionCode region,
   LocaleRef *locale
);
```

Parameters

lang

A Mac OS LangCode value, specifying the language for which to create a LocaleRef. If you wish to specify only a region, not a language as well, you can pass the constant kTextLanguageDontCare (from TextCommon.h). The LocaleRefFromLangOrRegionCode function requires values for either the lang or region parameters, or both.

region

A Mac OS `RegionCode` value, specifying the region for which to create a `LocaleRef`. If you wish to specify only a language, not a region as well, you can pass the constant `kTextRegionDontCare` (from TextCommon.h). The `LocaleRefFromLangOrRegionCode` function requires values for either the `lang` or `region` parameters, or both.

locale

A pointer to a value of type `LocaleRef`. On return, the `LocaleRef` value contains a valid reference to locale data. Note that the `LocaleRefFromLangOrRegionCode` function can move memory, so the `locale` parameter should not point to memory that can move.

Return Value

A result code. The `LocaleRefFromLangOrRegionCode` function returns `paramErr` if no value is provided for either the `lang` or `region` parameters, or if both values are provided but they are inconsistent, or if a value provided is invalid. The function returns `paramErr` if the `locale` parameter is `NULL`. It can also return memory errors or resource errors. Finally, if the tables used for mapping language and region codes are invalid, the function returns `kLocalesTableFormatErr` (-30002) in CarbonLib and Mac OS 9 (in Mac OS 8.6, `paramErr` is returned).

Discussion

A `LocaleRef` is an opaque type that references static locale data. You typically provide a `LocaleRef` value to the locale-sensitive Unicode Utilities functions and to some Locale Utilities functions such as `LocaleGetName` (page 1258) and `LocaleOperationGetName` (page 1264).

You can use the `LocaleRefFromLangOrRegionCode` function to convert a Mac OS language and/or region code to a `LocaleRef` value. Additionally, you can use the function `LocaleRefFromLocaleString` (page 1266) to convert a locale part string—or an Internet language tag or POSIX/Java locale string—to a `LocaleRef` value.

You should not save `LocaleRef` values in a file or other persistent storage, because a given `LocaleRef` is not guaranteed to be valid across multiple launches of your application. For persistent storage, you can either save the original value or string used to construct the `LocaleRef`, or you can use the function `LocaleRefGetPartString` (page 1267) to convert a `LocaleRef` to a locale part string and save that.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleRefFromLocaleString

Converts a string containing locale data to a locale reference.

```
OSStatus LocaleRefFromLocaleString (
   const char localeString[],
   LocaleRef *locale
);
```

Parameters

localeString

An ASCII string containing an Internet RFC 1766-style language tag, or a POSIX-style or Java-style locale string, or a Mac OS locale part string. A locale part string is an ASCII string whose full form is "lan-var.sc-v_rg-v", where "lan-var" specifies the language and variant, ".sc-v" specifies the script & variant, and "_rg-v" specifies the region and variant. Any of those three parts can be omitted furthermore, the variant part "-var" or "-v" within any of those parts may be omitted.

locale

A pointer to a value of type `LocaleRef`. On return, the `LocaleRef` value contains a valid reference to locale data. Note that the `LocaleRefFromLocaleString` function can move memory, so the `locale` parameter should not point to memory that can move.

Return Value

A result code. The function returns `paramErr` if the `localeString` or `locale` parameters are `NULL`, or if the value provided in `localeString` is invalid. It can also return memory errors.

Discussion

A `LocaleRef` is an opaque type that references static locale data. You typically provide a `LocaleRef` value to the locale-sensitive Unicode Utilities functions and to some Locale Utilities functions such as `LocaleGetName` (page 1258) and `LocaleOperationGetName` (page 1264).

You can use the `LocaleRefFromLocaleString` function to convert a locale part string—or an Internet language tag or POSIX/Java locale string—to a `LocaleRef` value. Additionally, you can use the function `LocaleRefFromLangOrRegionCode` (page 1265) to convert a Mac OS language and/or region code to a `LocaleRef` value.

You should not save `LocaleRef` values in a file or other persistent storage, because a given `LocaleRef` is not guaranteed to be valid across multiple launches of your application. For persistent storage, you can either save the original value or string used to construct the `LocaleRef`, or you can use the function `LocaleRefGetPartString` (page 1267) to convert a `LocaleRef` back to a locale part string and save that.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleRefGetPartString

Converts a locale reference to a string containing locale data.

```
OSStatus LocaleRefGetPartString (
   LocaleRef locale,
   LocalePartMask partMask,
   ByteCount maxStringLen,
   char partString[]
);
```

Parameters

locale

The `LocaleRef` value to convert to string format. You can pass `NULL` for the default system locale.

partMask

A `LocalePartMask` value specifying the kinds of locale information to include in the string. Available kinds of locale information include language, script, region, and their respective variants.

maxStringLen

A `ByteCount` value specifying the length of the `char` array being passed in the `partString` parameter. The amount of storage should typically be at least 4 times the number of parts requested.

partString

An array of `char` values. On return, the array contains the new part string. The full form of the returned string is "lan-var.sc-v_rg-v" where "lan-var" specifies the language and variant, ".sc-v" specifies the script & variant, and "_rg-v" specifies the region and variant. Fields not specified by the `partMask` parameter (as well as any field separator that precedes them) are not included in the returned string.

Return Value

A result code. The function returns `paramErr` if the `partString` parameter is `NULL`, or if the locale is invalid. It returns `kLocalesBufferTooSmallErr` (-30001) if the value supplied in the `maxStringLen` parameter is too small for the requested string.

Discussion

The `LocaleRefGetPartString` function converts a `LocaleRef` value to a string containing locale information. You can use a locale part string to tag or specify language or locale in persistent storage.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

LocaleStringToLangAndRegionCodes

Converts a string containing locale data to Mac OS language and region codes.

```
OSStatus LocaleStringToLangAndRegionCodes (
   const char localeString[],
   LangCode *lang,
   RegionCode *region
);
```

Parameters

localeString

An ASCII string containing an Internet RFC 1766-style language tag, or a POSIX-style or Java-style locale string, or a Mac OS locale part string. If you have a `LocaleRef` value, you can obtain a locale string from the function `LocaleRefGetPartString` (page 1267). A locale part string is an ASCII string whose full form is "lan-var.sc-v_rg-v", where "lan-var" specifies the language and variant, ".sc-v" specifies the script & variant, and "_rg-v" specifies the region and variant. Any of those three parts can be omitted furthermore, the variant part "-var" or "-v" within any of those parts may be omitted.

lang

A pointer to a `LangCode` value, or pass `NULL`, if you do not want to obtain a language code. On return, `LocaleStringToLangAndRegionCodes` produces the appropriate Mac OS language code for the locale part string provided in the `localeString` parameter. Note that you can set either the `lang` or the `region` parameter to `NULL`, but not both.

region

A pointer to a `RegionCode` value or pass `NULL`, if you do not want to obtain a region code. On return, `LocaleStringToLangAndRegionCodes` produces the appropriate Mac OS region code for the locale part string provided in the `localeString` parameter. Note that you can set either the `region` or the `lang` parameter to `NULL`, but not both.

Return Value

A result code. If the `localeString` parameter is `NULL` or if the string cannot be mapped to an existing language code and region code, the `LocaleStringToLangAndRegionCodes` function returns `paramErr`. If the required resource is invalid, the function can return `kLocalesTableFormatErr` (-30002). The function can also return Resource Manager errors.

Discussion

The `LocaleStringToLangAndRegionCodes` function maps from a locale string to a combination of Mac OS language code and region code.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Declared In

`MacLocales.h`

Data Types

LocaleAndVariant

Identifies a specific locale and/or sub-class of locale-sensitive operations.

```
struct LocaleAndVariant {
    LocaleRef locale;
    LocaleOperationVariant opVariant;
};
typedef struct LocaleAndVariant LocaleAndVariant;
```

Fields

`locale`

A `LocaleRef` value, encapsulating information regarding language, script, and/or region.

`opVariant`

A `LocaleOperationVariant` value, identifying an individual sub-class of locale-sensitive operations. The `opVariant` field of a `LocaleAndVariant` value may be 0 for entries that do not have a specific operation variant.

Discussion

You use the function `LocaleOperationGetLocales` (page 1263) to obtain a list of all the locale-and-variant combinations available for a given class of operations. The `LocaleOperationGetLocales` function specifies these combinations using the `LocaleAndVariant` type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacLocales.h`

LocaleNameMask

Specifies named parts of locale data.

```
typedef UInt32 LocaleNameMask;
```

Discussion

The bits set in a `LocaleNameMask` value determine the kind of localized names that are produced by the functions `LocaleGetName` (page 1258) and `LocaleGetIndName` (page 1257). For a description of the `LocaleNameMask` values, see "Locale Name Masks" (page 1272).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacLocales.h`

LocaleOperationClass

Identifies individual classes of locale-sensitive operations.

```
typedef FourCharCode LocaleOperationClass;
```

Discussion

Locale-sensitive Unicode Utilities operations fall into several classes, such as collation, text break determination, and date and time formatting. You use the `LocaleOperationClass` type to specify these classes.

Specific `LocaleOperationClass` values depend on the Locale Utilities client. Values from Unicode Utilities include `kUnicodeCollationClass ('ucol')` and `kUnicodeTextBreakClass ('ubrk')`. For example, the locales and collation variants available for collation operations can be determined by calling the functions `LocaleOperationCountLocales` (page 1261) and `LocaleOperationGetLocales` (page 1263) with the `opClass` parameter set to the `kUnicodeCollationClass` constant.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacLocales.h`

LocaleOperationVariant

Identifies individual sub-classes of locale-sensitive operations.

```
typedef FourCharCode LocaleOperationVariant;
```

Discussion
Locale-sensitive Unicode Utilities operations fall into several classes, such as collation, text break determination, and date and time formatting. You use the type `LocaleOperationClass` (page 1270) to specify these classes. Some of these classes also have sub-classes of their operations. For example, sub-classes of collation operations include dictionary vs. bibliographic collation, and radical-stroke vs. pinyin collation.

For classes such as collation, the `LocaleOperationVariant` type provides an operation-specific variant field. This field is analogous to the `@variant` part of a POSIX locale string or the final `_VARIANT` part of a Java locale string.

You can use `LocaleOperationVariant` values in the functions `LocaleGetName` (page 1258) , `LocaleGetIndName` (page 1257) , and `LocaleCountNames` (page 1256) to obtain localized names for operation variants.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacLocales.h`

LocalePartMask

Specifies kinds of locale data.

```
typedef UInt32 LocalePartMask;
```

Discussion
The bits set in a `LocalePartMask` value determine the kinds of locale information that are produced by the function `LocaleRefGetPartString` (page 1267). For a description of the `LocalePartMask` values, see "Locale Part Masks" (page 1273).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacLocales.h

LocaleRef

An opaque type that refers to locale information.

```
typedef struct OpaqueLocaleRef * LocaleRef;
```

Discussion
A LocaleRef is an opaque type that references static locale data. You typically provide a LocaleRef value to the locale-sensitive Unicode Utilities functions and to some Locale Utilities functions such as LocaleGetName (page 1258) and LocaleOperationGetName (page 1264).

To obtain a LocaleRef, you can use the function LocaleRefFromLangOrRegionCode (page 1265) to convert a Mac OS language and/or region code to a LocaleRef value. Additionally, you can use the function LocaleRefFromLocaleString (page 1266) to convert a locale part string—or an Internet language tag or POSIX/Java locale string—to a LocaleRef value.

You should not save LocaleRef values in a file or other persistent storage, since a given LocaleRef is not guaranteed to be valid across multiple launches of your application. For persistent storage, you can either save the original value or string used to construct the LocaleRef, or you can use the function LocaleRefGetPartString (page 1267) to convert a LocaleRef to a locale part string and save that.

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacLocales.h

Constants

Locale Name Masks

Specify named parts of locale data.

```
enum {
    kLocaleNameMask = 1L << 0,
    kLocaleOperationVariantNameMask = 1L << 1,
    kLocaleAndVariantNameMask = 0x00000003
};
```

Constants
kLocaleNameMask
If the bit specified by this mask is set, then the name for a locale is specified.
Available in Mac OS X v10.0 and later.
Declared in MacLocales.h.

`kLocaleOperationVariantNameMask`
If the bit specified by this mask is set, then the name for an operation variant is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleAndVariantNameMask`
If the bits specified by this mask are set, then the name for a locale-and-variant combination is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

Discussion
The bits set in a `LocaleNameMask` value determine the kind of localized names that are produced by the functions `LocaleGetName` (page 1258) and `LocaleGetIndName` (page 1257). With a `LocaleNameMask` value, you can specify the name of a locale alone, the name of an operation variant alone, or the name for the combination of the two.

Locale Part Masks

Specify kinds of locale data.

```
enum {
    kLocaleLanguageMask = 1L << 0,
    kLocaleLanguageVariantMask = 1L << 1,
    kLocaleScriptMask = 1L << 2,
    kLocaleScriptVariantMask = 1L << 3,
    kLocaleRegionMask = 1L << 4,
    kLocaleRegionVariantMask = 1L << 5,
    kLocaleAllPartsMask = 0x0000003F
};
```

Constants
`kLocaleLanguageMask`
If the bit specified by this mask is set, then a ISO 639-1 or -2 language code is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleLanguageVariantMask`
If the bit specified by this mask is set, then a custom string for a language variant is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleScriptMask`
If the bit specified by this mask is set, then a ISO 15924 script code is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleScriptVariantMask`
If the bit specified by this mask is set, then a custom string for a script variant is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleRegionMask`
If the bit specified by this mask is set, then a ISO 3166 country/region code is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleRegionVariantMask`
If the bit specified by this mask is set, then a custom string for a region variant is specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

`kLocaleAllPartsMask`
If the bits specified by this mask are set, then all types (language and variant, script and variant, and region and variant) of locale information are specified.

Available in Mac OS X v10.0 and later.

Declared in `MacLocales.h`.

Discussion
The bits set in a `LocalePartMask` value determine the kinds of locale information that are produced by the function `LocaleRefGetPartString` (page 1267).

Mathematical and Logical Utilities Reference

Framework:	CoreServices/CoreServices.h
Declared in	ToolUtils.h FixMath.h Math64.h fp.h MacTypes.h

Overview

Important: This is a preliminary document. Although it has been reviewed for technical accuracy, it is not final. Apple Computer is supplying this information to help you plan for the adoption of the technologies and programming interfaces described herein. This information is subject to change, and software implemented according to this document should be tested with final operating system software and final documentation. For information about updates to this and other developer documentation, you can check the ADC Reference Library Revision List. To receive notification of documentation updates, you can sign up for ADC's free Online Program and receive the weekly Apple Developer Connection News email newsletter. (See http://developer.apple.com/membership for more details about the Online Program.)

You can use the Mathematical and Logical Utilities to perform mathematical and logical operations in Mac OS X programming. This document describes functions you can use to:

- Perform low-level logical manipulation of bits and bytes when using a compiler that does not directly support such manipulations.
- Save disk space by using simple compression and decompression routines.
- Obtain a pseudorandom number.
- Perform mathematical operations with two fixed-point data types supported directly by the Operating System.
- Convert numeric variables of different types.

With the exception of the mathematical operations and conversions, these utilities are intended for programmers who occasionally need to access some of these features and do not require that the algorithms used to implement them be sophisticated. For example, if you are developing an advanced mathematical application, the pseudorandom number generator built into Mac OS might be too simplistic to fit your needs. Similarly, if you wish to access individual bits of memory in a time-critical loop, these routines are probably too slow to be practical.

Carbon supports the Mathematical and Logical Utilities, with the exception of those functions that are 68K-specific. However there are several important differences between the implementation of the Mathematical and Logical Utilities in Mac OS 9 and its implementation in Mac OS X.

The implementation in Carbon on Mac OS X of many floating-point functions defined in `fp.h` is not as accurate as the implementation of those functions in MathLib on Mac OS 8 and 9 (as accessed either directly or through CarbonLib). There are a number of reasons for this difference, including the different expectations of Mac OS 9 and UNIX floating-point clients, compiler limitations, and the need in for an implementation that's independent of assumptions about the size and layout of floating-point data types.

Functions which take parameters or return values of type long double are not exported by the Core Services framework on Mac OS X. Instead, these functions have been replaced with macros that map to the corresponding double-typed functions. While these functions are exported by CarbonLib, CFM applications calling these functions on Mac OS X should note that the implementations of the long double functions on Mac OS X actually have only double precision, with the following four exceptions: `num2decl`, `dec2numl`, `x80told`, and `ldtox80`.

Functions by Task

Converting Among 32-Bit Numeric Types

`Fix2Frac` (page 1297)
Converts a `Fixed` number to a `Fract` number.

`Fix2Long` (page 1298)
Converts a `Fixed` number to a `LongInt` number.

`Frac2Fix` (page 1305)
Converts a `Fract` number to a `Fixed` number.

`Long2Fix` (page 1314)
Converts a `LongInt` number to a `Fixed` number.

Converting Between Fixed-Point and Floating-Point Values

`FixedToFloat` (page 1300)
Converts a `Fixed` number to a `float` number.

`FractToFloat` (page 1308)
Converts a `Fract` number to a `float` number.

`FloatToFixed` (page 1302)
Converts a `float` number to a `Fixed` number.

`FloatToFract` (page 1303)
Converts a `float` number to a `Fract` number.

`Fix2X` (page 1298)
Converts a `Fixed` number to an `Extended` number.

`Frac2X` (page 1305)
Converts a `Fract` number to an `Extended` number.

`X2Fix` (page 1344)
Converts an `Extended` number to a `Fixed` number.

`X2Frac` (page 1344)
Converts an `Extended` number to a `Fract` number.

Converting Between Fixed-Point and Integral Values

`FixRatio` (page 1301)
Obtains the `Fixed` equivalent of a fraction.

`FixRound` (page 1302)
Rounds a fixed-point number to the nearest integer.

Getting and Setting Memory Values

`HiWord` (page 1310)
Obtains the high-order word of a long word.

`LoWord` (page 1315)
Obtains the low-order word of a long word.

Multiplying and Dividing Fixed-Point Numbers

`FixDiv` (page 1299)
Divides two variables of the same type (`Fixed`, `Fract`, or `LongInt`) or to divide a `LongInt` or `Fract` number by a `Fixed` number.

`FixMul` (page 1300)
Multiplies a variable of type `Fixed` with another variable of type `Fixed` or with a variable of type `Fract` or `LongInt`.

`FracDiv` (page 1306)
Divides two variables of the same type (`Fract`, `Fixed`, or `LongInt`) or to divide a `LongInt` or `Fixed` number by a `Fract` number.

`FracMul` (page 1307)
Multiplies a variable of type `Fract` with another variable of type `Fract` or with a variable of type `Fixed` or `LongInt`.

Performing Calculations on Fixed-Point Numbers

`FixATan2` (page 1299)
Obtains a fast approximation of the arctangent of a fraction.

`FracCos` (page 1306)
Obtains a fast approximation of the cosine of a `Fixed` number.

`FracSin` (page 1307)
Obtains a fast approximation of the sine of a `Fixed` number.

FracSqrt (page 1308)
Obtains the square root of a Fract number.

Performing Logical Operations

BitAnd (page 1287)
Performs the AND logical operation on two long words.

BitNot (page 1288)
Performs the NOT logical operation on a long word.

BitOr (page 1288)
Performs the OR logical operation on two long words.

BitShift (page 1289)
Shifts bits in a long word.

BitXor (page 1290)
Performs the XOR logical operation on two long words.

Testing and Setting Bits

BitClr (page 1287)
Clears a particular bit (to a value of 0).

BitSet (page 1289)
Sets a particular bit (to a value of 1).

BitTst (page 1290)
Determines whether a given bit is set.

Miscellaneous Functions

acos (page 1284)

acosh (page 1285)

annuity (page 1285)

asin (page 1285)

asinh (page 1286)

atan (page 1286)

atan2 (page 1286)

atanh (page 1287)

Functions

acos

```
double_t acos (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

acosh

```
double_t acosh (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

annuity

```
double annuity (
   double rate,
   double periods
);
```

Parameters

rate

periods

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

asin

```
double_t asin (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

asinh

```
double_t asinh (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

atan

```
double_t atan (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

atan2

```
double_t atan2 (
   double_t y,
   double_t x
);
```

Parameters

y

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

atanh

```
double_t atanh (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

BitAnd

Performs the AND logical operation on two long words.

```
long BitAnd (
   long value1,
   long value2
);
```

Parameters

value1
A long word.

value2
A long word.

Return Value
A long word that is the result of the AND operation on the long words passed as arguments. Each bit in the returned value is set if and only if the corresponding bit is set in both value1 and value2.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
ToolUtils.h

BitClr

Clears a particular bit (to a value of 0).

```
void BitClr (
   void *bytePtr,
   long bitNum
);
```

Parameters

bytePtr
A pointer to a byte in memory.

bitNum
The bit to be cleared, specified as a positive offset from the high-order bit of the byte pointed to by the `bytePtr` parameter. The bit being cleared need not be in the same byte pointed to by `bytePtr`.

Special Considerations

The bit numbering scheme used by the `BitClr` function is the opposite of the MC680x0 numbering. To convert an MC680x0 bit number to the format required by the `BitClr` function, subtract the MC680x0 bit number from the highest bit number.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitNot

Performs the `NOT` logical operation on a long word.

```
long BitNot (
   long value
);
```

Parameters

value
A long word.

Return Value
A long word that is the result of the `NOT` operation on the long word passed in as an argument. Each bit in the returned value is set if and only if the corresponding bit is not set in `value`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitOr

Performs the `OR` logical operation on two long words.

```
long BitOr (
   long value1,
   long value2
);
```

Parameters

value1
A long word.

value2
A long word.

Return Value
A long word that is the result of the `OR` operation on the long words passed as arguments. Each bit in the returned value is set if and only if the corresponding bit is set in `value1` or `value2`, or in both `value1` and `value2`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitSet

Sets a particular bit (to a value of 1).

```
void BitSet (
   void *bytePtr,
   long bitNum
);
```

Parameters

`bytePtr`
A pointer to a byte in memory.

`bitNum`
The bit to be set, specified as a positive offset from the high-order bit of the byte pointed to by the `bytePtr` parameter. The bit being set need not be in the byte pointed to by `bytePtr`.

Special Considerations

The bit numbering scheme used by the `BitSet` function is the opposite of the MC680x0 numbering. To convert an MC680x0 bit number to the format required by the `BitSet` function, subtract the MC680x0 bit number from the highest bit number.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitShift

Shifts bits in a long word.

```
long BitShift (
   long value,
   short count
);
```

Parameters

`value`
A long word.

count

The number of bits to shift. If this number is positive, `BitShift` shifts this many positions to the left; if this number is negative, `BitShift` shifts this many positions to the right. The value in this parameter is converted to the result of `MOD` 32.

Return Value
A long word that is the result of shifting the bits in the long word passed in as an argument. The shift's direction and extent are determined by the `count` parameter. Zeroes are shifted into empty positions regardless of the direction of the shift.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitTst

Determines whether a given bit is set.

```
Boolean BitTst (
   const void *bytePtr,
   long bitNum
);
```

Parameters

bytePtr

A pointer to a byte in memory.

bitNum

The bit to be tested, specified as a positive offset from the high-order bit of the byte pointed to by the `bytePtr` parameter. The bit being tested need not be in the byte pointed to by `bytePtr`.

Return Value
`TRUE` if the specified bit is set (that is, has a value of 1) and `FALSE` if the bit is cleared (that is, has a value of 0).

Special Considerations

The bit numbering scheme used by the `BitTst` function is the opposite of the MC680x0 numbering. To convert an MC680x0 bit number to the format required by the `BitTst` function, subtract the MC680x0 bit number from the highest bit number.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`ToolUtils.h`

BitXor

Performs the `XOR` logical operation on two long words.

```
long BitXor (
   long value1,
   long value2
);
```

Parameters

value1

A long word.

value2

A long word.

Return Value

A long word that is the result of the XOR operation on the long words passed in as arguments. Each bit in the returned value is set if and only if the corresponding bit is set in either value1 or value2, but not in both value1 and value2.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

ToolUtils.h

ceil

```
double_t ceil (
   double_t x
);
```

Parameters

x

Return Value

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

Aperture Edit Plugin - Borders & Titles

Declared In

fp.h

compound

```
double compound (
   double rate,
   double periods
);
```

Parameters

rate

periods

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

copysign

```
double_t copysign (
   double_t x,
   double_t y
);
```

Parameters

x

y

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

cos

```
double_t cos (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

cosh

```
double_t cosh (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

dec2f

```
float dec2f (
   const decimal *d
);
```

Parameters

d

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

dec2l

```
long dec2l (
   const decimal *d
);
```

Parameters

d

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

dec2num

```
double_t dec2num (
   const decimal *d
);
```

Parameters

d

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

dec2s

```
short dec2s (
   const decimal *d
);
```

Parameters

d

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

dec2str

```
void dec2str (
   const decform *f,
   const decimal *d,
   char *s
);
```

Parameters

f

d

s

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

dtox80

```
void dtox80 (
   const double *x,
   extended80 *x80
);
```

Parameters

x

x80

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

erf

```
double_t erf (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

erfc

```
double_t erfc (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

exp

```
double_t exp (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

exp2

```
double_t exp2 (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

expm1

```
double_t expm1 (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

fabs

```
double_t fabs (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
HID Calibrator
HID Config Save
HID Explorer
SIMD Primer

Declared In
`fp.h`

fdim

```
double_t fdim (
   double_t x,
   double_t y
);
```

Parameters

x

y

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

Fix2Frac

Converts a `Fixed` number to a `Fract` number.

```
Fract Fix2Frac (
   Fixed x
);
```

Parameters

x

The `Fixed` number to be converted to a `Fract` number.

Return Value
The `Fract` number equivalent to the `Fixed` number `x`. If `x` is greater than the maximum representable `Fract` number, the `Fix2Frac` function returns $7FFFFFFF. If `x` is less than the negative number with the highest absolute value, `Fix2Frac` returns $80000000.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

Fix2Long

Converts a `Fixed` number to a `LongInt` number.

```
SInt32 Fix2Long (
   Fixed x
);
```

Parameters

x
The `Fixed` number to be converted to a long integer.

Return Value
The long integer nearest to the `Fixed` number `x`. If `x` is halfway between two integers (0.5), it is rounded to the integer with the higher absolute value.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

Fix2X

Converts a `Fixed` number to an `Extended` number.

```
double Fix2X (
   Fixed x
);
```

Parameters

x
The `Fixed` number to be converted to an `Extended` number.

Return Value
The `Extended` equivalent of the `Fixed` number `x`.

Special Considerations

`Fix2X` does not move memory; you can call it at interrupt time.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

FixATan2

Obtains a fast approximation of the arctangent of a fraction.

```
Fixed FixATan2 (
   SInt32 x,
   SInt32 y
);
```

Parameters

x

The numerator of the fraction whose arctangent is to be obtained. This variable can be a `LongInt`, `Fixed`, or `Fract` number.

y

The denominator of the fraction whose arctangent is to be obtained. The number supplied in this variable must be of the same type as that of the number supplied in the `x` parameter.

Return Value
The arctangent of `y/x`, in radians.

Discussion
The approximation of p/4 used to compute the arctangent is the hexadecimal value 0.C910, making the approximation of p equal to 3.1416015625, while p itself equals 3.14159265.... Thus `FixATan2(1, 1)` equals the equivalent of the hexadecimal value 0.C910. Despite the approximation of p, the arctangent value obtained will usually be correct to several decimal places.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

FixDiv

Divides two variables of the same type (`Fixed`, `Fract`, or `LongInt`) or to divide a `LongInt` or `Fract` number by a `Fixed` number.

```
Fixed FixDiv (
   Fixed x,
   Fixed y
);
```

Parameters

x

The first operand, which can be a variable of type `Fixed` or a variable of type `Fract` or `LongInt`.

y

The second operand, which can be a variable of type `Fixed` or it can be a variable of the same type as the variable in parameter `x`.

Return Value
The quotient of the numbers in `x` and `y`. If the `y` parameter is in the format of a `Fixed` number, then the `x` parameter can be in the format of a `Fixed`, `Fract`, or `LongInt` number. If the `y` parameter is in the format of a `Fract` or `LongInt` number, then the `x` parameter must be in the same format.

The returned value is in the format of a `Fixed` number if both `x` and `y` are both `Fixed` numbers, both `Fract` numbers, or both `LongInt` numbers. Otherwise, the returned value is the same type as the number in the `x` parameter.

Division by zero results in $8000000 if `x` is negative, and $7FFFFFFF otherwise; thus the special case 0/0 yields $7FFFFFFF.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
SoftVDigX

Declared In
`FixMath.h`

FixedToFloat

Converts a `Fixed` number to a `float` number.

```
float FixedToFloat (
    Fixed x
);
```

Parameters

x
The `Fixed` number to be converted.

Return Value
The `float` equivalent of the `Fixed` number.

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`FixMath.h`

FixMul

Multiplies a variable of type `Fixed` with another variable of type `Fixed` or with a variable of type `Fract` or `LongInt`.

```
Fixed FixMul (
   Fixed a,
   Fixed b
);
```

Parameters

a

The first operand, which can be a variable of type `Fixed` or a variable of type `Fract` or `LongInt`.

b

The second operand, which can be a variable of type `Fixed` or a variable of type `Fract` or `LongInt`.

Return Value
The product of the numbers in `a` and `b`. At least one of `a` and `b` should be a variable of type `Fixed`.

The returned value is in the format of a `LongInt` if one of `a` or `b` is a `LongInt`. It is a `Fract` number if one of `a` or `b` is `Fract`. It is a `Fixed` number if both `a` and `b` are `Fixed` numbers.

Overflows are set to the maximum representable value with the correct sign ($80000000 for negative results and $7FFFFFFF for positive results).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FixRatio

Obtains the `Fixed` equivalent of a fraction.

```
Fixed FixRatio (
   short numer,
   short denom
);
```

Parameters

numer

The numerator of the fraction.

denom

The denominator of the fraction.

Return Value
The `Fixed` equivalent of the fraction `numer/denom`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
SoftVDigX

Declared In
`FixMath.h`

FixRound

Rounds a fixed-point number to the nearest integer.

```
short FixRound (
   Fixed x
);
```

Parameters

x

The `Fixed` number to be rounded.

Return Value

The `Integer` number nearest the `Fixed` number `x`. If the value is halfway between two integers (0.5), it is rounded up. Thus, 4.5 is rounded to 5, and –3.5 is rounded to –3.

Discussion

To round a negative `Fixed` number so that values halfway between two integers are rounded to the number with the higher absolute value, negate the number, round it, and then negate it again.

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

SoftVDigX

`FixMath.h`

FloatToFixed

Converts a `float` number to a `Fixed` number.

```
Fixed FloatToFixed (
    float x
);
```

Parameters

x

The `float` number to be converted.

Return Value

The `Fixed` equivalent of the `float` number.

Discussion

This function is implemented as an inline macro.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`FixMath.h`

FloatToFract

Converts a `float` number to a `Fract` number.

```
Fract FloatToFract (
    float x
);
```

Parameters

x

The `float` number to be converted.

Return Value

The `Fract` equivalent of the `float` number.

Discussion

This function is implemented as an inline macro.

Availability

Available in Mac OS X version 10.3 and later.

Parameters

x

A value of type `float` or `double`.

Return Value
Returns one of the FP_ values. See `FP_SNAN` (page 1351).

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

Frac2Fix

Converts a `Fract` number to a `Fixed` number.

```
Fixed Frac2Fix (
   Fract x
);
```

Parameters

x

The `Fract` number to be converted to a `Fixed` number.

Return Value
The `Fixed` number that best approximates the `Fract` number `x`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

Frac2X

Converts a `Fract` number to an `Extended` number.

```
double Frac2X (
   Fract x
);
```

Parameters

x

The `Fract` number to be converted to an `Extended` number.

Return Value
The `Extended` equivalent of the `Fract` number `x`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FracCos

Obtains a fast approximation of the cosine of a `Fixed` number.

```
Fract FracCos (
   Fixed x
);
```

Parameters

x

The `Fixed` number expressed in radians, whose cosine is to be calculated.

Return Value
The cosine, expressed in radians, of the `Fixed` number `x`.

Discussion
The approximation of p/4 used to compute the cosine is the hexadecimal value 0.C910, making the approximation of p equal to 3.1416015625, while p itself equals 3.14159265.... Despite the approximation of p, the cosine value obtained is usually correct to several decimal places.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FracDiv

Divides two variables of the same type (`Fract`, `Fixed`, or `LongInt`) or to divide a `LongInt` or `Fixed` number by a `Fract` number.

```
Fract FracDiv (
   Fract x,
   Fract y
);
```

Parameters

x

The first operand, which can be a variable of type `Fract` or a variable of type `Fixed` or `LongInt`.

y

The second operand, which can be a variable of type `Fract` or a variable of the same type as the variable in parameter `a`.

Return Value
The quotient of the numbers in `a` and `b`. If the `b` parameter is in the format of a `Fract` number, then the `a` parameter can be in the format of a `Fract`, a `Fixed`, or a `LongInt` number. If the `b` parameter is in the format of a `Fixed` or a `LongInt` number, then the `a` parameter must be in the same format.

The returned value is in the format of a `Fract` number if `a` and `b` are both `Fract` numbers, both `Fixed` numbers, or both `LongInt` numbers. Otherwise, the returned value is in the same format as the number in the `a` parameter.

Division by zero results in $8000000 if `a` is negative, and $7FFFFFFF otherwise; thus the special case 0/0 yields $7FFFFFFF.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FracMul

Multiplies a variable of type `Fract` with another variable of type `Fract` or with a variable of type `Fixed` or `LongInt`.

```
Fract FracMul (
   Fract x,
   Fract y
);
```

Parameters

x
The first operand, which can be a variable of type `Fract` or a variable of type `Fixed` or `LongInt`.

y
The second operand, which can be a variable of type `Fract` or a variable of type `Fixed` or `LongInt`.

Return Value
The product of the numbers in `a` and `b`. At least one of `a` or `b` should be a variable of type `Fract`.

The returned value is in the format of a `LongInt` number if one of `a` and `b` is a `LongInt` number. It is a `Fixed` number if one of `a` or `b` is a `Fixed` number. It is a `Fract` number if both `a` and `b` are `Fract` numbers.

Overflows are set to the maximum representable value with the correct sign ($80000000 for negative results and $7FFFFFFF for positive results).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FracSin

Obtains a fast approximation of the sine of a `Fixed` number.

```
Fract FracSin (
   Fixed x
);
```

Parameters

x

The `Fixed` number expressed in radians, whose sine is to be calculated.

Return Value
The sine, expressed in radians, of the `Fixed` number `x`.

Discussion
The approximation of p/4 used to compute the sine is the hexadecimal value 0.C910, making the approximation of p equal to 3.1416015625, while p itself equals 3.14159265.... Despite the approximation of p, the sine value obtained is usually correct to several decimal places.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FracSqrt

Obtains the square root of a `Fract` number.

```
Fract FracSqrt (
   Fract x
);
```

Parameters

x

The `Fract` number to obtain a square root of. This parameter is interpreted as being unsigned in the range 0 through 4 – 2–30, inclusive. That is, the bit of the `Fract` number that ordinarily has weight -2 is instead interpreted as having weight 2.

Return Value
The square root of the specified `Fract` number. The result is unsigned in the range 0 through 2, inclusive.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`FixMath.h`

FractToFloat

Converts a `Fract` number to a `float` number.

```
float FixedToFract (
    Fract x
);
```

Parameters

x

The `Fract` number to be converted.

Return Value

The `float` equivalent of the `Fract` number.

Discussion

This function is implemented as an inline macro.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`FixMath.h`

frexp

```
double_t frexp (
   double_t x,
   int *exponent
);
```

Parameters

x

exponent

Return Value

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`fp.h`

gamma

```
double_t gamma (
   double_t x
);
```

Parameters

x

Return Value

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

Gamma Filter for FxPlug and AE

SoftVDigX

Declared In
fp.h

HiWord

Obtains the high-order word of a long word.

```
SInt16 HiWord (
    SInt32 x
);
```

Parameters

x
The long word whose high word is to be returned.

Return Value
The high-order word of the long word specified by the `x` parameter.

Discussion
One use of this function is to obtain the integral part of a fixed-point number.

To copy a range of bytes from one memory location to another, you should ordinarily use the Memory Manager function, `BlockMove`.

Availability

Declared In
ToolUtils.h

hypot

```
double_t hypot (
   double_t x,
   double_t y
);
```

Parameters

x

y

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
pyport.h

isfinite

```
long isfinite (
    float x
);
```

Parameters

x

A value of type `float` or `double`.

Return Value
Returns a non-zero value only if the argument is finite.

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

isnan

```
long isnan (
    float x
);
```

Parameters

x

A value of type `float` or `double`.

Return Value
Returns a non-zero value only if the argument is not a number (NaN).

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

isnormal

```
long isnormal (
    float x
);
```

Parameters

x

A value of type `float` or `double`.

Return Value
Returns a non-zero value only if the argument is normalized.

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

ldexp

```
double_t ldexp (
   double_t x,
   int n
);
```

Parameters

x

n

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

lgamma

```
double_t lgamma (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

log

```
double_t log (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

log10

```
double_t log10 (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
WhackedTV

Declared In
`fp.h`

log1p

```
double_t log1p (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

log2

```
double_t log2 (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

logb

```
double_t logb (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

Long2Fix

Converts a `LongInt` number to a `Fixed` number.

```
Fixed Long2Fix (
   SInt32 x
);
```

Parameters

x

The long integer to be converted to a `Fixed` number.

Return Value
The `Fixed` number equivalent to the long integer `x`. If `x` is greater than the maximum representable fixed-point number, the `Long2Fix` function returns $7FFFFFFF. If `x` is less than the negative number with the highest absolute value, `Long2Fix` returns $80000000.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
ASCIIMoviePlayerSample

Declared In
`FixMath.h`

LoWord

Obtains the low-order word of a long word.

```
SInt16 LoWord (
    SInt32 x
);
```

Parameters

x

The long word whose low word is to be returned.

Return Value
The low-order word of the long word specified by the `x` parameter.

Discussion
One use of this function is to obtain the fractional part of a fixed-point number.

To copy a range of bytes from one memory location to another, you should ordinarily use the Memory Manager function, `BlockMove`.

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

scalb

```
double_t scalb (
   double_t x,
   _scalb_n_type n
);
```

Parameters

x

n

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

signbit

```
long signbit (
    float x
);
```

Parameters

x

A value of type `float` or `double`, NaN, infinity, or zero.

Return Value
Returns a non-zero value only if the sign of the argument is negative.

Discussion
This function is implemented as an inline macro.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`fp.h`

sin

```
double_t sin (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

str2dec

```
void str2dec (
   const char *s,
   short *ix,
   decimal *d,
   short *vp
);
```

Parameters

s

ix

d

vp

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

tan

```
double_t tan (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

tanh

```
double_t tanh (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

trunc

```
_trunc_return_type trunc (
   double_t x
);
```

Parameters

x

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

U32SetU

```
UInt32 U32SetU (
   UInt64 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Add

```
UInt64 U64Add (
   UInt64 left,
   UInt64 right
);
```

Parameters

x

y

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64And

```
Boolean U64And (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64BitwiseAnd

```
UInt64 U64BitwiseAnd (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64BitwiseEor

```
UInt64 U64BitwiseEor (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64BitwiseNot

```
UInt64 U64BitwiseNot (
   UInt64 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64BitwiseOr

```
UInt64 U64BitwiseOr (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Compare

```
SInt32 U64Compare (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Div

Under evaluation

```
UInt64 U64Div (
   UInt64 dividend,
   UInt64 divisor
);
```

Parameters

dividend

divisor

Return Value

Availability

Declared In
Math64.h

U64Divide

```
UInt64 U64Divide (
   UInt64 dividend,
   UInt64 divisor,
   UInt64 *remainder
);
```

Parameters

dividend

divisor

remainder

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Eor

```
Boolean U64Eor (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Max

```
UInt64 U64Max (
   void
);
```

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Multiply

```
UInt64 U64Multiply (
   UInt64 left,
   UInt64 right
);
```

Parameters

xparam

yparam

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Not

```
Boolean U64Not (
   UInt64 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Or

```
Boolean U64Or (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Set

```
UInt64 U64Set (
   SInt32 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64SetU

```
UInt64 U64SetU (
   UInt32 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64ShiftLeft

```
UInt64 U64ShiftLeft (
   UInt64 value,
   UInt32 shift
);
```

Parameters

value

shift

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64ShiftRight

```
UInt64 U64ShiftRight (
   UInt64 value,
   UInt32 shift
);
```

Parameters

value

shift

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

U64Subtract

```
UInt64 U64Subtract (
   UInt64 left,
   UInt64 right
);
```

Parameters

left

right

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

UInt64ToSInt64

```
SInt64 UInt64ToSInt64 (
   UInt64 value
);
```

Parameters

value

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
Math64.h

WideAdd

```
wide * WideAdd (
   wide *target,
   const wide *source
);
```

Parameters

target

source

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
SoftVDigX

Declared In
FixMath.h

WideBitShift

```
wide * WideBitShift (
   wide *target,
   SInt32 shift
);
```

Parameters

src

shift

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideCompare

```
short WideCompare (
   const wide *target,
   const wide *source
);
```

Parameters

target

source

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideDivide

```
SInt32 WideDivide (
   const wide *dividend,
   SInt32 divisor,
   SInt32 *remainder
);
```

Parameters

dividend

divisor

remainder

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideMultiply

```
wide * WideMultiply (
   SInt32 multiplicand,
   SInt32 multiplier,
   wide *target
);
```

Parameters

multiplicand

multiplier

target

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideNegate

```
wide * WideNegate (
   wide *target
);
```

Parameters

target

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideShift

```
wide * WideShift (
   wide *target,
   SInt32 shift
);
```

Parameters

target

shift

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideSquareRoot

```
UInt32 WideSquareRoot (
   const wide *source
);
```

Parameters

source

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideSubtract

```
wide * WideSubtract (
   wide *target,
   const wide *source
);
```

Parameters

target

source

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

WideWideDivide

```
wide * WideWideDivide (
   wide *dividend,
   SInt32 divisor,
   SInt32 *remainder
);
```

Parameters

dividend

divisor

remainder

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
FixMath.h

X2Fix

Converts an `Extended` number to a `Fixed` number.

```
Fixed X2Fix (
   double x
);
```

Parameters

x

The `Extended` number to be converted to a `Fixed` number.

Return Value

The best `Fixed` approximation of the `Extended` number `x`. If `x` is greater than the maximum representable `Fixed` number, the `X2Fix` function returns $7FFFFFFF. If `x` is less than the negative number with the highest absolute value, `X2Fix` returns $80000000.

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

LiveVideoMixer2

Declared In

`FixMath.h`

X2Frac

Converts an `Extended` number to a `Fract` number.

```
Fract X2Frac (
   double x
);
```

Parameters

x

The `Extended` number to be converted to a `Fract` number.

Return Value

The best `Fract` approximation of the `Extended` number `x`. If `x` is greater than the maximum representable `Fract` number, the `X2Frac` function returns $7FFFFFFF. If `x` is less than the negative number with the highest absolute value, `X2Frac` returns $80000000.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`FixMath.h`

x80tod

```
double x80tod (
   const extended80 *x80
);
```

Parameters

x80

Return Value

Availability
Available in Mac OS X version 10.0 and later.

Declared In
fp.h

Data Types

decform

```
struct decform {
    char style;
    char unused;
    short digits;
};
typedef struct decform decform;
```

Fields
style
unused
digits

Availability
Available in Mac OS X v10.0 and later.

Declared In
fp.h

decimal

```
struct decimal {
    char sgn
    char unused
    short exp
    struct {
        unsigned char length;
        unsigned char text[36];
        unsigned char pad;
    } sig;
};
typedef struct decimal decimal;
```

Fields

`sgn`

`unused`

`exp`

`length`

`text`

`pad`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`fp.h`

double_t

```
typedef double double_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`fp.h`

fenv_t

```
typedef SInt32 fenv_t;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared In
`fenv.h`

fexcept_t

```
typedef SInt32 fexcept_t;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared In
`fenv.h`

Fixed

Defines a data type for fixed-point decimal numbers.

```
typedef SInt32 Fixed;
```

Discussion
This data type uses a 16-bit signed integer and a 16-bit fraction to represent fixed-point decimal numbers in the interval:

$$[-32768, 32767 + ((2^{16} - 1) / 2^{16})]$$

For example, the number 1.5 would be represented as `0x00018000`, and the number -1.3 would be represented as `0xFFFEB334`. To convert numbers between `Fixed` and `float`, you can use the functions `FixedToFloat` (page 1300) and `FloatToFixed` (page 1302).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IOMacOSTypes.h`

Fract

Defines a high-precision data type for fixed-point decimal numbers.

```
typedef SInt32 Fract;
```

Discussion
This data type uses a 2-bit signed integer and a 30-bit fraction to represent fixed-point decimal numbers in the interval

$$[-2, 1 + ((2^{30} - 1) / 2^{30})]$$

with higher precision than the `Fixed` (page 1347) data type. For example, the number 1.5 would be represented as `0x60000000`, and the number -1.3 would be represented as `0xACCCCCCD`. To convert numbers between `Fract` and `float`, you can use the functions `FractToFloat` (page 1308) and `FloatToFract` (page 1303).

Availability
Available in Mac OS X v10.0 and later.

Declared In
IOMacOSTypes.h

float_t

```
typedef float float_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
fp.h

relop

```
typedef short relop;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
fp.h

_scalb_n_type

```
typedef int _scalb_n_type;
```

_trunc_return_type

```
typedef double_t _trunc_return_type;
```

Constants

DECSTROUTLEN

```
enum {
    DECSTROUTLEN = 80
};
```

Constants
DECSTROUTLEN

FE_INEXACT

Definitions of floating-point exception macros.

```
enum {
    FE_INEXACT                  = 0x02000000,
    FE_DIVBYZERO                = 0x04000000,
    FE_UNDERFLOW                = 0x08000000,
    FE_OVERFLOW                 = 0x10000000,
    FE_INVALID                  = 0x20000000,
    FE_ALL_EXCEPT               = 0x3E000000
};
```

Constants

FE_INEXACT
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in fenv.h.

FE_DIVBYZERO
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in fenv.h.

FE_UNDERFLOW
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in fenv.h.

FE_OVERFLOW
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in fenv.h.

`FE_INVALID`
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in `fenv.h`.

`FE_ALL_EXCEPT`
Available in Mac OS X v10.1 through Mac OS X v10.1.
Declared in `fenv.h`.

FE_LDBLPREC

```
enum {
    FE_LDBLPREC = 0,
    FE_DBLPREC = 1,
    FE_FLTPREC = 2
};
```

Constants
`FE_LDBLPREC`
`FE_DBLPREC`
`FE_FLTPREC`

FE_TONEAREST

Definitions of rounding direction macros.

```
enum {
    FE_TONEAREST                = 0x00000000,
    FE_TOWARDZERO               = 0x00000001,
    FE_UPWARD                   = 0x00000002,
    FE_DOWNWARD                 = 0x00000003
};
```

Constants
`FE_TONEAREST`
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in `fenv.h`.

`FE_TOWARDZERO`
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in `fenv.h`.

`FE_UPWARD`
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in `fenv.h`.

`FE_DOWNWARD`
Available in Mac OS X v10.0 through Mac OS X v10.1.
Declared in `fenv.h`.

fixed1

```
enum {
    fixed1 = 0x00010000,
    fract1 = 0x40000000,
    positiveInfinity = 0x7FFFFFFF,
    negativeInfinity = 0x80000000
};
```

Constants

`fixed1`

`fract1`

`positiveInfinity`

`negativeInfinity`

FP_SNAN

```
enum {
    FP_SNAN = 0,
    FP_QNAN = 1,
    FP_INFINITE = 2,
    FP_ZERO = 3,
    FP_NORMAL = 4,
    FP_SUBNORMAL = 5
};
```

Constants

`FP_SNAN`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

`FP_QNAN`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

`FP_INFINITE`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

`FP_ZERO`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

`FP_NORMAL`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

`FP_SUBNORMAL`

Available in Mac OS X v10.0 through Mac OS X v10.1.

Declared in `fp.h`.

Relational Operator

```
typedef short relop;
enum {
    GREATERTHAN = 0,
    LESSTHAN = 1,
    EQUALTO = 2,
    UNORDERED = 3
};
```

Constants

`GREATERTHAN`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

`LESSTHAN`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

`EQUALTO`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

`UNORDERED`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

SIGDIGLEN

```
enum {
    SIGDIGLEN = 36
};
```

Constants

`SIGDIGLEN`

Special Values

```
#define HUGE_VAL
#define INFINITY
```

Constants

`HUGE_VAL`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

`INFINITY`
Available in Mac OS X v10.0 and later.
Declared in `fp.h`.

Memory Management Utilities Reference

Framework: CoreServices/CoreServices.h
Declared in OSUtils.h

Overview

Applications can use the Memory Management Utilities to

- ensure that their callback routines, interrupt tasks, and stand-alone code could access application global variables or QuickDraw global variables
- add elements to and remove them from an operating-system queue
- ensure that they function properly in both 24- and 32-bit modes
- ensure that data or instructions in the microprocessor's internal caches remain consistent with data or instructions in RAM

While Carbon supports most of the Memory Management Utilities, there are changes to functions that assume a 68K runtime environment.

- Functions that flush caches on 68K processors (such as `FlushInstructionCache`, `FlushDataCache`, and `FlushCodeCacheRange`) are no longer supported.
- Functions such as `SetA5` or `SetCurrentA5` do nothing when running in Mac OS X. However, these functions should work normally when running in Mac OS 8 or 9.
- The functions `GetMMUMode` and `SwapMMUMode` are not supported because all PowerPC applications use 32-bit addressing, even if they are not Carbon-compliant.
- The `SysEnvirons` function is no longer supported since the Gestalt Manager can provide the same information. You should call the functions `FindFolder` and `Gestalt` instead.

For a list of unsupported functions, see the Carbon Specification.

Functions by Task

Determining the Measurement System

`IsMetric` (page 1361)
Verifies whether the current script system is using the metric system or the English system of measurement.

Reading and Writing Location Data

`ReadLocation` (page 1362)
Obtains information about a geographic location or time zone.

`WriteLocation` (page 1365) Deprecated in Mac OS X v10.0
Changes the geographic location or time-zone information stored in extended parameter RAM. (Deprecated. There is no replacement because you cannot set this information in Mac OS X.)

Setting and Restoring the A5 Register

`SetA5` (page 1363) Deprecated in Mac OS X v10.4
Sets the A5 register to the address specified. (Deprecated. There is no replacement because Mac OS X doesn't use the A5 variable.)

`SetCurrentA5` (page 1364) Deprecated in Mac OS X v10.4
Sets the value in register A5 to the value of the low-memory global variable CurrentA5. (Deprecated. There is no replacement because Mac OS X doesn't use the A5 variable.)

Getting the User and Computer Name

`CSCopyMachineName` (page 1355)
Returns a reference to the CFString that represents the computer name.

`CSCopyUserName` (page 1356)
Returns a reference to the CFString that represents the user name.

Managing a Queue

`Enqueue` (page 1359)
Adds elements directly to an operating-system queue or a queue that you create.

`Dequeue` (page 1356)
Removes a queue element directly from an operating-system queue or from a queue that you have created.

`DTUninstall` (page 1358)
(Deprecated. You should restructure your application to use threads, such as those supplied by Multiprocessing Services.)

`DTInstall` (page 1358) Deprecated in Mac OS X v10.4
Adds the specified task record to the deferred-task queue. (Deprecated. You should restructure your application to use threads, such as those supplied by Multiprocessing Services.)

Working With Parameter RAM

`InitUtil` (page 1360) Deprecated in Mac OS X v10.3
Copies the contents of parameter RAM into low memory. (Deprecated. There is no replacement because Mac OS X doesn't require this initialization.)

`GetSysPPtr` (page 1360) Deprecated in Mac OS X v10.4
: Returns a pointer to the low-memory copy of parameter RAM. (Deprecated. There is no replacement; this function always returns `NULL` in Mac OS X.)

`WriteParam` (page 1366) Deprecated in Mac OS X v10.4
: Write the modified values in the system parameters data structure to parameter RAM. (Deprecated. There is no replacement, because this function does nothing in Mac OS X.)

Miscellaneous

`Delay` (page 1356)
: Delays execture for the specified amount of time.

`TickCount` (page 1365)
: Obtains the current number of ticks (a tick is approximately 1/60 of a second) since the system last started up.

`MakeDataExecutable` (page 1362)
: Notifies the system that the specified data is subject to execution.

Working With Universal Procedure Pointers

`NewDeferredTaskUPP` (page 1362)
: Creates a new universal procedure pointer (UPP) to a deferred-task callback.

`InvokeDeferredTaskUPP` (page 1361)
: Calls a deferred-task callback.

`DisposeDeferredTaskUPP` (page 1358)
: Disposes of a universal procedure pointer (UPP) to a deferred-task callback.

Functions

CSCopyMachineName

Returns a reference to the CFString that represents the computer name.

```
CFStringRef CSCopyMachineName (
   void
);
```

Return Value
A `CFStringRef`. See the Base Services documentation for a description of the `CFStringRef` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

CSCopyUserName

Returns a reference to the CFString that represents the user name.

```
CFStringRef CSCopyUserName (
   Boolean useShortName
);
```

Parameters

useShortName

A Boolean value that specifies whether to return the short name or full name of the user.

Return Value

A `CFStringRef`. See the Base Services documentation for a description of the `CFStringRef` data type.

Discussion

The function `CSCopyUserName` returns a `CFStringRef` based on the read UID (RUID, as returned by `getuid`) of the calling process. This can result in unexpected behavior (that is, `CSCopyUserName` returning different results than `SCDynamicStoreCopyConsoleUser`) for processes that manipulate their UID.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

Delay

Delays execture for the specified amount of time.

```
void Delay (
   unsigned long numTicks,
   unsigned long *finalTicks
);
```

Parameters

numTicks

finalTicks

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

Dequeue

Removes a queue element directly from an operating-system queue or from a queue that you have created.

```
OSErr Dequeue (
   QElemPtr qElement,
   QHdrPtr qHeader
);
```

Parameters

qElement

A pointer to a queue element to remove from a queue.

qHeader

A pointer to a queue header.

Return Value

A result code. See "Memory Management Utilities Result Codes" (page 1376).

Discussion

The `Dequeue` function attempts to find the queue element specified by the `qElement` parameter in the queue specified by the `qHeader` parameter. If `Dequeue` finds the element, it removes the element from the queue, adjusts the other elements in the queue accordingly, and returns `noErr`. Otherwise, it returns `qErr`, indicating that it could not find the element in the queue. The `Dequeue` function does not deallocate the memory occupied by the queue element.

For a description of the `QElem` record, see `QElem` (page 1369); for a description of the `QHdr` record, see `QHdr` (page 1370).

The `Dequeue` function disables interrupts as it searches through the queue for the element to be removed. The time during which interrupts are disabled depends on the length of the queue and the position of the entry in the queue. The `Dequeue` function can be called at interrupt time. However, the `Dequeue` function is ordinarily used only by system software and, whenever possible, you should manipulate an operating-system queue indirectly, by calling special-purpose removal functions. You can use the Queue Utilities functions for directly manipulating queues that you create. Use the following functions instead of `Dequeue`:

- `SlotVRemove`

  Removes a slot-based VBL task. This function is available with the Vertical Retrace Manager.

- `VRemove`

  Removes a system-based VBL task. This function is available with the Vertical Retrace Manager.

- `WaitNextEvent`

  Removes an Event. This function is available with the Event manager.

- `SIntRemove`

  Removes a slot interrupt task. This function is available with the Slot Manager.

- `NMRemove`

  Removes a Notification request. This function is available with the Notification Manager.

- `SleepQRemove`

  Removes a Sleep task. This function is available with the Power Manager.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

DisposeDeferredTaskUPP

Disposes of a universal procedure pointer (UPP) to a deferred-task callback.

```
void DisposeDeferredTaskUPP (
   DeferredTaskUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `DeferredTaskProcPtr` (page 1367) for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

DTInstall

Adds the specified task record to the deferred-task queue. (Deprecated in Mac OS X v10.4. You should restructure your application to use threads, such as those supplied by Multiprocessing Services.)

```
OSErr DTInstall (
   DeferredTaskPtr dtTaskPtr
);
```

Parameters

dtTaskPtr

Return Value

A result code. See "Memory Management Utilities Result Codes" (page 1376).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OSUtils.h`

DTUninstall

(Deprecated in Mac OS X v10.4. You should restructure your application to use threads, such as those supplied by Multiprocessing Services.)

```
OSErr DTUninstall (
   DeferredTaskPtr dtTaskPtr
);
```

Availability

Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

Enqueue

Adds elements directly to an operating-system queue or a queue that you create.

```
void Enqueue (
   QElemPtr qElement,
   QHdrPtr qHeader
);
```

Parameters

qElement
A pointer to the queue element to add to a queue.

qHeader
A pointer to a queue header.

Discussion
The `Enqueue` function adds the queue element specified by the `qElement` parameter to the end of the queue specified by the `qHeader` parameter. The specified queue header is updated to reflect the new queue element.

For a description of the `QElem` record, see `QElem` (page 1369); for a description of the `QHdr` record, see `QHdr` (page 1370).

Because interrupt functions are likely to manipulate operating-system queues, interrupts are disabled for a short time while the specified queue is updated. You can call the `Enqueue` function at interrupt time. However, the `Enqueue` function is ordinarily used only by system software. Whenever possible, you should manipulate an operating-system queue indirectly, by calling special-purpose functions whenever possible, instead of the `Enqueue` function. You can use the Queue Utilities functions for directly manipulating queues that you create. Use the following functions instead of `Enqueue`:

- `SlotVInstall`

  Installs a slot-based VBL task. This function is available with the Vertical Retrace Manager.

- `VInstall`

  Installs a system-based VBL task. This function is available with the Vertical Retrace Manager.

- `AddDrive`

  Adds a disk drive. This function is available with the Device Manager.

- `PPostEvent` and `PostEvent`

  Installs an Event. This function is available with the Event manager.

- `DTInstall`

  Installs a deferred task. This function is available with the Memory Management Utilities.

- `SIntInstall`

  Installs a slot interrupt task. This function is available with the Slot Manager.

- `NMInstall`

  Installs a Notification request. This function is available with the Notification Manager.

- `SleepQInstall`

  Installs a Sleep task. This function is available with the Power Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

GetSysPPtr

Returns a pointer to the low-memory copy of parameter RAM. (Deprecated in Mac OS X v10.4. There is no replacement; this function always returns `NULL` in Mac OS X.)

```
SysPPtr GetSysPPtr (
   void
);
```

Return Value
See the description of the `SysPPtr` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

InitUtil

Copies the contents of parameter RAM into low memory. (Deprecated in Mac OS X v10.3. There is no replacement because Mac OS X doesn't require this initialization.)

```
OSErr InitUtil (
   void
);
```

Return Value
A result code. See "Memory Management Utilities Result Codes" (page 1376).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

InvokeDeferredTaskUPP

Calls a deferred-task callback.

```
void InvokeDeferredTaskUPP (
   long dtParam,
   DeferredTaskUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeDeferredTaskUPP`, as the system calls your deferred-task callback for you. See the callback `DeferredTaskProcPtr` (page 1367) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

IsMetric

Verifies whether the current script system is using the metric system or the English system of measurement.

```
Boolean IsMetric (
   void
);
```

Return Value
`TRUE` if the metric system is being used; `FALSE` if the English system is being used.

Discussion
The `IsMetric` function examines the `metricSys` field of the numeric-format resource (resource type `'itl0'`) to determine if the current script is using the metric system. A value of 255 in the `metricSys` field indicates that the metric system (centimeters, kilometers, milligrams, degrees Celsius, and so on) is being used. A value of 0 in the `metricSys` field indicates that the English system of measurement (inches, miles, ounces, degrees Fahrenheit, and so on) is used.

If you want to use units of measurement different from that of the current script, you need to override the value of the `metricSys` field in the current numeric-format resource. You can do this by using your own version of the numeric-format resource instead of the current script system's default international resource.

The `IsMetric` function is the same as the `IUMetric` function, which was previously available with the International Utilities Package.

Special Considerations

The `IsMetric` function may move or purge blocks in the heap calling it may cause problems if you've dereferenced a handle. Do not call this function from within interrupt code, such as in a completion function or a VBL task.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

MakeDataExecutable

Notifies the system that the specified data is subject to execution.

```
void MakeDataExecutable (
   void *baseAddress,
   unsigned long length
);
```

Parameters

baseAddress

The starting address of the data to be flushed.

length

The length of the data pointed to by the `baseAddress` parameter.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`OSUtils.h`

NewDeferredTaskUPP

Creates a new universal procedure pointer (UPP) to a deferred-task callback.

```
DeferredTaskUPP NewDeferredTaskUPP (
   DeferredTaskProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your deferred-task callback.

Return Value

On return, a UPP to a deferred-task callback. See the description of the `DeferredTaskUPP` data type.

Discussion

See the callback `DeferredTaskProcPtr` (page 1367) for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

ReadLocation

Obtains information about a geographic location or time zone.

```
void ReadLocation (
   MachineLocation *loc
);
```

Parameters

loc

On return, the fields of the geographic location structure containing the geographic location and the time-zone information.The `ReadLocation` procedure reads the stored geographic location and time zone of the Macintosh computer from extended parameter RAM.

You can get values for the latitude, longitude, daylight savings time (DST), or Greenwich mean time (GMT). If the geographic location record has never been set, all fields contain 0.

Discussion

The latitude and longitude are stored as `Fract` values, giving accuracy to within one foot. For example, a `Fract` value of 1.0 equals 90 degrees –1.0 equals –90 degrees and –2.0 equals –180 degrees.

To convert these values to a degrees format, you need to convert the `Fract` values first to the `Fixed` data type, then to the `LongInt` data type. Use the Mathematical and Logical Utilities functions `Fract2Fix` and `Fix2Long` to accomplish this task.

The DST value is a signed byte value that specifies the offset for the `hour` field—whether to add one hour, subtract one hour, or make no change at all.

The GMT value is in seconds east of GMT. For example, San Francisco is at –28,800 seconds (8 hours * 3,600 seconds per hour) east of GMT. The `gmtDelta` field is a 3-byte value contained in a long word, so you must take care to get it properly.

The `ReadLocation` function was previously available with the Script Manager.

For more information on the geographic location record, see `MachineLocation` (page 1368).

For more information on the `Fract` data type and the conversion routines `Long2Fix`, `Fix2Fract`, `Fract2Fix`, and `Fix2Long`, see Mathematical and Logical Utilities.

Special Considerations

Do not call the `ReadLocation` function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

SetA5

Sets the A5 register to the address specified. (Deprecated in Mac OS X v10.4. There is no replacement because Mac OS X doesn't use the A5 variable.)

```
long SetA5 (
   long newA5
);
```

Parameters

newA5

The value to which the A5 register is to be changed.

Return Value
The value in the A5 register before SetA5 changes it to `newA5`.

Discussion
In interrupt code that accesses application global variables, use the `SetA5` function first to restore a value previously saved using `SetCurrentA5`, and then, at the end of the code, to restore the A5 register to the value it had before the first call to `SetA5`.

Carbon Porting Notes

68K-specific. Does nothing in PowerPC native code.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

SetCurrentA5

Sets the value in register A5 to the value of the low-memory global variable CurrentA5. (Deprecated in Mac OS X v10.4. There is no replacement because Mac OS X doesn't use the A5 variable.)

```
long SetCurrentA5 (
   void
);
```

Return Value
The value in the A5 register before SetCurrentA5 changes it to the value of the low-memory global variable CurrentA5.

Discussion
The `CurrentA5` variable points to the boundary between the parameters and global variables of the current application.

You cannot reliably call `SetCurrentA5` in code that executes at interrupt time unless you first guarantee that your application is the current process (for example, by calling the Process Manager function `GetCurrentProcess`). In general, you should call `SetCurrentA5` at noninterrupt time and then pass the returned value to the interrupt code.

Carbon Porting Notes

68K-specific. Does nothing in PowerPC native code.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

TickCount

Obtains the current number of ticks (a tick is approximately 1/60 of a second) since the system last started up.

```
UInt32 TickCount (
   void
);
```

Discussion
The `TickCount` function returns an unsigned 32-bit integer that indicates the current number of ticks since the system last started up. You can use this value to compare the number of ticks that have elapsed since a given event or other action occurred. For example, you could compare the current value returned by `TickCount` with the value of the `when` field of an event structure.

The tick count is incremented during the vertical retrace interrupt, but this interrupt can be disabled. Your application should not rely on the tick count to increment with absolute precision. Your application also should not assume that the tick count always increments by 1 an interrupt task might keep control for more than one tick. If your application keeps track of the previous tick count and then compares this value with the current tick count, your application should compare the two values by checking for a "greater than or equal" condition rather than "equal to previous tick count plus 1."

Do not rely on the tick count being exact; it is usually accurate to within one tick, but this level of accuracy is not guaranteed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell
Simple DrawSprocket

Declared In
`OSUtils.h`

WriteLocation

Changes the geographic location or time-zone information stored in extended parameter RAM. (Deprecated in Mac OS X v10.0. There is no replacement because you cannot set this information in Mac OS X.)

```
void WriteLocation (
   const MachineLocation *loc
);
```

Parameters
loc
The geographic location and time-zone information to write to the extended parameter RAM.

Discussion
The latitude and longitude are stored in the geographic location structure as `Fract` values, giving accuracy to within 1 foot. For example, a `Fract` value of 1.0 equals 90 degrees –1.0 equals –90 degrees and –2.0 equals –180 degrees.

Use the functions `Long2Fix` and `Fix2Fract` to convert longitude and latitude values to the `Fixed` data type and then to the `Fract` data type for storage.

Use the daylight savings time value signed byte value to specify the offset for the `hour` field—whether to add one hour, subtract one hour, or make no change at all.

The Greenwich mean time value is in seconds east of GMT. For example, San Francisco is at –28,800 seconds (8 hours * 3,600 seconds per hour) east of GMT.The `gmtDelta` field is a 3-byte value contained in a long word. When writing `gmtDelta`, mask off the top byte because it is reserved. Preserve the value of `dlsDelta`.

The `WriteLocation` function was previously available with the Script Manager.

For more information on the geographic location record, see `MachineLocation` (page 1368).

For more information on the `Fract` data type and the conversion routines `Long2Fix`, `Fix2Fract`, `Fract2Fix`, and `Fix2Long`, see Mathematical and Logical Utilities.

Special Considerations
Do not call the `WriteLocation` function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

WriteParam

Write the modified values in the system parameters data structure to parameter RAM. (Deprecated in Mac OS X v10.4. There is no replacement, because this function does nothing in Mac OS X.)

```
OSErr WriteParam (
   void
);
```

Return Value
A result code. See "Memory Management Utilities Result Codes" (page 1376).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OSUtils.h`

Callbacks

DeferredTaskProcPtr

Defines a pointer to a deferred-task callback.

```
typedef void (*DeferredTaskProcPtr) (
    long dtParam
);
```

If you name your function `MyDeferredTaskProc`, you would declare it like this:

```
void MyDeferredTaskProc (
    long dtParam
);
```

Parameters

dtParam

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

Data Types

DeferredTask

Contains information related to a deferred task.

```
struct DeferredTask {
    volatile QElemPtr qLink;
    short qType;
    volatile short dtFlags;
    DeferredTaskUPP dtAddr;
    long dtParam;
    long dtReserved;
};
typedef struct DeferredTask DeferredTask;
typedef DeferredTask * DeferredTaskPtr;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

DeferredTaskUPP

Defines a universal procedure pointer to a deferred-task callback.

```
typedef DeferredTaskProcPtr DeferredTaskUPP;
```

Discussion
For more information, see the description of the `DeferredTaskProcPtr` (page 1367) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

MachineLocation

Contains information about the geographical location of a computer.

```
struct MachineLocation {
    Fract latitude
    Fract longitude
    union {
    #if TARGET_RT_BIG_ENDIAN
        SInt8 dlsDelta;
    #endif
        long gmDelta;
        struct {
        #if TARGET_RT_LITTLE_ENDIAN
            SInt8 pad[3];
        #endif
            SInt8 Delta;
        } dls;
    } u;
};
typedef struct MachineLocation MachineLocation;
```

Fields

`latitude`
The location's latitude, in fractions of a great circle. For example, Copenhagen, Denmark is at 55.43 degrees north latitude. When writing the latitude to extended parameter RAM with the `WriteLocation` procedure, you must convert this value to a `Fract` data type. (For example, a `Fract` value of 1.0 equals 90 degrees –1.0 equals –90 degrees and –2.0 equals –180 degrees.) For more information on the `Fract` data type, see Mathematical and Logical Utilities.

`longitude`
The location's longitude, in fractions of a great circle. For example, Copenhagen, Denmark is at 12.34 degrees east longitude. When writing the longitude to extended parameter RAM with the `WriteLocation` procedure, you must convert this value to a `Fract` data type. (For example, a `Fract` value of 1.0 equals 90 degrees –1.0 equals –90 degrees and –2.0 equals –180 degrees.

`dlsDelta`
A value that represents the current state of daylight savings time.

`gmDelta`
`pad`
`delta`

A signed byte value representing the hour offset for daylight saving time. This field is a 1-byte value contained in a long word. It should be preserved when writing `gmtDelta`.

Discussion
The geographic location and time-zone information of a Macintosh computer are stored in extended parameter RAM. The `MachineLocation` data type defines the format for the geographic location record.

The `ReadLocation` and `WriteLocation` procedures use the geographic location record to read and store the geographic location and time zone information in extended parameter RAM. If the geographic location record has never been set, all fields contain 0.

In order for MachineLocation to be endian-safe, a new member has been added to the 'u' union in the structure. You are encouraged to use the new member instead of the old one.

If your code looked like this:

```
MachineLocation.u.dlsDelta = 1;
```

you should change it to this:

```
MachineLocation.u.dls.Delta = 1;
```

to be endian safe. The `gmtDelta` remains the same; the low 24-bits are used. Remember that order of assignment DOES matter.

This will overwrite results:

```
MachineLocation.u.dls.Delta = 0xAA;          // u = 0xAAGGGGGG; G=Garbage
MachineLocation.u.gmtDelta = 0xBBBBBB;       // u = 0x00BBBBBB;
```

when in fact reversing the assignment would have preserved the values:

```
MachineLocation.u.gmtDelta = 0xBBBBBB;       // u = 0x00BBBBB;
MachineLocation.u.dls.Delta = 0xAA;          // u = 0xAABBBBBB;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

QElem

Contains information about a queue element.

```
struct QElem {
    QElem * qLink;
    short qType;
    short qData[1];
};
typedef struct QElem QElem;
typedef QElem * QElemPtr;
```

Fields

`qLink`

The type of the queue element. For a description of the values which you can use in this field, see "Queue Types" (page 1374).

`qType`

A variable array of data. The type of data and the length depend upon the queue type, specified in the `qType` field.

`qData`

Discussion

A queue element is a single entry in a queue. Each operating-system queue created and maintained by the Macintosh Operating System consists of a queue header and a linked list of queue elements. The exact structure of an element in an operating-system queue depends on the type of the queue. The `QElem` data type defines the available queue elements.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSUtils.h`

QHdr

Contains information about the event queue.

```
struct QHdr {
    volatile short qFlags;
    volatile QElemPtr qHead;
    volatile QElemPtr qTail;
};
typedef struct QHdr QHdr;
typedef QHdr * QHdrPtr;
```

Fields

`qFlags`

Queue flags.

`qHead`

First queue entry.

`qTail`

Last queue entry.

Discussion

The event queue consists of a header followed by the actual entries in the queue. The event queue has the same header as all standard Macintosh Operating System queues. The `Qhdr` structure defines the queue header.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSUtils.h

SysEnvRec

Contains information about the system environment.

```
struct SysEnvRec {
    short environsVersion;
    short machineType;
    short systemVersion;
    short processor;
    Boolean hasFPU;
    Boolean hasColorQD;
    short keyBoardType;
    short atDrvrVersNum;
    short sysVRefNum;
};
typedef struct SysEnvRec SysEnvRec;
```

Fields

`environsVersion`

The version number of the `SysEnvirons` function that was used to fill in the record.

When you call the `SysEnvirons` function, you specify a version number to ensure that you receive a system environment record that matches your expectations. If you request a more recent version of `SysEnvirons` than is available, `SysEnvirons` places its own version number in the `environsVersion` field and returns a function result `envVersTooBig`.

`machineType`

A code for the Macintosh model. See "Macintosh Model Codes" (page 1373). Use the `Gestalt` function to obtain information about machine types not listed among these constants.

`systemVersion`

The version number of the current System file, represented as two byte-long numbers with one or more implied decimal points. The value $0410, for example, represents system software version 4.1.

If you call `SysEnvirons` when a system earlier than 4.1 is running, the MPW glue places $0 in this field and returns a result code of `envNotPresent`.

`processor`

A code for the microprocessor. See "Microprocessor Codes" (page 1374).

`hasFPU`

A Boolean value that indicates whether hardware floating-point processing is available.

`hasColorQD`

A Boolean value that indicates whether Color QuickDraw is present. This field says nothing about the presence of a color monitor.

`keyBoardType`

A code for the keyboard type. See "Keyboard Constants" (page 1373). Use the `Gestalt` function to obtain information about keyboard types not listed among these constants.

If the Apple Desktop Bus is in use, this field returns the keyboard type of the keyboard on which the last keystroke was made.

`atDrvrVersNum`
: The version number of the AppleTalk driver (specifically, the .MPP driver) currently installed. If AppleTalk is not loaded, this field is 0.

`sysVRefNum`
: The working-directory reference number of the folder or volume that holds the open System file.

Discussion
The `SysEnvirons` function fills in a system environment record, which describes some aspects of the software and hardware environment.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

SysParmType

Contains settings used by the system at startup.

```
struct SysParmType {
    UInt8 valid;
    UInt8 aTalkA;
    UInt8 aTalkB;
    UInt8 config;
    short portA;
    short portB;
    long alarm;
    short font;
    short kbdPrint;
    short volClik;
    short misc;
};
typedef struct SysParmType SysParmType;
typedef SysParmType * SysPPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSUtils.h`

Constants

Addressing Errors

Specify a type of addressing error.

```
enum {
    false32b = 0,
    true32b = 1
};
```

Constants

`false32b`

Indicates a 24-bit addressing error.

Available in Mac OS X v10.0 and later.

Declared in `OSUtils.h`.

`true32b`

Indicates a 32-bit addressing error.

Available in Mac OS X v10.0 and later.

Declared in `OSUtils.h`.

Keyboard Constants

Specify keyboard types.

```
enum {
    envUnknownKbd = 0,
    envMacKbd = 1,
    envMacAndPad = 2,
    envMacPlusKbd = 3,
    envAExtendKbd = 4,
    envStandADBKbd = 5,
    envPrtblADBKbd = 6,
    envPrtblISOKbd = 7,
    envStdISOADBKbd = 8,
    envExtISOADBKbd = 9
};
```

Macintosh Model Codes

Specify models of Macintosh computers.

```
enum {
    envMac = -1,
    envXL = -2,
    envMachUnknown = 0,
    env512KE = 1,
    envMacPlus = 2,
    envSE = 3,
    envMacII = 4,
    envMacIIx = 5,
    envMacIIcx = 6,
    envSE30 = 7,
    envPortable = 8,
    envMacIIci = 9,
    envMacIIfx = 11
};
```

Microprocessor Codes

Specify types of microprocessors.

```
enum {
    envCPUUnknown = 0,
    env68000 = 1,
    env68010 = 2,
    env68020 = 3,
    env68030 = 4,
    env68040 = 5
};
```

Queue Types

Specifies queue types.

```
enum {
    dummyType = 0,
    vType = 1,
    ioQType = 2,
    drvQType = 3,
    evType = 4,
    fsQType = 5,
    sIQType = 6,
    dtQType = 7,
    nmType = 8
};
typedef SignedByte QTypes;
```

Constants

`dummyType`

Reserved.

Available in Mac OS X v10.0 and later.

Declared in `OSUtils.h`.

`vType`
Specifies a vertical retrace queue type. See the Vertical Retrace Manager for more information.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`ioQType`
Specifies a file I/O or driver I/O queue type.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`drvQType`
Specifies a drive queue type.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`evType`
Specifies an event queue type. See the Event Manager for more information.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`fsQType`
Specifies a volume-control-block queue type.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`sIQType`
Specifies a slot interrupt queue type. See the Slot Manager for more information.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`dtQType`
Specifies a deferred task queue type. See Memory Management Utilities for more information.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`nmType`
Specifies a notification queue type. See the Notification Manager for more information.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

Discussion
The different queue types that are accessible to your application are defined by the `QTypes` data type. Each of these enumerated queue types determines a different type of queue element. These constants are used in the `qtype` field of the `QElem` (page 1369) structure.

Sorting Constants

Specify the result types for the function `RelString`.

```
enum {
    sortsBefore = -1,
    sortsEqual = 0,
    sortsAfter = 1
};
```

Constants

`sortsBefore`
Indicates the first string is less than the second string.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`sortsEqual`
Indicates the first string is equivalent to the second string.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

`sortsAfter`
Indicates the first string is greater than the second string.
Available in Mac OS X v10.0 and later.
Declared in `OSUtils.h`.

Assorted Use Constants

Defines constants to indicate use of various things, such as to use MIDE or AppleTalk.

```
enum {
    useFree = 0,
    useATalk = 1,
    useAsync = 2,
    useExtClk = 3,
    useMIDI = 4
};
```

Version Number

Specifies the version of the current system environment.

```
enum {
    curSysEnvVers = 2
};
```

Result Codes

The most common result codes returned by Memory Management Utilities are listed in the table below. Memory Management Utilities may also return the following errors:

`noErr` (0)
`paramErr` (-50)

prWrErr (-87)
prInitErr (-88)
memROZErr (-99)
memFullErr (-108)
nilHandleErr (-109)
memWZErr (-111)
memPurErr (-112)
memBCErr (-115)
memLockedErr (-117)
notEnoughMemoryErr (-620)
notHeldErr (-621)
cannotMakeContiguousErr (-622)
notLockedErr (-623)
interruptsMaskedErr (-624)
cannotDeferErr (-625)

Result Code	Value	Description
qErr	-1	Queue element not found during deletion. Available in Mac OS X v10.0 and later.
vTypErr	-2	Invalid queue element. Available in Mac OS X v10.0 and later.
corErr	-3	Core routine number out of range Available in Mac OS X v10.0 and later.
unimpErr	-4	Unimplemented core routine. Available in Mac OS X v10.0 and later.
SlpTypeErr	-5	Invalid queue element. Available in Mac OS X v10.0 and later.
hwParamErr	-502	Processor does not support flushing a range. Available in Mac OS X v10.0 and later.

Memory Manager Reference

Framework: CoreServices/CoreServices.h

Declared in MacMemory.h

Overview

The Memory Manager was the memory management solution for versions of the Macintosh operating system prior to Mac OS X. It remains available for compatibility with legacy applications and for new applications that must work with legacy Carbon code that requires handles.

In previous versions of the Macintosh operating system, developers used the Memory Manager to set up an application's memory partition at launch time, to manage an application's heap, to minimize application memory fragmentation, and to implement a scheme to avoid low-memory conditions. All of these operations are now handled transparently by Mac OS X.

In the Mac OS X Memory Manager, many functions are deprecated, the callbacks are not functional, and the data types and constants are not used. In Mac OS X there is no need to set up or manage an application memory partition or to manage pointers. To allocate memory, in most cases you simply use the C functions `malloc` or `calloc`. Mac OS X ensures that every application has access to as much memory as it needs—up to 4 gigabytes of addressable space per 32-bit process.

Mac OS X does not support functions for accessing the system heap, as the system heap is unavailable to applications in Mac OS X. Starting with Mac OS X v10.3, Memory Manager is thread safe, and the `MemError` (page 1410) function now returns error codes on a per-thread basis.

For information on memory management issues when porting a legacy Macintosh application to Mac OS X, refer to the Carbon Porting Guide and to Technical Note 2130, Memory Allocation Recommendations on Mac OS X.

Functions by Task

Allocating and Releasing Nonrelocatable Blocks of Memory

`DisposePtr` (page 1391)
Releases memory occupied by a nonrelocatable block.

`NewPtr` (page 1416)
Allocates a nonrelocatable block of memory of a specified size.

`NewPtrClear` (page 1417)
Allocates a nonrelocatable block of memory of a specified size with all its bytes set to 0.

Allocating and Releasing Relocatable Blocks of Memory

`DisposeHandle` (page 1390)
Releases memory occupied by a relocatable block.

`NewEmptyHandle` (page 1413)
Initializes a new handle without allocating any memory for it to control.

`NewHandle` (page 1414)
Allocates a new relocatable memory block of a specified size in the current heap zone.

`NewHandleClear` (page 1415)
Allocates a relocatable block of memory of a specified size with all its bytes set to 0.

Allocating Temporary Memory

`TempNewHandle` (page 1430)
Allocates a new relocatable block of temporary memory.

Assessing Memory Conditions

`MemError` (page 1410)
Determines if an application's last direct call to a Memory Manager function executed successfully.

`LMGetMemErr` (page 1406)
Returns the result of the last Memory Manager function without clearing the value.

`LMSetMemErr` (page 1407)
Sets the value which will be returned by the `MemError` function.

`MaxBlock` (page 1409) Deprecated in Mac OS X v10.5
Returns a fixed value for block size that is compatible with most applications. (Deprecated. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

`StackSpace` (page 1427) Deprecated in Mac OS X v10.5
Returns the amount of space between the bottom of the stack and the top of the application heap. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

Changing the Sizes of Relocatable and Nonrelocatable Blocks

`GetHandleSize` (page 1394)
Returns the logical size of the relocatable block corresponding to a handle.

`GetPtrSize` (page 1395)
Returns the logical size of the nonrelocatable block corresponding to a pointer.

`SetHandleSize` (page 1425)
Changes the logical size of the relocatable block corresponding to the specified handle.

`SetPtrSize` (page 1426)
Changes the logical size of the nonrelocatable block corresponding to a pointer.

Managing Relocatable Blocks

`EmptyHandle` (page 1392)
Purges a relocatable block and sets the corresponding handle's master pointer to `NULL`.

`HLockHi` (page 1399)
Sets the lock bit on the block.

`ReallocateHandle` (page 1422)
Allocates a new relocatable block of a specified size and sets a handle's master pointer to point to the new block.

`RecoverHandle` (page 1423)
Returns a handle to a relocatable block pointed to by a specified `pointer`.

Manipulating Blocks of Memory

`BlockMove` (page 1385)
Copies a sequence of bytes from one location in memory to another.

`BlockMoveData` (page 1386)

`BlockMoveDataUncached` (page 1387)

`BlockMoveUncached` (page 1387)

`BlockZero` (page 1388)

`BlockZeroUncached` (page 1388)

`HandAndHand` (page 1396)
Concatenates two relocatable blocks.

`HandToHand` (page 1396)
Copies all of the data from one relocatable block to a new relocatable block.

`PtrAndHand` (page 1418)
Concatenates part or all of a memory block to the end of a relocatable block.

`PtrToHand` (page 1419)
Copies data referenced by a pointer to a new relocatable block.

`PtrToXHand` (page 1419)
Copies data referenced by a pointer to an existing relocatable block.

Setting the Properties of Relocatable Blocks

`HClrRBit` (page 1397)
Clears the resource flag of a relocatable block.

`HGetState` (page 1398)
Returns a signed byte representing the current properties of a relocatable block.

`HLock` (page 1398)
Prevents a relocatable block from moving within its heap zone.

`HSetRBit` (page 1402)
Sets the resource flag of a relocatable block.

`HSetState` (page 1402)
Restores the properties of a relocatable block.

`HUnlock` (page 1403)
Allows a relocatable block to move in its heap zone.

Miscellaneous

`IsHandleValid` (page 1405)
Checks that a handle is valid.

`IsHeapValid` (page 1405)
Always returns true in Mac OS X.

`IsPointerValid` (page 1406)
Checks that a pointer is valid.

Deprecated Functions

You should avoid using the functions listed in this section.

`FlushMemory` (page 1393)
Makes a portion of the address space clean. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

`LMGetApplZone` (page 1406)
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

`LMSetApplZone` (page 1407)
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

`FreeMem` (page 1393) Deprecated in Mac OS X v10.5
Returns the total amount of free space in the current heap zone. (Deprecated. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

`MaxMem` (page 1409) Deprecated in Mac OS X v10.5
Returns the size, in bytes, of the largest contiguous free block in the current heap zone. (Deprecated. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

`TempDisposeHandle` (page 1427) Deprecated in Mac OS X v10.5
Releases a relocatable block in the temporary heap. (Deprecated. Use `DisposeHandle` (page 1390) instead; Mac OS X does not have a separate temporary memory heap.)

`CheckAllHeaps` (page 1388) Deprecated in Mac OS X v10.4
Checks all known heaps for validity. (Deprecated. There is no replacement function; an application has access only to its own heap in Mac OS X.)

`CompactMem` (page 1389) Deprecated in Mac OS X v10.4
Compacts the heap by moving relocatable blocks as needed. (Deprecated. There is no replacement function; memory compaction is never needed and never performed in Mac OS X.)

DisposeGrowZoneUPP (page 1390) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

DisposePurgeUPP (page 1391) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement function; heaps are never purged in Mac OS X, so the purge function is never called.)

DisposeUserFnUPP (page 1392) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

GetGrowZone (page 1394) Deprecated in Mac OS X v10.4
Returns the current heap zone's grow-zone function. (Deprecated. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never used.)

GZSaveHnd (page 1395) Deprecated in Mac OS X v10.4
Returns a relocatable block to be protected during grow-zone operations. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

HNoPurge (page 1400) Deprecated in Mac OS X v10.4
Marks a relocatable block as unpurgeable. (Deprecated. There is no replacement function; heaps are never purged in Mac OS X.)

HoldMemory (page 1400) Deprecated in Mac OS X v10.4
Makes a portion of the address space resident in physical memory and ineligible for paging. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

HPurge (page 1401) Deprecated in Mac OS X v10.4
Marks a relocatable block as purgeable. (Deprecated. There is no replacement function; heaps are never purged in Mac OS X.)

InvokeGrowZoneUPP (page 1403) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

InvokePurgeUPP (page 1404) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement function; heaps are never purged in Mac OS X, so the purge function is never called.)

InvokeUserFnUPP (page 1404) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

LMGetSysZone (page 1407) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

LMSetSysZone (page 1408) Deprecated in Mac OS X v10.4
(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

MakeMemoryNonResident (page 1408) Deprecated in Mac OS X v10.4
Makes pages in the specified range immediately available for reuse. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

MakeMemoryResident (page 1408) Deprecated in Mac OS X v10.4
Makes a portion of the address space resident in physical memory. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

`MoreMasterPointers` (page 1411) Deprecated in Mac OS X v10.4

Allocates a specified number of master pointers in the current heap zone. (Deprecated. There is no replacement function; master pointers do not need to be pre-allocated in Mac OS X.)

`MoreMasters` (page 1411) Deprecated in Mac OS X v10.4

Allocates a block of master pointers in the current heap zone. (Deprecated. There is no replacement function; master pointers do not need to be pre-allocated in Mac OS X.)

`MoveHHi` (page 1412) Deprecated in Mac OS X v10.4

Moves a relocatable block as high in memory as possible. (Deprecated. There is no replacement function; there is no benefit to moving handles high in memory in Mac OS X.)

`NewGrowZoneUPP` (page 1414) Deprecated in Mac OS X v10.4

(Deprecated. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

`NewPurgeUPP` (page 1417) Deprecated in Mac OS X v10.4

(Deprecated. There is no replacement function; heaps are never purged in Mac OS X, so the purge function is never called.)

`NewUserFnUPP` (page 1418) Deprecated in Mac OS X v10.4

(Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

`PurgeMem` (page 1420) Deprecated in Mac OS X v10.4

Purges the current heap zone until the specified number of bytes are available. (Deprecated. There is no replacement; heaps are never purged in Mac OS X, so this function does nothing.)

`PurgeSpace` (page 1421) Deprecated in Mac OS X v10.4

Determines the total amount of free memory and the size of the largest allocatable block in the current heap zone if it were purged. (Deprecated. There is no replacement; heaps are never purged in Mac OS X.)

`PurgeSpaceContiguous` (page 1421) Deprecated in Mac OS X v10.4

(Deprecated. There is no replacement; heaps are never purged in Mac OS X.)

`PurgeSpaceTotal` (page 1422) Deprecated in Mac OS X v10.4

(Deprecated. There is no replacement; heaps are never purged in Mac OS X.)

`ReleaseMemoryData` (page 1423) Deprecated in Mac OS X v10.4

Releases the data of a portion of the address space. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

`ReserveMem` (page 1424) Deprecated in Mac OS X v10.4

Reserves space for a block of memory as close to the bottom of the current heap zone as possible. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

`SetGrowZone` (page 1425) Deprecated in Mac OS X v10.4

Specifies the current heap zone's grow-zone function. (Deprecated. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

`TempFreeMem` (page 1428) Deprecated in Mac OS X v10.4

Returns the maximum amount of free memory in the temporary heap. (Deprecated. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

`TempHLock` (page 1428) Deprecated in Mac OS X v10.4

Locks a relocatable block in the temporary heap. (Deprecated. Use `HLock` (page 1398) instead; Mac OS X does not have a separate temporary memory heap.)

`TempHUnlock` (page 1429) Deprecated in Mac OS X v10.4

Unlocks a relocatable block in the temporary heap. (Deprecated. Use `HUnlock` (page 1403) instead; Mac OS X does not have a separate temporary memory heap.)

`TempMaxMem` (page 1429) Deprecated in Mac OS X v10.4
: Returns the maximum amount of temporary memory available. (Deprecated. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

`TempTopMem` (page 1430) Deprecated in Mac OS X v10.4
: Returns the location of the top of the temporary heap. (Deprecated. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

`TopMem` (page 1431) Deprecated in Mac OS X v10.4
: Returns a pointer to the byte at the top of an application's partition. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

`UnholdMemory` (page 1431) Deprecated in Mac OS X v10.4
: Makes a currently held range of memory eligible for paging again. (Deprecated. There is no replacement; this function does nothing in Mac OS X.)

Functions

BlockMove

Copies a sequence of bytes from one location in memory to another.

```
static void BlockMove (
   const void *srcPtr,
   void *destPtr,
   Size byteCount
);
```

Parameters

srcPtr
: The address of the first byte to copy.

destPtr
: The destination address.

byteCount
: The number of bytes to copy. If the value of `byteCount` is 0, `BlockMove` does nothing.

Discussion

The `BlockMove` function copies the specified number of bytes from the address designated by srcPtr to that designated by `destPtr`. It updates no pointers.

The `BlockMove` function works correctly even if the source and destination blocks overlap.

You can safely call `BlockMove` at interrupt time. Even though it moves memory, `BlockMove` does not move relocatable blocks, but simply copies bytes.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

The `BlockMove` function currently flushes the processor caches whenever it moves more than 12 bytes. This behavior can adversely affect your application's performance. You might want to avoid calling `BlockMove` to move small amounts of data in memory if there is no possibility of moving stale data or instructions. For more information about stale data and instructions, see the discussion of the processor caches in the chapter "Memory Management Utilities" in *Inside Macintosh: Memory*.

Special Considerations

Beginning in Mac OS X v10.4, the `BlockMove` function is inlined to a direct call to the POSIX `memmove` function. For more information, see the header file `MacMemory.h`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

BlockMoveData

```
static void BlockMoveData (
   const void *srcPtr,
   void *destPtr,
   Size byteCount
);
```

Parameters

srcPtr

destPtr

byteCount

Discussion
You should not make any assumptions about the state of the destination memory while `BlockMoveData` is executing. In the intermediate state, values may be present that are neither the original nor the final ones. For example, this function may use the 'dcbz' instruction. If the underlying memory is not cacheable, if the memory is write-through instead of copy-back, or if the cache block is flushed for some reason, the 'dcbz' instruction will write zeros to the destination. You can avoid the use of the 'dcbz' instruction by calling `BlockMoveDataUncached`, but even that function makes no other guarantees about the memory block's intermediate state.

Special Considerations

Beginning in Mac OS X v10.4, the `BlockMoveData` function is inlined to a direct call to the POSIX `memmove` function. For more information, see the header file `MacMemory.h`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

BlockMoveDataUncached

```
static void BlockMoveDataUncached (
   const void *srcPtr,
   void *destPtr,
   Size byteCount
);
```

Parameters

srcPtr

destPtr

byteCount

Discussion

You should not make any assumptions about the state of the destination memory while `BlockMoveDataUncached` is executing. In the intermediate state, values may be present that are neither the original nor the final ones.

Special Considerations

Beginning in Mac OS X v10.4, the `BlockMoveDataUncached` function is inlined to a direct call to the POSIX `memmove` function. For more information, see the header file `MacMemory.h`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

BlockMoveUncached

```
static void BlockMoveUncached (
   const void *srcPtr,
   void *destPtr,
   Size byteCount
);
```

Parameters

srcPtr

destPtr

byteCount

Special Considerations

Beginning in Mac OS X v10.4, the `BlockMoveUncached` function is inlined to a direct call to the POSIX `memmove` function. For more information, see the header file `MacMemory.h`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`MacMemory.h`

CheckAllHeaps

Checks all known heaps for validity. (Deprecated in Mac OS X v10.4. There is no replacement function; an application has access only to its own heap in Mac OS X.)

```
Boolean CheckAllHeaps (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

CompactMem

Compacts the heap by moving relocatable blocks as needed. (Deprecated in Mac OS X v10.4. There is no replacement function; memory compaction is never needed and never performed in Mac OS X.)

```
Size CompactMem (
   Size cbNeeded
);
```

Parameters

cbNeeded
The size, in bytes, of the block for which CompactMem should attempt to make room.

Return Value
The size, in bytes, of the largest contiguous free block available after compacting the heap zone. CompactMem does not actually allocate that block.

Discussion
The Memory Manager automatically compacts the heap when a memory request fails. However, you can use the CompactMem function to compact the current heap zone manually.

CompactMem compacts the current heap zone not by purging blocks, but rather by moving unlocked, relocatable blocks down until they encounter nonrelocatable blocks or locked, relocatable blocks. CompactMem continues compacting until it either finds a contiguous block of at least cbNeeded free bytes or compacts the entire zone.

To compact the entire heap zone, call CompactMem(maxSize).

Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because CompactMem moves memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

DisposeGrowZoneUPP

(Deprecated in Mac OS X v10.4. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

```
void DisposeGrowZoneUPP (
   GrowZoneUPP userUPP
);
```

Parameters

userUPP

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

MacMemory.h

DisposeHandle

Releases memory occupied by a relocatable block.

```
void DisposeHandle (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Discussion

The `DisposeHandle` function releases the memory occupied by the relocatable block whose handle is `h`. It also frees the handle's master pointer for other uses.

Do not use `DisposeHandle` to dispose of a handle obtained from the Resource Manager (for example, by a previous call to `GetResource`), use `ReleaseResource` instead. If, however, you have called `DetachResource` on a resource handle, you should dispose of the storage by calling `DisposeHandle`.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Special Considerations

After a call to `DisposeHandle`, all handles to the released block become invalid and should not be used again. Any subsequent calls to `DisposeHandle` using an invalid handle might crash your application.

Availability

Available in Mac OS X v10.0 and later.

WhackedTV

Declared In
MacMemory.h

DisposePtr

Releases memory occupied by a nonrelocatable block.

```
void DisposePtr (
   Ptr p
);
```

Parameters

p
A pointer to the nonrelocatable block you want to dispose of.

Discussion
When you no longer need a nonrelocatable block, call the `DisposePtr` function to free it for other uses.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

After a call to `DisposePtr`, all pointers to the released block become invalid and should not be used again. Any subsequent use of a pointer to the released block might cause a system error.

Availability
Available in Mac OS X v10.0 and later.

MacMemory.h

DisposePurgeUPP

(Deprecated in Mac OS X v10.4. There is no replacement function; heaps are never purged in Mac OS X, so the purge function is never called.)

```
void DisposePurgeUPP (
   PurgeUPP userUPP
);
```

Parameters

userUPP

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

DisposeUserFnUPP

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void DisposeUserFnUPP (
   UserFnUPP userUPP
);
```

Parameters
userUPP

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

EmptyHandle

Purges a relocatable block and sets the corresponding handle's master pointer to NULL.

```
void EmptyHandle (
   Handle h
);
```

Parameters
h
A handle to a relocatable block.

Discussion
The EmptyHandle function purges the relocatable block whose handle is h and sets the handle's master pointer to NULL. The EmptyHandle function allows you to free memory taken by a relocatable block without freeing the relocatable block's master pointer for other uses. The block whose handle is h must be unlocked but need not be purgeable.

Note that if there are multiple handles to the relocatable block, then calling the EmptyHandle function empties them all, because all of the handles share a common master pointer. When you later use ReallocateHandle to reallocate space for the block, the master pointer is updated, and all of the handles reference the new block correctly.

To purge all of the blocks in a heap zone that are marked purgeable, use the PurgeMem (page 1420) function.

To free the memory taken up by a relocatable block and release the block's master pointer for other uses, use the DisposeHandle (page 1390) function.

Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

FlushMemory

Makes a portion of the address space clean. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr FlushMemory (
   void *address,
   unsigned long count
);
```

Return Value
This function always returns a value of `noErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

FreeMem

Returns the total amount of free space in the current heap zone. (Deprecated in Mac OS X v10.5. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

```
long FreeMem (
   void
);
```

Return Value
Returns a fixed value for heap size that is compatible with most applications.

Discussion
In Mac OS 8 and 9, this function returns the total amount of free space in the current heap zone. In Mac OS X, this function always returns a large fixed value because applications run in a large, protected memory space.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Special Considerations

Even though `FreeMem` does not move or purge memory, you should not call it at interrupt time because the heap might be in an inconsistent state.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacMemory.h

GetGrowZone

Returns the current heap zone's grow-zone function. (Deprecated in Mac OS X v10.4. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never used.)

```
GrowZoneUPP GetGrowZone (
   void
);
```

Return Value
See the description of the GrowZoneUPP data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

GetHandleSize

Returns the logical size of the relocatable block corresponding to a handle.

```
Size GetHandleSize (
   Handle h
);
```

Parameters

h
A handle to a relocatable block.

Return Value
The logical size, in bytes, of the relocatable block whose handle is h. In case of error, the function return 0.

Discussion
Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

You should not call GetHandleSize at interrupt time because the heap might be in an inconsistent state.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell
SoftVDigX

Declared In
MacMemory.h

GetPtrSize

Returns the logical size of the nonrelocatable block corresponding to a pointer.

```
Size GetPtrSize (
   Ptr p
);
```

Parameters

p
A pointer to a nonrelocatable block.

Return Value
The logical size, in bytes, of the nonrelocatable block pointed to by p. In case of error, the function returns 0.

Discussion
Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

GZSaveHnd

Returns a relocatable block to be protected during grow-zone operations. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
Handle GZSaveHnd (
   void
);
```

Return Value
A handle to a block of memory that the Memory Manager reserves during grow-zone operations. Your grow-zone function must not move, purge, or delete this block. This function returns NULL if there is no such block.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

HandAndHand

Concatenates two relocatable blocks.

```
OSErr HandAndHand (
   Handle hand1,
   Handle hand2
);
```

Parameters

hand1

A handle to the first relocatable block, whose contents do not change but are concatenated to the end of the second relocatable block.

hand2

A handle to the second relocatable block, whose size the Memory Manager expands so that it can concatenate the information from `hand1` to the end of the contents of this block.

Return Value

A result code. See "Memory Manager Result Codes" (page 1443).

Discussion

The `HandAndHand` function concatenates the information from the relocatable block specified by `hand1` onto the end of the relocatable block specified by `hand2`. The `hand1` variable remains unchanged.

Because the `HandAndHand` function dereferences the handle `hand1`, you must call the `HLock` function to lock the block before calling `HandAndHand`. Afterward, you can call the `HUnlock` function to unlock it. Alternatively, you can save the block's original state by calling the `HGetState` function, lock the block by calling `HLock`, and then restore the original settings by calling `HSetState`.

Because `HandAndHand` moves memory, you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacMemory.h`

HandToHand

Copies all of the data from one relocatable block to a new relocatable block.

```
OSErr HandToHand (
   Handle *theHndl
);
```

Parameters

theHndl

A handle to the relocatable block whose data `HandToHand` will copy. On return, `theHndl` contains a handle to a new relocatable block whose data duplicates the original.

Return Value

A result code. See "Memory Manager Result Codes" (page 1443).

Discussion

The `HandToHand` function attempts to copy the information in the relocatable block to which `theHndl` is a handle; if successful, `HandToHand` sets `theHndl` to a handle pointing to the new relocatable block.

If successful in creating a new relocatable block, the HandToHand function does not duplicate the properties of the original block. The new block is unlocked, unpurgeable, and not a resource. Call HLock, HPurge, or HSetRBit (or the combination of HGetState and HSetState) to adjust the properties of the new block.

To copy only part of a relocatable block into a new relocatable block, use the PtrToHand (page 1419) function. Before calling PtrToHand, lock and dereference the handle pointing to the relocatable block you want to copy.

Because HandToHand replaces its parameter with the new handle, you should retain the original parameter value somewhere else, otherwise you will not be able to access it. Here is an example:

```
Handle original, copy;
OSErr myErr;
...
copy = original;
        /*both handles access same block*/
myErr = HandToHand(copy);
        /*copy now points to copy of block*/
```

Because HandToHand allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

HClrRBit

Clears the resource flag of a relocatable block.

```
void HClrRBit (
   Handle h
);
```

Parameters

h

A handle to a relocatable block. HClrRBit does nothing if the flag for the relocatable block pointed to by h is already cleared.

Discussion
The Resource Manager uses this function extensively, but you probably will not need to use it.

To disassociate the data in a resource handle from the resource file, you should use the Resource Manager function DetachResource instead of this function.

Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

HGetState

Returns a signed byte representing the current properties of a relocatable block.

```
SInt8 HGetState (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Return Value

A signed byte (char) containing the flags of the master pointer for the given handle. In case of error, the value returned is meaningless.

Discussion

The `HGetState` function returns a signed byte (char) containing the flags of the master pointer for the given handle. You can save this byte, change the state of any of the flags using the functions described in this section, and then restore their original states by passing the byte to the `HSetState` function.

You can use bit-manipulation functions on the returned signed byte to determine the value of a given attribute. Currently the following bits are used:

If an error occurs during an attempt to get the state flags of the specified relocatable block, `HGetState` returns the low-order byte of the result code as its function result. For example, if the handle `h` points to a master pointer whose value is `NULL`, then the signed byte returned by `HGetState` will contain the value –109.

You may also call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

SoftVDigX

Declared In

`MacMemory.h`

HLock

Prevents a relocatable block from moving within its heap zone.

```
void HLock (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Discussion

If you plan to dereference a handle and then allocate, move, or purge memory (or call a function that does so), then you should lock the handle before using the dereferenced handle.

If the block is already locked, `HLock` does nothing.

If you plan to lock a relocatable block for long periods of time, you can prevent fragmentation by ensuring that the block is as low as possible in the heap zone. To do this, see the description of the `ReserveMem` (page 1424) function.

If you plan to lock a relocatable block for short periods of time, you can prevent heap fragmentation by moving the block to the top of the heap zone before locking. For more information, see the description of the `MoveHHi` (page 1412) function.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTMetaData
SoftVDigX

Declared In
`MacMemory.h`

HLockHi

Sets the lock bit on the block.

```
void HLockHi (
   Handle h
);
```

Parameters

h
A handle to a relocatable block.

Discussion
The `HLockHi` function is an alternative to using the two functions `MoveHHi` (deprecated in Mac OS X) and `HLock`. Because the `MoveHHi` function does not move memory in Mac OS X, there is no benefit to using this function.

This function will not return a meaningful error code. If you call `HLockHi` on a locked handle, it will return `noErr` (not `memLockedErr`) because it is not an error to call `HLock` on a locked handle.

Do not call `HLockHi` on blocks in the system heap. Do not call `HLockHi` from a desk accessory.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

HNoPurge

Marks a relocatable block as unpurgeable. (Deprecated in Mac OS X v10.4. There is no replacement function; heaps are never purged in Mac OS X.)

```
void HNoPurge (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Discussion

The `HNoPurge` function marks the relocatable block, to which `h` is a handle, as unpurgeable. If the block is already unpurgeable, `HNoPurge` does nothing.

The `HNoPurge` function does not reallocate memory for a handle if it has already been purged.

If you want to reallocate memory for a relocatable block that has already been purged, you can use the `ReallocateHandle` (page 1422) function.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

HoldMemory

Makes a portion of the address space resident in physical memory and ineligible for paging. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr HoldMemory (
   void *address,
   unsigned long count
);
```

Parameters

address

A pointer indicating the starting address of the range of memory to be held in RAM.

count

The size, in bytes, of the range of memory to be held in RAM.

Return Value

This function always returns a value of `noErr`.

Discussion
If the starting address you supply to the `HoldMemory` function is not on a page boundary, then `HoldMemory` rounds down to the nearest page boundary. Similarly, if the specified range does not end on a page boundary, `HoldMemory` rounds up the value you pass in the `count` parameter so that the entire range of memory is held.

Even though `HoldMemory` does not move or purge memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

HPurge

Marks a relocatable block as purgeable. (Deprecated in Mac OS X v10.4. There is no replacement function; heaps are never purged in Mac OS X.)

```
void HPurge (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Discussion
The `HPurge` function marks the relocatable block, to which `h` is a handle, as purgeable. If the block is already purgeable, `HPurge` does nothing.

The Memory Manager might purge the block when it needs to purge the heap zone containing the block to satisfy a memory request. A direct call to the `MaxMem` function would also purge blocks marked as purgeable.

Once you mark a relocatable block as purgeable, you should make sure that handles to the block are not empty before you access the block. If they are empty, you must reallocate space for the block and recopy the block's data from another source, such as a resource file, before using the information in the block.

If the block to which `h` is a handle is locked, `HPurge` does not unlock the block but does mark it as purgeable. If you later call `HUnlock` on `h`, the block is subject to purging.

If the Memory Manager has purged a block, you can reallocate space for it by using the `ReallocateHandle` (page 1422) function.

You can immediately free the space taken by a handle without disposing of it by calling the function `EmptyHandle` (page 1392). This function does not require that the block be purgeable.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
MacMemory.h

HSetRBit

Sets the resource flag of a relocatable block.

```
void HSetRBit (
   Handle h
);
```

Parameters

h

A handle to a relocatable block. HSetRBit does nothing if the flag for the relocatable block pointed to by h is already set.

Discussion
The Resource Manager uses this function extensively, but you probably will not need to use it.

When the resource flag is set, the Resource Manager identifies the associated relocatable block as belonging to a resource. This can cause problems if that block wasn't actually read from a resource.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

HSetState

Restores the properties of a relocatable block.

```
void HSetState (
   Handle h,
   SInt8 flags
);
```

Parameters

h

A handle to a relocatable block.

flags

A signed byte (char) specifying the properties to which you want to set the relocatable block.

Discussion
You can use HSetState to restore properties of a block after a call to HGetState. See the description of the `HGetState` function for a list of the currently used bits in the flags byte. Because additional bits of the `flags` byte could become significant in future versions of system software, use `HSetState` only with a byte returned

by HGetState. If you need to set two or three properties of a relocatable block at once, it is better to use the functions that set individual properties than to manipulate the bits returned by HGetState and then call HSetState.

Call the function MemError (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

IsHandleValid

Checks that a handle is valid.

```
Boolean IsHandleValid (
   Handle h
);
```

Parameters

h
The handle to check.

Return Value
Returns `true` if the specified handle is valid. If the handle is `NULL` or if the handle refers to memory which was not properly allocated, `IsHandleValid` returns `false`. In Mac OS 8 and 9, `IsHandleValid` also returns `false` if the given handle is empty. In Mac OS X, however, zero-length blocks are considered valid and `IsHandleValid` returns `true` for an empty handle.

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

IsHeapValid

Always returns true in Mac OS X.

```
Boolean IsHeapValid (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

IsPointerValid

Checks that a pointer is valid.

```
Boolean IsPointerValid (
   Ptr p
);
```

Parameters

p

The pointer to check.

Return Value

Returns `true` if the specified pointer is valid. If the pointer is `NULL` or if the pointer points to memory which was not properly allocated, `IsPointerValid` returns `false`. In Mac OS 8 and 9, `IsPointerValid` also returns `false` if the given pointer points to a zero-length block in memory. In Mac OS X, however, zero-length blocks are considered valid and `IsPointerValid` returns `true`.

Availability

Available in Mac OS X v10.0 and later.

Available in Mac OS X v10.0 and later.

Declared In
MacMemory.h

LMSetSysZone

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSysZone (
   THz value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

MakeMemoryNonResident

Makes pages in the specified range immediately available for reuse. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr MakeMemoryNonResident (
   void *address,
   unsigned long count
);
```

Return Value
This function always returns a value of `noErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

MakeMemoryResident

Makes a portion of the address space resident in physical memory. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr MakeMemoryResident (
   void *address,
   unsigned long count
);
```

Return Value
A result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
MacMemory.h

MaxBlock

Returns a fixed value for block size that is compatible with most applications. (Deprecated in Mac OS X v10.5. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

```
long MaxBlock (
   void
);
```

Return Value
The maximum contiguous space, in bytes, that you could obtain after compacting the current heap zone. `MaxBlock` does not actually do the compaction.

Discussion
In Mac OS X, this function always returns a large value because virtual memory is always available to fulfill any request for memory.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacMemory.h

MaxMem

Returns the size, in bytes, of the largest contiguous free block in the current heap zone. (Deprecated in Mac OS X v10.5. There is no replacement function; you can assume that any reasonable memory allocation will succeed.)

```
Size MaxMem (
   Size *grow
);
```

Parameters

grow

On return, the maximum number of bytes by which the current heap zone can grow. After a call to `MaxApplZone`, `MaxMem` always sets this parameter to 0.

Return Value
The size, in bytes, of the largest contiguous free block in the zone after the compacting and purging.

Discussion
In Mac OS 8 and 9, the `MaxMem` function compacts the current heap zone and purges all relocatable, unlocked, and purgeable blocks from the zone. If the current zone is the original application zone, the `grow` parameter is set to the maximum number of bytes by which the zone can grow. For any other heap zone, `grow` is set to 0. `MaxMem` does not actually expand the zone or call the zone's grow-zone function.

In Mac OS X, the `MaxMem` function returns a large fixed value because applications run in a large, protected memory space.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

MemError

Determines if an application's last direct call to a Memory Manager function executed successfully.

```
OSErr MemError (
   void
);
```

Return Value
A result code. See "Memory Manager Result Codes" (page 1443).

Discussion
For each thread, `MemError` yields the result code produced by the last Memory Manager function your application called directly.

`MemError` is useful during application debugging. You might also use `MemError` as one part of a memory-management scheme to identify instances in which the Memory Manager rejects overly large memory requests by returning the error code `memFullErr`.

To view the result codes that `MemError` can produce, see "Memory Manager Result Codes" (page 1443).

Do not rely on `MemError` as the only component of a memory-management scheme. For example, suppose you call `NewHandle` or `NewPtr` and receive the result code `noErr`, indicating that the Memory Manager was able to allocate sufficient memory. In this case, you have no guarantee that the allocation did not deplete your application's memory reserves to levels so low that simple operations might cause your application to crash. Instead of relying on `MemError`, check before making a memory request that there is enough memory both to fulfill the request and to support essential operations.

Version Notes
Starting with Mac OS X v10.3, the `MemError` function provides error codes on a per-thread basis.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

MoreMasterPointers

Allocates a specified number of master pointers in the current heap zone. (Deprecated in Mac OS X v10.4. There is no replacement function; master pointers do not need to be pre-allocated in Mac OS X.)

```
void MoreMasterPointers (
   UInt32 inCount
);
```

Parameters

inCount

The number of master pointers you want to allocate in a single nonrelocatable block.

Carbon Porting Notes

Carbon applications should use this function instead of `MoreMasters` to allocate a nonrelocatable block of master pointers in the current heap zone.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

MoreMasters

Allocates a block of master pointers in the current heap zone. (Deprecated in Mac OS X v10.4. There is no replacement function; master pointers do not need to be pre-allocated in Mac OS X.)

```
void MoreMasters (
   void
);
```

Discussion
In the application heap, a block of master pointers consists of 64 master pointers, and in the system heap, a block consists of 32 master pointers. (These values are likely to increase in future versions of system software.) When you initialize additional heap zones, you can specify the number of master pointers you want to have in a block of master pointers.

The Memory Manager automatically calls the `MoreMasters` function once for every new heap zone, including the application heap zone.

Call `MoreMasters` several times at the beginning of your program to prevent the Memory Manager from running out of master pointers in the middle of application execution. If it does run out, it allocates more, possibly causing heap fragmentation.

You should call `MoreMasters` at the beginning of your program enough times to ensure that the Memory Manager never needs to call it for you. For example, if your application never allocates more than 300 relocatable blocks in its heap zone, then five calls to the `MoreMasters` should be enough. It's better to call `MoreMasters` too many times than too few. For instance, if your application usually allocates about 100 relocatable blocks but might allocate 1000 in a particularly busy session, call `MoreMasters` enough times to accommodate the largest amount.

If you initialize a new zone, you can specify the number of master pointers that a master pointer block should contain.

Call the `MemError` (page 1410) function to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `MoreMasters` allocates memory, you should not call it at interrupt time.

The calls to `MoreMasters` at the beginning of your application should be in the main code segment of your application or in a segment that the main segment never unloads.

Carbon Porting Notes

You should instead use `MoreMasterPointers` (page 1411).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

MoveHHi

Moves a relocatable block as high in memory as possible. (Deprecated in Mac OS X v10.4. There is no replacement function; there is no benefit to moving handles high in memory in Mac OS X.)

```
void MoveHHi (
   Handle h
);
```

Parameters

h

A handle to a relocatable block.

Discussion

This function moves a relocatable block as high in memory as possible to help prevent heap fragmentation. The `MoveHHi` function attempts to move the relocatable block referenced by the handle `h` upward until it reaches a nonrelocatable block, a locked relocatable block, or the top of the heap.

If you plan to lock a relocatable block for a short period of time, use the `MoveHHi` function, which moves the block to the top of the heap and thus helps prevent heap fragmentation.

If you call `MoveHHi` to move a handle to a resource that has its `resChanged` bit set, the Resource Manager updates the resource by using the `WriteResource` function to write the contents of the block to disk. If you want to avoid this behavior, call the Resource Manager function `SetResPurge(FALSE)` before you call `MoveHHi`, and then call `SetResPurge(TRUE)` to restore the default setting.

By using the `MoveHHi` function on relocatable blocks you plan to allocate for short periods of time, you help prevent islands of immovable memory from accumulating in (and thus fragmenting) the heap.

Do not use the `MoveHHi` function to move blocks you plan to lock for long periods of time. The `MoveHHi` function moves such blocks to the top of the heap, perhaps preventing other blocks already at the top of the heap from moving down once they are unlocked. Instead, use the `ReserveMem` function before allocating such blocks, thus keeping them in the bottom partition of the heap, where they do not prevent relocatable blocks from moving.

If you frequently lock a block for short periods of time and find that calling `MoveHHi` each time slows down your application, you might consider leaving the block always locked and calling the `ReserveMem` function before allocating it.

Once you move a block to the top of the heap, be sure to lock it if you do not want the Memory Manager to move it back to the middle partition as soon as it can. (The `MoveHHi` function cannot move locked blocks; be sure to lock blocks after, not before, calling `MoveHHi`.)

Using the `MoveHHi` function without taking other precautionary measures to prevent heap fragmentation is useless, because even one small nonrelocatable or locked relocatable block in the middle of the heap might prevent `MoveHHi` from moving blocks to the top of the heap.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

NewEmptyHandle

Initializes a new handle without allocating any memory for it to control.

```
Handle NewEmptyHandle (
   void
);
```

Return Value
A handle with its master pointer set to `NULL`.

Discussion
The Resource Manager uses this function extensively, but you probably will not need to use it.

When you want to allocate memory for the empty handle, use the `ReallocateHandle` (page 1422) function.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

NewGrowZoneUPP

(Deprecated in Mac OS X v10.4. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

```
GrowZoneUPP NewGrowZoneUPP (
   GrowZoneProcPtr userRoutine
);
```

Parameters
userRoutine

Return Value
See the description of the `GrowZoneUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

NewHandle

Allocates a new relocatable memory block of a specified size in the current heap zone.

```
Handle NewHandle (
   Size byteCount
);
```

Parameters
byteCount
The requested size, in bytes, of the relocatable block. Maximum size is 2 GB, the maximum size for variables of type `Size`.

Return Value
A handle to the new block. If `NewHandle` cannot allocate a block of the requested size, it returns `NULL`.

Discussion
The `NewHandle` function pursues all available avenues to create a block of the requested size, including compacting the heap zone, increasing its size, and purging blocks from it. If all of these techniques fail and the heap zone has a grow-zone function installed, `NewHandle calls the function`. Then `NewHandle`

tries again to free the necessary amount of memory, once more compacting and purging the heap zone if necessary. If `NewHandle` still cannot allocate memory, `NewHandle` calls the grow-zone function again, unless that function had returned 0, in which case `NewHandle` gives up and returns `NULL`.

If the `NewHandle` function succeeds in creating the requested block, this new block is unlocked and unpurgeable.

If you allocate a relocatable block that you plan to lock for long periods of time, you can prevent heap fragmentation by allocating the block as low as possible in the heap zone. To do this, see the description of the function `ReserveMem` (page 1424).

If you plan to lock a relocatable block for short periods of time, you might want to move it to the top of the heap zone to prevent heap fragmentation. For more information, see the description of the function `MoveHHi` (page 1412).

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `NewHandle` allocates memory, you should not call it at interrupt time.

Do not try to manufacture your own handles without this function by simply assigning the address of a variable of type `Ptr` to a variable of type `Handle`. The resulting "fake handle" would not reference a relocatable block and could cause a system crash.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

NewHandleClear

Allocates a relocatable block of memory of a specified size with all its bytes set to 0.

```
Handle NewHandleClear (
   Size byteCount
);
```

Parameters

byteCount
The requested size (in bytes) of the relocatable block. The `NewHandleClear` function sets each of these bytes to 0.

Return Value
A handle to the new block. If `NewHandleClear` cannot allocate a block of the requested size, it returns `NULL`.

Discussion
The `NewHandleClear` function works like the `NewHandle` function, but sets all bytes in the new block to 0 instead of leaving the contents of the block undefined.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `NewHandleClear` allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
LiveVideoMixer2
SoftVDigX

Declared In
`MacMemory.h`

NewPtr

Allocates a nonrelocatable block of memory of a specified size.

```
Ptr NewPtr (
   Size byteCount
);
```

Parameters

byteCount

The requested size (in bytes) of the nonrelocatable block. In Mac OS X, if you pass a value of zero, this function returns NULL, and `MemError` is set to `paramErr`. In Mac OS 9 and earlier, if you pass a value of zero, this function returns a valid zero length pointer.

Return Value
A pointer to the new block. If `NewPtr` fails to allocate a block of the requested size, it returns `NULL`.

Discussion
The `NewPtr` function attempts to reserve space as low in the heap zone as possible for the new block. If it is able to reserve the requested amount of space, `NewPtr` allocates the nonrelocatable block in the gap `ReserveMem` creates. Otherwise, `NewPtr` returns `NULL` and generates a `memFullErr` error.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `NewPtr` allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

NewPtrClear

Allocates a nonrelocatable block of memory of a specified size with all its bytes set to 0.

```
Ptr NewPtrClear (
   Size byteCount
);
```

Parameters

byteCount

The requested size (in bytes) of the nonrelocatable block.

Return Value

A pointer to the new block. If NewPtrClear fails to allocate a block of the requested size, it returns `NULL`.

Discussion

The `NewPtrClear` function works much as the `NewPtr` function does, but sets all bytes in the new block to 0 instead of leaving the contents of the block undefined.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `NewPtrClear` allocates memory, you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

NewPurgeUPP

(Deprecated in Mac OS X v10.4. There is no replacement function; heaps are never purged in Mac OS X, so the purge function is never called.)

```
PurgeUPP NewPurgeUPP (
   PurgeProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `PurgeUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
MacMemory.h

NewUserFnUPP

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UserFnUPP NewUserFnUPP (
   UserFnProcPtr userRoutine
);
```

Parameters
userRoutine

Return Value
See the description of the UserFnUPP data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

PtrAndHand

Concatenates part or all of a memory block to the end of a relocatable block.

```
OSErr PtrAndHand (
   const void *ptr1,
   Handle hand2,
   long size
);
```

Parameters
ptr1
A pointer to the beginning of the data that the Memory Manager is to concatenate onto the end of the relocatable block.
hand2
A handle to the relocatable block, whose size the Memory Manager expands so that it can concatenate the information from ptr1 onto the end of this block.
size
The number of bytes of the block referenced by ptr1 to copy.

Return Value
A result code. See "Memory Manager Result Codes" (page 1443).

Discussion
The PtrAndHand function takes the number of bytes specified by the size parameter, beginning at the location specified by ptr1, and concatenates them onto the end of the relocatable block to which hand2 is a handle. The contents of the source block remain unchanged.

Because `PtrAndHand` allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`MacMemory.h`

PtrToHand

Copies data referenced by a pointer to a new relocatable block.

```
OSErr PtrToHand (
   const void *srcPtr,
   Handle *dstHndl,
   long size
);
```

Parameters

srcPtr
The address of the first byte to copy.

dstHndl
A handle for which you have not yet allocated any memory. The `PtrToHand` function allocates memory for the handle and copies the specified number of bytes beginning at `srcPtr` into it. The dstHndl parameter is an output parameter that will hold the result. Its value on entry is ignored. If no error occurs, on exit it points to an unlocked, non-purgeable Handle of the requested size.

size
The number of bytes to copy.

Return Value
A result code. See "Memory Manager Result Codes" (page 1443).

Discussion
If you dereference and lock a handle, the `PtrToHand` function can copy its data to a new handle. However, for copying data from one handle to another, the `HandToHand` (page 1396) function is more efficient.

Because `PtrToHand` allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

PtrToXHand

Copies data referenced by a pointer to an existing relocatable block.

```
OSErr PtrToXHand (
   const void *srcPtr,
   Handle dstHndl,
   long size
);
```

Parameters

srcPtr

The address of the first byte to copy.

dstHndl

A handle to an existing relocatable block.

size

The number of bytes to copy.

Return Value

A result code. See "Memory Manager Result Codes" (page 1443).

Discussion

The `PtrToXHand` function copies the specified number of bytes from the location specified by `srcPtr` to the handle specified by `dstHndl`.

Because `PtrToXHand` affects memory, you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacMemory.h`

PurgeMem

Purges the current heap zone until the specified number of bytes are available. (Deprecated in Mac OS X v10.4. There is no replacement; heaps are never purged in Mac OS X, so this function does nothing.)

```
void PurgeMem (
   Size cbNeeded
);
```

Parameters

cbNeeded

The size, in bytes, of the block for which `PurgeMem` should attempt to make room.

Discussion

The Memory Manager purges the heap automatically when a memory request fails. However, you can use `PurgeMem` to purge the current heap zone manually.

The `PurgeMem` function sequentially purges blocks from the current heap zone until it either allocates a contiguous block of the specified size or purges the entire zone. If `PurgeMem` purges the entire zone without creating a contiguous block of the specified size, `PurgeMem` generates the result code `memFullErr`.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

The `PurgeMem` function purges only relocatable, unlocked, purgeable blocks. The function does not actually attempt to allocate the memory.

To purge the entire heap zone, call `PurgeMem(maxSize)`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

PurgeSpace

Determines the total amount of free memory and the size of the largest allocatable block in the current heap zone if it were purged. (Deprecated in Mac OS X v10.4. There is no replacement; heaps are never purged in Mac OS X.)

```
void PurgeSpace (
   long *total,
   long *contig
);
```

Parameters

total

On return, the total amount of free memory, in bytes, in the current heap zone if it were purged. This amount includes space that is already free.

contig

On return, the size of the largest contiguous block of free memory in the current heap zone if it were purged.

Discussion
The `PurgeSpace` function does not actually purge the current heap zone.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

PurgeSpaceContiguous

(Deprecated in Mac OS X v10.4. There is no replacement; heaps are never purged in Mac OS X.)

```
long PurgeSpaceContiguous (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

PurgeSpaceTotal

(Deprecated in Mac OS X v10.4. There is no replacement; heaps are never purged in Mac OS X.)

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

ReallocateHandle

Allocates a new relocatable block of a specified size and sets a handle's master pointer to point to the new block.

```
void ReallocateHandle (
   Handle h,
   Size byteCount
);
```

Parameters

h

A handle to a relocatable block.

byteCount

The desired new logical size (in bytes) of the relocatable block. The new block is unlocked and unpurgeable.

Discussion
Usually you use `ReallocateHandle` to reallocate space for a block that you have emptied or the Memory Manager has purged. If the handle references an existing block, `ReallocateHandle` releases that block before creating a new one.

If many handles reference a single purged, relocatable block, you need to call `ReallocateHandle` on just one of them.

To reallocate space for a resource that has been purged, you should call `LoadResource`, not `ReallocateHandle`. To resize relocatable blocks, you should call the `SetHandleSize` (page 1425) function.

Currently in Mac OS 8 and 9, the `ReallocateHandle` function releases any existing relocatable block referenced by the handle `h` before allocating a new one. This behavior means that if an error occurs when calling `ReallocateHandle`, the handle `h` will be set to `NULL`. This behavior does not occur in the Mac OS X implementation.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `ReallocateHandle` might purge and allocate memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

RecoverHandle

Returns a handle to a relocatable block pointed to by a specified `pointer`.

```
Handle RecoverHandle (
   Ptr p
);
```

Parameters

p
The master pointer to a relocatable block.

Return Value
A handle to a relocatable block point to by p. If `p` does not point to a valid block, the results of `RecoverHandle` are undefined.

Discussion
The Memory Manager does not allow you to change relocatable blocks into nonrelocatable blocks, or vice-versa. However, if you no longer have access to a handle but still have access to its master pointer p, you can use the `RecoverHandle` function to recreate a handle to the relocatable block referenced by p.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Even though `RecoverHandle` does not move or purge memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

ReleaseMemoryData

Releases the data of a portion of the address space. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr ReleaseMemoryData (
   void *address,
   unsigned long count
);
```

Return Value
This function always returns a value of `noErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

ReserveMem

Reserves space for a block of memory as close to the bottom of the current heap zone as possible. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
void ReserveMem (
   Size cbNeeded
);
```

Parameters

cbNeeded
The number of bytes to reserve near the bottom of the heap.

Discussion
The `ReserveMem` function attempts to create free space for the specified number of contiguous logical bytes at the lowest possible position in the current heap zone. It pursues every available means of placing the block as close as possible to the bottom of the zone, including moving other relocatable blocks upward, expanding the zone (if possible), and purging blocks from it.

Use the `ReserveMem` function when allocating a relocatable block that you intend to lock for long periods of time. This helps prevent heap fragmentation because it reserves space for the block as close to the bottom of the heap as possible. Consistent use of `ReserveMem` for this purpose ensures that all locked, relocatable blocks and nonrelocatable blocks are together at the bottom of the heap zone and thus do not prevent unlocked relocatable blocks from moving about the zone.

Because `ReserveMem` does not actually allocate the block, you must combine calls to `ReserveMem` with calls to the `NewHandle` function.

Do not use the `ReserveMem` function for a relocatable block you intend to lock for only a short period of time. If you do so and then allocate a nonrelocatable block above it, the relocatable block becomes trapped under the nonrelocatable block when you unlock that relocatable block.

It isn't necessary to call `ReserveMem` to reserve space for a nonrelocatable block, because the `NewPtr` function calls it automatically.

Also, you do not need to call `ReserveMem` to reserve memory before you load a locked resource into memory, because the Resource Manager calls `ReserveMem` automatically.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because the `ReserveMem` function could move and purge memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

SetGrowZone

Specifies the current heap zone's grow-zone function. (Deprecated in Mac OS X v10.4. There is no replacement function; heaps never grow in Mac OS X, so the grow-zone function is never called.)

```
void SetGrowZone (
   GrowZoneUPP growZone
);
```

Parameters

growZone

A pointer to the grow-zone function. A `NULL` value removes any previous grow-zone function from the zone.

Discussion
To specify a grow-zone function for the current heap zone, pass a pointer to that function to the `SetGrowZone` function. Usually you call this function early in the execution of your application.

If you initialize your own heap zones besides the application and system zones, you can alternatively specify a grow-zone function as a parameter to the `InitZone` function.

The Memory Manager calls the grow-zone function only after exhausting all other avenues of satisfying a memory request, including compacting the zone, increasing its size (if it is the original application zone and is not yet at its maximum size), and purging blocks from it.

See "Grow-Zone Operations" for a complete description of a grow-zone function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

SetHandleSize

Changes the logical size of the relocatable block corresponding to the specified handle.

```
void SetHandleSize (
   Handle h,
   Size newSize
);
```

Parameters

h

A handle to a relocatable block.

newSize

The desired new logical size, in bytes, of the relocatable block.

Discussion

`SetHandleSize` tries to change the size of the allocation to *newSize*. If there is not enough room to enlarge the memory allocation pointed to by *h*, `SetHandleSize` creates a new allocation, copies as much of the old data pointed to by *h* as will fit to the new allocation, and frees the old allocation. `SetHandleSize` might need to move the relocatable block to obtain enough space for the resized block. Thus, for best results you should unlock a block before resizing it.

An attempt to increase the size of a locked block might fail, because of blocks above and below it that are either nonrelocatable or locked. You should be prepared for this possibility.

Instead of using the `SetHandleSize` function to set the size of a handle to `0`, you can use the `EmptyHandle` (page 1392) function.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `SetHandleSize` allocates memory, you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

SoftVDigX

Declared In

`MacMemory.h`

SetPtrSize

Changes the logical size of the nonrelocatable block corresponding to a pointer.

```
void SetPtrSize (
   Ptr p,
   Size newSize
);
```

Parameters

p

A pointer to a nonrelocatable block.

newSize

The desired new logical size, in bytes, of the nonrelocatable block.

Discussion
An attempt to increase the size of a nonrelocatable block might fail because of a block above it that is either nonrelocatable or locked. You should be prepared for this possibility.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Because `SetPtrSize` allocates memory, you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacMemory.h`

StackSpace

Returns the amount of space between the bottom of the stack and the top of the application heap. (Deprecated in Mac OS X v10.5. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
long StackSpace (
   void
);
```

Return Value
The current amount of stack space, in bytes, between the current stack pointer and the application heap.

Discussion
Usually you determine the maximum amount of stack space needed before you ship your application. Thus this function is generally useful only during debugging to determine how big to make the stack. However, if your application calls a recursive function that conceivably could call itself many times, that function should keep track of the stack space and take appropriate action if it becomes too low.

Call the function `MemError` (page 1410) to get the result code. See "Memory Manager Result Codes" (page 1443).

Special Considerations

StackSpace must not be called at interrupt time, as it may alter location MemErr.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

TempDisposeHandle

Releases a relocatable block in the temporary heap. (Deprecated in Mac OS X v10.5. Use `DisposeHandle` (page 1390) instead; Mac OS X does not have a separate temporary memory heap.)

```
void TempDisposeHandle (
   Handle h,
   OSErr *resultCode
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

TempFreeMem

Returns the maximum amount of free memory in the temporary heap. (Deprecated in Mac OS X v10.4. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

```
long TempFreeMem (
   void
);
```

Return Value
The total amount of free temporary memory, in bytes, that you could allocate by calling `TempNewHandle`. Because these bytes might be dispersed throughout memory, it is ordinarily not possible to allocate a single relocatable block of that size.

Discussion
Returns the total amount of memory available for temporary allocation.

Special Considerations

In Mac OS X, there is no separate temporary memory heap. This function always returns a large value, because virtual memory is always available to fulfill any request for memory. You can assume that any reasonable memory allocation request will succeed.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

TempHLock

Locks a relocatable block in the temporary heap. (Deprecated in Mac OS X v10.4. Use `HLock` (page 1398) instead; Mac OS X does not have a separate temporary memory heap.)

```
void TempHLock (
   Handle h,
   OSErr *resultCode
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

TempHUnlock

Unlocks a relocatable block in the temporary heap. (Deprecated in Mac OS X v10.4. Use `HUnlock` (page 1403) instead; Mac OS X does not have a separate temporary memory heap.)

```
void TempHUnlock (
   Handle h,
   OSErr *resultCode
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacMemory.h

TempMaxMem

Returns the maximum amount of temporary memory available. (Deprecated in Mac OS X v10.4. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

```
Size TempMaxMem (
   Size *grow
);
```

Parameters

grow

On return, this parameter always contains 0 after the function call because temporary memory does not come from the application's heap zone, and only that zone can grow. Ignore this parameter.

Return Value
The size of the largest contiguous block available for temporary allocation.

Discussion
Compacts the current heap zone and returns the size of the largest contiguous block available for temporary allocation.

Special Considerations

In Mac OS X, there is no separate temporary memory heap. This function always returns a large value, because virtual memory is always available to fulfill any request for memory. You can assume that any reasonable memory allocation request will succeed.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

TempNewHandle

Allocates a new relocatable block of temporary memory.

```
Handle TempNewHandle (
   Size logicalSize,
   OSErr *resultCode
);
```

Parameters

`logicalSize`

The requested logical size, in bytes, of the new temporary block of memory.

`resultCode`

On return, the result code from the function call. See "Memory Manager Result Codes" (page 1443).

Return Value

A handle to a block of size `logicalSize`. If it cannot allocate a block of that size, the function returns `NULL`.

Discussion

Before calling `TempNewHandle`, you should call `TempFreeMem` or `TempMaxMem` to make sure that there is enough free space to satisfy the request.

Because `TempNewHandle` might allocate memory, you should not call it at interrupt time.

Carbon Porting Notes

Temporary memory allocations will actually come from the applications's address space in Mac OS X. However, Carbon applications running under Mac OS 8.x will be able to get true temporary memory.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacMemory.h`

TempTopMem

Returns the location of the top of the temporary heap. (Deprecated in Mac OS X v10.4. There is no replacement function; Mac OS X does not have a separate temporary memory heap.)

```
Ptr TempTopMem (
   void
);
```

Discussion
In Mac OS X, this function always returns `NULL`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

TopMem

Returns a pointer to the byte at the top of an application's partition. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
Ptr TopMem (
   void
);
```

Discussion
Deprecated. Refer to `MacMemory.h` for information on replacement functions.

`TopMem` obtains a pointer to the byte at the top of an application's partition, directly above the jump table. `TopMem` does this to maintain compatibility with programs that check `TopMem` to find out how much memory is installed in a computer. The preferred method of obtaining this information is with the `Gestalt` function.

The function exhibits special behavior at startup time, and the value it returns controls the amount by which an extension can lower the value of the global variable `BufPtr` at startup time. If you are writing a system extension, you should not lower the value of `BufPtr` by more than `MemTop DIV 2 + 1024`. If you do lower `BufPtr` too far, the startup process generates an out-of-memory system error.

You should never need to call `TopMem` except during the startup process.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

UnholdMemory

Makes a currently held range of memory eligible for paging again. (Deprecated in Mac OS X v10.4. There is no replacement; this function does nothing in Mac OS X.)

```
OSErr UnholdMemory (
   void *address,
   unsigned long count
);
```

Parameters

address

A pointer indicating the starting address of the range of memory to be released.

count

The size, in bytes, of the range of memory to be released.

Return Value

This function always returns a value of `noErr`.

Discussion

If the starting address you supply to the `UnholdMemory` function is not on a page boundary, then `UnholdMemory` rounds down to the nearest page boundary. Similarly, if the specified range does not end on a page boundary, `UnholdMemory` rounds up the value you pass in the `count` parameter so that the entire range of memory is released.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

Callbacks

All Memory Manager callbacks are deprecated in Mac OS X. They are non-functional.

GrowZoneProcPtr

Deprecated.

```
typedef long (*GrowZoneProcPtr) (
    Size cbNeeded
);
```

If you name your function `MyGrowZoneProc`, you would declare it like this:

```
long MyGrowZoneProc (
    Size cbNeeded
);
```

Parameters

cbNeeded

The physical size, in bytes, of the needed block, including the block header. The grow-zone function should attempt to create a free block of at least this size.

Return Value
The number of bytes of memory the function has freed.

Discussion
User-defined function that creates free space in the heap.

Whenever the Memory Manager has exhausted all available means of creating space within your application heap—including purging, compacting, and (if possible) expanding the heap—it calls your application-defined grow-zone function. The grow-zone function can do whatever is necessary to create free space in the heap. Typically, a grow-zone function marks some unneeded blocks as purgeable or releases an emergency memory reserve maintained by your application.

The grow-zone function should return a nonzero value equal to the number of bytes of memory it has freed, or zero if it is unable to free any. When the function returns a nonzero value, the Memory Manager once again purges and compacts the heap zone and tries to reallocate memory. If there is still insufficient memory, the Memory Manager calls the grow-zone function again (but only if the function returned a nonzero value the previous time it was called). This mechanism allows your grow-zone function to release just a little bit of memory at a time. If the amount it releases at any time is not enough, the Memory Manager calls it again and gives it the opportunity to take more drastic measures.

The Memory Manager might designate a particular relocatable block in the heap as protected; your grow-zone function should not move or purge that block. You can determine which block, if any, the Memory Manager has protected by calling the `GZSaveHnd` function in your grow-zone function.

Remember that the Memory Manager calls a grow-zone function while attempting to allocate memory. As a result, your grow-zone function should not allocate memory itself or perform any other actions that might indirectly cause memory allocation (such as calling functions in unloaded code segments or displaying dialog boxes).

You install a grow-zone function by passing its address to the `InitZone` function when you create a new heap zone or by calling the `SetGrowZone` function at any other time.

Your grow-zone function might be called at a time when the system is attempting to allocate memory and the value in the A5 register is not correct. If your function accesses your application's A5 world or makes any trap calls, you need to set up and later restore the A5 register by calling `SetCurrentA5` and `SetA5`. See the chapter "Memory Management Utilities" in this book for a description of these two functions.

Because of the optimizations performed by some compilers, the actual work of the grow-zone function and the setting and restoring of the A5 register might have to be placed in separate functions.

See the chapter "Introduction to Memory Management" for a definition of a sample grow-zone function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

PurgeProcPtr

Deprecated.

```
typedef void (*PurgeProcPtr) (
    Handle blockToPurge
);
```

If you name your function `MyPurgeProc`, you would declare it like this:

```
void MyPurgeProc (
    Handle blockToPurge
);
```

Parameters

blockToPurge

A handle to the block that is about to be purged.

Discussion

User-defined function called when the Memory Manager needs to purge a block or allocate memory.

Whenever the Memory Manager needs to purge a block from the application heap, it first calls any application-defined purge-warning function that you have installed. The purge-warning function can, if necessary, save the contents of that block or otherwise respond to the warning.

Your purge-warning function is called during a memory-allocation request. As a result, you should not call any functions that might cause memory to be moved or purged. In particular, if you save the data of the block in a file, the file should already be open when your purge-warning function is called, and you should write the data synchronously.

You should not dispose of or change the purgeable status of the block whose handle is passed to your function.

To install a purge-warning function, you need to assign its address to the `purgeProc` field of the associated zone header.

Note that if you call the Resource Manager function `SetResPurge` with the parameter `TRUE`, any existing purge-warning function is replaced by a purge-warning function installed by the Resource Manager. You can execute both warning functions by calling `SetResPurge`, saving the existing value of the `purgeProc` field of the zone header, and then reinstalling your purge-warning function. Your purge-warning function should call the Resource Manager's purge-warning function internally.

Your purge-warning function might be called at a time when the system is attempting to allocate memory and the value in the A5 register is not correct. If your function accesses your application's A5 world or makes any trap calls, you need to set up and later restore the A5 register by calling `SetCurrentA5` and `SetA5`.

Because of the optimizations performed by some compilers, the actual work of the purge-warning function and the setting and restoring of the A5 register might have to be placed in separate functions.

The Memory Manager calls your purge-warning function for every handle that is about to be purged (not necessarily for every purgeable handle in your heap, however). Your function should be able to determine quickly whether the handle that the Memory Manager is about to purge points to data you need to save or otherwise process.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacMemory.h

UserFnProcPtr

Deprecated.

```
typedef void (*UserFnProcPtr) (
    void *parameter
);
```

If you name your function `MyUserFnProc`, you would declare it like this:

```
void MyUserFnProc (
    void * parameter
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacMemory.h

Data Types

All Memory Manager data types are deprecated in Mac OS X. They are not used.

BackingFileID

Deprecated.

```
typedef struct * BackingFileID;
```

Special Considerations

FileViewAccess

Deprecated.

```
typedef UInt32 FileViewAccess;
enum {
    kFileViewAccessReadBit = 0,
    kFileViewAccessWriteBit = 1,
    kFileViewAccessExecuteBit = 2,
    kFileViewAccessReadMask = 1,
    kFileViewAccessWriteMask = 2,
    kFileViewAccessExecuteMask = 4,
    kFileViewAccessExcluded = 0,
    kFileViewAccessReadOnly = 5,
    kFileViewAccessReadWrite = 7
};
```

Special Considerations

FileViewID

Deprecated.

```
typedef struct * FileViewID;
```

Special Considerations

FileViewInformation

Deprecated.

```
struct FileViewInformation {
    ProcessSerialNumber owningProcess;
    LogicalAddress viewBase;
    ByteCount viewLength;
    BackingFileID backingFile;
    UInt64 backingBase;
    FileViewAccess access;
    ByteCount guardLength;
    FileViewOptions options;
};
```

FileViewOptions

Deprecated.

```
typedef OptionBits FileViewOptions;
```

GrowZoneUPP

Deprecated.

```
typedef GrowZoneProcPtr GrowZoneUPP;
```

Discussion
For more information, see the description of the GrowZoneUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

LogicalToPhysicalTable

Deprecated.

```
struct LogicalToPhysicalTable {
    MemoryBlock logical;
    MemoryBlock physical[8];
};
typedef struct LogicalToPhysicalTable LogicalToPhysicalTable;
```

Fields

`logical`
A logical block of memory whose corresponding physical blocks are to be determined.

`physical`
A physical translation table that identifies the blocks of physical memory corresponding to the logical block identified in the `logical` field.

Discussion
The `GetPhysical` function uses a translation table to hold information about a logical address range and its corresponding physical addresses. A translation table is defined by the data type LogicalToPhysicalTable.

Special Considerations

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

MappedFileAttributes

Deprecated.

```
typedef UInt32 MappedFileAttributes;
enum {
    kIsMappedScratchFile = 1
};
```

MappedFileInformation

Deprecated.

```
struct MappedFileInformation {
    ProcessSerialNumber owningProcess;
    FSRef *ref;
    HFSUniStr255 *forkName;
    MappingPrivileges privileges;
    UInt64 currentSize;
    MappedFileAttributes attributes;
};
```

MappingPrivileges

Deprecated.

```
typedef UInt32 MappingPrivileges;
enum {
    kInvalidMappedPrivileges = 0,
    kCanReadMappedFile = 1,
    kCanWriteMappedFile = 2,
    kNoProcessMappedFile = -2147483648,
    kValidMappingPrivilegesMask = -2147483645
};
```

Special Considerations

MemoryBlock

Deprecated.

```
struct MemoryBlock {
    void * address;
    unsigned long count;
};
typedef struct MemoryBlock MemoryBlock;
```

Fields

`address`
A pointer to the beginning of a block of memory.

`count`
The number of bytes in the block of memory.

Discussion

The `GetPhysical` function uses a structure of type MemoryBlock to hold information about a block of memory, either logical or physical.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacMemory.h`

PurgeUPP

Deprecated.

```
typedef PurgeProcPtr PurgeUPP;
```

Discussion
For more information, see the description of the PurgeUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

StatusRegisterContents

Deprecated.

```
typedef  StatusRegisterContents;
```

Special Considerations

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

UserFnUPP

Deprecated.

```
typedef UserFnProcPtr UserFnUPP;
```

Discussion
For more information, see the description of the UserFnUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

VolumeVirtualMemoryInfo

Deprecated.

```
struct VolumeVirtualMemoryInfo {
    PBVersion version;
    SInt16 volumeRefNum;
    Boolean inUse;
    UInt8 _fill;
    UInt32 vmOptions;
};
typedef struct VolumeVirtualMemoryInfo VolumeVirtualMemoryInfo;
typedef VolumeVirtualMemoryInfo * VolumeVirtualMemoryInfoPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

Zone

Deprecated.

```
struct Zone {
    Ptr bkLim;
    Ptr purgePtr;
    Ptr hFstFree;
    long zcbFree;
    GrowZoneUPP gzProc;
    short moreMast;
    short flags;
    short cntRel;
    short maxRel;
    short cntNRel;
    SInt8 heapType;
    SInt8 unused;
    short cntEmpty;
    short cntHandles;
    long minCBFree;
    PurgeUPP purgeProc;
    Ptr sparePtr;
    Ptr allocPtr;
    short heapData;
};
typedef struct Zone Zone;
typedef Zone * THz;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacMemory.h`

Constants

All Memory Manager constants are deprecated in Mac OS X. They are not used.

Default Physical Entry Count Constant

Deprecated.

```
enum {
    defaultPhysicalEntryCount = 8
};
```

Discussion
The defaultPhysicalEntryCount constant represents the default number of physical blocks in a table.

k32BitHeap

Deprecated.

```
enum {
    k32BitHeap = 1,
    kNewStyleHeap = 2,
    kNewDebugHeap = 4
};
```

kFileViewInformationVersion1

Deprecated.

```
enum {
    kFileViewInformationVersion1 = 1
};
```

kHandleIsResourceBit

Deprecated.

```
enum {
    kHandleIsResourceBit = 5,
    kHandlePurgeableBit = 6,
    kHandleLockedBit = 7
};
```

kHandleIsResourceMask

Deprecated.

```
enum {
    kHandleIsResourceMask = 0x20,
    kHandlePurgeableMask = 0x40,
    kHandleLockedMask = 0x80
};
```

kMapEntireFork

Deprecated.

```
enum {
    kMapEntireFork = -1
};
```

Constants
`kMapEntireFork`

kMappedFileInformationVersion1

Deprecated.

```
enum {
    kMappedFileInformationVersion1 = 1
};
```

kPageInMemory

Deprecated.

```
typedef short PageState;
enum {
    kPageInMemory = 0,
    kPageOnDisk = 1,
    kNotPaged = 2
};
```

Discussion
The `GetPageState` function obtains the state value of a page of logical memory. The `PageState` data type defines constants that represent these possible state values.

Debuggers need a way to display the contents of memory without paging or to display the contents of pages currently on disk. The `GetPageState` function obtains a constant from the PageState data type to specify the state of a page containing a virtual address. A debugger can use this information to determine whether certain memory addresses should be referenced. Note that ROM and I/O space are not pageable and therefore are considered not paged.

kVolumeVirtualMemoryInfoVersion1

Deprecated.

```
enum {
    kVolumeVirtualMemoryInfoVersion1 = 1
};
```

maxSize

Deprecated.

```
enum {
    maxSize = 0x7FFFFFF0
};
```

Result Codes

The most common result codes returned by the Memory Manager are listed below.

Result Code	Value	Description
`menuPrgErr`	84	A menu was purged. Available in Mac OS X v10.0 and later.
`negZcbFreeErr`	33	A heap has been corrupted. Available in Mac OS X v10.0 and later.
`memROZErr`	-99	Operation on a read-only zone. This result code is not relevant in Mac OS X. Available in Mac OS X v10.0 and later.
`memFullErr`	-108	Not enough memory in heap. Available in Mac OS X v10.0 and later.
`nilHandleErr`	-109	Handle argument is `NULL`. Available in Mac OS X v10.0 and later.
`memAdrErr`	-110	Address is odd or out of range. Available in Mac OS X v10.0 and later.
`memWZErr`	-111	Attempt to operate on a free block. Available in Mac OS X v10.0 and later.
`memPurErr`	-112	Attempt to purge a locked or unpurgeable block. Available in Mac OS X v10.0 and later.
`memAZErr`	-113	Address in zone check failed. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
memPCErr	-114	Pointer check failed. Available in Mac OS X v10.0 and later.
memBCErr	-115	Block check failed. Available in Mac OS X v10.0 and later.
memSCErr	-116	Size check failed. Available in Mac OS X v10.0 and later.
memLockedErr	-117	Block is locked. Available in Mac OS X v10.0 and later.

Mixed Mode Manager Reference

Framework: CoreServices/CoreServices.h

Declared in MixedMode.h

Overview

Mac OS X does not require the Mixed Mode Manager, and does not support its functions. These unsupported functions are listed in the Appendix. The functions have been removed from the Mixed Mode Manager and redefined as macros for the purpose of source compatibility with code ported to CFM. See the header file MixedMode.h for details on these macros and their usage.

You do not need to remove Mixed Mode Manager calls from your application for compatibility with Mac OS X, and may want to retain them for source code compatibility with previous versions of the Mac OS.

The Mixed Mode Manager managed the mixed-mode architecture of PowerPC processor-based computers running 680x0-based code (including system software, applications, and stand-alone code modules). The Mixed Mode Manager cooperated with the 68LC040 Emulator to provide a fast, efficient, and virtually transparent method for code in one instruction set architecture to call code in another architecture. The Mixed Mode Manager handled all the details of switching between architectures.

The Mixed Mode Manager was intended to operate transparently to most applications and other software.

Although Mac OS X does not run 68K code, Carbon supports universal procedure pointers (UPPs) transparently, so you do not have to change them or remove them from your code. You may want to keep Mixed Mode Manager calls in your application to maintain source code compatibility with the previous versions of the Mac OS. Mixed Mode Manager calls from Carbon applications running on Mac OS 8 or 9 will function normally.

The Mixed Mode Manager was used by developers who

- wanted to recompile their applications into PowerPC code and their applications passed the address of some routines to the Mac OS using a reference of type `ProcPtr`
- created applications–written in either PowerPC or 680x0 code–that support installable code modules that might be written in a different architecture
- wrote stand-alone code (for example, a VBL task or a component) that could be called from either the PowerPC native environment or the 680x0 emulated environment
- wrote debuggers or other software that needed to know about the structure of the stack at any time (for example, during a mode switch)

Mac OS X will not run 68K code. Although Carbon supports universal procedure pointers (UPPs), applications should use ProcPtrs for their own code and plug-ins and use the new system-supplied UPP creation functions for Toolbox callback UPPs. You still need to dispose of those UPPs (using the corresponding disposal function), so that any allocated memory can be cleaned up when your application is running on Mac OS 8 or 9.

Data Types

MixedModeStateRecord

Contains mixed mode state information.

```
struct MixedModeStateRecord {
    UInt32 state1;
    UInt32 state2;
    UInt32 state3;
    UInt32 state4;
};
typedef struct MixedModeStateRecord MixedModeStateRecord;
```

Fields

`state1`

`state2`

`state3`

`state4`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MixedMode.h`

ProcInfoType

Defines a data type used to encode a routine's procedure information.

```
typedef unsigned long ProcInfoType;
```

Discussion

The Mixed Mode Manager uses a long word of type `ProcInfoType` to encode a routine's procedure information, which contains essential information about the calling conventions and other features of a routine. These values specify

- the routine's calling conventions
- the sizes and locations of the routine's parameters, if any
- the size and location of the routine's result, if any

The Mixed Mode Manager provides a number of constants that you can use to specify the procedure information. See "Procedure Information Size Constants" (page 1455) , "ProcInfo Field Offset And Width Constants" (page 1456) , "Calling Convention Constants" (page 1450) , "Special Case Calling Convention Constants" (page 1464) , and "Register Constants" (page 1459).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MixedMode.h`

RDFlagsType

Defines a data type for routine descriptor flags.

```
typedef UInt8 RDFlagsType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MixedMode.h`

RoutineDescriptor

Contains information used by the Mixed Mode Manager to execute a routine.

```
struct RoutineDescriptor {
    UInt16 goMixedModeTrap;
    SInt8 version;
    RDFlagsType routineDescriptorFlags;
    UInt32 reserved1;
    UInt8 reserved2;
    UInt8 selectorInfo;
    UInt16 routineCount;
    RoutineRecord routineRecords[1];
};
typedef struct RoutineDescriptor RoutineDescriptor;
typedef RoutineDescriptor * RoutineDescriptorPtr;
typedef RoutineDescriptorPtr RoutineDescriptorHandle;
```

Fields

`goMixedModeTrap`
: An A-line instruction that is used privately by the Mixed Mode Manager. When the emulator encounters this instruction, it transfers control to the Mixed Mode Manager. This field contains the value $AAFE.

`version`
: The version number of the `RoutineDescriptor` data type.

`routineDescriptorFlags`
: A set of routine descriptor flags. Currently, all the bits in this field should be set to 0, unless you are specifying a routine descriptor for a dispatched routine.

`reserved1`
: Reserved. This field must initially be 0.

`reserved2`
: Reserved. This field must be 0.

`selectorInfo`
: Reserved. This field must be 0.

`routineCount`
: The index of the final routine record in the following array, of routineRecords. Because the `routineRecords` array is zero-based, this field does not contain an actual count of the routine records contained in that array. Often, you will use a routine descriptor to describe a single procedure, in which case this field should contain the value 0. You can, however, construct a routine descriptor that contains pointers to both 680x0 and PowerPC code (known as a “fat” routine descriptor). In that case, this field should contain the value 1.

`routineRecords`
: An array of routine records for the routines described by this routine descriptor. See "`RoutineRecord`" (page 1448) for the structure of a routine record. This array is zero-based.

Discussion
A routine descriptor is a data structure used by the Mixed Mode Manager to execute a routine. The external interface to a routine descriptor is through a universal procedure pointer, of type `UniversalProcPtr`, which is defined as a procedure pointer (if the code is 680x0 code) or as a pointer to a routine descriptor (if the code is PowerPC code). A routine descriptor is defined by the `RoutineDescriptor` data type.

Your application (or other software) should never attempt to guide its execution by inspecting the value in the `ISA` field of a routine record and jumping to the address in the `procDescriptor` field.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MixedMode.h`

RoutineFlagsType

Defines a data type for routine flags.

```
typedef unsigned short RoutineFlagsType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MixedMode.h`

RoutineRecord

Cntains information about a particular routine.

```
struct RoutineRecord {
    ProcInfoType procInfo;
    SInt8 reserved1;
    ISAType ISA;
    RoutineFlagsType routineFlags;
    ProcPtr procDescriptor;
    UInt32 reserved2;
    UInt32 selector;
};
typedef struct RoutineRecord RoutineRecord;
typedef RoutineRecord * RoutineRecordPtr;
typedef RoutineRecordPtr RoutineRecordHandle;
```

Fields

`procInfo`

A value of type `ProcInfoType` that encodes essential information about the routine's calling conventions and parameters. See "Procedure Information Size Constants" (page 1455), "ProcInfo Field Offset And Width Constants" (page 1456), "Calling Convention Constants" (page 1450), "Special Case Calling Convention Constants" (page 1464), and "Register Constants" (page 1459) for descriptions of the constants you can use to set this field.

`reserved1`

Reserved. This field must be 0.

`ISA`

The instruction set architecture of the routine. See "Instruction Set Architectures" (page 1452) for a complete listing of the constants you can use to set this field.

`routineFlags`

A value of type `RoutineFlagsType` that contains a set of flags describing the routine. See "Routine Entry Point Flags" (page 1463), "Fragment Flags" (page 1452), "ISA Flags" (page 1453), "Routine Selector Flags" (page 1463), and "Default Routine Flags" (page 1451) for descriptions of the constants you can use to set this field.

`procDescriptor`

A pointer to the routine's code. If the routine consists of 680x0 code and the `kProcDescriptorIsAbsolute` flag is set in the `routineFlags` field, then this field contains the address of the routine's entry point. If the routine consists of 680x0 code and the `kProcDescriptorIsRelative` flag is set, then this field contains the offset from the beginning of the routine descriptor to the routine's entry point. If the routine consists of PowerPC code, the `kFragmentIsPrepared` flag is set, and the `kProcDescriptorIsAbsolute` flag is set, then this field contains the address of the routine's transition vector. If the routine consists of PowerPC code, the `kFragmentNeedsPreparing` flag is set, and the `kProcDescriptorIsRelative` flag is set, then this field contains the offset from the beginning of the routine descriptor to the routine's entry point.

`reserved2`

Reserved. This field must be 0.

`selector`

Reserved. This field must be 0. For routines that are dispatched, this field contains the routine selector.

Discussion

A routine record is a data structure that contains information about a particular routine. The routine descriptor specifies, among other things, the instruction set architecture of the routine, the number and size of the routine's parameters, the routine's calling conventions, and the routine's location in memory. At least one routine record is contained in the `routineRecords` field of a routine descriptor. A routine record is defined by the `RoutineRecord` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MixedMode.h`

Constants

Calling Convention Constants

Specify a routine's calling conventions.

```
typedef unsigned short CallingConventionType;
enum {
    kPascalStackBased = 0,
    kCStackBased = 1,
    kRegisterBased = 2,
    kD0DispatchedPascalStackBased = 8,
    kD1DispatchedPascalStackBased = 12,
    kD0DispatchedCStackBased = 9,
    kStackDispatchedPascalStackBased = 14,
    kThinkCStackBased = 5
};
```

Constants

`kPascalStackBased`
The routine follows normal Pascal calling conventions.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kCStackBased`
The routine follows the C calling conventions employed by the MPW development environment.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterBased`
The parameters are passed in registers.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kD0DispatchedPascalStackBased`
The parameters are passed on the stack according to Pascal conventions, and the routine selector is passed in register D0.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kD1DispatchedPascalStackBased`
The parameters are passed on the stack according to Pascal conventions, and the routine selector is passed in register D1.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kD0DispatchedCStackBased`
The parameters are passed on the stack according to C conventions, and the routine selector is passed in register D0.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kStackDispatchedPascalStackBased`
The routine selector and the parameters are passed on the stack.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kThinkCStackBased`
The routine follows the C calling conventions employed by the THINK C software development environment. Arguments are passed on the stack from right to left, and a result is returned in register D0. All arguments occupy an even number of bytes on the stack. An argument having the size of a `char` is passed in the high-order byte. You should always provide function prototypes; failure to do so may cause THINK C to generate code that is incompatible with this parameter-passing convention.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
These constants are used by the `ProcInfoType` (page 1446) type to specify a routine's calling conventions.

Default Routine Flags

Specify defaults for a routine.

```
enum {
    kRoutineIsNotDispatchedDefaultRoutine = 0x00,
    kRoutineIsDispatchedDefaultRoutine = 0x10
};
```

Constants
`kRoutineIsNotDispatchedDefaultRoutine`
This routine is not the default routine for a set of routines that is dispatched using a routine selector.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRoutineIsDispatchedDefaultRoutine`
This routine is the default routine for a set of routines that is dispatched using a routine selector. If a set of routines is dispatched using a routine selector and the routine corresponding to a specified selector cannot be found, this default routine is called. This routine must be able to accept the same procedure information for all routines. If possible, it is passed the procedure information passed in a call to `CallUniversalProc`.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
The `routineFlags` field of a routine record contains a set of flags that specify information about a routine. You can use constants to specify the desired routine flags. Currently, only 5 of the 16 bits in a routine flags word are defined. You should set all the other bits to 0.

In general, you should use the constant `kRoutineIsNotDispatchedDefaultRoutine`. The constant and `kRoutineIsDispatchedDefaultRoutine` is reserved for use with selector-based system software routines.

Fragment Flags

Used in the `routineFlags` field of a routine record.

```
enum {
    kFragmentIsPrepared = 0x00,
    kFragmentNeedsPreparing = 0x02
};
```

Constants

`kFragmentIsPrepared`

The fragment containing the code to be executed is already loaded into memory and prepared by the Code Fragment Manager.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kFragmentNeedsPreparing`

The fragment containing the code to be executed needs to be loaded into memory and prepared by the Code Fragment Manager. If this flag is set, the `kPowerPCISA` and `kProcDescriptorIsRelative` flags should also be set.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion

The `routineFlags` field of a routine record contains a set of flags that specify information about a routine. You can use constants to specify the desired routine flags. Currently, only 5 of the 16 bits in a routine flags word are defined. You should set all the other bits to 0.

Instruction Set Architectures

Used in the `ISA` field of a routine record.

```
typedef SInt8 ISAType;
enum {
    kM68kISA = 0,
    kPowerPCISA = 1
};
```

Constants

`kM68kISA`

The routine consists of Motorola 680x0 code.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kPowerPCISA`

The routine consists of PowerPC code.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
The `ISA` field of a routine record contains a flag that specifies the instruction set architecture of a routine. You can use constants to specify the instruction set architecture.

ISA Flags

Used in the `routineFlags` field of a routine record.

```
enum {
    kUseCurrentISA = 0x00,
    kUseNativeISA = 0x04
};
```

Constants

`kUseCurrentISA`
If possible, use the current instruction set architecture when executing a routine.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kUseNativeISA`
Use the native instruction set architecture when executing a routine.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

Discussion
The `routineFlags` field of a routine record contains a set of flags that specify information about a routine. You can use constants to specify the desired routine flags. Currently, only 5 of the 16 bits in a routine flags word are defined. You should set all the other bits to 0.

Current Mixed Mode State

Specifies the current version of the mixed-mode state record.

```
enum {
    kCurrentMixedModeStateRecord = 1
};
```

RTA Types

```
typedef SInt8 RTAType;
enum {
    kOld68kRTA = 0 << 4,
    kPowerPCRTA = 0 << 4,
    kCFM68kRTA = 1 << 4
};
```

Constants

`kOld68kRTA`
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kPowerPCRTA`
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kCFM68kRTA`
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

Procedure Descriptors

```
enum {
    kProcDescriptorIsProcPtr = 0x00,
    kProcDescriptorIsIndex = 0x20
};
```

Constants

`kProcDescriptorIsProcPtr`
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kProcDescriptorIsIndex`
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

Routine Descriptor Version

Specifies the version of routine descriptor.

```
enum {
    kRoutineDescriptorVersion = 7
};
```

Special Case Constant

Used to specify a special case.

```
enum {
    kSpecialCase = 0x000F
};
```

Constants

`kSpecialCase`
The routine is a special case. You can use the following constants to specify a special case.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

kX86ISA

```
enum {
    kX86ISA = 2
};
```

Constants

`kX86ISA`

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

kX86RTA

```
enum {
    kX86RTA = 2 << 4
};
```

Constants

`kX86RTA`

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

_MixedModeMagic

```
enum {
    _MixedModeMagic = 0xAAFE
};
```

Constants

`_MixedModeMagic`

Procedure Information Size Constants

Specify the size (in bytes) of a value encoded in the procedure information for a routine.

```
enum {
    kNoByteCode = 0,
    kOneByteCode = 1,
    kTwoByteCode = 2,
    kFourByteCode = 3
};
```

Constants

`kNoByteCode`

The value occupies no bytes.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kOneByteCode`
The value occupies 1 byte.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kTwoByteCode`
The value occupies 2 bytes.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kFourByteCode`
The value occupies 4 bytes.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

Discussion
These constants are used by the `ProcInfoType` (page 1446) to specify the size (in bytes) of a value encoded in a routine's procedure information.

ProcInfo Field Offset And Width Constants

Specify offsets to fields and the widths of the fields within a value.

```
enum {
    kCallingConventionWidth = 4,
    kCallingConventionPhase = 0,
    kCallingConventionMask = 0x0F,
    kResultSizeWidth = 2,
    kResultSizePhase = kCallingConventionWidth,
    kResultSizeMask = 0x30,
    kStackParameterWidth = 2,
    kStackParameterPhase = (kCallingConventionWidth + kResultSizeWidth),
    kStackParameterMask = 0xFFFFFFC0,
    kRegisterResultLocationWidth = 5,
    kRegisterResultLocationPhase = (kCallingConventionWidth + kResultSizeWidth),
    kRegisterParameterWidth = 5,
    kRegisterParameterPhase = (kCallingConventionWidth + kResultSizeWidth
+ kRegisterResultLocationWidth),
    kRegisterParameterMask = 0x7FFFF800,
    kRegisterParameterSizePhase = 0,
    kRegisterParameterSizeWidth = 2,
    kRegisterParameterWhichPhase = kRegisterParameterSizeWidth,
    kRegisterParameterWhichWidth = 3,
    kDispatchedSelectorSizeWidth = 2,
    kDispatchedSelectorSizePhase = (kCallingConventionWidth + kResultSizeWidth),
    kDispatchedParameterPhase = (kCallingConventionWidth + kResultSizeWidth
+ kDispatchedSelectorSizeWidth),
    kSpecialCaseSelectorWidth = 6,
    kSpecialCaseSelectorPhase = kCallingConventionWidth,
    kSpecialCaseSelectorMask = 0x03F0
};
```

Constants

`kCallingConventionWidth`
The number of bits in the procedure information that encode the calling convention information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kCallingConventionPhase`
The offset from the least significant bit in the procedure information to the calling convention information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kCallingConventionMask`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kResultSizeWidth`
The number of bits in the procedure information that encode the function result size information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kResultSizePhase`
The offset from the least significant bit in the procedure information to the function result size information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kResultSizeMask`
A mask for the bits in the procedure information that encode the function result size information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kStackParameterWidth`
The number of bits in the procedure information that encode the size of a stack-based parameter.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kStackParameterPhase`
The offset from the least significant bit in the procedure information to the stack parameter information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kStackParameterMask`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterResultLocationWidth`
The number of bits in the procedure information that encode which register the result will be stored in.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterResultLocationPhase`
The offset from the least significant bit in the procedure information to the result register information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterWidth`
The number of bits in the procedure information that encode the information about a register-based parameter.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterPhase`
The offset from the least significant bit in the procedure information to the register parameter information.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterMask`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterSizePhase`
The offset from the beginning of a register parameter information field to the encoded size of the parameter.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterSizeWidth`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterWhichPhase`
The offset from the beginning of a register parameter information field to the encoded register.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kRegisterParameterWhichWidth`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kDispatchedSelectorSizeWidth`
The number of bits in the procedure information that encode the size of a routine-dispatching selector.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kDispatchedSelectorSizePhase`
The offset from the least significant bit in the procedure information to the selector size information of a routine that is dispatched though a selector.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kDispatchedParameterPhase`
The offset from the least significant bit in the procedure information to the parameter information of a routine that is dispatched though a selector.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseSelectorWidth`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseSelectorPhase`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseSelectorMask`
Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
The offsets to fields and the widths of the fields within a value of type `ProcInfoType` (page 1446) are defined by constants.

Register Constants

Specify registers that are encoded in the procedure information for a routine.

```
enum {
    kRegisterD0 = 0,
    kRegisterD1 = 1,
    kRegisterD2 = 2,
    kRegisterD3 = 3,
    kRegisterD4 = 8,
    kRegisterD5 = 9,
    kRegisterD6 = 10,
    kRegisterD7 = 11,
    kRegisterA0 = 4,
    kRegisterA1 = 5,
    kRegisterA2 = 6,
    kRegisterA3 = 7,
    kRegisterA4 = 12,
    kRegisterA5 = 13,
    kRegisterA6 = 14,
    kCCRegisterCBit = 16,
    kCCRegisterVBit = 17,
    kCCRegisterZBit = 18,
    kCCRegisterNBit = 19,
    kCCRegisterXBit = 20
};
typedef unsigned short registerSelectorType;
```

Constants

`kRegisterD0`
Register D0.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD1`
Register D1.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD2`
Register D2.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD3`
Register D3.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD4`
Register D4.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD5`
Register D5.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD6`
Register D6.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterD7`
Register D7.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA0`
Register A0.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA1`
Register A1.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA2`
Register A2.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA3`
Register A3.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA4`
Register A4.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA5`
Register A5.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kRegisterA6`
Register A6.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kCCRegisterCBit`
The C (carry) flag of the Status Register.
Available in Mac OS X v10.0 and later.
Declared in `MixedMode.h`.

`kCCRegisterVBit`
The V (overflow) flag of the Status Register.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kCCRegisterZBit`
The Z (zero) flag of the Status Register.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kCCRegisterNBit`
The N (negative) flag of the Status Register.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kCCRegisterXBit`
The X (extend) flag of the Status Register.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
For register-based routines, the registers are encoded in the routine's procedure information using these constants.

Routine Descriptor Flags

Specify attributes of the described routine.

```
enum {
    kSelectorsAreNotIndexable = 0x00,
    kSelectorsAreIndexable = 0x01
};
```

Constants
`kSelectorsAreNotIndexable`
For dispatched routines, the recognized routine selectors are not contiguous.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSelectorsAreIndexable`
For dispatched routines, the recognized routine selectors are contiguous and therefore indexable.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
The `routineDescriptorFlags` field of a routine descriptor contains a set of routine descriptor flags that specify attributes of the described routine. You can use constants to specify the routine descriptor flags. In general, you should use the constant `kSelectorsAreNotIndexable` when constructing your own routine descriptors; the value `kSelectorsAreIndexable` is reserved for use by Apple.

Routine Entry Point Flags

Specify information about the entry point for a routine.

```
enum {
    kProcDescriptorIsAbsolute = 0x00,
    kProcDescriptorIsRelative = 0x01
};
```

Constants

`kProcDescriptorIsAbsolute`

The address of the routine's entry point specified in the `procDescriptor` field of a routine record is an absolute address.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kProcDescriptorIsRelative`

The address of the routine's entry point specified in the `procDescriptor` field of a routine record is relative to the beginning of the routine descriptor. If the code is contained in a resource and its absolute location is not known until run time, you should set this flag.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion

The `routineFlags` field of a routine record contains a set of flags that specify information about a routine. You can use constants to specify the desired routine flags. Currently, only 5 of the 16 bits in a routine flags word are defined. You should set all the other bits to 0.

Routine Selector Flags

Specify whether or not to pass a selector to a routine.

```
enum {
    kPassSelector = 0x00,
    kDontPassSelector = 0x08
};
```

Constants

`kPassSelector`

Pass the routine selector to the target routine as a parameter.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kDontPassSelector`

Do not pass the routine selector to the target routine as a parameter. You should not use this flag for 680x0 routines.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion

The `routineFlags` field of a routine record contains a set of flags that specify information about a routine. You can use constants to specify the desired routine flags. Currently, only 5 of the 16 bits in a routine flags word are defined. You should set all the other bits to 0.

In general, you should use the constant `kPassSelector`. The constant `kDontPassSelector` is reserved for use with selector-based system software routines.

Special Case Calling Convention Constants

Specify the calling conventions for a routine.

```
enum {
    kSpecialCaseHighHook = 0,
    kSpecialCaseCaretHook = 0,
    kSpecialCaseEOLHook = 1,
    kSpecialCaseWidthHook = 2,
    kSpecialCaseTextWidthHook = 2,
    kSpecialCaseNWidthHook = 3,
    kSpecialCaseDrawHook = 4,
    kSpecialCaseHitTestHook = 5,
    kSpecialCaseTEFindWord = 6,
    kSpecialCaseProtocolHandler = 7,
    kSpecialCaseSocketListener = 8,
    kSpecialCaseTERecalc = 9,
    kSpecialCaseTEDoText = 10,
    kSpecialCaseGNEFilterProc = 11,
    kSpecialCaseMBarHook = 12
};
```

Constants

`kSpecialCaseHighHook`

The routine follows the calling conventions documented in Inside Macintosh: Text; a rectangle is on the stack and a pointer is in register A3; no result is returned.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseCaretHook`

The routine follows the calling conventions documented in Inside Macintosh: Text; a rectangle is on the stack and a pointer is in register A3; no result is returned.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseEOLHook`

Parameters are passed to the routine in registers A3, A4, and D0, and output is returned in the Z flag of the Status Register. An `EOLHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseWidthHook`

Parameters are passed to the routine in registers A0, A3, A4, D0, and D1, and output is returned in register D1. A `WIDTHHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseTextWidthHook`
Parameters are passed to the routine in registers A0, A3, A4, D0, and D1, and output is returned in register D1. A `TextWidthHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseNWidthHook`
Parameters are passed to the routine in registers A0, A2, A3, A4, D0, and D1, and output is returned in register D1. An `nWIDTHHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseDrawHook`
Parameters are passed to the routine in registers A0, A3, A4, D0, and D1, and no result is returned. A `DRAWHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseHitTestHook`
Parameters are passed to the routine in registers A0, A3, A4, D0, D1, and D2, and output is returned in registers D0, D1, and D2. A `HITTESTHook` routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseTEFindWord`
Parameters are passed to the routine in registers A3, A4, D0, and D2, and output is returned in registers D0 and D1. A `TEFindWord` hook has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseProtocolHandler`
Parameters are passed to the routine in registers A0, A1, A2, A3, A4, and in the low-order word of register D1; output is returned in the Z flag of the Status Register. A protocol handler has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseSocketListener`
Parameters are passed to the routine in registers A0, A1, A2, A3, A4, in the low-order byte of register D0, and in the low-order word of register D1; output is returned in the Z flag of the Status Register. A socket listener has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseTERecalc`
Parameters are passed to the routine in registers A3 and D7, and output is returned in registers D2, D3, and D4. A TextEdit line-start recalculation routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseTEDoText`
Parameters are passed to the routine in registers A3, D3, D4, and D7, and output is returned in registers A0 and D0. A TextEdit text-display, hit-test, and caret-positioning routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseGNEFilterProc`
Parameters are passed to the routine in registers A1 and D0 and on the stack, and output is returned on the stack. A `GetNextEvent` filter procedure has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

`kSpecialCaseMBarHook`
Parameters are passed to the routine on the stack, and output is returned in register D0. A menu bar hook routine has these calling conventions.

Available in Mac OS X v10.0 and later.

Declared in `MixedMode.h`.

Discussion
These constants are used by the `ProcInfoType` (page 1446) type to specify a routine's calling conventions.

Result Codes

The most common result codes returned by the Mixed Mode Manager are listed below.

Result Code	Value	Description
`mmInternalError`	-2526	An internal error has occurred. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availabilty information by using the Mixed Mode Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Multiprocessing Services Reference

Framework:	CoreServices/CoreServices.h
Declared in	Multiprocessing.h MultiprocessingInfo.h
Companion guide	Multiprocessing Services Programming Guide

Overview

Multiprocessing Services is an API that lets you create preemptive tasks in your application that can run on one or more microprocessors. Unlike the cooperative threads created by the Thread Manager, Multiprocessing Services automatically divides processor time among the available tasks, so that no particular task can monopolize the system. This document is relevant to you if you want to add multitasking capability to your Mac OS applications.

In Mac OS X, Carbon supports Multiprocessing Services with the following restrictions:

- Debugging functions are not implemented. Use the mach APIs provided by the system to implement debugging services.
- Opaque notification IDs are local to your process; they are not globally addressable across processes.
- Global memory allocation is not supported.

Functions by Task

Determining Multiprocessing Services And Processor Availability

`_MPIsFullyInitialized` (page 1508)
Indicates whether Multiprocessing Services is available for use.

`MPGetNextCpuID` (page 1489)
Obtains the next CPU ID in the list of physical processors of the specified memory coherence group.

`MPProcessors` (page 1493)
Returns the number of processors on the host computer.

`MPProcessorsScheduled` (page 1493)
Returns the number of active processors available on the host computer.

Creating and Handling Message Queues

`MPCreateQueue` (page 1478)
Creates a message queue.

`MPDeleteQueue` (page 1484)
Deletes a message queue.

`MPNotifyQueue` (page 1492)
Sends a message to the specified message queue.

`MPSetQueueReserve` (page 1497)
Reserves space for messages on a specified message queue.

`MPWaitOnQueue` (page 1506)
Obtains a message from a specified message queue.

Creating and Handling Semaphores

`MPCreateSemaphore` (page 1478)
Creates a semaphore.

`MPDeleteSemaphore` (page 1485)
Removes a semaphore.

`MPSignalSemaphore` (page 1502)
Signals a semaphore.

`MPWaitOnSemaphore` (page 1507)
Waits on a semaphore

Creating and Scheduling Tasks

`MPCreateTask` (page 1479)
Creates a preemptive task.

`MPCurrentTaskID` (page 1481)
Obtains the task ID of the currently-executing preemptive task

`MPSetTaskType` (page 1499)
Sets the type of the task.

`MPExit` (page 1487)
Allows a task to terminate itself

`MPGetNextTaskID` (page 1490)
Obtains the next task ID in the list of available tasks.

`MPSetTaskWeight` (page 1500)
Assigns a relative weight to a task, indicating how much processor time it should receive compared to other available tasks.

`MPTaskIsPreemptive` (page 1502)
Determines whether a task is preemptively scheduled.

`MPTerminateTask` (page 1503)
Terminates an existing task.

MPYield (page 1507)
Allows a task to yield the processor to another task.

Handling Critical Regions

MPCreateCriticalRegion (page 1476)
Creates a critical region object.

MPDeleteCriticalRegion (page 1483)
Removes the specified critical region object.

MPEnterCriticalRegion (page 1486)
Attempts to enter a critical region.

MPExitCriticalRegion (page 1487)
Exits a critical region.

Handling Event Groups

MPCreateEvent (page 1477)
Creates an event group.

MPDeleteEvent (page 1483)
Removes an event group.

MPSetEvent (page 1496)
Merges event flags into a specified event group.

MPWaitForEvent (page 1505)
Retrieves event flags from a specified event group.

Handling Kernel Notifications

MPCauseNotification (page 1476)
Signals a kernel notification.

MPCreateNotification (page 1477)
Creates a kernel notification

MPDeleteNotification (page 1484)
Removes a kernel notification.

MPModifyNotification (page 1491)
Adds a simple notification to a kernel notification.

MPModifyNotificationParameters (page 1492)

Accessing Per-Task Storage Variables

MPAllocateTaskStorageIndex (page 1472)
Returns an index number to access per-task storage.

`MPDeallocateTaskStorageIndex` (page 1482)
Frees an index number used to access per-task storage

`MPGetTaskStorageValue` (page 1490)
Gets the storage value stored at a specified index number.

`MPSetTaskStorageValue` (page 1499)
Sets the storage value for a given index number.

Memory Allocation Functions

`MPAllocate` (page 1471)
Allocates a nonrelocatable memory block. (Deprecated. Use `MPAllocateAligned` instead.)

`MPAllocateAligned` (page 1472)
Allocates a nonrelocatable memory block.

`MPBlockClear` (page 1474)
Clears a block of memory.

`MPBlockCopy` (page 1474)
Copies a block of memory.

`MPDataToCode` (page 1481)
Designates the specified block of memory as executable code.

`MPFree` (page 1488)
Frees memory allocated by `MPAllocateAligned`.

`MPGetAllocatedBlockSize` (page 1489)
Returns the size of a memory block.

Remote Calling Functions

`MPRemoteCall` (page 1494)
Calls a non-reentrant function and blocks the current task.

`MPRemoteCallCFM` (page 1495)
Calls a non-reentrant function and blocks the current task.

Timer Services Functions

`MPArmTimer` (page 1473)
Arms the timer to expire at a given time.

`MPCancelTimer` (page 1475)
Cancels an armed timer.

`MPCreateTimer` (page 1480)
Creates a timer.

`MPDelayUntil` (page 1482)
Blocks the calling task until a specified time.

`MPDeleteTimer` (page 1485)
Removes a timer.

`MPSetTimerNotify` (page 1500)
Sets the notification information associated with a timer.

Exception Handling Functions

`MPDisposeTaskException` (page 1486)
Removes a task exception.

`MPExtractTaskState` (page 1488)
Extracts state information from a suspended task.

`MPSetExceptionHandler` (page 1496)
Sets an exception handler for a task.

`MPSetTaskState` (page 1498)
Sets state information for a suspended task.

`MPThrowException` (page 1504)
Throws an exception to a specified task.

Debugger Support Functions

`MPRegisterDebugger` (page 1494)
Registers a debugger.

`MPUnregisterDebugger` (page 1504)
Unregisters a debugger.

Functions

MPAllocate

Allocates a nonrelocatable memory block. (**Deprecated.** Use `MPAllocateAligned` instead.)

```
LogicalAddress MPAllocate (
    ByteCount size
);
```

Parameters

size
The size, in bytes, of the memory block to allocate.

Return Value
A pointer to the allocated memory. If the function cannot allocate the requested memory or the requested alignment, the returned address is `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPAllocateAligned

Allocates a nonrelocatable memory block.

```
LogicalAddress MPAllocateAligned (
   ByteCount size,
   UInt8 alignment,
   OptionBits options
);
```

Parameters

size

The size, in bytes, of the memory block to allocate.

alignment

The desired alignment of the allocated memory block. See "Memory Allocation Alignment Constants" (page 1523) for a list of possible values to pass. Note that there will be a minimum alignment regardless of the requested alignment. If the requested memory block is 4 bytes or smaller, the block will be at least 4-byte aligned. If the requested block is greater than 4 bytes, the block will be at least 8-byte aligned.

options

Any optional information to use with this call. See "Memory Allocation Option Constants" (page 1525) for a list of possible values to pass.

Return Value

A pointer to the allocated memory. If the function cannot allocate the requested memory or the requested alignment, the returned address is `NULL`.

Discussion

The memory referenced by the returned address is guaranteed to be accessible by the application's cooperative task and any preemptive tasks that it creates, but not by other applications or their preemptive tasks. Any existing non-global heap blocks are freed when the application terminates. As with all shared memory, you must explicitly synchronize access to allocated heap blocks using a notification mechanism.

You can replicate the effect of the older `MPAllocate` function by calling `MPAllocateAligned` with 32-byte alignment and no options.

Also see the function `MPFree` (page 1488).

Special Considerations

Mac OS X does not support allocation of global (cross address space) or resident memory with this function. In addition, passing the `kMPAllocateNoGrowthMask` constant in the `options` parameter has no effect in Mac OS X, since memory allocation is done with sparse heaps.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPAllocateTaskStorageIndex

Returns an index number to access per-task storage.

```
OSStatus MPAllocateTaskStorageIndex (
   TaskStorageIndex *taskIndex
);
```

Parameters

index

On return, `index` contains an index number you can use to store task data.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
A call to the function `MPAllocateTaskStorageIndex` returns an index number that is common across all tasks in the current process. You can use this index number in calls to `MPSetTaskStorageValue` (page 1499) and `MPGetTaskStorageValue` (page 1490) to set a different value for each task using the same index.

You can think of the task storage area as a two dimensional array cross-referenced by the task storage index number and the task ID. Note that since the amount of per-task storage is determined when the task is created, the number of possible index values associated with a task is limited.

Also see the function `MPDeallocateTaskStorageIndex` (page 1482).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPArmTimer

Arms the timer to expire at a given time.

```
OSStatus MPArmTimer (
   MPTimerID timerID,
   AbsoluteTime *expirationTime,
   OptionBits options
);
```

Parameters

timerID

The ID of the timer you want to arm.

expirationTime

A pointer to a value that specifies when you want the timer to expire. Note that if you arm the timer with a time that has already passed, the timer expires immediately.

options

Any optional actions. See "Timer Option Masks" (page 1532) for a list of possible values.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If the timer has already expired, the reset does not take place and the function returns `kMPInsufficientResourcesErr`.

Discussion
The expiration time is an absolute time, which you can generate by calling the Driver Services Library function `UpTime`. When the timer expires, a notification is sent to the notification mechanism specified in the last `MPSetTimerNotify` (page 1500) call. If the specified notification ID has become invalid, no action is taken when the timer expires. The timer itself is deleted when it expires unless you specified the `kMPPreserveTimerID` option in the options parameter.

Also see the function `MPCancelTimer` (page 1475).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPBlockClear

Clears a block of memory.

```
void MPBlockClear (
   LogicalAddress address,
   ByteCount size
);
```

Parameters

address
The starting address of the memory block you want to clear.

size
The number of bytes you want to clear.

Discussion
As with all shared memory, your application must synchronize access to the memory blocks to avoid data corruption. `MPBlockClear` ensures the clearing stays within the bounds of the area specified by `size`, but the calling task can be preempted during the copying process.

Note that you can call this function from an interrupt handler.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPBlockCopy

Copies a block of memory.

```
void MPBlockCopy (
   LogicalAddress source,
   LogicalAddress destination,
   ByteCount size
);
```

Parameters

source

The starting address of the memory block you want to copy.

destination

The location to which you want to copy the memory block.

size

The number of bytes to copy.

Discussion

This function simply calls through to the Driver Services Library function `BlockMoveData`. Note that you should not make any assumptions about the state of the destination memory while this function is executing. In the intermediate state, values may be present that are neither the original nor the final ones. For example, this function may use the `'dcbz'` instruction. If the underlying memory is not cacheable, if the memory is write-through instead of copy-back, or if the cache block is flushed for some reason, the `'dcbz'` instruction will write zeros to the destination. You can avoid the use of the `'dcbz'` instruction by calling `BlockMoveDataUncached`, but even that function makes no other guarantees about the memory block's intermediate state.

As with all shared memory, your application must synchronize access to the memory blocks to avoid data corruption. `MPBlockCopy` ensures the copying stays within the bounds of the area specified by `size`, but the calling task can be preempted during the copying process.

Note that you can call this function from an interrupt handler.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPCancelTimer

Cancels an armed timer.

```
OSStatus MPCancelTimer (
   MPTimerID timerID,
   AbsoluteTime *timeRemaining
);
```

Parameters

timerID

The ID of the armed timer you want to cancel.

timeRemaining

On return, the `timeRemaining` contains the time remaining before the timer would have expired.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533). If the timer has already expired, this function returns `kMPInsufficientResourcesErr`.

Discussion
Also see the function `MPArmTimer` (page 1473).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCauseNotification

Signals a kernel notification.

```
OSStatus MPCauseNotification (
   MPNotificationID notificationID
);
```

Parameters

notificationID
The ID of the kernel notification you want to signal.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
You call this function to signal a kernel notification much as you would signal any simple notification (for example, `MPNotifyQueue` (page 1492)).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateCriticalRegion

Creates a critical region object.

```
OSStatus MPCreateCriticalRegion (
   MPCriticalRegionID *criticalRegion
);
```

Parameters

criticalRegion
On return, the `criticalRegion` contains the ID of the newly created critical region object.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Also see the function `MPDeleteCriticalRegion` (page 1483).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateEvent

Creates an event group.

```
OSStatus MPCreateEvent (
   MPEventID *event
);
```

Parameters

event

On return, `event` contains the ID of the newly created event group.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Event groups are created from dynamically allocated internal resources. Other tasks may be competing for these resources so it is possible that this function will not be able to create an event group.

Also see the function `MPDeleteEvent` (page 1483).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateNotification

Creates a kernel notification

```
OSStatus MPCreateNotification (
   MPNotificationID *notificationID
);
```

Parameters

notificationID

On return, `notificationID` points to the newly created kernel notification.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
After creating the kernel notification object, you can add simple notifications by calling the function `MPModifyNotification` (page 1491).

Also see the function `MPDeleteNotification` (page 1484).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateQueue

Creates a message queue.

```
OSStatus MPCreateQueue (
   MPQueueID *queue
);
```

Parameters

queue
On return, the variable contains the ID of the newly created message queue.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If a queue could not be created, `MPCreateQueue` returns `kMPInsufficientResourcesErr`.

Discussion
This call creates a message queue, which can be used to notify (that is, send) and wait for (that is, receive) messages consisting of three pointer-sized values in a preemptively safe manner.

Message queues are created from dynamically allocated internal resources. Other tasks may be competing for these resources so it is possible this function may not be able to create a queue.

See also the functions `MPDeleteQueue` (page 1484) and `MPSetQueueReserve` (page 1497).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateSemaphore

Creates a semaphore.

```
OSStatus MPCreateSemaphore (
   MPSemaphoreCount maximumValue,
   MPSemaphoreCount initialValue,
   MPSemaphoreID *semaphore
);
```

Parameters

maximumValue
The maximum allowed value of the semaphore.

initialValue
The initial value of the semaphore.

semaphore
On return, `semaphore` contains the ID of the newly–created semaphore.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
If you want to create a binary semaphore, you can call the macro `MPCreateBinarySemaphore (MPSemaphoreID *semaphore)` instead, which simply calls `MPCreateSemaphore` with both `maximumValue` and `initialValue` set to 1.

Also see the function `MPDeleteSemaphore` (page 1485).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateTask

Creates a preemptive task.

```
OSStatus MPCreateTask (
   TaskProc entryPoint,
   void *parameter,
   ByteCount stackSize,
   MPQueueID notifyQueue,
   void *terminationParameter1,
   void *terminationParameter2,
   MPTaskOptions options,
   MPTaskID *task
);
```

Parameters

entryPoint
A pointer to the task function. The task function should take a single pointer-sized parameter and return a value of type `OSStatus`.

parameter
The parameter to pass to the task function.

stackSize
The size of the stack assigned to the task. Note that you should be careful not to exceed the bounds of the stack, since stack overflows may not be detected. Specifying zero for the size will result in a default stack size of 4KB.

Note that in Mac OS X prior to version 10.1, this parameter is ignored, and all stacks have the default size of 512 KB. Versions 10.1 and later do not have this limitation.

notifyQueue
The ID of the message queue to which the system will send a message when the task terminates. You specify the first two values of the message in the parameters `terminationParameter1` and `terminationParameter2` respectively. The last message value contains the result code of the task function.

terminationParameter1
A pointer-sized value that is sent to the message queue specified by the parameter `notifyQueue` when the task terminates.

terminationParameter2
A pointer-sized value that is sent to the message queue specified by the parameter `notifyQueue` when the task terminates.

options

Optional attributes of the preemptive task. See "Task Creation Options" (page 1528) for a list of possible values.

task

On return, `task` points to the ID of the newly created task.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If `MPCreateTask` could not create the task because some critical resource was not available, the function returns `kMPInsufficientResourcesErr`. Usually this is due to lack of memory to allocate the internal data structures associated with the task or the stack. The function also returns `kMPInsufficientResourcesErr` if any reserved option bits are set.

Discussion
Tasks are created in the unblocked state, ready for execution. A task can terminate in the following ways:

- By returning from its entry point
- By calling `MPExit` (page 1487)
- When specified as the target of an `MPTerminateTask` (page 1503) call
- If a hardware-detected exception or programming exception occurs and no exception handler is installed
- If the application calls `ExitToShell`

Task resources (its stack, active timers, internal structures related to the task, and so on) are reclaimed by the system when the task terminates. The task's address space is inherited from the process address space. All existing tasks are terminated when the owning process terminates.

To set the relative processor weight to be assigned to a task, use the function `MPSetTaskWeight` (page 1500).

See also the function `MPTerminateTask` (page 1503).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCreateTimer

Creates a timer.

```
OSStatus MPCreateTimer (
   MPTimerID *timerID
);
```

Parameters

timerID

On return, the `timerID` contains the ID of the newly created timer.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
You can use a timer to notify an event, queue, or semaphore after a specified amount of time has elapsed.

Timer objects are created from dynamically-allocated internal resources. Other tasks may be competing for these resources so it is possible this function may not be able to create one.

To specify the notification mechanism to signal, use the function `MPSetTimerNotify` (page 1500).

Also see the functions `MPDeleteTimer` (page 1485) and `MPArmTimer` (page 1473).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCurrentTaskID

Obtains the task ID of the currently-executing preemptive task

```
MPTaskID MPCurrentTaskID (
   void
);
```

Return Value
The task ID of the current preemptive task. See the description of the `MPTaskID` data type.

Discussion
Returns the ID of the current preemptive task. If called from a cooperative task, this function returns an ID which is different than the ID of any preemptive task. Nonpreemptive processes may or may not have different task IDs for each application; future implementations of this API may behave differently in this regard.

Note that you can call this function from an interrupt handler.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDataToCode

Designates the specified block of memory as executable code.

```
void MPDataToCode (
   LogicalAddress address,
   ByteCount size
);
```

Parameters

address
The starting address of the memory block you want to designate as code.

size
The size of the memory block.

Discussion
Since processors need to differentiate between code and data in memory, you should call this function to tag any executable code that your tasks may generate.

Note that you can call this function from an interrupt handler.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Multiprocessing.h`

MPDeallocateTaskStorageIndex

Frees an index number used to access per-task storage

```
OSStatus MPDeallocateTaskStorageIndex (
   TaskStorageIndex taskIndex
);
```

Parameters
index
The index number you want to deallocate.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Also see the function `MPAllocateTaskStorageIndex` (page 1472).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDelayUntil

Blocks the calling task until a specified time.

```
OSStatus MPDelayUntil (
   AbsoluteTime *expirationTime
);
```

Parameters
expirationTime
The time to unblock the task.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
You cannot call this function from a cooperative task.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteCriticalRegion

Removes the specified critical region object.

```
OSStatus MPDeleteCriticalRegion (
   MPCriticalRegionID criticalRegion
);
```

Parameters

criticalRegion
The critical region object you want to remove.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Calling this function unblocks all tasks waiting to enter the critical region and their respective `MPEnterCriticalRegion` (page 1486) calls will return with the result code `kMPDeletedErr`.

Also see the function `MPCreateCriticalRegion` (page 1476).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteEvent

Removes an event group.

```
OSStatus MPDeleteEvent (
   MPEventID event
);
```

Parameters

event
The ID of the event group you want to remove.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
After deletion, the event ID becomes invalid, and all internal resources associated with the event group are reclaimed. Calling this function unblocks all tasks waiting on the event group and their respective `MPWaitForEvent` (page 1505) calls will return with the result code `kMPDeletedErr`.

Also see the function `MPCreateEvent` (page 1477).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteNotification

Removes a kernel notification.

```
OSStatus MPDeleteNotification (
   MPNotificationID notificationID
);
```

Parameters

notificationID
The ID of the notification you want to remove.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Also see the function `MPCreateNotification` (page 1477).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteQueue

Deletes a message queue.

```
OSStatus MPDeleteQueue (
   MPQueueID queue
);
```

Parameters

queue
The ID of the message queue you want to delete.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
After calling `MPDeleteQueue`, the specified queue ID becomes invalid, and all internal resources associated with the queue (including queued messages) are reclaimed. Any tasks waiting on the queue are unblocked and their respective `MPWaitOnQueue` (page 1506) calls will return with the result code `kMPDeletedErr`.

Also see the function `MPCreateQueue` (page 1478).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteSemaphore

Removes a semaphore.

```
OSStatus MPDeleteSemaphore (
   MPSemaphoreID semaphore
);
```

Parameters

semaphore
The ID of the semaphore you want to remove.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Calling this function unblocks all tasks waiting on the semaphore and the tasks' respective `MPWaitOnSemaphore` (page 1507) calls will return with the result code `kMPDeletedErr`.

Also see the function `MPCreateSemaphore` (page 1478).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDeleteTimer

Removes a timer.

```
OSStatus MPDeleteTimer (
   MPTimerID timerID
);
```

Parameters

timerID
The ID of the timer you want to remove.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
After deletion, the timer ID becomes invalid, and all internal resources associated with the timer are reclaimed.

Also see the function `MPCreateTimer` (page 1480).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPDisposeTaskException

Removes a task exception.

```
OSStatus MPDisposeTaskException (
   MPTaskID task,
   OptionBits action
);
```

Parameters

task

The task whose exception you want to remove.

action

Any actions to perform on the task. For example, you can enable single-stepping when the task resumes, or you can pass the exception on to another handler. See "Task Exception Disposal Constants" (page 1528) for a listing of possible values.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533). If the specified action is invalid or unsupported, or if the specified task is not suspended, this function returns `kMPInsufficientResourcesErr`.

Discussion

This function removes the task exception and allows the task to resume operation. If desired, you can enable single-stepping or branch-stepping, or propagate the exception instead.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPEnterCriticalRegion

Attempts to enter a critical region.

```
OSStatus MPEnterCriticalRegion (
   MPCriticalRegionID criticalRegion,
   Duration timeout
);
```

Parameters

criticalRegion

The ID of the critical region you want to enter.

timeout

The maximum time to wait for entry before timing out. See "Timer Duration Constants" (page 1531) for a list of constants you can use to specify the wait interval.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion

If another task currently occupies the critical region, the current task is blocked until the critical region is released or until the designated timeout expires. Otherwise the task enters the critical region and `MPEnterCriticalRegion` increments the region's use count.

Once a task enters a critical region it can make further calls to `MPEnterCriticalRegion` without blocking (its use count increments for each call). However, each call to `MPEnterCriticalRegion` must be balanced by a call to `MPExitCriticalRegion` (page 1487) ; otherwise the region is not released for use by other tasks.

Note that you can enter a critical region from a cooperative task. Each cooperative task is treated as unique and different from any preemptive task. If you call this function from a cooperative task, you should specify only `kDurationImmediate` for the timeout length; other waits will cause the task to block.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPExit

Allows a task to terminate itself

```
void MPExit (
   OSStatus status
);
```

Parameters

`status`

An application-defined value that indicates termination status. This value is sent to the termination message queue in place of the task's result code.

Discussion
When called from within a preemptive task, the task terminates, and the value indicated by the parameter `status` is sent to the termination message queue you specified in `MPCreateTask` (page 1479). Note that you cannot call `MPExit` from outside a preemptive task.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPExitCriticalRegion

Exits a critical region.

```
OSStatus MPExitCriticalRegion (
   MPCriticalRegionID criticalRegion
);
```

Parameters

`criticalRegion`

The ID of the critical region you want to exit.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If the task does not own the critical region specified by `criticalRegion`, `MPExitCriticalRegion` returns `kMPInsufficientResourcesErr`.

Discussion
This function decrements the use count of the critical region object. When the use count reaches zero, ownership of the critical region object is released (which allows another task to use the critical region).

Also see the function `MPEnterCriticalRegion` (page 1486).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPExtractTaskState

Extracts state information from a suspended task.

```
OSStatus MPExtractTaskState (
   MPTaskID task,
   MPTaskStateKind kind,
   void *info
);
```

Parameters

task

The task whose state information you want to obtain.

kind

The kind of state information you want to obtain. See "Task State Constants" (page 1530) for a listing of possible values.

info

A pointer to a data structure to hold the state information. On return, the data structure holds the desired state information. The format of the data structure varies depending on the state information you want to retrieve. See the header file `MachineExceptions.h` for the formats of the various state information structures.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If you attempt to extract state information for a running task, this function returns `kMPInsufficientResourcesErr`.

Discussion
You can use this function to obtain register contents or exception information about a particular task.

Also see the function `MPSetTaskState` (page 1498).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPFree

Frees memory allocated by `MPAllocateAligned`.

```
void MPFree (
   LogicalAddress object
);
```

Parameters

object

A pointer to the memory you want to release.

Discussion
Also see the function `MPAllocateAligned` (page 1472).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPGetAllocatedBlockSize

Returns the size of a memory block.

```
ByteCount MPGetAllocatedBlockSize (
   LogicalAddress object
);
```

Parameters

object

The address of the memory block whose size you want to determine.

Return Value
The size of the allocated memory block, in bytes.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPGetNextCpuID

Obtains the next CPU ID in the list of physical processors of the specified memory coherence group.

```
OSStatus MPGetNextCpuID (
   MPCoherenceID owningCoherenceID,
   MPCpuID *cpuID
);
```

Parameters

owningCoherenceID

The ID of the memory coherence group whose physical processor IDs you want to obtain. Pass `kMPInvalidIDErr`, as only one coherence group, internal RAM, is currently defined.

cpuID

On return, `cpuID` points to the ID of the next physical processor.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
By iterating on this function (after calling `MPProcessors` (page 1493) , for example), you can obtain the IDs of all the processors available on the host computer. Generally, you would only use this function in diagnostic programs.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MultiprocessingInfo.h`

MPGetNextTaskID

Obtains the next task ID in the list of available tasks.

```
OSStatus MPGetNextTaskID (
   MPProcessID owningProcessID,
   MPTaskID *taskID
);
```

Parameters

owningProcessID
The ID of the process (typically the application) that owns the tasks. This ID is the same as the process ID handled by the Code Fragment Manager.

taskID
On return, `taskID` points to ID of the next task in the list of tasks.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
By iterating on this function, you can obtain the IDs of all the tasks in a given process. These tasks may be running, ready, or blocked. Generally you would only use this function in diagnostic programs.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MultiprocessingInfo.h`

MPGetTaskStorageValue

Gets the storage value stored at a specified index number.

```
TaskStorageValue MPGetTaskStorageValue (
   TaskStorageIndex taskIndex
);
```

Parameters

index
The index number of the storage value you want to obtain.

Return Value
The value stored at the specified index number. See the description of the `TaskStorageValue` data type.

Discussion
Calling this function from within a task effectively reads a value in a two-dimensional array cross-referenced by task storage index value and the task ID.

Note that since this function does not return any status information, it may not be immediately obvious whether the returned storage value is valid.

Also see the function `MPSetTaskStorageValue` (page 1499).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPModifyNotification

Adds a simple notification to a kernel notification.

```
OSStatus MPModifyNotification (
   MPNotificationID notificationID,
   MPOpaqueID anID,
   void *notifyParam1,
   void *notifyParam2,
   void *notifyParam3
);
```

Parameters

notificationID
The ID of the kernel notification you want to add to..

anID
The ID of the simple notification (semaphore, message group, or event group) you want to add to the kernel notification.

notifyParam1
If `anID` specifies an event group, this parameter should contain the flags to set in the event group when `MPCauseNotification` (page 1476) is called. If `anID` specifies a message queue, this parameter should contain the first pointer-sized value of the message to be sent to the message queue when `MPCauseNotification` (page 1476) is called.

notifyParam2
If `anID` specifies a message queue, this parameter should contain the second pointer-sized value of the message to be sent to the message queue when `MPCauseNotification` (page 1476) is called. Pass `NULL` if you don't need this parameter.

notifyParam3
If `anID` specifies a message queue, this parameter should contain the third pointer-sized value of the message sent to the message queue when `MPCauseNotification` (page 1476) is called. Pass `NULL` if you don't need this parameter.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
You specify the parameters for the simple notifications just as if you were calling the `MPSetTimerNotify` (page 1500) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPModifyNotificationParameters

```
OSStatus MPModifyNotificationParameters (
   MPNotificationID notificationID,
   MPOpaqueIDClass kind,
   void *notifyParam1,
   void *notifyParam2,
   void *notifyParam3
);
```

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Multiprocessing.h`

MPNotifyQueue

Sends a message to the specified message queue.

```
OSStatus MPNotifyQueue (
   MPQueueID queue,
   void *param1,
   void *param2,
   void *param3
);
```

Parameters

queue
The queue ID of the message queue you want to notify.

param1
The first pointer-sized value of the message to send.

param2
The second pointer-sized value of the message to send.

param3
The third pointer-sized value of the message to send.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
This function sends a message to the specified queue, which consist of the three parameters, `param1`, `param2`, and `param3`. The system does not interpret the three values which comprise the text of the message. If tasks are waiting on the specified queue, the first waiting task is unblocked and the task's `MPWaitOnQueue` (page 1506) function completes.

Depending on the queue mode, the system either allocates messages dynamically or assigns them to memory reserved for the queue. In either case, if no more memory is available for messages `MPNotifyQueue` returns `kMPInsufficientResourcesErr`.

You can call this function from an interrupt handler if messages are reserved on the queue. For more information about queueing modes and reserving messages, see `MPSetQueueReserve` (page 1497).

Also see the function `MPWaitOnQueue` (page 1506).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPProcessors

Returns the number of processors on the host computer.

```
ItemCount MPProcessors (
   void
);
```

Return Value
The number of physical processors on the host computer.

Discussion
See also the function `MPProcessorsScheduled` (page 1493).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPProcessorsScheduled

Returns the number of active processors available on the host computer.

```
ItemCount MPProcessorsScheduled (
   void
);
```

Return Value
The number of active processors available on the host computer.

Discussion
The number of active processors is defined as the number of processors scheduled to run tasks. This number varies while the system is running. Advanced power management facilities may stop or start scheduling processors in the system to control power consumption or to maintain a proper operating temperature.

See also the function `MPProcessors` (page 1493).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPRegisterDebugger

Registers a debugger.

```
OSStatus MPRegisterDebugger (
   MPQueueID queue,
   MPDebuggerLevel level
);
```

Parameters

queue

The ID of the queue to which you want exception messages and other information to be sent.

level

The level of this debugger with respect to other debuggers. Exceptions and informational messages are sent first to the debugger with the highest level. If more than one debugger attempts to register at a particular level, only the first debugger is registered. Other attempts return an error.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
In Mac OS X, this function is available but is not implemented. Use system debugging services to write a debugger for Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPRemoteCall

Calls a non-reentrant function and blocks the current task.

```
void * MPRemoteCall (
    MPRemoteProcedure remoteProc,
    void *parameter,
    MPRemoteContext context
);
```

Parameters

remoteProc

A pointer to the application-defined function you want to call. See `MPRemoteProcedure` (page 1508) for more information about the form of this function.

parameter

A pointer to a parameter to pass to the application-defined function. For example, this value could point to a data structure or a memory location.

context

This parameter is ignored; specify `kMPOwningProcessRemoteContext`.

Return Value

The value that your remote procedure callback returned.

Discussion

You use this function to execute code on your application's main task. The *remoteProc* function is scheduled on the application's main run loop and run in the default mode (`kCFRunloopDefaultMode`). If you call this function from your application's main task, the *remoteProc* function is executed immediately in the current mode without blocking the task; otherwise, calling this function blocks the current task until the remote call completes.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPRemoteCallCFM

Calls a non-reentrant function and blocks the current task.

```
void * MPRemoteCallCFM (
   MPRemoteProcedure remoteProc,
   void *parameter,
   MPRemoteContext context
);
```

Parameters

remoteProc

A pointer to the application-defined CFM (Code Fragment Manager) function you want to call. See `MPRemoteProcedure` (page 1508) for more information about the form of this function.

parameter

A pointer to a parameter to pass to the application-defined function. For example, this value could point to a data structure or a memory location.

context

This parameter is ignored; specify `kMPOwningProcessRemoteContext`.

Return Value
The value that your remote procedure callback returned.

Discussion
You use this function to execute code on your application's main task. The *remoteProc* function is scheduled on the application's main run loop and run in the default mode (`kCFRunloopDefaultMode`). If you call this function from your application's main task, the *remoteProc* function is executed immediately in the current mode without blocking the task; otherwise, calling this function blocks the current task until the remote call completes.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Multiprocessing.h`

MPSetEvent

Merges event flags into a specified event group.

```
OSStatus MPSetEvent (
   MPEventID event,
   MPEventFlags flags
);
```

Parameters

event
The ID of the event group you want to set.

flags
The flags you want to merge into the event group.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
The flags are logically ORed with the current flags in the event group. This procedure is an atomic operation to ensure that multiple updates do not get lost. If tasks are waiting on this event group, the first waiting task is unblocked.

Note that you can call this function from an interrupt handler.

Also see the function `MPWaitForEvent` (page 1505).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetExceptionHandler

Sets an exception handler for a task.

```
OSStatus MPSetExceptionHandler (
   MPTaskID task,
   MPQueueID exceptionQ
);
```

Parameters

task

The task to associate with the exception handler.

exceptionQ

The message queue to which an exception message will be sent.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
When an exception handler is set and an exception occurs, the task is suspended and a message is sent to the message queue specified by `exceptionQ`. The message contains the following information:

- The first pointer-sized value contains the ID of the task in which the exception occurred.
- The second pointer-sized value contains the type of exception that occurred. See the header file `MachineExceptions.h` for a listing of exception types.
- The last pointer-sized value is set to `NULL` (reserved for future use).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetQueueReserve

Reserves space for messages on a specified message queue.

```
OSStatus MPSetQueueReserve (
   MPQueueID queue,
   ItemCount count
);
```

Parameters

queue

The ID of the queue whose messages you want to reserve.

count

The number of messages to reserve.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
`MPNotifyQueue` (page 1492) allocates spaces for messages dynamically; that is, memory to hold the message is allocated for the queue at the time of the call. In most cases this method is both speed and storage efficient. However, it is possible that, due to lack of memory resources, space for the message may not be available at the time of the call; in such cases, `MPNotifyQueue` (page 1492) will return `kInsufficientResourcesErr`.

If you must have guaranteed message delivery, or if you need to call `MPNotifyQueue` (page 1492) from an interrupt handler, you should reserve space on the specified queue by calling `MPSetQueueReserve`. Because such allocated space is reserved for duration of the queue's existence, you should avoid straining internal system resources by reserving messages only when absolutely necessary. Note that if you have reserved messages on a queue, additional space cannot be added dynamically if the number of messages exceeds the number reserved for that queue.

The number of reserved messages is set to `count`, lowering or increasing the current number of reserved messages as required. If `count` is set to zero, no messages are reserved for the queue, and space for messages is allocated dynamically.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetTaskState

Sets state information for a suspended task.

```
OSStatus MPSetTaskState (
   MPTaskID task,
   MPTaskStateKind kind,
   void *info
);
```

Parameters

task

The task whose state information you want to set.

kind

The kind of state information you want to set. See "Task State Constants" (page 1530) for a listing of possible values. Note that some state information is read-only and cannot be changed using this function.

info

A pointer to a data structure holding the state information you want to set. The format of the data structure varies depending on the state information you want to set. See the header file `MachineExceptions.h` for the formats of the various state information structures.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If you specify `kMPTaskState32BitMemoryException` for the state information, this function returns `kMPInsufficientResourcesErr`, since the exception state information is read-only. Attempting to set state information for a running task will also return `kMPInsufficientResourcesErr`.

Discussion
You can use this function to set register contents or exception information for a particular task. However, some state information, such as the exception information (as specified by `kMPTaskState32BitMemoryException`) as well as the `MSR`, `ExceptKind`, `DSISR`, and `DAR` machine registers (specified under `kMPTaskStateMachine`) are read-only. Attempting to set the read-only machine registers will do nothing, while attempting to set the exception information will return an error.

Also see the function `MPExtractTaskState` (page 1488).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetTaskStorageValue

Sets the storage value for a given index number.

```
OSStatus MPSetTaskStorageValue (
   TaskStorageIndex taskIndex,
   TaskStorageValue value
);
```

Parameters

index
The index number whose storage value you want to set.

value
The value you want to set.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
Typically you use `MPSetTaskStorageValue` to store pointers to task-specific structures or data.

Calling this function from within a task effectively assigns a value in a two-dimensional array cross-referenced by task storage index value and the task ID.

Also see the function `MPGetTaskStorageValue` (page 1490).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetTaskType

Sets the type of the task.

```
OSStatus MPSetTaskType (
   MPTaskID task,
   OSType taskType
);
```

Return Value
The `noErr` result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
This function does nothing and should not be used.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Multiprocessing.h`

MPSetTaskWeight

Assigns a relative weight to a task, indicating how much processor time it should receive compared to other available tasks.

```
OSStatus MPSetTaskWeight (
   MPTaskID task,
   MPTaskWeight weight
);
```

Parameters

task
The ID of the task to which you want to assign a weighting.

weight
The relative weight to assign. This value can range from 1 to 10,000, with the default value being 100.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
The approximate processor share is defined as:

```
weight of the task / total weight of available tasks
```

For a set of ready tasks, the amount of CPU time dedicated to the tasks will be determined by the dynamically computed share. Note that the processor share devoted to tasks may deviate from the suggested weighting if critical tasks require attention. For example, a real-time task (such as a QuickTime movie) may require more than its relative weight of processor time, and the scheduler will adjust proportions accordingly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSetTimerNotify

Sets the notification information associated with a timer.

```
OSStatus MPSetTimerNotify (
   MPTimerID timerID,
   MPOpaqueID anID,
   void *notifyParam1,
   void *notifyParam2,
   void *notifyParam3
);
```

Parameters

timerID

The ID of the timer whose notification information you want to set.

notificationID

The ID of the notification mechanism to associate with the timer. This value should be the ID of an event group, a message queue, or a semaphore.

notifyParam1

If `anID` specifies an event group, this parameter should contain the flags to set in the event group when the timer expires. If `anID` specifies a message queue, this parameter should contain the first pointer-sized value of the message to be sent to the message queue when the timer expires.

notifyParam2

If `anID` specifies a message queue, this parameter should contain the second pointer-sized value of the message to be sent to the message queue when the timer expires. Pass `NULL` if you don't need this parameter.

notifyParam3

If `anID` specifies a message queue, this parameter should contain the third pointer-sized value of the message sent to the message queue when the timer expires. Pass `NULL` if you don't need this parameter.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion

When the timer expires, Multiprocessing Services checks the notification ID, and if it is valid, notifies the related notification mechanisms (that is, event groups, queues, or semaphores) you had specified in your `MPSetTimerNotify` (page 1500) calls.

You can specify multiple notification mechanisms by calling this function several times. For example, you can call `MPSetTimerNotify` to specify a message queue and then call it again to specify a semaphore. When the timer expires, a message is sent to the message queue and the appropriate semaphore is signaled. You cannot, however, specify more than one notification per notification mechanism (for example, if you call `MPSetTimerNotify` twice, specifying different messages or message queues in each call, the second call will overwrite the first). Note that if a call to `MPSetTimerNotify` returns an error, any previous calls specifying the same timer are still valid; previously set notifications will still be notified when the timer expires.

You can set the notification information at any time. If the timer is armed, it will modify the notification parameters dynamically. If the timer is disarmed, it will modify the notification parameters to be used for the next `MPArmTimer` (page 1473) call.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPSignalSemaphore

Signals a semaphore.

```
OSStatus MPSignalSemaphore (
   MPSemaphoreID semaphore
);
```

Parameters

semaphore

The ID of the semaphore you want to signal.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533). If the value of the semaphore was already at the maximum, `MPSignalSemaphore` returns `kInsufficientResourcesErr`.

Discussion

If tasks are waiting on the semaphore, the oldest (first queued) task is unblocked so that the corresponding `MPWaitOnSemaphore` (page 1507) call for that task completes. Otherwise, if the value of the semaphore is not already equal to its maximum value, it is incremented by one.

Note that you can call this function from an interrupt handler.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPTaskIsPreemptive

Determines whether a task is preemptively scheduled.

```
Boolean MPTaskIsPreemptive (
   MPTaskID taskID
);
```

Parameters

taskID

The task you want to check. Pass `kMPNoID` or `kInvalidID` if you want to specify the current task.

Return Value

If true, the task is preemptively scheduled. If false, the task is cooperatively scheduled.

Discussion

If you have code that may be called from either cooperative or preemptive tasks, that code can call `MPTaskIsPreemptive` if its actions should differ depending on its execution environment.

Note that you can call this function from an interrupt handler.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Multiprocessing.h`

MPTerminateTask

Terminates an existing task.

```
OSStatus MPTerminateTask (
   MPTaskID task,
   OSStatus terminationStatus
);
```

Parameters

task

The ID of the task you wish to terminate.

terminationStatus

A value of type `OSStatus` indicating termination status. This value is sent to the termination status message queue you specified in `MPCreateTask` (page 1479) in place of the task function's result code.

Return Value

A result code. See "Multiprocessing Services Result Codes" (page 1533). If the task to be terminated is already in the process of termination, `MPTerminateTask` returns `kMPInsufficientResourcesErr`. You do not need to take any additional action if this occurs.

Discussion

You should be very careful when calling `MPTerminateTask`. As defined, this call will asynchronously and abruptly terminate a task, potentially leaving whatever structures or resources it was operating upon in an indeterminate state. Mac OS X exacerbates this problem, as MP tasks can use many more system services that are not expecting client threads to asynchronously terminate, and these services do not take the rather complicated steps necessary to protect against, or recover from, such a situation.

However, there are situations in which calling `MPTerminateTask` is useful and relatively safe. One such situation is when your application or service is quitting and you know that the task you wish to terminate is waiting on an MP synchonization construct (queue, event, semaphore or critical region). While you could do this more cleanly by waking the task and causing it to exit on its own, doing so may not always be practical.

For example, suppose you have several service tasks performing background processing for your application. These service tasks wait on a queue, onto which the application places requests for processing. When the task is done with a request, it notifies another queue, which the application polls. Since the main application task is placing items on the shared queue, and receiving notifications when the requests are done, it can track whether or not there are outstanding requests being processed. If all outstanding requests have, in fact, been processed, it is relatively safe to terminate a task (or all tasks) waiting on the request queue.

You should not assume that the task has completed termination when this call returns; the proper way to synchronize with task termination is to wait on the termination queue (specified in `MPCreateTask` (page 1479)) until a message appears. Because task termination is a multistage activity, it is possible for a preemptive task to attempt to terminate a task that is already undergoing termination. In such cases, `MPTerminateTask` returns `kMPInsufficientResourcesErr`.

Note that Multiprocessing Services resources (event groups, queues, semaphores, and critical regions) owned by a preemptive task are not released when that task terminates. If a task has a critical region locked when it terminates, the critical region remains in the locked state. Multiprocessing Services resources no longer needed should be explicitly deleted by the task that handles the termination message. All Multiprocessing Services resources created by tasks are released when their owning process (that is, the host application) terminates.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPThrowException

Throws an exception to a specified task.

```
OSStatus MPThrowException (
   MPTaskID task,
   MPExceptionKind kind
);
```

Parameters

task

The task to which the exception should be thrown.

kind

The type of exception to give to the task.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533). If the task is already suspended or if the task is not defined to take thrown exceptions, the function returns `kMPInsufficientResourcesErr`.

Discussion
The exception is treated in the same manner as any other exception taken by a task. However, since it is asynchronous, it may not be presented immediately.

By convention, you should set the exception kind to `kMPTaskStoppedErr` if you want to suspend a task. In general, you should do so only if you are debugging and wish to examine the state of the task. Otherwise you should block the task using one of the traditional notification mechanisms (such as a message queue).

An exception can be thrown at any time, whether that task is running, eligible to be run (that is, ready), or blocked. The task is suspended and an exception message may be generated the next time the task is about to run. Note that this may never occur— for example, if the task is deadlocked or the resource it is waiting on is never released. If the task is currently blocked when this function is executed, `kMPTaskBlockedErr` is returned. If the task was suspended immediately at the conclusion of this function call the return value is `kMPTaskStoppedErr`.

In Mac OS X, this function is available but is not implemented.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPUnregisterDebugger

Unregisters a debugger.

```
OSStatus MPUnregisterDebugger (
   MPQueueID queue
);
```

Parameters

queue

The ID of the queue whose debugger you want to unregister.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
In Mac OS X, this function is available but is not implemented. Use system debugging services to write a debugger for Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPWaitForEvent

Retrieves event flags from a specified event group.

```
OSStatus MPWaitForEvent (
   MPEventID event,
   MPEventFlags *flags,
   Duration timeout
);
```

Parameters

event

The event group whose flags you want to retrieve.

flags

On return, `flags` contains the flags of the specified event group. Pass `NULL` if you do not need any flag information.

timeout

The maximum time to wait for events before timing out. See "Timer Duration Constants" (page 1531) for a list of constants you can use to specify the wait interval.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
This function obtains event flags from the specified event group. The timeout specifies how long to wait for events if none are present when the call is made. If any flags are set when this function is called, all the flags in the event group are moved to the `flag` field and the event group is cleared. This obtaining and clearing action is an atomic operation to ensure that no updates are lost. If multiple tasks are waiting on an event group, only one can obtain any particular set of flags.

If you call this function from a cooperative task, you should specify only `kDurationImmediate` for the timeout length; other waits will cause the task to block.

Also see the function `MPSetEvent` (page 1496).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPWaitOnQueue

Obtains a message from a specified message queue.

```
OSStatus MPWaitOnQueue (
   MPQueueID queue,
   void **param1,
   void **param2,
   void **param3,
   Duration timeout
);
```

Parameters

queue
The ID of the message queue from which to receive the notification.

param1
On return, the first pointer-sized value of the notification message. Pass `NULL` if you do not need this portion of the message.

param2
On return, the second pointer-sized value of the notification message. Pass `NULL` if you do not need this portion of the message.

param3
On return, the third pointer-sized value of the notification message. Pass `NULL` if you do not need this portion of the message.

timeout
The time to wait for a notification before timing out. See "Timer Duration Constants" (page 1531) for a list of constants you can use to specify the wait interval.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
This function receives a message from the specified message queue. If no messages are currently available, the timeout specifies how long the function should wait for one. Tasks waiting on the queue are handled in a first in, first out manner; that is, the first task to wait on the queue receives the message from the `MPNotifyQueue` (page 1492) call.

After calling this function, when a message appears, it is removed from the queue and the three fields, `param1`, `param2`, and `param3` are set to the values specified by the message text. Note these parameters are pointers to variables to be set with the message text.

If you call this function from a cooperative task, you should specify only `kDurationImmediate` for the timeout length; other waits will cause the task to block.

Also see the function `MPNotifyQueue` (page 1492).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPWaitOnSemaphore

Waits on a semaphore

```
OSStatus MPWaitOnSemaphore (
   MPSemaphoreID semaphore,
   Duration timeout
);
```

Parameters

semaphore
The ID of the semaphore you want to wait on.

timeout
The maximum time the function should wait before timing out. See "Timer Duration Constants" (page 1531) for a list of constants you can use to specify the wait interval.

Return Value
A result code. See "Multiprocessing Services Result Codes" (page 1533).

Discussion
If the value of the semaphore is greater than zero, the value is decremented and the function returns with `noErr`. Otherwise, the task is blocked awaiting a signal until the specified timeout is exceeded.

If you call this function from a cooperative task, you should specify only `kDurationImmediate` for the timeout length; other waits will cause the task to block.

Also see the function `MPSignalSemaphore` (page 1502).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPYield

Allows a task to yield the processor to another task.

```
void MPYield (
   void
);
```

Discussion
This function indicates to the scheduler that another task can run. Other than possibly yielding the processor to another task or application, the call has no effect. Note that since tasks are preemptively scheduled, an implicit yield may occur at any point, whether or not this function is called.

In most cases you should not need to call this function. The most common use of `MPYield` is to release the processor when a task is in a loop in which further progress is dependent on other tasks, and the task cannot be blocked by waiting on a Multiprocessing Services resource. You should avoid such busy waiting whenever possible.

Note that you can call this function from an interrupt handler.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

_MPIsFullyInitialized

Indicates whether Multiprocessing Services is available for use.

```
Boolean _MPIsFullyInitialized (
   void
);
```

Return Value
If true, Multiprocessing Services is available for use; otherwise, false.

Declared In
`Multiprocessing.h`

Callbacks

MPRemoteProcedure

Defines a remote procedure call.

```
typedef void* (*MPRemoteProcedure) (
    void *parameter
);
```

For example, this is how you would declare the application-defined function if you were to name the function `MyRemoteProcedure`:

```
void* MyRemoteProcedure (
    void *parameter
);
```

Parameters

parameter
A pointer to the application-defined value you passed to the function `MPRemoteCallCFM` (page 1495). For example, this value could point to a data structure or a memory location.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

TaskProc

Defines the entry point of a task.

```
typedef OSStatus (*TaskProc) (
    void *parameter
);
```

For example, this is how you would declare the application-defined function if you were to name the function `MyTaskProc`:

```
OSStatus MyTaskProc (
    void *parameter
);
```

Parameters

parameter

A pointer to the application-defined value you passed to the function `MPCreateTask` (page 1479). For example, this value could point to a data structure or a memory location.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

Data Types

MPAddressSpaceID

```
typedef struct OpaqueMPAddressSpaceID * MPAddressSpaceID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPAddressSpaceInfo

```
struct MPAddressSpaceInfo {
    PBVersion version;
    MPProcessID processID;
    MPCoherenceID groupID;
    ItemCount nTasks;
    UInt32 vsid[16];
};
typedef struct MPAddressSpaceInfo MPAddressSpaceInfo;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`MultiprocessingInfo.h`

MPAreaID

```
typedef struct OpaqueMPAreaID * MPAreaID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPCoherenceID

Represents a memory coherence group.

```
typedef struct OpaqueMPCoherenceID * MPCoherenceID;
```

Discussion
A coherence group is the set of processors and other bus controllers that have cache-coherent access to memory. Mac OS 9 defines only one coherence group, which is all the processors that can access internal memory (RAM). Other coherence groups are possible; for example, a PCI card with its own memory and processors can comprise a coherence group.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPConsoleID

```
typedef struct OpaqueMPConsoleID * MPConsoleID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPCpuID

Represents a CPU ID.

```
typedef struct OpaqueMPCpuID * MPCpuID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPCriticalRegionID

Represents a critical region ID, which Multiprocessing Services uses to manipulate critical regions.

```
typedef struct OpaqueMPCriticalRegionID * MPCriticalRegionID;
```

Discussion
You obtain a critical region ID by calling the function MPCreateCriticalRegion (page 1476).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPCriticalRegionInfo

```
struct MPCriticalRegionInfo {
    PBVersion version;
    MPProcessID processID;
    OSType regionName;
    ItemCount nWaiting;
    MPTaskID waitingTaskID;
    MPTaskID owningTask;
    ItemCount count;
};
typedef struct MPCriticalRegionInfo MPCriticalRegionInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
MultiprocessingInfo.h

MPEventFlags

Represents event information for an event group.

```
typedef UInt32 MPEventFlags;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPEventID

Represents an event group ID, which Multiprocessing Services uses to manipulate event groups.

```
typedef struct OpaqueMPEventID * MPEventID;
```

Discussion
You obtain an event group ID by calling the function `MPCreateEvent` (page 1477).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPEventInfo

```
struct MPEventInfo {
    PBVersion version;
    MPProcessID processID;
    OSType eventName;
    ItemCount nWaiting;
    MPTaskID waitingTaskID;
    MPEventFlags events;
};
typedef struct MPEventInfo MPEventInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MultiprocessingInfo.h`

MPExceptionKind

Represents the kind of exception thrown.

```
typedef UInt32 MPExceptionKind;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPNotificationID

Represents a notification ID, which Multiprocessing Services uses to manipulate kernel notifications.

```
typedef struct OpaqueMPNotificationID * MPNotificationID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPNotificationInfo

```
struct MPNotificationInfo {
    PBVersion version;
    MPProcessID processID;
    OSType notificationName;
    MPQueueID queueID;
    void * p1;
    void * p2;
    void * p3;
    MPEventID eventID;
    MPEventFlags events;
    MPSemaphoreID semaphoreID;
};
typedef struct MPNotificationInfo MPNotificationInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
MultiprocessingInfo.h

MPOpaqueID

Represents a generic notification ID (that is, an ID that could be a queue ID, event ID, kernel notification ID, or semaphore ID).

```
typedef struct OpaqueMPOpaqueID * MPOpaqueID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Multiprocessing.h

MPOpaqueIDClass

```
typedef UInt32 MPOpaqueIDClass;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPPageSizeClass

```
typedef UInt32 MPPageSizeClass;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPProcessID

Represents a process ID.

```
typedef struct OpaqueMPProcessID * MPProcessID;
```

Discussion
Note that this process ID is identical to the process ID (or context ID) handled by the Code Fragment Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPQueueID

Represents a queue ID, which Multiprocessing Services uses to manipulate message queues.

```
typedef struct OpaqueMPQueueID * MPQueueID;
```

Discussion
You obtain a queue ID by calling the function `MPCreateQueue` (page 1478).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPQueueInfo

```
struct MPQueueInfo {
    PBVersion version;
    MPProcessID processID;
    OSType queueName;
    ItemCount nWaiting;
    MPTaskID waitingTaskID;
    ItemCount nMessages;
    ItemCount nReserved;
    void * p1;
    void * p2;
    void * p3;
};
typedef struct MPQueueInfo MPQueueInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MultiprocessingInfo.h`

MPSemaphoreCount

Represents a semaphore count.

```
typedef ItemCount MPSemaphoreCount;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSemaphoreID

Represents a semaphore ID, which Multiprocessing Services uses to manipulate semaphores.

```
typedef struct OpaqueMPSemaphoreID * MPSemaphoreID;
```

Discussion
You obtain a semaphore ID by calling the function `MPCreateSemaphore` (page 1478).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPSemaphoreInfo

```
struct MPSemaphoreInfo {
    PBVersion version;
    MPProcessID processID;
    OSType semaphoreName;
    ItemCount nWaiting;
    MPTaskID waitingTaskID;
    ItemCount maximum;
    ItemCount count;
};
typedef struct MPSemaphoreInfo MPSemaphoreInfo;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MultiprocessingInfo.h`

MPTaskID

Represents a task ID.

```
typedef struct OpaqueMPTaskID * MPTaskID;
```

Discussion
You obtain a task ID by calling the function `MPCreateTask` (page 1479).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPTaskInfo

Contains information about a task.

```
struct MPTaskInfo {
    PBVersion version;
    OSType name;
    OSType queueName;
    UInt16 runState;
    UInt16 lastCPU;
    UInt32 weight;
    MPProcessID processID;
    AbsoluteTime cpuTime;
    AbsoluteTime schedTime;
    AbsoluteTime creationTime;
    ItemCount codePageFaults;
    ItemCount dataPageFaults;
    ItemCount preemptions;
    MPCpuID cpuID;
    MPOpaqueID blockedObject;
    MPAddressSpaceID spaceID;
    LogicalAddress stackBase;
    LogicalAddress stackLimit;
    LogicalAddress stackCurr;
};
typedef struct MPTaskInfo MPTaskInfo;
```

Fields

`version`
: The version of this data structure.

`name`
: The name of the task.

`queueName`
: A four-byte code indicating the status of the queue waiting on the task.

`runState`
: The current state of the task (running, ready, or blocked).

`lastCPU`
: The address of the last processor that ran this task.

`weight`
: The weighting assigned to this task.

`processID`
: The ID of the process that owns this task.

`cpuTime`
: The accumulated CPU time used by the task.

`schedTime`
: The time when the task was last scheduled.

`creationTime`
: The time when the task was created.

`codePageFaults`
: The number of page faults that occurred during code execution.

`dataPageFaults`
: The number of page faults that occurred during data access.

`preemptions`
: The number of times this task was preempted.

`cpuID`
The ID of the last processor that ran this task.

`blockedObject`
Reserved for use by Mac OS X.

`spaceID`
Address space ID of this task.

`stackBase`
The lowest memory address of the task's stack.

`stackLimit`
The highest memory address of the task's stack.

`stackCurr`
The current stack address.

Discussion
If you specify the `kMPTaskStateTaskInfo` constant when calling the function `MPExtractTaskState` (page 1488) , Multiprocessing Services returns state information in an `MPTaskInfo` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPTaskInfoVersion2

```
struct MPTaskInfoVersion2 {
    PBVersion version;
    OSType name;
    OSType queueName;
    UInt16 runState;
    UInt16 lastCPU;
    UInt32 weight;
    MPProcessID processID;
    AbsoluteTime cpuTime;
    AbsoluteTime schedTime;
    AbsoluteTime creationTime;
    ItemCount codePageFaults;
    ItemCount dataPageFaults;
    ItemCount preemptions;
    MPCpuID cpuID;
};
typedef struct MPTaskInfoVersion2 MPTaskInfoVersion2;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPTaskStateKind

```
typedef UInt32 MPTaskStateKind;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPTaskWeight

Represents the relative processor weighting of a task.

```
typedef UInt32 MPTaskWeight;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

MPTimerID

Represents a timer ID.

```
typedef struct OpaqueMPTimerID * MPTimerID;
```

Discussion
You obtain a timer ID by calling the function `MPCreateTimer` (page 1480).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

TaskStorageIndex

Represents a task storage index value used by functions described in "Accessing Per-Task Storage Variables."

```
typedef ItemCount TaskStorageIndex;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

TaskStorageValue

Represents a task storage value used by functions described in "Accessing Per-Task Storage Variables."

```
typedef LogicalAddress TaskStorageValue;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Multiprocessing.h`

Constants

Allocation constants

The maximum memory allocation size.

```
enum {
    kMPMaxAllocSize = 1024L * 1024 * 1024
};
```

Constants
`kMPMaxAllocSize`
The maximum allocation size: 1GB.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

Task IDs

Use to specify no task ID.

```
enum {
    kMPNoID = kInvalidID
};
```

Constants
`kMPNoID`
No task ID.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

Discussion
Used when calling `MPTaskIsPreemptive` (page 1502) if you want to specify the current task.

Data Structure Version Constants

Data structure version information constants.

```
enum {
    kMPQueueInfoVersion = 1L | (kOpaqueQueueID << 16),
    kMPSemaphoreInfoVersion = 1L | (kOpaqueSemaphoreID << 16),
    kMPEventInfoVersion = 1L | (kOpaqueEventID << 16),
    kMPCriticalRegionInfoVersion = 1L | (kOpaqueCriticalRegionID << 16),
    kMPNotificationInfoVersion = 1L | (kOpaqueNotificationID << 16),
    kMPAddressSpaceInfoVersion = 1L | (kOpaqueAddressSpaceID << 16)
};
```

Constants

`kMPQueueInfoVersion`
The `MPQueueInfo` structure version.
Available in Mac OS X v10.0 and later.
Declared in `MultiprocessingInfo.h`.

`kMPSemaphoreInfoVersion`
The `MPSemaphoreInfo` structure version.
Available in Mac OS X v10.0 and later.
Declared in `MultiprocessingInfo.h`.

`kMPEventInfoVersion`
The `MPEventInfo` structure version.
Available in Mac OS X v10.0 and later.
Declared in `MultiprocessingInfo.h`.

`kMPCriticalRegionInfoVersion`
The `MPCriticalRegionInfo` structure version.
Available in Mac OS X v10.0 and later.
Declared in `MultiprocessingInfo.h`.

`kMPNotificationInfoVersion`
The `MPNotificationInfo` structure version.
Available in Mac OS X v10.0 and later.
Declared in `MultiprocessingInfo.h`.

`kMPAddressSpaceInfoVersion`
The `MPAddressSpaceInfo` structure version.
Available in Mac OS X v10.1 and later.
Declared in `MultiprocessingInfo.h`.

Values for the MPOpaqueIDClass type

Constants indicating the source of a generic notification.

```
enum {
    kOpaqueAnyID = 0,
    kOpaqueProcessID = 1,
    kOpaqueTaskID = 2,
    kOpaqueTimerID = 3,
    kOpaqueQueueID = 4,
    kOpaqueSemaphoreID = 5,
    kOpaqueCriticalRegionID = 6,
    kOpaqueCpuID = 7,
    kOpaqueAddressSpaceID = 8,
    kOpaqueEventID = 9,
    kOpaqueCoherenceID = 10,
    kOpaqueAreaID = 11,
    kOpaqueNotificationID = 12,
    kOpaqueConsoleID = 13
};
```

Constants

`kOpaqueAnyID`
Any source.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueProcessID`
A process.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueTaskID`
A task.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueTimerID`
A timer.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueQueueID`
A queue.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueSemaphoreID`
A semaphore.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueCriticalRegionID`
A critical region.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueCpuID`
A CPU.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueAddressSpaceID`
An address space.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueEventID`
An event.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueCoherenceID`
A coherence group.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueAreaID`
An area.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueNotificationID`
A notification.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kOpaqueConsoleID`
A console.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

Memory Allocation Alignment Constants

Specify the alignment of the desired memory block when calling the `MPAllocateAligned` function.

```
enum {
    kMPAllocateDefaultAligned = 0,
    kMPAllocate8ByteAligned = 3,
    kMPAllocate16ByteAligned = 4,
    kMPAllocate32ByteAligned = 5,
    kMPAllocate1024ByteAligned = 10,
    kMPAllocate4096ByteAligned = 12,
    kMPAllocateMaxAlignment = 16,
    kMPAllocateAltiVecAligned = kMPAllocate16ByteAligned,
    kMPAllocateVMXAligned = kMPAllocateAltiVecAligned,
    kMPAllocateVMPageAligned = 254,
    kMPAllocateInterlockAligned = 255
};
```

Constants

`kMPAllocateDefaultAligned`
Use the default alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocate8ByteAligned`
Use 8-byte alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocate16ByteAligned`
Use 16-byte alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocate32ByteAligned`
Use 32-byte alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocate1024ByteAligned`
Use 1024-byte alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocate4096ByteAligned`
Use 4096-byte alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocateMaxAlignment`
Use the maximum alignment (65536 byte).
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocateAltiVecAligned`
Use AltiVec alignment.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPAllocateVMXAligned`
Use VMX (now called AltiVec) alignment.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateVMPageAligned`
Use virtual memory page alignment. This alignment is set at runtime.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateInterlockAligned`
Use interlock alignment, which is the alignment needed to allow the use of CPU interlock instructions (that is, `lwarx` and `stwcx`.) on the returned memory address. This alignment is set at runtime. In most cases you would never need to use this alignment.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Memory Allocation Option Constants

Specify optional actions when calling the `MPAllocateAligned` function.

```
enum {
    kMPAllocateClearMask = 0x0001,
    kMPAllocateGloballyMask = 0x0002,
    kMPAllocateResidentMask = 0x0004,
    kMPAllocateNoGrowthMask = 0x0010,
    kMPAllocateNoCreateMask = 0x0020
};
```

Constants

`kMPAllocateClearMask`
Zero out the allocated memory block.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateGloballyMask`
Allocate memory from in memory space that is visible to all processes. Note that such globally-allocated space is not automatically reclaimed when the allocating process terminates. By default, `MPAllocateAligned` (page 1472) allocates memory from process-specific (that is, not global) memory.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateResidentMask`
Allocate memory from resident memory only (that is, the allocated memory is not pageable).

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateNoGrowthMask`
Do not attempt to grow the pool of available memory. Specifying this option is useful, as attempting to grow memory may cause your task to block until such memory becomes available.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPAllocateNoCreateMask`
Do not attempt to create the pool if it does not yet exist.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

MPDebuggerLevel

Indicates the debugger level.

```
typedef UInt32 MPDebuggerLevel;
enum {
    kMPLowLevelDebugger = 0x00000000,
    kMPMidLevelDebugger = 0x10000000,
    kMPHighLevelDebugger = 0x20000000
};
```

Constants

`kMPLowLevelDebugger`
The low-level debugger.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

`kMPMidLevelDebugger`
The mid-level debugger.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

`kMPHighLevelDebugger`
The high-level debugger.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

Library Version Constants

Identifies the current library version.

```
enum {
    MPLibrary_MajorVersion = 2,
    MPLibrary_MinorVersion = 3,
    MPLibrary_Release = 1,
    MPLibrary_DevelopmentRevision = 1
};
```

Constants

`MPLibrary_MajorVersion`
Major version number.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`MPLibrary_MinorVersion`
Minor version number.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`MPLibrary_Release`
Release number.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`MPLibrary_DevelopmentRevision`
Development revision number.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Remote Call Context Option Constants

Specify which contexts are allowed to execute the callback function when using `MPRemoteCall`.

```
enum {
    kMPAnyRemoteContext = 0,
    kMPOwningProcessRemoteContext = 1,
    kMPInterruptRemoteContext = 2,
    kMPAsyncInterruptRemoteContext = 3
};
typedef UInt8 MPRemoteContext;
```

Constants

`kMPAnyRemoteContext`
Any cooperative context can execute the function. Note that the called function may not have access to any of the owning context's process-specific low-memory values.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPOwningProcessRemoteContext`
Only the context that owns the task can execute the function.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPInterruptRemoteContext`
Unsupported in Mac OS X.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

`kMPAsyncInterruptRemoteContext`
Unsupported in Mac OS X.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

Discussion
These constants are used to support older versions of Mac OS and are ignored in Mac OS X.

Task Creation Options

Specify optional actions when calling the `MPCreateTask` function.

```
enum {
    kMPCreateTaskSuspendedMask = 1L << 0,
    kMPCreateTaskTakesAllExceptionsMask = 1L << 1,
    kMPCreateTaskNotDebuggableMask = 1L << 2,
    kMPCreateTaskValidOptionsMask = kMPCreateTaskSuspendedMask |
kMPCreateTaskTakesAllExceptionsMask | kMPCreateTaskNotDebuggableMask
};
typedef OptionBits MPTaskOptions;
```

Constants

`kMPCreateTaskSuspendedMask`

Unsupported in Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPCreateTaskTakesAllExceptionsMask`

The task will take all exceptions, including those normally handled by the system, such as page faults.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPCreateTaskNotDebuggableMask`

Unsupported in Mac OS X.

Available in Mac OS X v10.1 and later.

Declared in `Multiprocessing.h`.

`kMPCreateTaskValidOptionsMask`

Include all valid options for this task.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Task Exception Disposal Constants

Specify actions to take on an exception when passed in the `action` parameter of the `MPDisposeTaskException` function.

```
enum {
    kMPTaskPropagate = 0,
    kMPTaskResumeStep = 1,
    kMPTaskResumeBranch = 2,
    kMPTaskResumeMask = 0x0000,
    kMPTaskPropagateMask = 1 << kMPTaskPropagate,
    kMPTaskResumeStepMask = 1 << kMPTaskResumeStep,
    kMPTaskResumeBranchMask = 1 << kMPTaskResumeBranch
};
```

Constants

`kMPTaskPropagate`
The exception is propagated.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskResumeStep`
The task is resumed and single step is enabled.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskResumeBranch`
The task is resumed and branch stepping is enabled.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskResumeMask`
Resume the task.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskPropagateMask`
Propagate the exception to the next debugger level.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskResumeStepMask`
Resume the task and enable single stepping.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

`kMPTaskResumeBranchMask`
Resume the task and enable branch stepping.
Available in Mac OS X v10.0 and later.
Declared in `Multiprocessing.h`.

Task Information Structure Version Constant

Indicates the current version of the `MPTaskInfo` structure (returned as the first field).

```
enum {
    kMPTaskInfoVersion = 3
};
```

Constants

`kMPTaskInfoVersion`

The current version of the task information structure.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Task Run State Constants

Indicate the state of the task when returned as part of the `MPTaskInfo` data structure.

```
enum {
    kMPTaskBlocked = 0,
    kMPTaskReady = 1,
    kMPTaskRunning = 2
};
```

Constants

`kMPTaskBlocked`

The task is blocked..

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskReady`

The task is ready for execution.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskRunning`

The task is currently running.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Task State Constants

Specify what states you want to set or obtain when calling the `MPExtractTaskState` or `MPSetTaskState` functions.

```
enum {
    kMPTaskStateRegisters = 0,
    kMPTaskStateFPU = 1,
    kMPTaskStateVectors = 2,
    kMPTaskStateMachine = 3,
    kMPTaskState32BitMemoryException = 4,
    kMPTaskStateTaskInfo = 5
};
```

Constants

`kMPTaskStateRegisters`
The task's general-purpose (GP) registers. The `RegisterInformationPowerPC` structure in `MachineExceptions.h` defines the format of this information.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskStateFPU`
The task's floating point registers. The `FPUInformationPowerPC` structure in `MachineExceptions.h` defines the format of this information.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskStateVectors`
The task's vector registers. The `VectorInformationPowerPC` structure in `MachineExceptions.h` defines the format of this information.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskStateMachine`
The task's machine registers. The `MachineInformationPowerPC` structure in `MachineExceptions.h` defines the format of this information. Note that the MSR, ExceptKind, DSISR, and DAR registers are read-only.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskState32BitMemoryException`
The task's exception information for older 32-bit memory exceptions (that is, memory exceptions on 32-bit CPUs). The `MemoryExceptionInformation` structure in `MachineExceptions.h` defines the format of this information. This exception information is read-only.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTaskStateTaskInfo`
Static and dynamic information about the task, as described by the data structure `MPTaskInfo` (page 1516). This task information is read-only.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Timer Duration Constants

Specify the maximum time a task should wait for an event to occur.

```
enum {
    kDurationImmediate = 0,
    kDurationForever = 0x7FFFFFFF,
    kDurationMillisecond = 1,
    kDurationMicrosecond = -1
};
```

Constants

`kDurationImmediate`

The task times out immediately, whether or not the event has occurred. If the event occurred, the return status is `noErr`. If the event did not occur, the return status is `kMPTimeoutErr` (assuming no other errors occurred).

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kDurationForever`

The task waits forever. The blocking call waits until either the event occurs, or until the object being waited upon (such as a message queue) is deleted.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kDurationMillisecond`

The task waits one millisecond before timing out.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kDurationMicrosecond`

The task waits one microsecond before timing out.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Discussion

You can use these constants in conjunction with other values to indicate specific wait intervals. For example, to wait 1 second, you can pass `kDurationMillisecond * 1000`.

Timer Option Masks

Indicate optional actions when calling `MPArmTimer`.

```
enum {
    kMPPreserveTimerIDMask = 1L << 0,
    kMPTimeIsDeltaMask = 1L << 1,
    kMPTimeIsDurationMask = 1L << 2
};
```

Constants

`kMPPreserveTimerIDMask`

Specifying this mask prevents the timer from being deleted when it expires.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTimeIsDeltaMask`

Specifying this mask indicates that the specified time should be added to the previous expiration time to form the new expiration time. You can use this mask to compensate for timing drift caused by the finite amount of time required to arm the timer, receive the notification, and so on.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

`kMPTimeIsDurationMask`

Specifying this mask indicates that the specified expiration time is of type `Duration`. You can use this mask to avoid having to call time conversion routines when specifying an expiration time.

Available in Mac OS X v10.0 and later.

Declared in `Multiprocessing.h`.

Result Codes

Result codes defined for Multiprocessing Services are listed below.

Result Code	Value	Description
`kMPIterationEndErr`	-29275	Available in Mac OS X v10.0 and later.
`kMPPrivilegedErr`	-29276	Available in Mac OS X v10.0 and later.
`kMPProcessCreatedErr`	-29288	Available in Mac OS X v10.0 and later.
`kMPProcessTerminatedErr`	-29289	Available in Mac OS X v10.0 and later.
`kMPTaskCreatedErr`	-29290	Available in Mac OS X v10.0 and later.
`kMPTaskBlockedErr`	-29291	The desired task is blocked. Available in Mac OS X v10.0 and later.
`kMPTaskStoppedErr`	-29292	The desired task is stopped. Available in Mac OS X v10.0 and later.
`kMPDeletedErr`	-29295	The desired notification the function was waiting upon was deleted. Available in Mac OS X v10.0 and later.
`kMPTimeoutErr`	-29296	The designated timeout interval passed before the function could take action. Available in Mac OS X v10.0 and later.
`kMPInsufficientResourcesErr`	-29298	Could not complete task due to unavailable Multiprocessing Services resources. Note that many functions return this value as a general error when the desired action could not be performed. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`kMPInvalidIDErr`	-29299	Invalid ID value. For example, an invalid message queue ID was passed to `MPNotifyQueue`. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can determine which system software calls are preemptively-safe for Multiprocessing Services by using the preemptive function attribute selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Pascal String Utilities Reference

Framework:	CoreServices/CoreServices.h
Declared in	MC68000Test.h ddrt.h Disassembler68k.h PLStringFuncs.h IntEnv.h MacRuntime.h MPWLibsDebug.h

Overview

Pascal String Utilities is an API that provides functions for performing common string manipulations, such as concatenation and copying, on Pascal strings. Although Unicode is the preferred encoding for strings on Mac OS X, you may find these functions useful if your application handles Pascal strings as well.

This category also includes structures and constants defining the PEF binary storage format.

Carbon fully supports the functions that assist you in manipulating Pascal strings.

Important: Pascal String Utilities is deprecated as of Mac OS X v10.4. You should update your applications to use Core Foundation Strings (CFStrings) instead. If you need to convert Pascal strings, you can use functions like `CFStringCreateWithPascalString` to do so.

Functions

PLpos

(Deprecated in Mac OS X v10.4. Use Core Foundation strings (CFStrings) instead. See *CFString Reference*.)

```
short PLpos (
   ConstStr255Param str1,
   ConstStr255Param searchStr
);
```

Parameters

str1

str2

Return Value

Discussion

Special Considerations

If you need to convert Pascal strings, you can use functions like `CFStringCreateWithPascalString` to do so.

Version Notes

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PLStringFuncs.h`

PLstrcat

(Deprecated in Mac OS X v10.4. Use Core Foundation strings (CFStrings) instead. See *CFString Reference*.)

```
StringPtr PLstrcat (
   StringPtr str,
   ConstStr255Param append
);
```

Parameters

str1

str2

Return Value

Discussion

Special Considerations

If you need to convert Pascal strings, you can use functions like `CFStringCreateWithPascalString` to do so.

Version Notes

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Power Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Power.h

Overview

The Power Manager controls power to the internal hardware devices of battery-powered Macintosh computers (such PowerBook computers). The Power Manager automatically shuts off power to internal devices to conserve power whenever the computer has not been used for a predetermined amount of time. In addition, the Power Manager allows your application or other software to

- install a procedure that is executed when power to internal devices is about to be shut off or when power has just been restored
- set a timer to wake up the computer at some time in the future
- set or disable the wakeup timer and read its current setting
- enable, disable, or delay the CPU idle feature
- read the current CPU clock speed
- control power to the internal modem and serial ports
- read the status of the internal modem
- read the state of the battery charge and the status of the battery charger

Most applications do not need to know whether they are executing on a battery-powered Macintosh computer because the transition between power states is largely invisible. As a result, most applications do not need to use Power Manager routines. You need Power Manager only if you are writing a program--such as a device driver--that must control power to some subsystem of a battery-powered Macintosh computer or that might be affected by the idle or sleep state.

Carbon supports Power Manager functions prior to Power Manager 2.0. However, many of these functions do nothing on Mac OS X; these calls have been retained in Carbon as the only means for implementing power management on Mac OS 8 and 9. Before using any of the Power Manager API, you should call the `PMFeatures` function to check the availability of the feature you wish to use. On Mac OS X, use the functions provided in IOKit for power management. For more information on IOKit, see I/O Kit Fundamentals.

Functions by Task

Function descriptions are grouped by the tasks for which you use the functions. For an alphabetical list of functions, go to the API index at the end of the document.

Controlling the Idle State

`CurrentProcessorSpeed` (page 1593)
Returns the current effective clock speed of the CPU in megahertz.

`DisableIdle` (page 1595) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`EnableIdle` (page 1596) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`IdleUpdate` (page 1606) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use `UpdateSystemActivity` instead.)

Controlling and Reading the Wakeup Timer

`DisableWUTime` (page 1595) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetWUTime` (page 1604) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`SetWUTime` (page 1618) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

Controlling the Sleep Queue

`SleepQInstall` (page 1619)
Adds an entry to the sleep queue.

`SleepQRemove` (page 1619)
Removes an entry from the sleep queue.

Controlling Serial Power

`AOff` (page 1590) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`AOn` (page 1590) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`AOnIgnoreModem` (page 1590) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`BOff` (page 1592) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

BOn (page 1593) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

Reading the Status of the Internal Modem

ModemStatus (page 1610) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

Reading the Status of the Battery and of the Battery Charger

BatteryStatus (page 1592) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

Miscellaneous

BatteryCount (page 1591)

DisposeHDSpindownUPP (page 1596)
Unimplemented.
DisposePMgrStateChangeUPP (page 1596)
Unimplemented
DisposeSleepQUPP (page 1596)

GetCPUSpeed (page 1598)
Returns the current effective clock speed of the CPU in megahertz.
InvokeHDSpindownUPP (page 1607)
Unimplemented.
InvokePMgrStateChangeUPP (page 1607)
Unimplemented.
InvokeSleepQUPP (page 1608)

MaximumProcessorSpeed (page 1610)

MinimumProcessorSpeed (page 1610)

NewHDSpindownUPP (page 1611)
Unimplemented.
NewPMgrStateChangeUPP (page 1611)
Unimplemented.
NewSleepQUPP (page 1612)

UpdateSystemActivity (page 1620)

`FullProcessorSpeed` (page 1597) Deprecated in Mac OS X v10.5
Unimplemented.

`PMFeatures` (page 1612) Deprecated in Mac OS X v10.5

`PMSelectorCount` (page 1613) Deprecated in Mac OS X v10.5
Unimplemented.

`SetProcessorSpeed` (page 1615) Deprecated in Mac OS X v10.5
Unimplemented.

`SetSpindownDisable` (page 1617) Deprecated in Mac OS X v10.5
Unimplemented.

`AutoSleepControl` (page 1591) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`DelaySystemIdle` (page 1594) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`DimmingControl` (page 1594) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`EnableProcessorCycling` (page 1597) Deprecated in Mac OS X v10.0
Unimplemented.

`GetBatteryTimes` (page 1598) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetBatteryVoltage` (page 1598) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetDimmingTimeout` (page 1599) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetDimSuspendState` (page 1599) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetHardDiskTimeout` (page 1600) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetIntModemInfo` (page 1600) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetLastActivity` (page 1601) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetScaledBatteryInfo` (page 1601) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetSCSIDiskModeAddress` (page 1602) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetSleepTimeout` (page 1602) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetSoundMixerState` (page 1603) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetStartupTimer` (page 1603) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

`GetWakeupTimer` (page 1604) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

HardDiskPowered (page 1605) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

HardDiskQInstall (page 1605) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

HardDiskQRemove (page 1606) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

IsAutoSlpControlDisabled (page 1608) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

IsDimmingControlDisabled (page 1608) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

IsProcessorCyclingEnabled (page 1609) Deprecated in Mac OS X v10.0
Unimplemented.

IsSpindownDisabled (page 1609) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

PMgrStateQInstall (page 1612) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

PMgrStateQRemove (page 1613) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetDimmingTimeout (page 1614) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetDimSuspendState (page 1614) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetHardDiskTimeout (page 1615) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetIntModemState (page 1615) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetSCSIDiskModeAddress (page 1616) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetSleepTimeout (page 1616) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetSoundMixerState (page 1617) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetStartupTimer (page 1617) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SetWakeupTimer (page 1618) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

SpinDownHardDisk (page 1620) Deprecated in Mac OS X v10.0
Unimplemented. (Deprecated. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

Functions

AOff

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void AOff (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

AOn

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void AOn (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

AOnIgnoreModem

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void AOnIgnoreModem (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

AutoSleepControl

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void AutoSleepControl (
   Boolean enableSleep
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

BatteryCount

```
short BatteryCount (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

BatteryStatus

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr BatteryStatus (
   Byte *status,
   Byte *power
);
```

Parameters

Status

On return, the referenced value holds the status of the battery charger and the voltage level of the battery, described in BatteryByte Bits (page 1631).The connChangedBit is set when the charger connection is changed—either connected or disconnected. When this bit is set, the Power Manager IC sends an interrupt to the CPU.

The `batteryLowBit` is set whenever battery voltage drops below the value set in parameter RAM. The Power Manager IC sends an interrupt to the CPU once every second when battery voltage is low.If the `batteryDeadBit` were set, it would indicate a dead battery; however, the Power Manager automatically shuts the system down when the battery voltage drops below a preset level, so this bit is always 0.

Power

On return, the referenced value contains the `Power` value you can use to estimate the battery voltage:

voltage = ((`Power`/100) + 5.12) volts

Due to the nature of lead-acid batteries, the battery power remaining is difficult to measure accurately. Temperature, load, and other factors can alter the measured voltage by 30 percent or more. The Power Manager takes as many of these factors into account as possible, but the voltage measurement can still be in error by up to 10 percent. The measurement is most accurate when the Macintosh Portable has been in the sleep state for at least 30 minutes.

Return Value

A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

BOff

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void BOff (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

BOn

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void BOn (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

CurrentProcessorSpeed

Returns the current effective clock speed of the CPU in megahertz.

```
short CurrentProcessorSpeed (
   void
);
```

Return Value
The clock speed of the CPU in megahertz (MHz). One MHz represents one million cycles per second.

Special Considerations

Prior to Mac OS X 10.4, this function returns the maximum clock speed, not the current effective clock speed.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Power.h`

DelaySystemIdle

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr DelaySystemIdle (
   void
);
```

Return Value

A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

DimmingControl

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void DimmingControl (
   Boolean enableSleep
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In
`Power.h`

DisableIdle

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void DisableIdle (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

DisableWUTime

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr DisableWUTime (
   void
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

DisposeHDSpindownUPP

Unimplemented.

```
void DisposeHDSpindownUPP (
   HDSpindownUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

DisposePMgrStateChangeUPP

Unimplemented

```
void DisposePMgrStateChangeUPP (
   PMgrStateChangeUPP userUPP
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

DisposeSleepQUPP

```
void DisposeSleepQUPP (
   SleepQUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

EnableIdle

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void EnableIdle (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

EnableProcessorCycling

Unimplemented. (Deprecated in Mac OS X v10.0.)

```
void EnableProcessorCycling (
   Boolean enable
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

FullProcessorSpeed

Unimplemented. (Deprecated in Mac OS X v10.5.)

```
Boolean FullProcessorSpeed (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Power.h`

GetBatteryTimes

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void GetBatteryTimes (
   short whichBattery,
   BatteryTimeRec *theTimes
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetBatteryVoltage

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Fixed GetBatteryVoltage (
   short whichBattery
);
```

Return Value

See the Mac Types documentation for a description of the `Fixed` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetCPUSpeed

Returns the current effective clock speed of the CPU in megahertz.

```
long GetCPUSpeed (
   void
);
```

Return Value
The clock speed of the CPU in megahertz.

Discussion
For more information, see `CurrentProcessorSpeed` (page 1593).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

GetDimmingTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
UInt8 GetDimmingTimeout (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `UInt8` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

GetDimSuspendState

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Boolean GetDimSuspendState (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetHardDiskTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
UInt8 GetHardDiskTimeout (
   void
);
```

Return Value

See the Mac Types documentation for a description of the `UInt8` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetIntModemInfo

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
UInt32 GetIntModemInfo (
   void
);
```

Return Value

See the Mac Types documentation for a description of the `UInt32` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetLastActivity

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr GetLastActivity (
   ActivityInfo *theActivity
);
```

Return Value

A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetScaledBatteryInfo

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void GetScaledBatteryInfo (
   short whichBattery,
   BatteryInfo *theInfo
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

GetSCSIDiskModeAddress

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
short GetSCSIDiskModeAddress (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

GetSleepTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
UInt8 GetSleepTimeout (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `UInt8` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

GetSoundMixerState

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr GetSoundMixerState (
   SoundMixerByte *theSoundMixerByte
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

GetStartupTimer

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr GetStartupTimer (
   StartupTime *theTime
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetWakeupTimer

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void GetWakeupTimer (
   WakeupTime *theTime
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

GetWUTime

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr GetWUTime (
   long *wuTime,
   Byte *wuFlag
);
```

Parameters

WUTime

On return, the referenced value holds the current setting of the wakeup timer specified as the number of seconds since midnight, January 1, 1904.

WUFlag

On return, the low order bit of the referenced value is set to 1 if and only if the wakeup timer is enabled. The other bits in `WUFlag` are reserved.

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

HardDiskPowered

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Boolean HardDiskPowered (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

HardDiskQInstall

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr HardDiskQInstall (
   HDQueueElement *theElement
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

HardDiskQRemove

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr HardDiskQRemove (
   HDQueueElement *theElement
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

IdleUpdate

Unimplemented. (Deprecated in Mac OS X v10.0. Use `UpdateSystemActivity` instead.)

```
long IdleUpdate (
   void
);
```

Return Value
The `IdleUpdate` function returns the value in the `Ticks` global variable at the time the function was called.

Special Considerations
This function is unimplemented on Mac OS X. Use `UpdateSystemActivity(IdleActivity)` instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

InvokeHDSpindownUPP

Unimplemented.

```
void InvokeHDSpindownUPP (
   HDQueueElement *theElement,
   HDSpindownUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

InvokePMgrStateChangeUPP

Unimplemented.

```
void InvokePMgrStateChangeUPP (
   PMgrQueueElement *theElement,
   long stateBits,
   PMgrStateChangeUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

InvokeSleepQUPP

```
long InvokeSleepQUPP (
   long message,
   SleepQRecPtr qRecPtr,
   SleepQUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

IsAutoSlpControlDisabled

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Boolean IsAutoSlpControlDisabled (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

IsDimmingControlDisabled

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Boolean IsDimmingControlDisabled (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

IsProcessorCyclingEnabled

Unimplemented. (Deprecated in Mac OS X v10.0.)

```
Boolean IsProcessorCyclingEnabled (
   void
);
```

Return Value

See the Mac Types documentation for a description of the `Boolean` data type.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

IsSpindownDisabled

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
Boolean IsSpindownDisabled (
   void
);
```

Return Value

See the Mac Types documentation for a description of the `Boolean` data type.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

MaximumProcessorSpeed

```
short MaximumProcessorSpeed (
   void
);
```

Version Notes
`MaximumProcessorSpeed` is unimplemented on versions of Mac OS X prior to Mac OS X 10.1.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

MinimumProcessorSpeed

```
short MinimumProcessorSpeed (
   void
);
```

Special Considerations
`MinimumProcessorSpeed` is unimplemented on versions of Mac OS X prior to Mac OS X v10.1.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Power.h`

ModemStatus

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr ModemStatus (
   Byte *status
);
```

Parameters
Status
On return, the referenced variable has its bits set as indicated in ModemByte Bits (page 1639).

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

NewHDSpindownUPP

Unimplemented.

```
HDSpindownUPP NewHDSpindownUPP (
   HDSpindownProcPtr userRoutine
);
```

Return Value

See the description of the `HDSpindownUPP` data type.

Discussion

See the callback `HDSpindownProcPtr` (page 1620) for more information.

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Power.h`

NewPMgrStateChangeUPP

Unimplemented.

```
PMgrStateChangeUPP NewPMgrStateChangeUPP (
   PMgrStateChangeProcPtr userRoutine
);
```

Return Value

See the description of the `PMgrStateChangeUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

NewSleepQUPP

```
SleepQUPP NewSleepQUPP (
   SleepQProcPtr userRoutine
);
```

Return Value
See the description of the `SleepQUPP` data type.

Discussion
See the callback `SleepQProcPtr` (page 1622) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

PMFeatures

(Deprecated in Mac OS X v10.5.)

```
UInt32 PMFeatures (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `UInt32` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Power.h`

PMgrStateQInstall

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr PMgrStateQInstall (
   PMgrQueueElement *theElement
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

PMgrStateQRemove

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr PMgrStateQRemove (
   PMgrQueueElement *theElement
);
```

Return Value

A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

PMSelectorCount

Unimplemented. (Deprecated in Mac OS X v10.5.)

```
short PMSelectorCount (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Power.h`

SetDimmingTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetDimmingTimeout (
   UInt8 timeout
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetDimSuspendState

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetDimSuspendState (
   Boolean dimSuspendState
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetHardDiskTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetHardDiskTimeout (
   UInt8 timeout
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

SetIntModemState

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetIntModemState (
   short theState
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

SetProcessorSpeed

Unimplemented. (Deprecated in Mac OS X v10.5.)

```
Boolean SetProcessorSpeed (
   Boolean fullSpeed
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Power.h`

SetSCSIDiskModeAddress

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetSCSIDiskModeAddress (
   short scsiAddress
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetSleepTimeout

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetSleepTimeout (
   UInt8 timeout
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetSoundMixerState

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr SetSoundMixerState (
   SoundMixerByte *theSoundMixerByte
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetSpindownDisable

Unimplemented. (Deprecated in Mac OS X v10.5.)

```
void SetSpindownDisable (
   Boolean setDisable
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Power.h`

SetStartupTimer

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr SetStartupTimer (
   StartupTime *theTime
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetWakeupTimer

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SetWakeupTimer (
   WakeupTime *theTime
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`Power.h`

SetWUTime

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
OSErr SetWUTime (
   long wuTime
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

SleepQInstall

Adds an entry to the sleep queue.

```
void SleepQInstall (
   SleepQRecPtr qRecPtr
);
```

Parameters

qRecPtr

A pointer to a sleep queue record that you must provide.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Power.h`

SleepQRemove

Removes an entry from the sleep queue.

```
void SleepQRemove (
   SleepQRecPtr qRecPtr
);
```

Parameters

qRecPtr

A pointer to a sleep queue record that you provided when you added your routine to the sleep queue.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Power.h`

SpinDownHardDisk

Unimplemented. (Deprecated in Mac OS X v10.0. Use I/O Kit instead; see *I/O Kit Fundamentals*.)

```
void SpinDownHardDisk (
   void
);
```

Special Considerations

The I/O Kit Framework header file IOPMLib.h (in *I/O Kit Framework Reference*) provides access to common power management facilites, such as initiating system sleep, getting current idle timer values, registering for sleep/wake notifications, and preventing system sleep. For additional information about power management for device drivers, see *I/O Kit Fundamentals* and *I/O Kit Device Driver Design Guidelines*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.0.

Not available to 64-bit applications.

Declared In

`Power.h`

UpdateSystemActivity

```
OSErr UpdateSystemActivity (
   UInt8 activity
);
```

Return Value

A result code. See "Power Manager Result Codes" (page 1654).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Power.h`

Callbacks

HDSpindownProcPtr

```
typedef void (*HDSpindownProcPtr) (
    HDQueueElement * theElement
);
```

If you name your function `MyHDSpindownCallback`, you would declare it like this:

```
void MyHDSpindownCallback (
    HDQueueElement * theElement
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

PMgrStateChangeProcPtr

```
typedef void (*PMgrStateChangeProcPtr) (
    PMgrQueueElement * theElement,
    long stateBits
);
```

If you name your function `MyPMgrStateChangeCallback`, you would declare it like this:

```
void MyPMgrStateChangeCallback (
    PMgrQueueElement * theElement,
    long stateBits
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

PowerHandlerProcPtr

```
typedef OSStatus (*PowerHandlerProcPtr) (
    UInt32 message,
    void * param,
    UInt32 refCon,
    RegEntryID * regEntryID
);
```

If you name your function `MyPowerHandlerCallback`, you would declare it like this:

```
OSStatus MyPowerHandlerCallback (
    UInt32 message,
    void * param,
    UInt32 refCon,
    RegEntryID * regEntryID
);
```

Return Value
A result code. See "Power Manager Result Codes" (page 1654).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

SleepQProcPtr

```
typedef long (*SleepQProcPtr) (
    long message,
    SleepQRecPtr qRecPtr
);
```

If you name your function `MySleepQProc`, you would declare it like this:

```
long MySleepQProc (
    long message,
    SleepQRecPtr qRecPtr
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

Data Types

ActivityInfo

```
struct ActivityInfo {
    short ActivityType;
    unsigned long ActivityTime;
};
typedef struct ActivityInfo ActivityInfo;
```

Fields

`ActivityType`
A short representing the type of activity to fetch.

`ActivityTime`
An unsigned long representing the time of the last activity in ticks.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

BatteryByte

```
typedef SInt8 BatteryByte;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Power.h

BatteryInfo

```
struct BatteryInfo {
    UInt8 flags;
    UInt8 warningLevel;
    UInt8 reserved;
    UInt8 batteryLevel;
};
typedef struct BatteryInfo BatteryInfo;
```

Fields

`flags`
An unsigned, 8-bit integer representing battery state information.

`warningLevel`
An unsigned, 8-bit integer representing a scaled warning level. The value of this field is in the range of 0-255.

`reserved`
This field is reserved for internal use.

`batteryLevel`
An unsigned, 8-bit integer representing a scaled battery level. The value for this field is in the range of 0-255.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Power.h

BatteryTimeRec

```
struct BatteryTimeRec {
    unsigned long expectedBatteryTime;
    unsigned long minimumBatteryTime;
    unsigned long maximumBatteryTime;
    unsigned long timeUntilCharged;
};
typedef struct BatteryTimeRec BatteryTimeRec;
```

Fields

`expectedBatteryTime`
An unsigned long representing in seconds, the estimated battery time remaining.

`minimumBatteryTime`
An unsigned long representing in seconds, the minimum battery time remaining.

`maximumBatteryTime`
An unsigned long representing in seconds, the maximum battery time remaining.

`timeUntilCharged`
An unsigned long representing in seconds, the time remaining until the battery is fully charged.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

DevicePowerInfo

```
struct DevicePowerInfo {
    UInt32 version;
    RegEntryID regID;
    OptionBits flags;
    UInt32 minimumWakeTime;
    UInt32 sleepPowerNeeded;
};
typedef struct DevicePowerInfo DevicePowerInfo;
```

Fields

`version`
The version of this structure.

`regID`
The Registry Entry ID for the device.

`flags`
A value of type `OptionBits` representing device power information.

`minimumWakeTime`
The minimum number of seconds before the device sleeps again.

`sleepPowerNeeded`
The milliwatts the device requires in the sleep state.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

HDQueueElement

```
struct HDQueueElement {
    struct HDQueueElement * hdQLink;
    short hdQType;
    short hdFlags;
    HDSpindownUPP hdProc;
    long hdUser;
};
typedef struct HDQueueElement HDQueueElement;
```

Fields

`hdQLink`
A pointer to the next queue element.

`hdQType`
A value of type short representing the queue element type.

`hdFlags`
A value of type short representing flags.

`hdProc`
A pointer to the hard drive spindown routine to call.

`hdUser`
A user-defined value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

HDSpindownUPP

```
typedef HDSpindownProcPtr HDSpindownUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

ModemByte

```
typedef SInt8 ModemByte;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

PMgrQueueElement

```
struct PMgrQueueElement {
    struct PMgrQueueElement * pmQLink;
    short pmQType;
    short pmFlags;
    long pmNotifyBits;
    PMgrStateChangeUPP pmProc;
    long pmUser;
};
typedef struct PMgrQueueElement PMgrQueueElement;
```

Fields
`pmQLink`
A pointer to the next queue element.

`pmQType`
A value of type short representing the queue element type.

`pmFlags`
A value of type short representing flags.

`pmNotifyBits`
A bitmap representing the changes of which you wish to be notified.

`pmProc`
A pointer to the routine to call.

`pmUser`
A user-defined value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

PMgrStateChangeUPP

```
typedef PMgrStateChangeProcPtr PMgrStateChangeUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

PMResultCode

```
typedef long PMResultCode;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

PowerLevel

```
typedef UInt32 PowerLevel;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

PowerSourceID

```
typedef SInt16 PowerSourceID;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`Power.h`

PowerSourceParamBlock

```
struct PowerSourceParamBlock {
    PowerSourceID sourceID;
    UInt16 sourceCapacityUsage;
    UInt32 sourceVersion;
    OptionBits sourceAttr;
    OptionBits sourceState;
    UInt32 currentCapacity;
    UInt32 maxCapacity;
    UInt32 timeRemaining;
    UInt32 timeToFullCharge;
    UInt32 voltage;
    SInt32 current;
    UInt32 lowWarnLevel;
    UInt32 deadWarnLevel;
    UInt32 reserved[16];
};
typedef struct PowerSourceParamBlock PowerSourceParamBlock;
typedef PowerSourceParamBlock * PowerSourceParamBlockPtr;
```

Fields

`sourceID`
A unique ID assigned by the Power Manager.

`sourceCapacityUsage`
An unsigned, 16-bit integer representing current capacity usage.

`sourceVersion`
An unsigned, 32-bit integer indicating the version of this record.

`sourceAttr`
A value of type `OptionBits` representing power source attributes.

`sourceState`
A value of type `OptionBits` representing power source states.

`currentCapacity`
The current capacity represented in milliwatts or percentage.

`maxCapacity`
The full capacity represented in milliwatts.

`timeRemaining`
The time remaining represented in milliwatt-hours.

`timeToFullCharge`
The time required to charge represented in milliwatt-hours.

`voltage`
The voltage represented in millivolts.

`current`
The current represented in milliamperes. This value may be negative if the power source is consuming.

`lowWarnLevel`
The low warning level represented in milliwatts, or percentage depending on the representation of `sourceCapacityUsage`.

`deadWarnLevel`
The dead warming level represented in milliwatts, or percentage depending on the representation of `sourceCapacityUsage`.

`reserved`
This field is reserved for future expansion.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`Power.h`

PowerSourceParamBlockPtr

```
typedef PowerSourceParamBlock* PowerSourceParamBlockPtr;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`Power.h`

PowerSummary

```
struct PowerSummary {
    UInt32 version;
    OptionBits flags;
    UInt32 sleepPowerAvailable;
    UInt32 sleepPowerNeeded;
    UInt32 minimumWakeTime;
    ItemCount deviceCount;
    DevicePowerInfo devices[1];
};
typedef struct PowerSummary PowerSummary;
```

Fields
`version`
An unsigned, 32-bit integer indicating the version of this record.

`flags`
A value of type `OptionBits` representing power summary information.

`sleepPowerAvailable`
An unsigned, 32-bit integer indicating the milliwatts available during sleep.

`sleepPowerNeeded`
: An unsigned, 32-bit integer indicating the milliwatts needed during sleep.

`minimumWakeTime`
: An unsigned, 32-bit integer indicating the minimum number of seconds required before sleeping again.

`deviceCount`
: The number of device power info records.

`devices`
: An array of device power info records.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

SleepQRec

```
struct SleepQRec {
    SleepQRecPtr sleepQLink;
    short sleepQType;
    SleepQUPP sleepQProc;
    short sleepQFlags;
};
typedef struct SleepQRec SleepQRec;
typedef SleepQRec * SleepQRecPtr;
```

Fields
`sleepQLink`
: A pointer to the next element in the queue. This pointer is maintained by the Power Manager; your application should not modify this field.

`sleepQType`
: A short indicating the type of the queue, which must be the constant `sleepQType` (16).

`sleepQProc`
: A pointer to the routine that you provide.

`sleepQFlags`
: A short containing flags which is reserved for use by Apple Computer, Inc.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

SleepQRecPtr

```
typedef SleepQRec *SleepQRecPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

SleepQUPP

```
typedef SleepQProcPtr SleepQUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Power.h`

SoundMixerByte

```
typedef SInt8 SoundMixerByte;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

StartupTime

```
struct StartupTime {
    unsigned long startTime;
    Boolean startEnabled;
    SInt8 filler;
};
typedef struct StartupTime StartupTime;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Power.h`

WakeupTime

```
struct WakeupTime {
    unsigned long wakeTime;
    Boolean wakeEnabled;
    SInt8 filler;
};
typedef struct WakeupTime WakeupTime;
```

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Power.h`

Constants

Apple Event Types and Errors

```
enum {
    kAEMacPowerMgtEvt = 'pmgt',
    kAEMacToWake = 'wake',
    kAEMacLowPowerSaveData = 'pmsd',
    kAEMacEmergencySleep = 'emsl',
    kAEMacEmergencyShutdown = 'emsd'
};
```

BatteryByte Bits

```
enum {
    chargerConnBit = 0,
    hiChargeBit = 1,
    chargeOverFlowBit = 2,
    batteryDeadBit = 3,
    batteryLowBit = 4,
    connChangedBit = 5
};
```

Constants

`chargerConnBit`
When this bit is set, it indicates the charger is connected.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hiChargeBit`
When this bit is set, it indicates charging at fastest rate.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`chargeOverFlowBit`
When this bit is set, it indicates the hicharge counter has overflowed.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`batteryDeadBit`
Always 0.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`batteryLowBit`
When this bit is set, it indicates the battery is low.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`connChangedBit`
When this bit is set, it indicates the charger connection has changed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

BatteryByte Masks

```
enum {
    chargerConnMask = 0x01,
    hiChargeMask = 0x02,
    chargeOverFlowMask = 0x04,
    batteryDeadMask = 0x08,
    batteryLowMask = 0x10,
    connChangedMask = 0x20
};
```

Constants

`chargerConnMask`
The charger is connected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hiChargeMask`
Charging at fastest rate.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`chargeOverFlowMask`
The hicharge counter has overflowed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`batteryDeadMask`
The battery is dead.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`batteryLowMask`
The battery is low.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`connChangedMask`
The connection has changed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

BatteryInfo Bits

```
enum {
    batteryInstalled = 7,
    batteryCharging = 6,
    chargerConnected = 5,
    upsConnected = 4,
    upsIsPowerSource = 3
};
```

Constants

`batteryInstalled`
When this bit is set, it indicates the battery is currently connected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`batteryCharging`
When this bit is set, it indicates the battery is being charged.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`chargerConnected`
When this bit is set, it indicates the charger is connected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`upsConnected`

When this bit is set, it indicates there is an uninterruptable power source (UPS) connected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`upsIsPowerSource`

When this bit is set, it indicates the UPS is the source of power.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Client Notification Bits

```
enum {
    pmSleepTimeoutChanged = 0,
    pmSleepEnableChanged = 1,
    pmHardDiskTimeoutChanged = 2,
    pmHardDiskSpindownChanged = 3,
    pmDimmingTimeoutChanged = 4,
    pmDimmingEnableChanged = 5,
    pmDiskModeAddressChanged = 6,
    pmProcessorCyclingChanged = 7,
    pmProcessorSpeedChanged = 8,
    pmWakeupTimerChanged = 9,
    pmStartupTimerChanged = 10,
    pmHardDiskPowerRemovedbyUser = 11,
    pmChargeStatusChanged = 12,
    pmPowerLevelChanged = 13,
    pmWakeOnNetActivityChanged = 14
};
```

Client Notification Masks

```
enum {
    pmSleepTimeoutChangedMask = (1 << pmSleepTimeoutChanged),
    pmSleepEnableChangedMask = (1 << pmSleepEnableChanged),
    pmHardDiskTimeoutChangedMask = (1 << pmHardDiskTimeoutChanged),
    pmHardDiskSpindownChangedMask = (1 << pmHardDiskSpindownChanged),
    pmDimmingTimeoutChangedMask = (1 << pmDimmingTimeoutChanged),
    pmDimmingEnableChangedMask = (1 << pmDimmingEnableChanged),
    pmDiskModeAddressChangedMask = (1 << pmDiskModeAddressChanged),
    pmProcessorCyclingChangedMask = (1 << pmProcessorCyclingChanged),
    pmProcessorSpeedChangedMask = (1 << pmProcessorSpeedChanged),
    pmWakeupTimerChangedMask = (1 << pmWakeupTimerChanged),
    pmStartupTimerChangedMask = (1 << pmStartupTimerChanged),
    pmHardDiskPowerRemovedbyUserMask = (1 << pmHardDiskPowerRemovedbyUser),
    pmChargeStatusChangedMask = (1 << pmChargeStatusChanged),
    pmPowerLevelChangedMask = (1 << pmPowerLevelChanged),
    pmWakeOnNetActivityChangedMask = (1 << pmWakeOnNetActivityChanged)
};
```

DevicePowerInfo Flags

```
enum {
    kDevicePCIPowerOffAllowed = (1L << 0),
    kDeviceSupportsPMIS = (1L << 1),
    kDeviceCanAssertPMEDuringSleep = (1L << 2),
    kDeviceUsesCommonLogicPower = (1L << 3),
    kDeviceDriverPresent = (1L << 4),
    kDeviceDriverSupportsPowerMgt = (1L << 5)
};
```

Constants

`kDevicePCIPowerOffAllowed`
If the bit specified by this mask is set, PCI power off is allowed for this device.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kDeviceSupportsPMIS`
If the bit specified by this mask is set, the device supports Power Manager Interface Specifications.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kDeviceCanAssertPMEDuringSleep`
If the bit specified by this mask is set, the device can assert the PME# line during sleep.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kDeviceUsesCommonLogicPower`
If the bit specified by this mask is set, the device uses common-logic power.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kDeviceDriverPresent`
If the bit specified by this mask is set, the device driver is present.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kDeviceDriverSupportsPowerMgt`
If the bit specified by this mask is set, the device driver installed a power handler.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

HDPwrQType Constants

```
enum {
    HDPwrQType = 0x4844,
    PMgrStateQType = 0x504D
};
```

Constants

`HDPwrQType`
The hard disk spindown queue element type.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`PMgrStateQType`
The Power Manager state queue element type.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

HDQueueElement Flags

```
enum {
    kHDQueuePostBit = 0,
    kHDQueuePostMask = (1 << kHDQueuePostBit)
};
```

Constants

`kHDQueuePostBit`
When this bit is set, it indicates the routine will be called on the second pass.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kHDQueuePostMask`
If the bit specified by this mask is set, it indicates the routine will be called on the second pass.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

kMediaPowerCSCode Constants

```
enum {
    kMediaPowerCSCode = 70
};
```

kUseDefaultMinimumWakeTime Constants

```
enum {
    kUseDefaultMinimumWakeTime = 0,
    kPowerSummaryVersion = 1,
    kDevicePowerInfoVersion = 1
};
```

Constants

`kUseDefaultMinimumWakeTime`
Defaults to 5 minutes.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kPowerSummaryVersion`
Version of `PowerSummary` structure.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kDevicePowerInfoVersion`
Version of `DevicePowerInfo` structure

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Modem State Bits

```
enum {
    hasInternalModem = 0,
    intModemRingDetect = 1,
    intModemOffHook = 2,
    intModemRingWakeEnb = 3,
    extModemSelected = 4,
    modemSetBit = 15
};
```

Constants

`hasInternalModem`
When this bit is set, it indicates an internal modem is installed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`intModemRingDetect`
When this bit is set, it indicates the internal modem has detected a ring.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`intModemOffHook`
When this bit is set, it indicates the internal modem is off the hook.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`intModemRingWakeEnb`
When this bit is set, it indicates wakeup on ring is enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`extModemSelected`
When this bit is set, it indicates external modem is selected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`modemSetBit`
When this bit is set, it indicates set bit. If 0, clear bit.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Discussion
These bits are in the bit field returned by the `GetIntModemInfo` (page 1600) function and set by the `SetIntModemState` (page 1615) function.

ModemByte Bits

```
enum {
    modemOnBit = 0,
    ringWakeUpBit = 2,
    modemInstalledBit = 3,
    ringDetectBit = 4,
    modemOnHookBit = 5
};
```

Constants
`modemOnBit`
When this bit is set, it indicates the modem is on.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`ringWakeUpBit`
When this bit is set, it indicates ring wakeup is enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`modemInstalledBit`
When this bit is set, it indicates an internal modem is installed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`ringDetectBit`
When this bit is set, it indicates an incoming call is detected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`modemOnHookBit`
When this bit is set, it indicates the modem is off the hook.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

ModemByte Masks

```
enum {
    modemOnMask = 0x01,
    ringWakeUpMask = 0x04,
    modemInstalledMask = 0x08,
    ringDetectMask = 0x10,
    modemOnHookMask = 0x20
};
```

Constants

`modemOnMask`
The modem is on.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`ringWakeUpMask`
Ring wakeup is enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`modemInstalledMask`
An internal modem is installed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`ringDetectMask`
An incoming call is detected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`modemOnHookMask`
The modem is off the hook.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Net Activity Wake Options

```
enum {
    kConfigSupportsWakeOnNetBit = 0,
    kWakeOnNetAdminAccessesBit = 1,
    kWakeOnAllNetAccessesBit = 2,
    kUnmountServersBeforeSleepingBit = 3,
    kConfigSupportsWakeOnNetMask = (1 << kConfigSupportsWakeOnNetBit),
    kWakeOnNetAdminAccessesMask = (1 << kWakeOnNetAdminAccessesBit),
    kWakeOnAllNetAccessesMask = (1 << kWakeOnAllNetAccessesBit),
    kUnmountServersBeforeSleepingMask = (1 << kUnmountServersBeforeSleepingBit)
};
```

PCI Bus PMIS Power Levels

```
enum {
    kPMDevicePowerLevel_On = 0,
    kPMDevicePowerLevel_D1 = 1,
    kPMDevicePowerLevel_D2 = 2,
    kPMDevicePowerLevel_Off = 3
};
```

Constants

`kPMDevicePowerLevel_On`

When this bit is set, it indicates the PCI bus is fully powered.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kPMDevicePowerLevel_D1`

Reserved.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kPMDevicePowerLevel_D2`

Reserved.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kPMDevicePowerLevel_Off`

When this bit is set, it indicates the main PCI bus power is off, but PCI standby power is available.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Power Capacity Types

```
enum {
    kCapacityIsActual = 0,
    kCapacityIsPercentOfMax = 1
};
```

Constants

`kCapacityIsActual`

The capacity is expressed as actual capacity in the same units as `maxCapacity`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kCapacityIsPercentOfMax`

The capacity is expressed as a percentage of `maxCapacity`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

Power Handler Wake Results

```
enum {
    kDeviceDidNotWakeMachine = 0,
    kDeviceRequestsFullWake = 1,
    kDeviceRequestsWakeToDoze = 2
};
```

Constants

`kDeviceDidNotWakeMachine`

The device did not wake the computer.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kDeviceRequestsFullWake`

The device did wake the computer and requests full wakeup.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kDeviceRequestsWakeToDoze`

The device did wake the computer and requests partial wakeup.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Discussion

On query by the Power Manager, these are result values returned by a power handler if the device the power handler represents woke the computer.

Power Manager Features Bits

```
enum {
    hasWakeupTimer = 0,
    hasSharedModemPort = 1,
    hasProcessorCycling = 2,
    mustProcessorCycle = 3,
    hasReducedSpeed = 4,
    dynamicSpeedChange = 5,
    hasSCSIDiskMode = 6,
    canGetBatteryTime = 7,
    canWakeupOnRing = 8,
    hasDimmingSupport = 9,
    hasStartupTimer = 10,
    hasChargeNotification = 11,
    hasDimSuspendSupport = 12,
    hasWakeOnNetActivity = 13,
    hasWakeOnLid = 14,
    canPowerOffPCIBus = 15,
    hasDeepSleep = 16,
    hasSleep = 17,
    supportsServerModeAPIs = 18,
    supportsUPSIntegration = 19,
    hasAggressiveIdling = 20,
    supportsIdleQueue = 21
};
```

Constants

`hasWakeupTimer`

When this bit is set, it indicates the wakeup timer is supported.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasSharedModemPort`

When this bit is set, it indicates the modem port is shared by the serial communications chip (SCC) and the internal modem.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasProcessorCycling`

When this bit is set, it indicates processor cycling is supported.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`mustProcessorCycle`

When this bit is set, it indicates processor cycling should not be turned off.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasReducedSpeed`

When this bit is set, it indicates the processor can be started up at a reduced speed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`dynamicSpeedChange`

When this bit is set, it indicates the processor speed can be switched dynamically.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasSCSIDiskMode`

When this bit is set, it indicates SCSI disk mode is supported.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`canGetBatteryTime`

When this bit is set, it indicates battery time can be calculated.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`canWakeupOnRing`

When this bit is set, it indicates wakeup when the modem detects a ring.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasDimmingSupport`

When this bit is set, it indicates dimming support is built in—display power management system (DPMS) standby by default.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasStartupTimer`

When this bit is set, it indicates the startup timer is supported.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasChargeNotification`

When this bit is set, it indicates the client can determine charge connect status change notification available.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`hasDimSuspendSupport`
When this bit is set, it indicates support of dimming LCD and CRT to DPMS suspend state.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hasWakeOnNetActivity`
When this bit is set, it indicates hardware supports wake on network activity.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hasWakeOnLid`
When this bit is set, it indicates hardware can wake when opened.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`canPowerOffPCIBus`
When this bit is set, it indicates hardware can power off PCI bus during sleep if cards allow.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hasDeepSleep`
When this bit is set, it indicates hardware supports deep sleep (hibernation) mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hasSleep`
When this bit is set, it indicates hardware supports normal sleep.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`supportsServerModeAPIs`
When this bit is set, it indicates hardware supports server mode API.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`supportsUPSIntegration`
When this bit is set, it indicates hardware supports UPS integration and reporting.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`hasAggressiveIdling`
When this bit is set, it indicates Power Manager only resets `OverallAct` on `UsrActivity`.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`supportsIdleQueue`
When this bit is set, it indicates Power Manager supports the idle queue.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Discussion
These bits are in the bit field returned by the `PMFeatures` (page 1612) function.

Power Source Attribute Bits

```
enum {
    bSourceIsBattery = 0,
    bSourceIsAC = 1,
    bSourceCanBeCharged = 2,
    bSourceIsUPS = 3,
    bSourceProvidesWarnLevels = 4,
    kSourceIsBatteryMask = (1 << bSourceIsBattery),
    kSourceIsACMask = (1 << bSourceIsAC),
    kSourceCanBeChargedMask = (1 << bSourceCanBeCharged),
    kSourceIsUPSMask = (1 << bSourceIsUPS),
    kSourceProvidesWarnLevelsMask = (1 << bSourceProvidesWarnLevels)
};
```

Constants
`bSourceIsBattery`
When this bit is set, it indicates the power source is a battery.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bSourceIsAC`
When this bit is set, it indicates the power source is AC.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bSourceCanBeCharged`
When this bit is set, it indicates the power source can be charged.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bSourceIsUPS`
When this bit is set, it indicates the power source is an uninterruptable power supply (UPS). `bSourceIsBattery` and `bSourceIsAC` should be set as well if appropriate.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bSourceProvidesWarnLevels`
When this bit is set, it indicates power source provides low power and dead battery warning levels.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceIsBatteryMask`
If the bit specified by this mask is set, the power source is a battery.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceIsACMask`
If the bit specified by this mask is set, the power source is AC.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceCanBeChargedMask`
If the bit specified by this mask is set, the power source can be charged.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceIsUPSMask`
If the bit specified by this mask is set, the power source is a UPS.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceProvidesWarnLevelsMask`
If the bit specified by this mask is set, the power source provides low power and dead battery warning levels.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

Power Source Capacity Usage Types

```
enum {
    kCurrentCapacityIsActualValue = 0,
    kCurrentCapacityIsPercentOfMax = 1
};
```

Constants

`kCurrentCapacityIsActualValue`
The current capacity is expressed as a real value in the same units as `maxCapacity`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kCurrentCapacityIsPercentOfMax`
The current capacity is expressed as a percentage of `maxCapacity`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

Power Source State Bits

```
enum {
    bSourceIsAvailable = 0,
    bSourceIsCharging = 1,
    bChargerIsAttached = 2,
    kSourceIsAvailableMask = (1 << bSourceIsAvailable),
    kSourceIsChargingMask = (1 << bSourceIsCharging),
    kChargerIsAttachedMask = (1 << bChargerIsAttached)
};
```

Constants

`bSourceIsAvailable`
When this bit is set, it indicates a power source is installed.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bSourceIsCharging`
When this bit is set, it indicates a power source is charging.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`bChargerIsAttached`
When this bit is set, it indicates a charger is connected.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceIsAvailableMask`
If the bit specified by this mask is set, the power source is installed.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kSourceIsChargingMask`
If the bit specified by this mask is set, the power source is charging.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

`kChargerIsAttachedMask`
If the bit specified by this mask is set, a charger is connected.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `Power.h`.

Power Source Version

```
enum {
    kVersionOnePowerSource = 1,
    kVersionTwoPowerSource = 2,
    kCurrentPowerSourceVersion = kVersionTwoPowerSource
};
```

Power Summary Flags

```
enum {
    kPCIPowerOffAllowed = (1L << 0)
};
```

Constants

`kPCIPowerOffAllowed`

If the bit specified by this mask is set, it indicates PCI power off is allowed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

Sleep Commands

Not recommended

```
enum {
    sleepRequest = kSleepRequest,
    sleepDemand = kSleepDemand,
    sleepWakeUp = kSleepWakeUp,
    sleepRevoke = kSleepRevoke,
    sleepUnlock = kSleepUnlock,
    sleepDeny = kSleepDeny,
    sleepNow = kSleepNow,
    dozeDemand = kDozeDemand,
    dozeWakeUp = kDozeWakeUp,
    dozeRequest = kDozeRequest,
    enterStandby = kEnterStandby,
    enterRun = kEnterRun,
    suspendRequestMsg = kSuspendRequest,
    suspendDemandMsg = kSuspendDemand,
    suspendRevokeMsg = kSuspendRevoke,
    suspendWakeUpMsg = kSuspendWakeUp,
    getPowerLevel = kGetPowerLevel,
    setPowerLevel = kSetPowerLevel
};
```

Constants

`sleepRequest`

A sleep request.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`sleepDemand`
A sleep demand.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`sleepWakeUp`
A wakeup demand.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`sleepRevoke`
A sleep request revocation.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

sleepQFlags Bits

```
enum {
    noCalls = 1,
    noRequest = 2,
    slpQType = 16,
    sleepQType = 16
};
```

Constants

`noCalls`
A `noCalls` queue type.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`noRequest`
A `noRequest` queue type.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`slpQType`
A `sleepQType` queue.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`sleepQType`
A `sleepQType` queue.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

sleepQProc Commands

```
enum {
    kSleepRequest = 1,
    kSleepDemand = 2,
    kSleepWakeUp = 3,
    kSleepRevoke = 4,
    kSleepUnlock = 4,
    kSleepDeny = 5,
    kSleepNow = 6,
    kDozeDemand = 7,
    kDozeWakeUp = 8,
    kDozeRequest = 9,
    kEnterStandby = 10,
    kEnterRun = 11,
    kSuspendRequest = 12,
    kSuspendDemand = 13,
    kSuspendRevoke = 14,
    kSuspendWakeUp = 15,
    kGetPowerLevel = 16,
    kSetPowerLevel = 17,
    kDeviceInitiatedWake = 18,
    kWakeToDoze = 19,
    kDozeToFullWakeUp = 20,
    kGetPowerInfo = 21,
    kGetWakeOnNetInfo = 22,
    kSuspendWakeToDoze = 23,
    kEnterIdle = 24,
    kStillIdle = 25,
    kExitIdle = 26
};
```

Constants

`kSleepDeny`

A non-zero value clients can use to deny requests.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`kDozeRequest`

Additional messages for Power Manager 2.0.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`kEnterStandby`

Idle queue only.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`kEnterRun`

Idle queue only.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`kEnterIdle`
Idle queue only.
Available in Mac OS X v10.1 and later.
Declared in `Power.h`.

`kStillIdle`
Idle queue only.
Available in Mac OS X v10.1 and later.
Declared in `Power.h`.

`kExitIdle`
Idle queue only.
Available in Mac OS X v10.1 and later.
Declared in `Power.h`.

SoundMixerByte Bits

```
enum {
    MediaBaySndEnBit = 0,
    PCISndEnBit = 1,
    ZVSndEnBit = 2,
    PCCardSndEnBit = 3
};
```

SoundMixerByte Masks

```
enum {
    MediaBaySndEnMask = 0x01,
    PCISndEnMask = 0x02,
    ZVSndEnMask = 0x04,
    PCCardSndEnMask = 0x08
};
```

Storage Media Sleep Modes

```
enum {
    kMediaModeOn = 0,
    kMediaModeStandBy = 1,
    kMediaModeSuspend = 2,
    kMediaModeOff = 3
};
```

Constants

`kMediaModeOn`
When this bit is set, it indicates the media is active—the drive is spinning at full power.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Power.h`.

`kMediaModeStandBy`
When this bit is set, it indicates the media is on standby. This is not implemented.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kMediaModeSuspend`
When this bit is set, it indicates the media is idle. This is not implemented.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

`kMediaModeOff`
When this bit is set, it indicates the media is asleep—the drive is not spinning and is at minimum power and maximum recovery time.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Power.h`.

System Activity Selectors

```
enum {
    OverallAct = 0,
    UsrActivity = 1,
    NetActivity = 2,
    HDActivity = 3,
    IdleActivity = 4
};
```

Constants

`OverallAct`
Delays idle sleep by a small amount. This will only delay power cycling if it's enabled, and will delay sleep by a small amount when `hasAggressiveIdling` is set.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`UsrActivity`
Delays idle sleep and dimming by timeout time.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`NetActivity`
Delays idle sleep and power cycling by small amount.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`HDActivity`
Delays hard drive spindown and idle sleep by small amount.

Available in Mac OS X v10.0 and later.

Declared in `Power.h`.

`IdleActivity`

Delays idle sleep by timeout time. The `IdleActivity` selector is not available unless the `hasAggressiveIdling` bit is set. Use `IdleActivity` where you used to use `OverallAct` if necessary. Don't use `IdleActivity` unless `hasAggressiveIdling` is set; when `hasAggressiveIdling` is not set, the use of `IdleActivity` is undefined, and will do different things depending on which Power Manager is currently running.

Available in Mac OS X v10.1 and later.

Declared in `Power.h`.

Result Codes

The most common result codes returned by Power Manager are listed below.

Result Code	Value	Description
`noErr`	0	No error Available in Mac OS X v10.0 and later.
`pmBusyErr`	-13000	Power Manager IC stuck busy Available in Mac OS X v10.0 and later.
`pmReplyTOErr`	-13001	Timed out waiting to begin reply handshake Available in Mac OS X v10.0 and later.
`pmSendStartErr`	-13002	Power Manager IC did not start handshake Available in Mac OS X v10.0 and later.
`pmSendEndErr`	-13003	During send, Power Manager did not finish handshake Available in Mac OS X v10.0 and later.
`pmRecvStartErr`	-13004	During receive, Power Manager did not start handshake Available in Mac OS X v10.0 and later.
`pmRecvEndErr`	-13005	During receive, Power Manager did not finish handshake Available in Mac OS X v10.0 and later.

Resource Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Resources.h

Overview

The Resource Manager allows applications to create, delete, open, read, modify, and write resources, get information about them, and alter the Resource Manager's search path. A resource is data of any kind stored in a defined format in a resource file. The Resource Manager keeps track of resources in memory and provides functions for the proper management of the resource chain. In Mac OS X, you should store resources in the data fork of a resource file.

Carbon applications have used Resource Manager resources to store the descriptions for user interface elements such as menus, windows, dialogs, controls, and icons. In addition, applications have used resources to store variable settings, such as the location of a document window at the time the user closes the window. When the user opens the document again, the application reads the information in the appropriate resource and restores the window to its previous location.

Functions by Task

Checking for Errors

`ResError` (page 1692)
Determines what error occurred, if any, after calling a Resource Manager function.

Closing Resource Forks

`CloseResFile` (page 1662)
Closes a resource fork before your application terminates.

Counting and Listing Resource Types

`Count1Resources` (page 1663)
Returns the total number of resources of a given type in the current resource file.

`Count1Types` (page 1663)
Returns the number of resource types in the current resource file.

`CountResources` (page 1664)
Returns the total number of available resources of a given type.

`CountTypes` (page 1664)
Returns the number of resource types in all resource forks open to your application.

`Get1IndResource` (page 1675)
Returns a handle to a resource of a given type in the current resource file.

`Get1IndType` (page 1675)
Gets a resource types available in the current resource file.

`GetIndResource` (page 1678)
Returns a handle to a resource of a given type in resource forks open to your application.

`GetIndType` (page 1678)
Gets a resource type available in resource forks open to your application.

Creating Resource Files and Forks

`FSCreateResourceFile` (page 1667)
Creates a file with a named fork for storing resource data.

`FSCreateResourceFork` (page 1668)
Creates a named fork for storing resource data.

`FSCreateResFile` (page 1666)
Creates a file with an empty resource fork.

`FSpCreateResFile` (page 1670) Deprecated in Mac OS X v10.5
Creates an empty resource fork in a new or existing file. (Deprecated. Use `FSCreateResourceFile` (page 1667) instead.)

`HCreateResFile` (page 1685) Deprecated in Mac OS X v10.5
Creates an empty resource fork, when the `FSpCreateResFile` function is not available. (Deprecated. Use `FSCreateResourceFile` (page 1667) instead.)

Disposing of Resources

`DetachResource` (page 1665)
Sets the value of a resource's handle in the resource map in memory to `NULL` while keeping the resource data in memory.

`ReleaseResource` (page 1691)
Releases the memory a resource occupies when you have finished using it.

`RemoveResource` (page 1692)
Removes a resource's entry from the current resource file's resource map in memory.

Getting a Unique Resource ID

`Unique1ID` (page 1698)
Gets a resource ID that's unique with respect to resources in the current resource file.

UniqueID (page 1699)
Gets a unique resource ID for a resource.

Getting and Setting Resource Fork Attributes

GetResFileAttrs (page 1682)
Gets the attributes of a resource fork.

SetResFileAttrs (page 1694)
Sets a resource fork's attributes.

Getting and Setting Resource Information

GetResAttrs (page 1681)
Gets a resource's attributes.

GetResInfo (page 1682)
Gets a resource's resource ID, resource type, and resource name.

SetResAttrs (page 1693)
Sets a resource's attributes in the resource map in memory.

SetResInfo (page 1694)
Sets the name and resource ID of a resource.

Getting and Setting the Current Resource File

CurResFile (page 1664)
Gets the file reference number of the current resource file.

HomeResFile (page 1685)
Gets the file reference number associated with a particular resource.

UseResFile (page 1700)
Sets the current resource file.

Getting Resource Sizes

GetMaxResourceSize (page 1679)
Returns the approximate size of a resource.

GetResourceSizeOnDisk (page 1684)
Returns the exact size of a resource.

Managing the Resource Chain

InsertResourceFile (page 1687)
Inserts a resource file into the current resource chain at the specified location.

`DetachResourceFile` (page 1666)
Removes a resource file from the resource chain.

`GetNextResourceFile` (page 1681)
Retrieves the next resource file in the resource chain.

`GetTopResourceFile` (page 1684)
Retrieves the topmost resource file in the current resource chain.

Modifying Resources

`AddResource` (page 1660)
Adds a resource to the current resource file's resource map in memory.

`ChangedResource` (page 1661)
Sets a flag in the resource's resource map entry in memory to show that you've made changes to a resource's data or to an entry in a resource map.

Opening Resource Forks

`FSOpenResourceFile` (page 1670)
Opens a named fork in an existing resource file.

`FSOpenOrphanResFile` (page 1669)
Opens a resource file that is persistent across all contexts.

`FSOpenResFile` (page 1669)
Opens the resource fork in a file specified with an `FSRef` structure.

`FSResourceFileAlreadyOpen` (page 1674)
Checks whether a resource file is open.

`FSpOpenOrphanResFile` (page 1671) Deprecated in Mac OS X v10.5
Opens a resource file that is persistent across all contexts. (Deprecated. Use `FSOpenOrphanResFile` (page 1669) instead.)

`FSpOpenResFile` (page 1671) Deprecated in Mac OS X v10.5
Opens the resource fork in a file specified with an `FSSpec` structure. (Deprecated. Use `FSOpenResourceFile` (page 1670) instead.)

`FSpResourceFileAlreadyOpen` (page 1673) Deprecated in Mac OS X v10.5
Checks whether a resource file is open. (Deprecated. Use `FSResourceFileAlreadyOpen` (page 1674) instead.)

`HOpenResFile` (page 1686) Deprecated in Mac OS X v10.5
Opens a file's resource fork, when the `FSpOpenResFile` function is not available. (Deprecated. Use `FSOpenResourceFile` (page 1670) instead.)

`OpenRFPerm` (page 1689) Deprecated in Mac OS X v10.5
Opens a file's resource fork, when the `FSpOpenResFile` and `HOpenResFile` functions are not available. (Deprecated. Use `FSOpenResourceFile` (page 1670) instead.)

Reading and Writing Partial Resources

`ReadPartialResource` (page 1690)
Reads part of a resource into memory and work with a small subsection of a large resource.

`SetResourceSize` (page 1696)
Sets the size of a resource on disk.

`WritePartialResource` (page 1701)
Writes part of a resource to disk when working with a small subsection of a large resource.

Reading Resources Into Memory

`Get1NamedResource` (page 1676)
Gets a named resource in the current resource file.

`Get1Resource` (page 1677)
Gets resource data for a resource in the current resource file.

`GetNamedResource` (page 1680)
Gets a named resource.

`GetResource` (page 1683)
Gets resource data for a resource specified by resource type and resource ID.

`LoadResource` (page 1688)
Gets resource data after you've called the `SetResLoad` function with the `load` parameter set to `FALSE` or when the resource is purgeable.

`SetResLoad` (page 1695)
Enables and disables automatic loading of resource data into memory for functions that return handles to resources.

Writing to Resource Forks

`SetResPurge` (page 1697)
Tells the Memory Manager to pass the handle of a resource to the Resource Manager before purging the data specified by that handle.

`UpdateResFile` (page 1700)
Updates the resource map and resource data for a resource fork without closing it.

`WriteResource` (page 1702)
Writes resource data in memory immediately to a file's resource fork.

Not Recommended

`GetNextFOND` (page 1680)
Gets the next FOND handle.

`InvokeResErrUPP` (page 1688)
Calls your callback function.

`NewResErrUPP` (page 1688)
Creates a new universal procedure pointer (UPP) to your callback function.

`DisposeResErrUPP` (page 1666)
Disposes of the universal procedure pointer (UPP) to your callback function.

Functions

AddResource

Adds a resource to the current resource file's resource map in memory.

```
void AddResource (
   Handle theData,
   ResType theType,
   ResID theID,
   ConstStr255Param name
);
```

Parameters

theData
A handle to data in memory to be added as a resource to the current resource file (not a handle to an existing resource). If the value of this parameter is an empty handle (that is, a handle whose master pointer is set to `NULL`), the Resource Manager writes zero-length resource data to disk when it updates the resource. If its value is either `NULL` or a handle to an existing resource, the function does nothing, and the `ResError` (page 1692) function returns the result code `addResFailed`. If the resource map becomes too large to fit in memory, the function does nothing, and `ResError` returns an appropriate result code. The same is true if the resource data in memory can't be written to the resource fork (for example, because the disk is full).

theType
The resource type of the resource to be added.

theID
The resource ID of the resource to be added.

name
The name of the resource to be added.

Discussion

This function sets the `resChanged` attribute to 1 it does not set any of the resource's other attributes—that is, all other attributes are set to 0. If the `resChanged` attribute of a resource has been set and your application calls the `UpdateResFile` (page 1700) function or quits, the Resource Manager writes both the resource map and the resource data for that resource to the resource fork of the corresponding file on disk. If the `resChanged` attribute for a resource has been set and your application calls the `WriteResource` (page 1702) function, the Resource Manager writes only the resource data for that resource to disk.

If you add a resource to the current resource file, the Resource Manager writes the entire resource map to disk when it updates the file. If you want any of your changes to the resource map or resource data to be temporary, you must restore the original information before the Resource Manager updates the file on disk.

The function doesn't verify whether the resource ID you pass in the parameter `theID` is already assigned to another resource of the same type. You should call the `UniqueID` (page 1699) or `Unique1ID` (page 1698) function to get a unique resource ID before adding a resource with this function.

When your application calls this function, the Resource Manager attempts to reserve disk space for the new resource. If the new resource data can't be written to the resource fork (for example, if there's not enough room on disk), the `resChanged` attribute is not set to 1. If this is the case and you call `UpdateResFile` or `WriteResource`, the Resource Manager won't know that resource data has been added. Thus, the function won't write the new resource data to the resource fork and won't return an error. For this reason, always make sure that the `ResError` function returns the result code `noErr` after a call to `AddResource`.

To copy an existing resource, get a handle to the resource you want to copy, call the `DetachResource` (page 1665) function, then call `AddResource`. To add the same resource data to several different resource forks, call the Memory Manager function `HandToHand` to duplicate the handle for each resource.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

ChangedResource

Sets a flag in the resource's resource map entry in memory to show that you've made changes to a resource's data or to an entry in a resource map.

```
void ChangedResource (
   Handle theResource
);
```

Parameters

theResource

A handle to the resource whose data you've changed. The function sets the `resChanged` attribute for that resource in the resource map in memory. If the `resChanged` attribute for a resource has been set and your application calls the `UpdateResFile` (page 1700) function or quits, the Resource Manager writes the resource data for that resource (and for all other resources whose `resChanged` attribute is set) and the entire resource map to the resource fork of the corresponding file on disk. If the `resChanged` attribute for a resource has been set and your application calls the `WriteResource` (page 1702) function, the Resource Manager writes only the resource data for that resource to disk.

If the given handle isn't a handle to a resource, if the modified resource data can't be written to the resource fork, or if the `resProtected` attribute is set for the modified resource, the function does nothing. To find out whether any of these errors occurred, call the `ResError` (page 1692) function.

Discussion
If you change information in the resource map with a call to the `SetResInfo` (page 1694) or `SetResAttrs` (page 1693) function and then call `ChangedResource` and `UpdateResFile`, the Resource Manager still writes both the resource map and the resource data to disk. If you want any of your changes to the resource map or resource data to be temporary, you must restore the original information before the Resource Manager updates the resource fork on disk.

After writing a resource to disk, the Resource Manager clears the resource's `resChanged` attribute in the appropriate entry of the resource map in memory.

When your application calls this function, the Resource Manager attempts to reserve enough disk space to contain the changed resource. The function reserves space every time you call it, but the resource is not actually written until you call `WriteResource` or `UpdateResFile`. Thus, if you call `ChangedResource`

several times before the resource is actually written, the function reserves much more space than is needed. If the resource is large, you may unexpectedly run out of disk space. When the resource is actually written, the file's end-of-file (EOF) is set correctly, and the next call to ChangedResource will work as expected.

If the modified resource data can't be written to the resource fork (for example, if there's not enough room on disk), the resChanged attribute is not set to 1. If this is the case and you call UpdateResFile or WriteResource, the Resource Manager won't know that the resource data has been changed. Thus, the function won't write the modified resource data to the resource fork and won't return an error. For this reason, always make sure that the ResError function returns the result code noErr after a call to ChangedResource.

If your application frequently changes the contents of resources (especially large resources), you should call WriteResource or UpdateResFile immediately after calling ChangedResource.

If you need to make changes to a purgeable resource using functions that may cause the Memory Manager to purge the resource, you should make the resource temporarily not purgeable. To do so, use the Memory Manager functions HGetState, HNoPurge, and HSetState to make sure the resource data remains in memory while you change it and until the resource data is written to disk. (You can't use the SetResAttrs function for this purpose, because the changes don't take effect immediately.) First call HGetState and HNoPurge, then change the resource as necessary. To make a change to a resource permanent, use ChangedResource and UpdateResFile or WriteResource; then call HSetState when you're finished. Or, instead of calling WriteResource to write the resource data immediately, you can call the SetResPurge (page 1697) function with the install parameter set to TRUE before making changes to purgeable resource data.

If your application doesn't make its resources purgeable, or if the changes you are making to a purgeable resource don't involve functions that may cause the resource to be purged, you don't need to take these precautions

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

CloseResFile

Closes a resource fork before your application terminates.

```
void CloseResFile (
   ResFileRefNum refNum
);
```

Parameters

refNum

The file reference number for the resource fork to close. If this parameter does not contain a file reference number for a file whose resource fork is open, the function does nothing, and the ResError (page 1692) function returns the result code resFNotFound. If the value of this parameter is 0, it represents the System file and is ignored. You cannot close the System file's resource fork.

Discussion
This function performs four tasks. First, it updates the file by calling the UpdateResFile (page 1700) function. Second, it releases the memory occupied by each resource in the resource fork by calling the DisposeHandle function. Third, it releases the memory occupied by the resource map. The fourth task is to close the resource fork.

When your application terminates, the Resource Manager automatically closes every resource fork open to your application except the System file's resource fork. You need to call this function only if you want to close a resource fork before your application terminates.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Simple DrawSprocket

Declared In
`Resources.h`

Count1Resources

Returns the total number of resources of a given type in the current resource file.

```
ResourceCount Count1Resources (
   ResType theType
);
```

Parameters

theType
The resource type of the resources to count.

Return Value
The total number of resources of the given type in the current resource file.

Discussion
To check for errors, call the `ResError` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

Count1Types

Returns the number of resource types in the current resource file.

```
ResourceCount Count1Types (
   void
);
```

Return Value
The total number of unique resource types in the current resource file.

Discussion
To check for errors, call the `ResError` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

CountResources

Returns the total number of available resources of a given type.

```
ResourceCount CountResources (
   ResType theType
);
```

Parameters

theType
A resource type.

Return Value
The total number of resources of the given type in all resource forks open to your application.

Discussion
To check for errors, call the ResError (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

CountTypes

Returns the number of resource types in all resource forks open to your application.

```
ResourceCount CountTypes (
   void
);
```

Return Value
The total number of unique resource types in all resource forks open to your application.

Discussion
To check for errors, call the ResError (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

CurResFile

Gets the file reference number of the current resource file.

```
ResFileRefNum CurResFile (
   void
);
```

Return Value
The file reference number associated with the current resource file. You can call this function when your application starts up (before opening the resource fork of any other file) to get the file reference number of your application's resource fork. If the current resource file is the System file, the function returns the actual file reference number. You can use this number or 0 with functions that take a file reference number for the System file. All Resource Manager functions recognize both 0 and the actual file reference number as referring to the System file.

Discussion
Most of the Resource Manager functions assume that the current resource file is the file on whose resource fork they should operate or, in the case of a search, the file where they should begin. In general, the current resource file is the last one whose resource fork your application opened unless you specify otherwise.

To check for errors, call the `ResError` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

`Resources.h`

DetachResource

Sets the value of a resource's handle in the resource map in memory to `NULL` while keeping the resource data in memory.

```
void DetachResource (
   Handle theResource
);
```

Parameters

`theResource`
A handle to the resource which you wish to detach. If this parameter doesn't contain a handle to a resource or if the resource's `resChanged` attribute is set, the function does nothing. To determine whether either of these errors occurred, call the `ResError` (page 1692) function.

Discussion
After this call, the Resource Manager no longer recognizes the handle as a handle to a resource. However, this function does not release the memory used for the resource data, and the master pointer is still valid. Thus, you can access the resource data directly by using the handle.

If your application subsequently calls a Resource Manager function to get the released resource, the Resource Manager assigns a new handle. You can use `DetachResource` if you want to access the resource data directly without using Resource Manager functions. You can also use the `DetachResource` function to keep resource data in memory after closing a resource fork.

To copy a resource and install an entry for the duplicate in the resource map, call `DetachResource`, then call the `AddResource` (page 1660) function using a different resource ID.

Special Considerations
Do not use this function to detach a System resource that might be shared by several applications.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTMetaData

Declared In
`Resources.h`

DetachResourceFile

Removes a resource file from the resource chain.

```
OSErr DetachResourceFile (
   ResFileRefNum refNum
);
```

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
If the file is not currently in the resource chain, this returns `resNotFound`. Otherwise, the resource file is removed from the resource chain.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

DisposeResErrUPP

Disposes of the universal procedure pointer (UPP) to your callback function.

```
void DisposeResErrUPP (
    ResErrUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

FSCreateResFile

Creates a file with an empty resource fork.

```
void FSCreateResFile (
    const FSRef *parentRef,
    UniCharCount nameLength,
    const UniChar *name,
    FSCatalogInfoBitmap whichInfo,
    const FSCatalogInfo *catalogInfo,
    FSRef *newRef,
    FSSpec *newSpec
);
```

Discussion
This function is not recommended. You should use a file's data fork instead of its resource fork to store resource data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

FSCreateResourceFile

Creates a file with a named fork for storing resource data.

```
OSErr FSCreateResourceFile (
   const FSRef *parentRef,
   UniCharCount nameLength,
   const UniChar *name,
   FSCatalogInfoBitmap whichInfo,
   const FSCatalogInfo *catalogInfo,
   UniCharCount forkNameLength,
   const UniChar *forkName,
   FSRef *newRef,
   FSSpec *newSpec
);
```

Parameters

parentRef
A pointer to the directory in which the resource file is to be created.

nameLength
The number of Unicode characters in the file's name.

name
A pointer to the Unicode name of the new resource file.

whichInfo
The catalog information fields to set. See the File Manager documentation for a description of the `FSCatalogInfoBitmap` data type.

catalogInfo
A pointer to the values for the catalog information fields. This pointer may be set to `NULL`. See the File Manager documentation for a description of the `FSCatalogInfo` data type.

forkNameLength
The number of Unicode characters in the fork's name.

forkName
A pointer to the Unicode name of the fork to initialize. If you pass `NULL` in this parameter, the data fork is used.

newRef
A pointer to a variable allocated by the caller, or `NULL`. On return, the new resource file.

newSpec
A pointer to a variable allocated by the caller, or `NULL`. On return, the new resource file.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
This function creates a new file and initializes the specified fork for storing resource data. If you don't specify the fork name, the data fork is used. This function makes it possible to store resources in the data fork of a file.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

FSCreateResourceFork

Creates a named fork for storing resource data.

```
OSErr FSCreateResourceFork (
   const FSRef *ref,
   UniCharCount forkNameLength,
   const UniChar *forkName,
   UInt32 flags
);
```

Parameters
ref
A pointer to the file to which to add the fork.

forkNameLength
The number of Unicode characters in the fork's name.

forkName
A pointer to the Unicode name of the fork to initialize. If you pass `NULL` in this parameter, the data fork is used.

flags
A value of type `UInt32`. You should pass `0`.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
This function creates the specified fork in an existing file and initializes the fork for storing resources. If the named fork already exists, this function does nothing and returns `errFSForkExists`. If you don't specify the fork name, the data fork is used. This function makes it possible to store resources in the data fork of a file.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Resources.h`

FSOpenOrphanResFile

Opens a resource file that is persistent across all contexts.

```
OSErr FSOpenOrphanResFile (
    const FSRef *ref,
    SignedByte permission,
    ResFileRefNum *refNum
);
```

Parameters

ref

A pointer to the resource file to open.

permission

A constant indicating the type of access with which to open the resource fork. For a description of the types of access you can request, see File Access Permission Constants in *File Manager Reference*.

refNum

A pointer to a variable allocated by the caller. On return, the reference number for accessing the open fork.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
This function loads a map and all preloaded resources into the system context and detaches the specified file from the context in which it was opened. If the file is already in the resource chain and a new instance is not opened, this function returns `paramErr`. Use this function with care, as it may fail if the map is very large or many resources are preloaded.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Resources.h`

FSOpenResFile

Opens the resource fork in a file specified with an `FSRef` structure.

```
ResFileRefNum FSOpenResFile (
    const FSRef *ref,
    SInt8 permission
);
```

Discussion
This function is not recommended. You should use a file's data fork instead of its resource fork to store resource data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

FSOpenResourceFile

Opens a named fork in an existing resource file.

```
OSErr FSOpenResourceFile (
   const FSRef *ref,
   UniCharCount forkNameLength,
   const UniChar *forkName,
   SInt8 permissions,
   ResFileRefNum *refNum
);
```

Parameters

ref
A pointer to the file containing the fork to open.

forkNameLength
The number of Unicode characters in the fork's name.

forkName
A pointer to the Unicode name of the fork to open. If you pass `NULL` in this parameter, the data fork is used.

permissions
A constant indicating the type of access with which to open the fork. For a description of the types of access you can request, see File Access Permission Constants in *File Manager Reference*.

refNum
A pointer to a variable allocated by the caller. On return, the reference number for accessing the open fork.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
This function allows any named fork of a file to be used for storing resources. Passing in a null fork name will result in the data fork being used. You should use a file's data fork to store resource data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

FSpCreateResFile

Creates an empty resource fork in a new or existing file. (Deprecated in Mac OS X v10.5. Use `FSCreateResourceFile` (page 1667) instead.)

```
void FSpCreateResFile (
   const FSSpec *spec,
   OSType creator,
   OSType fileType,
   ScriptCode scriptTag
);
```

Discussion
This function is not recommended. You should use a file's data fork instead of its resource fork to store resource data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Resources.h`

FSpOpenOrphanResFile

Opens a resource file that is persistent across all contexts. (Deprecated in Mac OS X v10.5. Use `FSOpenOrphanResFile` (page 1669) instead.)

```
OSErr FSpOpenOrphanResFile (
   const FSSpec *spec,
   SignedByte permission,
   ResFileRefNum *refNum
);
```

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
`FSpOpenOrphanResFile` should be used to open a resource file that is persistent across all contexts. `FSpOpenOrphanResFile` loads everything into the system context and detaches the file from the context in which it was opened. If the file is already in the resource chain and a new instance is not opened, `FSpOpenOrphanResFile` will return a `paramErr`. Use this function with care, as it can and will fail if the map is very large or a lot of resources are preloaded.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Resources.h`

FSpOpenResFile

Opens the resource fork in a file specified with an `FSSpec` structure. (Deprecated in Mac OS X v10.5. Use `FSOpenResourceFile` (page 1670) instead.)

```
ResFileRefNum FSpOpenResFile (
   const FSSpec *spec,
   SignedByte permission
);
```

Parameters

spec

A pointer to a file system specification record specifying the name and location of the file whose resource fork is to be opened. This function also makes the specified file the current resource file.

permission

A constant indicating the type of access with which to open the resource fork. For a description of the types of access you can request, see File Access Permission Constants in *File Manager Reference*.

Return Value

The file reference number for the resource fork. If the file reference number returned is greater than 0, you can use this number to refer to the resource fork in some other Resource Manager functions.

If you attempt to use this function to open a resource fork that is already open, it returns the existing file reference number or a new one, depending on the access permission for the existing access path. For example, your application receives a new file reference number after a successful request for read-only access to a file previously opened with write access, whereas it receives the same file reference number in response to a second request for write access to the same file. In this case, the function doesn't make that file the current resource file.

If the function fails to open the specified file's resource fork (for instance, because there's no file with the given file system specification record or because there are permission problems), it returns –1 as the file reference number. Use the `ResError` (page 1692) function to determine what kind of error occurred.

If an application attempts to open a second access path with write access and the application is different from the one that originally opened the resource fork, `FSpOpenResFile` returns –1, and the `ResError` function returns the result code `opWrErr`.

Discussion

This function is available only in System 7 and later versions of system software. You can determine whether `FSpOpenResFile` is available by calling the `Gestalt` function with the `gestaltFSAttr` selector code. If this function is not available to your application, you can use `HOpenResFile`, `OpenRFPerm`, or `OpenResFile` instead. The `HOpenResFile` (page 1686) function is preferred if `FSpOpenResFile` is not available. The `OpenRFPerm` (page 1689) function is an earlier version of `HOpenResFile` that is still supported but is more restricted in its capabilities.

The Resource Manager reads the resource map from the specified file's resource fork into memory. It also reads into memory every resource in the resource fork whose `resPreload` attribute is set.

You don't have to call this function to open the System file's resource fork or an application file's resource fork. These resource forks are opened automatically when the system and the application start up, respectively. To get the file reference number for your application, call the `CurResFile` (page 1664) function after your application starts up and before you open any other resource forks.

The `FSpOpenResFile` function checks that the information in the resource map is internally consistent. If it isn't, `ResError` returns the result code `mapReadErr`.

It's possible to create multiple, unique, read-only access paths to a resource fork using this function however, you should avoid doing so. If a resource fork is opened twice—once with read/write permission and once with read-only permission—two copies of the resource map exist in memory. If you change one of the resources in memory using one of the resource maps, the two resource maps become inconsistent and the file will appear damaged to the second resource map.

If you must use this technique for read-only access, call this function immediately before your application reads information from the file and close the file immediately afterward. Otherwise, your application may get unexpected results.

If you want to open the resource fork for another application (or any resource fork other than your application's that includes `'CODE'` resources), you must bracket your calls to this function with calls to the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE` and then to `TRUE`. You must also avoid making intersegment calls while the other application's resource fork is open. If you don't do this, the Segment Loader Manager treats any preloaded `'CODE'` resources as your code resources when you make an intersegment call that triggers a call to the `LoadSeg` function while the other application is first in the resource chain. In this case, your application can begin executing the other application's code, and severe problems will ensue. If you need to get `'CODE'` resources from the other application's resource fork, you can still prevent the Segment Loader Manager problem by calling the `UseResFile` (page 1700) function with your application's file reference number to make your application the current resource file.

To open a resource fork just for block-level operations, such as copying files without reading the resource map into memory, use the File Manager function `OpenRF`.

Special Considerations

Because there is no support for locking and unlocking file ranges on local disks in Mac OS X, regardless of whether File Sharing is enabled, you cannot open more than one path to a resource fork with read/ write permission. If you try to open a more than one path to a file's resource fork with `fsRdWrShPerm` permission, only the first attempt will succeed. Subsequent attempts will return an invalid reference number and the `ResError` function will return the error `opWrErr`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Resources.h`

FSpResourceFileAlreadyOpen

Checks whether a resource file is open. (Deprecated in Mac OS X v10.5. Use `FSResourceFileAlreadyOpen` (page 1674) instead.)

```
Boolean FSpResourceFileAlreadyOpen (
   const FSSpec *resourceFile,
   Boolean *inChain,
   ResFileRefNum *refNum
);
```

Parameters

resourceFile

The resource file to check.

inChain

A pointer to a variable allocated by the caller. On return, `true` if the resource file is in the resource chain, `false` otherwise.

refNum

A pointer to a variable allocated by the caller. On return, the reference number of the file if it is open.

Return Value

This function returns `true` if the resource file is already open and known by the Resource Manager—for example, it is either in the current resource chain or it is a detached resource file.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Resources.h`

FSResourceFileAlreadyOpen

Checks whether a resource file is open.

```
Boolean FSResourceFileAlreadyOpen (
   const FSRef *resourceFileRef,
   Boolean *inChain,
   ResFileRefNum *refNum
);
```

Parameters

resourceFileRef

The resource file to check.

inChain

A pointer to a variable allocated by the caller. On return, `true` if the resource file is in the resource chain, `false` otherwise.

refNum

A pointer to a variable allocated by the caller. On return, the reference number of the file if it is open.

Return Value

This function returns `true` if the resource file is already open and known by the Resource Manager—for example, it is either in the current resource chain or it is a detached resource file.

Availability

Available in Mac OS X v10.0 and later.

Declared In
Resources.h

Get1IndResource

Returns a handle to a resource of a given type in the current resource file.

```
Handle Get1IndResource (
   ResType theType,
   ResourceIndex index
);
```

Parameters

theType

A resource type.

index

An integer ranging from 1 to the number of resources of a given type returned by the Count1Resources (page 1663) function, which is the number of resources of that type in the current resource file.

Return Value
A handle to a resource of the given type. If you call Get1IndResource repeatedly over the entire range of the index, it returns handles to all resources of the given type in the current resource file. If you provide an index that is either 0 or negative, the function returns NULL, and the ResError (page 1692) function returns the result code resNotFound. If the given index is larger than the value returned by Count1Resources (page 1663), Get1IndResource (page 1675) returns NULL, and ResError (page 1692) returns the result code resNotFound. If the resource to be read won't fit into memory, the function returns NULL, and ResError (page 1692) returns the appropriate result code.

Discussion
The function reads the resource data into memory if it's not already there, unless you've called the SetResLoad (page 1695) function with the load parameter set to FALSE. If you've called SetResLoad with the load parameter set to FALSE and the data isn't already in memory, Get1IndResource (page 1675) returns an empty handle (that is, a handle whose master pointer is set to NULL). This can also happen if you read resource data for a purgeable resource into memory and then call SetResLoad (page 1695) with the load parameter set to FALSE. If the resource data is later purged and you call the Get1IndResource (page 1675) function, the function returns an empty handle. You should test for an empty handle in these situations. To make the handle a valid handle to resource data in memory, you can call the LoadResource (page 1688) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

Get1IndType

Gets a resource types available in the current resource file.

```
void Get1IndType (
   ResType *theType,
   ResourceIndex index
);
```

Parameters

theType

On return, the resource type with the specified index in the current resource file.

You can call this function repeatedly over the entire range of the index to get all the resource types available in the current resource file. If the given index isn't in the range from 1 to the number of resource types as returned by `Count1Types`, this parameter contains four null characters (ASCII code 0).

index

An integer ranging from 1 to the number of resource types in the current resource file, as returned by the `Count1Types` (page 1663) function.

Discussion
To check for errors, call the `ResError` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

Get1NamedResource

Gets a named resource in the current resource file.

```
Handle Get1NamedResource (
   ResType theType,
   ConstStr255Param name
);
```

Parameters

theType

The resource type of the resource about which you wish to retrieve data.

name

A name that uniquely identifies the resource about which you wish to retrieve data.

Return Value
If the function finds an entry for the resource in the current resource file's resource map and the entry contains a valid handle, the function returns that handle. If the entry contains a handle whose value is `NULL`, and if you haven't called the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE`, `Get1NamedResource` attempts to read the resource into memory. If it can't find the resource data, the function returns `NULL`, and the `ResError` (page 1692) function returns the result code `resNotFound`. The `Get1NamedResource` function also returns `NULL` if the resource data to be read into memory won't fit, in which case `ResError` returns an appropriate Memory Manager result code.

If you call this function with a resource type that can't be found in the resource map of the current resource file, the function returns `NULL`, but `ResError` returns the result code `noErr`. You should always check that the value of the returned handle is not `NULL`.

Discussion
The function searches the current resource file's resource map in memory for the specified resource. You can change the search order by calling the `UseResFile` (page 1700) function before `Get1NamedResource`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

Get1Resource

Gets resource data for a resource in the current resource file.

```
Handle Get1Resource (
   ResType theType,
   ResID theID
);
```

Parameters

theType
The resource type of the resource about which you wish to retrieve data.

theID
An integer that uniquely identifies the resource about which you wish to retrieve data.

Return Value
If the function finds an entry for the resource in the current resource file's resource map and the entry contains a valid handle, it returns that handle. If the entry contains a handle whose value is `NULL`, and if you haven't called the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE`, `Get1Resource` attempts to read the resource into memory.

If the function can't find the resource data, it returns `NULL`, and `ResError` returns the result code `resNotFound`. The `Get1Resource` function also returns `NULL` if the resource data to be read into memory won't fit, in which case `ResError` returns an appropriate Memory Manager result code.

If you call this function with a resource type that can't be found in the resource map of the current resource file, the function returns `NULL`, but `ResError` returns the result code `noErr`. You should always check that the value of the returned handle is not `NULL`.

Discussion
The function searches the current resource file's resource map in memory for the specified resource.

You can change the resource map search order by calling the `UseResFile` (page 1700) function before `Get1Resource`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTMetaData

Declared In
`Resources.h`

GetIndResource

Returns a handle to a resource of a given type in resource forks open to your application.

```
Handle GetIndResource (
   ResType theType,
   ResourceIndex index
);
```

Parameters

theType

A resource type.

index

An integer ranging from 1 to the number of resources of a given type returned by the `CountResources` (page 1664) function, which is the number of resources of that type in all resource forks open to your application.

Return Value

A handle to a resource of the given type. If you call this function repeatedly over the entire range of the index, it returns handles to all resources of the given type in all resource forks open to your application. The function returns handles for all resources in the most recently opened resource fork first, and then for those in resource forks opened earlier in reverse chronological order. If you provide an index to that is either 0 or negative, the function returns `NULL`, and the `ResError` (page 1692) function returns the result code `resNotFound`. If the given index is larger than the value returned by `CountResources`, the function returns `NULL`, and `ResError` (page 1692) returns the result code `resNotFound`. If the resource to be read won't fit into memory, the function returns `NULL`, and `ResError` (page 1692) returns the appropriate result code.

Discussion

This function reads the resource data into memory if it's not already there, unless you've called the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE`.

If you've called `SetResLoad` (page 1695) with the `load` parameter set to `FALSE` and the data isn't already in memory, the function returns an empty handle (a handle whose master pointer is set to NULL). This can also happen if you read resource data for a purgeable resource into memory and then call `SetResLoad` with the `load` parameter set to `FALSE`. If the resource data is later purged and you call the `GetIndResource` function, the function returns an empty handle. You should test for an empty handle in these situations. To make the handle a valid handle to resource data in memory, you can call the `LoadResource` (page 1688) function.

The `UseResFile` (page 1700) function affects which file the Resource Manager searches first when looking for a particular resource; this is not the case when you use `GetIndResource` to get an indexed resource.

If you want to find out how many resources of a given type are in a particular resource fork, set the current resource file to that resource fork, then call the `Count1Resources` (page 1663) function and use the `Get1IndResource` (page 1675) function to get handles to the resources of that type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

GetIndType

Gets a resource type available in resource forks open to your application.

```
void GetIndType (
   ResType *theType,
   ResourceIndex index
);
```

Parameters

theType

On return, a pointer to the resource type for the specified index among all the resource forks open to your application.

You can call this function repeatedly over the entire range of the index to get all the resource types available in all resource forks open to your application. If the given index isn't in the range from 1 to the number of resource types as returned by `CountTypes`, this parameter contains four null characters (ASCII code 0).

index

An integer ranging from 1 to the number of resource types in all resource forks open to your application, as returned by `CountTypes` (page 1664) function.

Discussion

To check for errors, call the `ResError` (page 1692) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

GetMaxResourceSize

Returns the approximate size of a resource.

```
long GetMaxResourceSize (
   Handle theResource
);
```

Parameters

theResource

A handle to the resource whose size you wish to retrieve.

Return Value

The approximate size, in bytes, of the resource. Unlike the `GetResourceSizeOnDisk` (page 1684) function, this function does not check the resource on disk instead, it either checks the resource size in memory or, if the resource is not in memory, calculates its size on the basis of information in the resource map in memory. This gives you an approximate size for the resource that you can count on as the resource's maximum size. It's possible that the resource is actually smaller than the offsets in the resource map indicate because the file has not yet been compacted. If you want the exact size of a resource on disk, either call `GetResourceSizeOnDisk` or call the `UpdateResFile` (page 1700) function before calling `GetMaxResourceSize`. If the handle isn't a handle to a valid resource, the function returns –1, and the `ResError` (page 1692) function returns the result code `resNotFound`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

GetNamedResource

Gets a named resource.

```
Handle GetNamedResource (
   ResType theType,
   ConstStr255Param name
);
```

Parameters

theType

The resource type of the resource about which you wish to retrieve data.

name

A name that uniquely identifies the resource about which you wish to retrieve data. Strings passed in this parameter are case-sensitive.

Return Value

If the function finds the specified resource entry in one of the resource maps and the entry contains a valid handle, the function returns that handle. If the entry contains a handle whose value is `NULL`, and if you haven't called the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE`, `GetNamedResource` attempts to read the resource into memory.

If the function can't find the resource data, it returns `NULL`, and the `ResError` (page 1692) function returns the result code `resNotFound`. The function also returns `NULL` if the resource data to be read into memory won't fit, in which case `ResError` returns an appropriate Memory Manager result code. If you call `GetNamedResource` with a resource type that can't be found in any of the resource maps of the open resource forks, the function returns `NULL` as well, but `ResError` returns the result code `noErr`. You should always check that the value of the returned handle is not `NULL`.

Discussion

The function searches the resource maps in memory for the specified resource. The resource maps in memory, which represent all the open resource forks, are arranged as a linked list. When the function searches this list, it starts with the current resource file and progresses through the list in order (that is, in reverse chronological order in which the resource forks were opened) until it finds the resource's entry in one of the resource maps.

You can change the resource map search order by calling the `UseResFile` (page 1700) function before `GetNamedResource`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

GetNextFOND

Gets the next FOND handle.

```
Handle GetNextFOND (
   Handle fondHandle
);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
Resources.h

GetNextResourceFile

Retrieves the next resource file in the resource chain.

```
OSErr GetNextResourceFile (
   ResFileRefNum curRefNum,
   ResFileRefNum *nextRefNum
);
```

Parameters

curRefNum

A value of type SInt16 representing the current reference number of a resource file.

nextRefNum

A pointer to a value of type SInt16. On return, this points to the next resource file in the resource chain.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
`GetNextResourceFile` can be used to iterate over resource files in the resource chain. By passing a valid reference number in the `curRefNum` parameter, the function returns the reference number of the next file in the resource chain. If the resource file specified by the `curRefNum` parameter is not found in the resource chain, the `GetNextResourceFile` function returns the error code `resFNotFound`. When the end of the chain is reached `GetNextResourceFile` returns `noErr` and the value of the `nextRefNum` parameter is `NIL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

GetResAttrs

Gets a resource's attributes.

```
ResAttributes GetResAttrs (
   Handle theResource
);
```

Parameters

theResource

A handle to the resource whose attributes you wish to retrieve. If the value of this parameter isn't a handle to a valid resource, the function does nothing, and the `ResError` (page 1692) function returns the result code `resNotFound`.

Return Value
The resource's attributes as recorded in its entry in the resource map in memory. The function returns the resource's attributes in the low-order byte of the function result. Each attribute is identified by a specific bit in the low-order byte. If the bit corresponding to an attribute contains 1, then that attribute is set if the bit contains 0, then that attribute is not set.

Discussion
To change a resource's attributes in the resource map in memory, use the `SetResAttrs` (page 1693) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

GetResFileAttrs

Gets the attributes of a resource fork.

```
ResFileAttributes GetResFileAttrs (
   ResFileRefNum refNum
);
```

Parameters

refNum

A file reference number for the resource fork whose attributes you want to get. Specify 0 in this parameter to get the attributes of the System file's resource fork.

Return Value
The attributes of the file's resource fork. If there's no open resource fork for the given file reference number, the function does nothing, and the `ResError` (page 1692) function returns the result code `resFNotFound`. Like individual resources, resource forks have attributes that are specified by bits in the low-order byte of a word.

Discussion
The Resource Manager sets the `mapChanged` attribute for the resource fork when you call the `ChangedResource` (page 1661), the `AddResource` (page 1660), or the `RemoveResource` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

GetResInfo

Gets a resource's resource ID, resource type, and resource name.

```
void GetResInfo (
   Handle theResource,
   ResID *theID,
   ResType *theType,
   Str255 name
);
```

Parameters

theResource

A handle to the resource for which you want to retrieve information. If the handle isn't a valid handle to a resource, the function does nothing to determine whether this has occurred, call the `ResError` (page 1692) function.

theID
On return, a pointer to the resource ID of the specified resource.

theType
On return, a pointer to the resource type of the specified resource.

name
On return, the name of the specified resource.

Discussion
To set a resource's ID, resource type, or resource name, use the `SetResInfo` (page 1694) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

GetResource

Gets resource data for a resource specified by resource type and resource ID.

```
Handle GetResource (
   ResType theType,
   ResID theID
);
```

Parameters

theType
The resource type of the resource about which you wish to retrieve data.

theID
An integer that uniquely identifies the resource about which you wish to retrieve data.

Return Value
If the function finds the specified resource entry in one of the resource maps and the entry contains a valid handle, it returns that handle. If the entry contains a a handle whose value is `NULL`, and if you haven't called the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE`, `GetResource` attempts to read the resource into memory.

If the function can't find the resource data, it returns `NULL`, and the `ResError` (page 1692) function returns the result code `resNotFound`. The `GetResource` function also returns `NULL` if the resource data to be read into memory won't fit, in which case `ResError` returns an appropriate Memory Manager result code. If you call `GetResource` with a resource type that can't be found in any of the resource maps of the open resource forks, the function returns `NULL`, but `ResError` returns the result code `noErr`. You should always check that the value of the returned handle is not `NULL`.

Discussion
The function searches the resource maps in memory for the specified resource. The resource maps in memory, which represent all the open resource forks, are arranged as a linked list. When searching this list, the function starts with the current resource file and progresses through the list (that is, searching the resource maps in reverse order of opening) until it finds the resource's entry in one of the resource maps.

Before reading the resource data into memory, the Resource Manager calls the Memory Manager to allocate a relocatable block for the resource data. The Memory Manager allocates the block, assigns a master pointer to the block, and returns to the Resource Manager a pointer to the master pointer. The Resource Manager then installs this handle in the resource map.

You can change the resource map search order by calling the `UseResFile` (page 1700) function before calling `GetResource`.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Simple DrawSprocket

Declared In
`Resources.h`

GetResourceSizeOnDisk

Returns the exact size of a resource.

```
long GetResourceSizeOnDisk (
   Handle theResource
);
```

Parameters

`theResource`
A handle to the resource whose size you wish to retrieve.

Return Value
The exact size, in bytes, of the resource. If the handle isn't a handle to a valid resource, the function returns –1, and the `ResError` (page 1692) function returns the result code `resNotFound`.

Discussion
This function checks the resource on disk, not in memory. You can call this function before reading a resource into memory to make sure there's enough memory available to do so successfully.

The `GetResourceSizeOnDisk` function is also available as the `SizeResource` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

GetTopResourceFile

Retrieves the topmost resource file in the current resource chain.

```
OSErr GetTopResourceFile (
   ResFileRefNum *refNum
);
```

Parameters

`refNum`
A pointer to a value of type `SInt16`. On return, this points to the top most resource file in the current resource chain.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711). If the resource chain is empty, `resFNotFound` is returned.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

HCreateResFile

Creates an empty resource fork, when the `FSpCreateResFile` function is not available. (Deprecated in Mac OS X v10.5. Use `FSCreateResourceFile` (page 1667) instead.)

```
void HCreateResFile (
   FSVolumeRefNum vRefNum,
   long dirID,
   ConstStr255Param fileName
);
```

Discussion
This function is not recommended. You should use a file's data fork instead of its resource fork to store resource data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Resources.h`

HomeResFile

Gets the file reference number associated with a particular resource.

```
ResFileRefNum HomeResFile (
   Handle theResource
);
```

Parameters
`theResource`
A handle to the resource for which you wish to get the associated file reference number.

Return Value
The file reference number for the resource fork containing the specified resource. If the given handle isn't a handle to a resource, the function returns –1, and the `ResError` (page 1692) function returns the result code `resNotFound`. If `HomeResFile` returns 0, the resource is in the System file's resource fork. If it returns 1, the resource is ROM-resident.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

HOpenResFile

Opens a file's resource fork, when the FSpOpenResFile function is not available. (Deprecated in Mac OS X v10.5. Use FSOpenResourceFile (page 1670) instead.)

```
ResFileRefNum HOpenResFile (
   FSVolumeRefNum vRefNum,
   long dirID,
   ConstStr255Param fileName,
   SInt8 permission
);
```

Parameters

vRefNum
The volume reference number of the volume on which the file is located.

dirID
The directory ID of the directory where the file is located.

fileName
The name of the file whose resource fork is to be opened.

permission
A constant indicating the type of access with which to open the resource fork. For a description of the types of access you can request, see File Access Permission Constants in *File Manager Reference*.

Return Value
The file reference number for the file. You can use this file reference number to refer to the file in other Resource Manager functions. The function also makes this file the current resource file. If the file's resource fork is already open, the function returns the file reference number but does not make that file the current resource file. If the function fails to open the specified file's resource fork (because there's no file with the specified name or because there are permission problems), it returns –1 as the file reference number. Use the ResError (page 1692) function to determine what kind of error occurred.

Versions of system software before System 7 do not allow you to use this function to open a second access path, with write access, to a resource fork. In this case, the function returns the reference number already assigned to the file.

Discussion
The Resource Manager reads the resource map from the resource fork of the specified file into memory. It also reads into memory every resource whose resPreload attribute is set.

You don't have to call this function to open the System file's resource fork or an application file's resource fork. These files are opened automatically when the system and the application start up, respectively. To get the file reference number for your application, call the CurResFile (page 1664) function after the application starts up and before you open the resource forks for any other files.

The HOpenResFile function checks that the information in the resource map is internally consistent. If it isn't, ResError returns the result code mapReadErr. It's possible to create multiple, unique, read-only access paths to a resource fork using HOpenResFile; however, you should avoid doing so, to prevent inconsistencies between multiple copies of the resource map. See the discussion of this issue in relation to FSpOpenResFile (page 1671). The HOpenResFile function works the same way.

To open a resource fork just for block-level operations, such as copying files without reading the resource map into memory, use the File Manager function `OpenRF`.

If you want to open the resource fork for another application (or any resource fork other than your application's that includes `'CODE'` resources), you must bracket your calls to `HOpenResFile` with calls to the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE` and then to `TRUE`. You must also avoid making intersegment calls while the other application's resource fork is open. The discussion of this issue in relation to `FSpOpenResFile` (page 1671) also applies to `HOpenResFile`.

Special Considerations

Because there is no support for locking and unlocking file ranges on local disks in Mac OS X, regardless of whether File Sharing is enabled, you cannot open more than one path to a resource fork with read/write permission. If you try to open a more than one path to a file's resource fork with `fsRdWrShPerm` permission, only the first attempt will succeed. Subsequent attempts will return an invalid reference number and the `ResError` function will return the error `opWrErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Resources.h`

InsertResourceFile

Inserts a resource file into the current resource chain at the specified location.

```
OSErr InsertResourceFile (
   ResFileRefNum refNum,
   RsrcChainLocation where
);
```

Parameters

refNum
A value of type SInt16 indicating the reference number of the resource file to insert into the resource chain.

where
A value of type RsrcChainLocation indicating where in the resource chain the resource file should be inserted. See the `RsrcChainLocation` data type.

Return Value
A result code. See "Resource Manager Result Codes" (page 1711).

Discussion
If the file is already in the resource chain, it is removed and reinserted at the specified location. If the file has been detached, it is added to the resource chain at the specified location Returns resFNotFound if it's not currently open.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

InvokeResErrUPP

Calls your callback function.

```
void InvokeResErrUPP (
    OSErr thErr,
    ResErrUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

LoadResource

Gets resource data after you've called the `SetResLoad` function with the `load` parameter set to `FALSE` or when the resource is purgeable.

```
void LoadResource (
    Handle theResource
);
```

Parameters

`theResource`

A handle to a resource. Given this handle, the function reads the resource data into memory. If the resource is already in memory, or if the this parameter doesn't contain a handle to a resource, then the function does nothing. To determine whether either of these situations occurred, call the `ResError` (page 1692) function. If the resource is already in memory, `ResError` returns `noErr`; if the handle is not a handle to a resource, `ResError` returns `resNotFound`.

Discussion
If you've changed the resource data for a purgeable resource and the resource is purged before being written to the file, the changes will be lost. In this case, this function rereads the original resource from the file's resource fork. You should use the `ChangedResource` (page 1661) or `SetResPurge` (page 1697) function before calling `LoadResource` to ensure that changes made to purgeable resources are written to the resource fork.

Availability
Available in Mac OS X 10.0 and later.

Declared In
`Resources.h`

NewResErrUPP

Creates a new universal procedure pointer (UPP) to your callback function.

```
ResErrUPP NewResErrUPP (
    ResErrProcPtr userRoutine
);
```

Return Value
See `ResErrUPP` (page 1704) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

OpenRFPerm

Opens a file's resource fork, when the `FSpOpenResFile` and `HOpenResFile` functions are not available. (Deprecated in Mac OS X v10.5. Use `FSOpenResourceFile` (page 1670) instead.)

```
ResFileRefNum OpenRFPerm (
   ConstStr255Param fileName,
   FSVolumeRefNum vRefNum,
   SInt8 permission
);
```

Parameters

`fileName`
The name of the file whose resource fork is to be opened.

`vRefNum`
The volume reference number or directory ID for the volume or directory in which the file is located.

`permission`
A constant indicating the type of access with which to open the resource fork. For a description of the types of access you can request, see File Access Permission Constants in *File Manager Reference*.

Return Value
The file reference number for the file whose resource fork it has opened. You can use this file reference number to refer to the file in other Resource Manager functions. The function also makes this file the current resource file. If the file's resource fork is already open, the function returns the file reference number but does not make that file the current resource file.

If the function fails to open the specified file's resource fork (because there's no file with the given name or because there are permission problems), it returns –1 as the file reference number. Use the `ResError` (page 1692) function to determine what kind of error occurred.

Versions of system software before System 7 do not allow you to use this function to open a second access path, with write access, to a resource fork. In this case, the function returns the reference number already assigned to the file.

Discussion
You can use this function if the `FSpOpenResFile` (page 1671) function is not available. You can determine whether `FSpOpenResFile` is available by calling the `Gestalt` function with the `gestaltFSAttr` selector code. The `HOpenResFile` function allows you to specify both a directory ID and a volume reference number, and is therefore preferred if `FSpOpenResFile` is not available. The `OpenRFPerm` is an earlier versions of `HOpenResFile` that is still supported but is more restricted in its capabilities.

The Resource Manager reads the resource map from the resource fork for the specified file into memory. It also reads into memory every resource in the resource fork whose `resPreload` attribute is set.

You don't have to call this function to open the System file's resource fork or an application file's resource fork. These files are opened automatically when the system and the application start up, respectively. To get the file reference number for your application, call the `CurResFile` (page 1664) function after the application starts up and before you open the resource forks for any other files.

This function checks that the information in the resource map is internally consistent. If it isn't, `ResError` returns the result code `mapReadErr`. It's possible to create multiple, unique, read-only access paths to a resource fork using this function however, you should avoid doing so, to prevent inconsistencies between multiple copies of the resource map.

To open a resource fork just for block-level operations, such as copying files without reading the resource map into memory, use the File Manager function `OpenRF`.

If you want to open the resource fork for another application (or any resource fork other than your application's that includes `'CODE'` resources), you must bracket your calls to this function with calls to the `SetResLoad` (page 1695) function with the `load` parameter set to `FALSE` and then to `TRUE`. You must also avoid making intersegment calls while the other application's resource fork is open.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Resources.h`

ReadPartialResource

Reads part of a resource into memory and work with a small subsection of a large resource.

```
void ReadPartialResource (
   Handle theResource,
   long offset,
   void *buffer,
   long count
);
```

Parameters

theResource
A handle to the resource you wish to read.

offset
The beginning of the resource subsection to be read, measured in bytes from the beginning of the resource.

buffer
A pointer to the buffer into which the partial resource is to be read. Your application is responsible for the buffer's memory management. You cannot use the `ReleaseResource` (page 1691) function to release the memory the buffer occupies.

count
The length of the resource subsection.

Discussion
This function always tries to read resources from disk. If a resource is already in memory, the Resource Manager still reads it from disk, and the `ResError` (page 1692) function returns the result code `resourceInMemory`. If you try to read past the end of a resource or the value of the `offset` parameter is out of bounds, `ResError` returns the result code `inputOutOfBounds`. If the handle in the parameter `theResource` doesn't refer to a resource in an open resource fork, `ResError` returns the result code `resNotFound`.

You may experience problems if you have a copy of a resource in memory when you are using the partial resource functions. If you have modified the copy in memory and then access the resource on disk using this function, the function reads the data on disk, not the data in memory, which is referenced through the resource's handle.

When using partial resource functions, you should call the `SetResLoad` (page 1695) function, specifying `FALSE` for the `load` parameter, before you call `GetResource`. Using the `SetResLoad` function prevents the Resource Manager from reading the entire resource into memory. Be sure to restore the normal state by calling `SetResLoad` again, with the `load` parameter set to `TRUE`, immediately after you call the `GetResource` (page 1683) function. Then use `ReadPartialResource` to read a portion of the resource into a buffer.

If the entire resource is in memory and you want only part of its data, it's faster to use the Memory Manager function `BlockMove` instead of the `ReadPartialResource` function. If you read a partial resource into memory and then change its size, you can use the `SetResourceSize` (page 1696) function to change the entire resource's size on disk as necessary

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

ReleaseResource

Releases the memory a resource occupies when you have finished using it.

```
void ReleaseResource (
   Handle theResource
);
```

Parameters

`theResource`

A handle to the resource which you wish to release. The function sets the master pointer of the resource's handle in the resource map in memory to `NULL`. If your application previously obtained a handle to that resource, the handle is no longer valid. If your application subsequently calls the Resource Manager to get the released resource, the Resource Manager assigns a new handle.

If the given resource isn't a handle to a resource, the function does nothing, and the `ResError` (page 1692) function returns the result code `resNotFound`. Be aware that `ReleaseResource` won't release a resource whose `resChanged` attribute has been set, but `ResError` still returns the result code `noErr`.

Special Considerations

Do not use this function to release a System resource that might be shared by several applications.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Simple DrawSprocket

Declared In
`Resources.h`

RemoveResource

Removes a resource's entry from the current resource file's resource map in memory.

```
void RemoveResource (
   Handle theResource
);
```

Parameters

theResource

A handle to the resource which you wish to detach. If the `resProtected` attribute for the resource is set or if this parameter doesn't contain a handle to a resource, the function does nothing, and the `ResError` (page 1692) function returns the result code `rmvResFailed`.

Discussion

The `RemoveResource` function does not dispose of the handle you pass into it; to do so you must call the Memory Manager function `DisposeHandle` after calling `RemoveResource`. You should dispose the handle if you want to release the memory before updating or closing the resource fork.

If you've removed a resource, the Resource Manager writes the entire resource map when it updates the resource fork, and all changes made to the resource map become permanent. If you want any of the changes to be temporary, you should restore the original information before the Resource Manager updates the resource fork.

The `RemoveResource` function is also available as the `RmveResource` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

ResError

Determines what error occurred, if any, after calling a Resource Manager function.

```
OSErr ResError (
   void
);
```

Return Value

A result code. See "Resource Manager Result Codes" (page 1711). If no error occurred, the function returns `noErr`. If an error occurs at the Resource Manager level, the function returns one of the result codes specific to the Resource Manager. If an error occurs at the Operating System level, the function returns an Operating System result code. In certain cases, the `ResError` function returns `noErr` even though a Resource Manager function was unable to perform the requested operation. See the individual function descriptions for details about the circumstances under which this happens.

Discussion

Resource Manager functions do not report error information directly. Instead, after calling a Resource Manager function, your application should call this function to determine whether an error occurred. You also can use this function to check for an error after application startup (system software opens the resource fork of your application during application startup).

Resource Manager functions usually return NULL or –1 as the function result when there's an error. For Resource Manager functions that return –1, your application can call the ResError function to determine the specific error that occurred. For Resource Manager functions that return handles, your application should always check whether the value of the returned handle is NULL. If it is, your application can use this function to obtain specific information about the nature of the error. Note, however, that in some cases ResError returns noErr even though the value of the returned handle is NULL.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTMetaData
Simple DrawSprocket

Declared In
Resources.h

SetResAttrs

Sets a resource's attributes in the resource map in memory.

```
void SetResAttrs (
   Handle theResource,
   ResAttributes attrs
);
```

Parameters

theResource

A handle to the resource whose attributes you wish to set. If the value of this parameter isn't a valid handle to a resource, the function does nothing, and the ResError (page 1692) function returns the result code resNotFound.

attrs

The resource attributes to set. The resProtected attribute changes immediately. Other attribute changes take effect the next time the specified resource is read into memory but are not made permanent until the Resource Manager updates the resource fork.

Each attribute is identified by a specific bit in the low-order byte of a word. If the bit corresponding to an attribute contains 1, then that attribute is set; if the bit contains 0, then that attribute is not set.

Discussion
This function changes the information in the resource map in memory, not in the file on disk. If you want the Resource Manager to write the modified resource map to disk after a subsequent call to the UpdateResFile (page 1700) function or when your application terminates, call the ChangedResource (page 1661) function after you call SetResAttrs.

Do not use this function to change a purgeable resource. If you make a purgeable resource nonpurgeable by setting the resPurgeable attribute with this function, the resource doesn't become nonpurgeable until the next time the specified resource is read into memory. Thus, the resource might be purged while you're changing it.

You can check for errors using the ResError function. SetResAttrs does not return an error if you are setting the attributes of a resource in a resource file that has a read-only resource map. To find out whether this is the case, use the GetResAttrs (page 1681) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

SetResFileAttrs

Sets a resource fork's attributes.

```
void SetResFileAttrs (
   ResFileRefNum refNum,
   ResFileAttributes attrs
);
```

Parameters

refNum

A file reference number for the resource fork whose attributes you want to set. If this value is 0, it represents the System file's resource fork. However, you shouldn't change the attributes of the System file's resource fork. If there's no resource fork with the given reference number, the function does nothing, and the `ResError` (page 1692) function returns the result code `noErr`.

attrs

The attributes to set. Like individual resources, resource forks have attributes that are specified by bits in the low-order byte of a word. When the Resource Manager first creates a resource fork after a call to `FSpOpenResFile` (page 1671) or a related function, it does not set any of the resource fork's attributes—that is, they are all set to 0.

Discussion
The Resource Manager sets the `mapChanged` attribute for the resource fork when you call the `ChangedResource` (page 1661), the `AddResource` (page 1660), or the `RemoveResource` (page 1692) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

SetResInfo

Sets the name and resource ID of a resource.

```
void SetResInfo (
   Handle theResource,
   ResID theID,
   ConstStr255Param name
);
```

Parameters

theResource

A handle to the resource whose name and ID you wish to set.

theID

The new resource ID. If the parameter `theResource` doesn't contain a handle to an existing resource, the function does nothing, and the `ResError` (page 1692) function returns the result code `resNotFound`.

name

The new name of the specified resource. If you pass an empty string for the `name` parameter, the resource name is not changed.

Discussion

The function changes the information in the resource map in memory, not in the resource file itself. Do not change a system resource's resource ID or name. Other applications may already access the resource and may not work properly if you change the resource ID, resource name, or both.

If the resource map becomes too large to fit in memory (for example, after an unnamed resource is given a name), this function does nothing, and `ResError` returns an appropriate Memory Manager result code. The same is true if the resource data in memory can't be written to the resource fork (for example, because the disk is full). If the `resProtected` attribute is set for the resource, `SetResInfo` does nothing, and `ResError` returns the result code `resAttrErr`.

If you want to write changes to the resource map on disk after updating the resource map in memory, call the `ChangedResource` (page 1661) function for the same resource after you call `SetResInfo`. Even if you don't call `ChangedResource` after using this function to change the name and resource ID of a resource, the change may be written to disk when the Resource Manager updates the resource fork. If you call `ChangedResource` for any resource in the same resource fork, or if you add or remove a resource, the Resource Manager writes the entire resource map to disk after a call to the `UpdateResFile` (page 1700) function or when your application terminates. In these cases, all changes to resource information in the resource map become permanent. If you want any of the changes to be temporary, you should restore the original information before the resource is updated.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

SetResLoad

Enables and disables automatic loading of resource data into memory for functions that return handles to resources.

```
void SetResLoad (
   Boolean load
);
```

Parameters

load

Determines whether Resource Manager functions should read resource data into memory. If you set this parameter to `TRUE`, Resource Manager functions that return handles will, during subsequent calls, automatically read resource data into memory if it is not already in memory; if you set this parameter to `FALSE`, Resource Manager functions will not automatically read resource data into memory. Instead, such functions return a handle whose master pointer is set to `NULL` unless the resource is already in memory. In addition, when first opening a resource fork the Resource Manager won't load into memory resources whose `resPreload` attribute is set. The default setting is `TRUE`.

If you call the function with this parameter set to `FALSE`, be sure to call `SetResLoad` with this parameter set to `TRUE` as soon as possible. Other parts of system software that call the Resource Manager expect this value to be `TRUE`, and some functions won't work if resources are not loaded automatically.

Discussion

You can use the `SetResLoad` function when you want to read from the resource map without reading the resource data into memory. To read the resource data into memory after a call to this function, call the `LoadResource` function.

To check for errors, call the `ResError` (page 1692) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

SetResourceSize

Sets the size of a resource on disk.

```
void SetResourceSize (
   Handle theResource,
   long newSize
);
```

Parameters

theResource

A handle to the resource which you wish to change.

newSize

The size, in bytes, that you want the resource to occupy on disk. If the specified size is smaller than the resource's current size on disk, you lose any data from the cutoff point to the end of the resource. If the specified size is larger than the resource's current size on disk, all data is preserved, but the additional area is uninitialized (arbitrary data).

Discussion
This function is normally used only with the `ReadPartialResource` (page 1690) and `WritePartialResource` (page 1701) functions.

This function sets the size field of the specified resource on disk without writing the resource data. You can change the size of any resource, regardless of the amount of memory you have available.

If you read a partial resource into memory and then change its size, you must use this function to change the entire resource's size on disk as necessary. For example, suppose the entire resource occupies 1 MB and you use `ReadPartialResource` to read in a 200 KB portion of the resource. If you then increase the size of this partial resource to 250 KB, you must call `SetResourceSize` to set the size of the resource on disk to 1.05 MB. Note that in this case you must also keep track of the resource data on disk and move any data that follows the original partial resource on disk. Otherwise, there will be no space for the additional 50 KB when you call `WritePartialResource` to write the modified partial resource to disk.

Under certain circumstances, the Resource Manager overrides the size you set with a call to this function. For instance, suppose you read an entire resource into memory by calling `GetResource` (page 1683) or related functions, then use `SetResourceSize` successfully to set the resource size on disk, and finally attempt to write the resource to disk using the `UpdateResFile` (page 1700) or `WriteResource` (page 1702) functions. In this case, the Resource Manager adjusts the resource size on disk to conform with the size of the resource in memory.

If the disk is locked or full, or the file is locked, this function does nothing, and the `ResError` (page 1692) function returns an appropriate File Manager result code. If the resource is in memory, the Resource Manager tries to set the size of the resource on disk. If the attempt succeeds, `ResError` returns the result code `resourceInMemory`, and the Resource Manager does not update the copy in memory. If the attempt fails, `ResError` returns an appropriate File Manager result code.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

SetResPurge

Tells the Memory Manager to pass the handle of a resource to the Resource Manager before purging the data specified by that handle.

```
void SetResPurge (
   Boolean install
);
```

Parameters

install

Specifies whether the Memory Manager checks with the Resource Manager before purging a resource handle.

Specify `TRUE` to make the Memory Manager pass the handle for a resource to the Resource Manager before purging the resource data to which the handle points. The Resource Manager determines whether the handle points to a resource in the application heap. It also checks if the resource's `resChanged` attribute is set to 1. If these two conditions are met, the Resource Manager calls the `WriteResource` (page 1702) function to write the resource's resource data to the resource fork before returning control to the Memory Manager.

If you call this function with this parameter set to `TRUE` and then call the Memory Manager function `MoveHHi` to move a handle to a resource, the Resource Manager calls the `WriteResource` function to write the resource data to disk even if the data has not been changed. To prevent this, call `SetResPurge` with this parameter set to `FALSE` before you call `MoveHHi`, then call `SetResPurge` again with this parameter set to `TRUE` immediately after you call `MoveHHi`.

Whenever you call this function with this parameter set to `TRUE`, the Resource Manager installs its own purge-warning function, overriding any purge-warning function you've specified to the Memory Manager.

Specify `FALSE` to restore the normal state, so that the Memory Manager purges resource data when it needs to without calling the Resource Manager.

Discussion

You can use this function in applications that modify purgeable resources. You should also take precautions in such applications to ensure that the resource won't be purged while you're changing it.

To check for errors, call the `ResError` (page 1692) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

Unique1ID

Gets a resource ID that's unique with respect to resources in the current resource file.

```
ResID Unique1ID (
   ResType theType
);
```

Parameters

theType

A resource type.

Return Value

A resource ID greater than 0 that isn't currently assigned to any resource of the specified type in the current resource file.

Discussion
You should use this function before adding a new resource to ensure that you don't duplicate a resource ID and override an existing resource.

To check for errors, call the `ResError` (page 1692) function.

For more information about restrictions on resource IDs for specific resource types, see `ResID` (page 1705).

In versions of system software earlier than System 7, this function may return a resource ID in the range 0 through 127, which is generally reserved for system resources. You should check that the resource ID returned is not in this range. If it is, call `UniqueID` again, and continue doing so until you get a resource ID greater than 127.

In System 7 and later versions, this function won't return a resource ID of less than 128.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Resources.h`

UniqueID

Gets a unique resource ID for a resource.

```
ResID UniqueID (
   ResType theType
);
```

Parameters

theType
A resource type.

Return Value
A resource ID greater than 0 that isn't currently assigned to any resource of the specified type in any open resource fork.

Discussion
You should use this function before adding a new resource to ensure that you don't duplicate a resource ID and override an existing resource.

To check for errors, call the `ResError` (page 1692) function.

For more information about restrictions on resource IDs for specific resource types, see `ResID` (page 1705).

In versions of system software earlier than System 7, this function may return a resource ID in the range 0 through 127, which is generally reserved for system resources. You should check that the resource ID returned is not in this range. If it is, call `UniqueID` again, and continue doing so until you get a resource ID greater than 127.

Version Notes
In System 7 and later versions, `UniqueID` won't return a resource ID of less than 128.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

UpdateResFile

Updates the resource map and resource data for a resource fork without closing it.

```
void UpdateResFile (
   ResFileRefNum refNum
);
```

Parameters

refNum

A file reference number for a resource fork. If there's no open resource fork with the given reference number, the function does nothing, and the ResError (page 1692) function returns the result code resNotFound. If the value of the refNum parameter is 0, it represents the System file's resource fork. If you call this function but the mapReadOnly attribute of the resource fork is set, the function does nothing, and the ResError function returns the result code resAttrErr.

Discussion
Given the reference number of a file whose resource fork is open, this function performs three tasks. The first task is to change, add, or remove resource data in the file's resource fork to match the resource map in memory. Changed resource data for each resource is written only if that resource's resChanged bit has been set by a successful call to the ChangedResource (page 1661) or AddResource (page 1660) function. The UpdateResFile function calls the WriteResource (page 1702) function to write changed or added resources to the resource fork.

The second task is to compact the resource fork, closing up any empty space created when a resource was removed, made smaller, or made larger. If a resource is made larger, the Resource Manager writes it at the end of the resource fork rather than at its original location. It then compacts the space occupied by the original resource data. The actual size of the resource fork is adjusted when a resource is removed or made larger, but not when a resource is made smaller.

The third task is to write the resource map in memory to the resource fork if your application has called the ChangedResource function for any resource listed in the resource map or if it has added or removed a resource. All changes to resource information in the resource map become permanent at this time; if you want any of these changes to be temporary, you must restore the original information before calling UpdateResFile.

Because the CloseResFile (page 1662) function calls UpdateResFile before it closes the resource fork, you need to call UpdateResFile directly only if you want to update the file without closing it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

UseResFile

Sets the current resource file.

```
void UseResFile (
   ResFileRefNum refNum
);
```

Parameters

refNum

The file reference number for the resource fork which you wish to set as the current resource fork.

Return Value

The function searches the list of files whose resource forks have been opened for the file specified here. If the specified file is found, the Resource Manager sets the current resource file to the specified file. If there's no resource fork open for a file with that reference number, the function does nothing. To set the current resource file to the System file, use 0 here.

Discussion

Open resource forks are arranged as a linked list with the most recently opened resource fork at the beginning. When searching open resource forks, the Resource Manager starts with the most recently opened file. You can call this function to set the current resource file to a file opened earlier, and thereby start subsequent searches with the specified file. In this way, you can cause any files higher in the resource chain to be left out of subsequent searches.

When a new resource fork is opened, this action overrides previous calls to this function and the entire list is searched. For example, if five resource forks are opened in the order R0, R1, R2, R3, and R4, the search order is R4-R3-R2-R1-R0. Calling `UseResFile(R2)` changes the search order to R2-R1-R0; R4 and R3 are not searched. When the resource fork of a new file (R5) is opened, the search order becomes R5-R4-R3-R2-R1-R0.

You typically call the `CurResFile` (page 1664) function to get and save the current resource file, `UseResFile` to set the current resource file to the desired file, then (after you are finished using the resource) `UseResFile` to restore the current resource file to its previous value. Calling `UseResFile(0)` causes the Resource Manager to search only the System file's resource map. This is useful if you no longer wish to override a system resource with one by the same name in your application's resource fork.

Most of the Resource Manager functions assume that the current resource file is the file on whose resource fork they should operate or, in the case of a search, the file where they should begin. In general, the current resource file is the last one whose resource fork your application opened unless you specify otherwise.

The `FSpOpenResFile` (page 1671) and `HOpenResFile` (page 1686) functions, which also set the current resource file, override previous calls to `UseResFile`.

To check for errors, call the `ResError` (page 1692) function.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

Simple DrawSprocket

Declared In

`Resources.h`

WritePartialResource

Writes part of a resource to disk when working with a small subsection of a large resource.

```
void WritePartialResource (
   Handle theResource,
   long offset,
   const void *buffer,
   long count
);
```

Parameters

theResource

A handle to the resource you wish to write to disk.

offset

The beginning of the resource subsection to write, measured in bytes from the beginning of the resource.

buffer

A pointer to the buffer containing the data to write. Your application is responsible for the buffer's memory management.

count

The length of the resource subsection to write.

Discussion

If the disk or the file is locked, the `ResError` (page 1692) function returns an appropriate File Manager result code. If you try to write past the end of a resource, the Resource Manager attempts to enlarge the resource. The `ResError` function returns the result code `writingPastEnd` if the attempt succeeds. If the Resource Manager cannot enlarge the resource, `ResError` returns an appropriate File Manager result code. If you pass an invalid value in the `offset` parameter, `ResError` returns the result code `inputOutOfBounds`.

This function tries to write the data from the buffer to disk. If the attempt is successful and the resource data (referenced through the resource's handle) is in memory, `ResError` returns the result code `resourceInMemory`. In this situation, be aware that the data of the resource subsection on disk matches the data from the buffer, not the resource data referenced through the resource's handle. If the attempt to write the data from the buffer to the disk fails, `ResError` returns an appropriate error.

When using partial resource functions, you should call the `SetResLoad` (page 1695) function, specifying `FALSE` for the `load` parameter, before you call the `GetResource` (page 1683) function. Doing so prevents the Resource Manager from reading the entire resource into memory. Be sure to restore the normal state by calling `SetResLoad` again, with the `load` parameter set to `TRUE`, immediately after you call `GetResource`.

If you read a partial resource into memory and then change its size, you must use the `SetResourceSize` (page 1696) function to change the entire resource's size on disk as necessary before you write the partial resource.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Resources.h`

WriteResource

Writes resource data in memory immediately to a file's resource fork.

```
void WriteResource (
   Handle theResource
);
```

Parameters

theResource

A handle to a resource. The function checks the `resChanged` attribute of this resource. If the `resChanged` attribute is set to 1, such as after a successful call to the `ChangedResource` (page 1661) or `AddResource` (page 1660) function, `WriteResource` writes the resource data in memory to the resource fork, then clears the `resChanged` attribute in the resource's resource map in memory.

If the resource is purgeable and has been purged, the function writes zero-length resource data to the resource fork. If the resource's `resProtected` attribute is set to 1, the function does nothing, and the `ResError` (page 1692) function returns the result code `noErr`. The same is true if the `resChanged` attribute is not set (that is, set to 0). If the given handle isn't a handle to a resource, `WriteResource` does nothing, and `ResError` returns the result code `resNotFound`.

Discussion

Note that this function does not write the resource's resource map entry to disk.

When your application calls `ChangedResource` or `AddResource`, the Resource Manager attempts to reserve disk space for the changed resource. If the modified resource data can't be written to the resource fork (for example, if there's not enough room on disk), the `resChanged` attribute is not set to 1. If this is the case and you call `WriteResource`, the Resource Manager won't know that the resource data has been changed. Thus, the function won't write the modified resource data to the resource fork and won't return an error. For this reason, always make sure that the `ResError` function returns the result code `noErr` after a call to `ChangedResource` or `AddResource`.

The resource fork is updated automatically when your application quits, when you call the `UpdateResFile` (page 1700) function, or when you call the `CloseResFile` (page 1662) function. Thus, you should call `WriteResource` only if you want to write just one or a few resources immediately.

Availability

Available in Mac OS X v10.0 and later.

```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

ResID

Defines a unique identifier for a resource of a given type.

```
typedef short ResID;
```

Discussion
A resource is identified by its resource type and resource ID (or, optionally, its resource type and resource name). The IDs for resources used by the system software and those used by applications are assigned from separate ranges. By using these ranges correctly, you can avoid resource ID conflicts.

In general, system resources use IDs in the range –32767 through 127, and application resources must use IDs that fall between 128 and 32767. The IDs for some categories of resources, such as definition functions and font families, fall in different ranges or in ranges that are broken down for more specific purposes.

You can use a resource name instead of a resource ID to identify a resource of a given type. Like a resource ID, a resource name should be unique within each type. If you assign the same resource name to two resources of the same type, the second assignment of the name overrides the first, thereby making the first resource inaccessible by name. When comparing resource names, the Resource Manager ignores case (but does not ignore diacritical marks).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Resources.h

ResType

Defines a unique identifier for a type of resource.

```
typedef FourCharCode ResType;
```

Discussion
The Resource Manager uses the resource type along with the resource ID to identify a resource. A resource type can be any sequence of four alphanumeric characters, including the space character.

You can define your own resource types, but they must not conflict with any of the standard resource types. When identifying resource types, the Resource Manager distinguishes between uppercase letters and their lowercase counterparts. Apple reserves for its own use all resource types that consist of all lowercase letters, all spaces, or all international characters (characters greater than $7F).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IOMacOSTypes.h`

Constants

Reference Number Constants

```
enum {
    kResFileNotOpened = -1,
    kSystemResFile = 0
};
```

Constants

`kResFileNotOpened`
Indicates the reference number returned as error when opening a resource file.
Available in Mac OS X v10.0 and later.
Declared in `Resources.h`.

`kSystemResFile`
Indicates the default reference number to the system file.
Available in Mac OS X v10.0 and later.
Declared in `Resources.h`.

Resource Attribute Bits

```
enum {
    resSysRefBit = 7,
    resSysHeapBit = 6,
    resPurgeableBit = 5,
    resLockedBit = 4,
    resProtectedBit = 3,
    resPreloadBit = 2,
    resChangedBit = 1,
};
```

Constants

`resSysRefBit`

If this attribute is set to 1, it is a system reference. If it is set to 0, it is a local reference.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resSysHeapBit`

This attribute indicates whether the resource is read into the system heap (`resSysHeapBit` attribute is set to 1) or your application's heap (`resSysHeapBit` attribute is set to 0).

If you are setting your resource's attributes with `SetResAttrs`, you should set this bit to 0 for your application's resources. Note that if you do set the `resSysHeapBit` attribute to 1 and the resource is too large for the system heap, the bit is cleared and the resource is read into the application heap.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resPurgeableBit`

If this attribute is set to 1, the resource is purgeable if it's 0, the resource is nonpurgeable. However, do not use `SetResAttrs` to make a purgeable resource nonpurgeable.

Because a locked resource is nonrelocatable and nonpurgeable, the `resLockedBit` attribute overrides the `resPurgeableBit` attribute.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resLockedBit`

If this attribute is 1, the resource is nonpurgeable regardless of whether `resPurgeableBit` is set. If it's 0, the resource is purgeable or nonpurgeable depending on the value of the `resPurgeableBit` attribute.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resProtectedBit`

If this attribute is set to 1, your application can't use Resource Manager functions to change the resource ID or resource name, modify the resource contents, or remove the resource from its resource fork. However, you can use the `SetResAttrs` function to remove this protection. Note that this attribute change takes effect immediately.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resPreloadBit`
: If this attribute is set to 1, the Resource Manager reads the resource's resource data into memory immediately after opening its resource fork. You can use this setting to make multiple resources available for your application as soon as possible, rather than reading each one into memory individually. If both the `resPreloadBit` attribute and the `resLockedBit` attribute are set, the Resource Manager loads the resource as low in the heap as possible.

  Available in Mac OS X v10.0 and later.

  Declared in `Resources.h`.

`resChangedBit`
: If this attribute is set to 1, the resource has been changed. If it's 0, the resource hasn't been changed. This attribute is used only while the resource map is in memory. The `resChangedBit` attribute must be 0 in the resource fork on disk.

  Do not use `SetResAttrs` to set the `resChangedBit` attribute. Be sure the `attrs` parameter passed to `SetResAttrs` doesn't change the current setting of this attribute. To set the `resChangedBit` attribute, call the `ChangedResource` function.

  Available in Mac OS X v10.0 and later.

  Declared in `Resources.h`.

Discussion
The `SetResAttrs` (page 1693) and `GetResAttrs` (page 1681) functions use these constants to refer to each attribute.

Resource Attribute Masks

```
enum {
    resSysHeap = 64,
    resPurgeable = 32,
    resLocked = 16,
    resProtected = 8,
    resPreload = 4,
    resChanged = 2,
};
```

Constants
`resSysHeap`
: Use to set or test for the `resSysHeapBit`.

  Available in Mac OS X v10.0 and later.

  Declared in `Resources.h`.

`resPurgeable`
: Use to set or test for the `resPurgeableBit`.

  Available in Mac OS X v10.0 and later.

  Declared in `Resources.h`.

`resLocked`
: Use to set or test for the `resLockedBit`.

  Available in Mac OS X v10.0 and later.

  Declared in `Resources.h`.

`resProtected`
Use to set or test for the `resProtectedBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resPreload`
Use to set or test for the `resPreloadBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`resChanged`
Use to set or test for the `resChangedBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

Resource Chain Location

Specify the location of the resource chain.

```
typedef SInt16 RsrcChainLocation
enum {
    kRsrcChainBelowSystemMap = 0,
    kRsrcChainBelowApplicationMap = 1,
    kRsrcChainAboveApplicationMap = 2,
    kRsrcChainAboveAllMaps = 4
};
```

Constants

`kRsrcChainBelowSystemMap`
Indicates the resource chain is below the system's resource map.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`kRsrcChainBelowApplicationMap`
Indicates the resource chain is below the application's resource map.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`kRsrcChainAboveApplicationMap`
Indicates the resource chain is above the application's resource map.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`kRsrcChainAboveAllMaps`
Indicates the resource chain is above all resource maps.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

Discussion

These constants and data type are for use with the Resource Manager chain manipulation routines under Carbon.

Resource Fork Attribute Bits

```
enum {
    mapReadOnlyBit = 7,
    mapCompactBit = 6,
    mapChangedBit = 5
};
```

Constants

`mapReadOnlyBit`

If this bit is set to 1, the Resource Manager doesn't write anything to the resource fork on disk. It also doesn't check whether the resource data can be written to disk when the resource map is modified. When this attribute is set to 1, the `ChangedResource` (page 1661) and `WriteResource` (page 1702) functions do nothing, but the function `ResError` (page 1692) returns the result code `noErr`.

If you set the `mapReadOnlyBit` attribute but later clear it, the resource data is written to disk even if there's no room for it. This operation may destroy the resource fork.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`mapCompactBit`

If this bit is set to 1, the Resource Manager compacts the resource fork when it updates the file. The Resource Manager sets this attribute when a resource is removed or when a resource is made larger and thus must be written at the end of a resource fork. You may want to set the `mapCompactBit` attribute to force the Resource Manager to compact a resource fork when your changes have made resources smaller.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`mapChangedBit`

If this bit is set to 1, the Resource Manager writes the resource map to disk when the file is updated. For example, you can set `mapChangedBit` if you've changed resource attributes only and don't want to call the `ChangedResource` (page 1661) function because you don't want to write the resource data to disk.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

Resource Fork Attribute Masks

```
enum{
    mapReadOnly = 128,
    mapCompact = 64,
    mapChanged = 32
};
```

Constants

`mapReadOnly`

Use to set or test for the `mapReadOnlyBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`mapCompact`

Use to set or test for the `mapCompactBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

`mapChanged`

Use to set or test for the `mapChangedBit`.

Available in Mac OS X v10.0 and later.

Declared in `Resources.h`.

Result Codes

The most common result codes returned by Resource Manager are listed in the table below. The Resource Manager may also return the following result codes: `noErr` (0), `dirFulErr` (-33), `dskFulErr` (-34), `nsvErr` (-35), `ioErr` (-36), `bdNamErr` (-37), `eofErr` (-39), `tmfoErr` (-42), `fnfErr` (-43), `wPrErr` (-44), `fLckdErr` (-45), `vLckdErr` (-46), `dupFNErr` (-48), `opWrErr` (-49), `permErr` (-54), `extFSErr` (-58), `memFullErr` (-108), `dirNFErr` (-120).

Result Code	Value	Description
`badExtResource`	-185	The extended resource has a bad format. Available in Mac OS X v10.0 and later.
`CantDecompress`	-186	Can't decompress a compressed resource. Available in Mac OS X v10.0 and later.
`resourceInMemory`	-188	The resource is already in memory. Available in Mac OS X v10.0 and later.
`writingPastEnd`	-189	Writing past the end of file. Available in Mac OS X v10.0 and later.
`inputOutOfBounds`	-190	The offset or count is out of bounds. Available in Mac OS X v10.0 and later.
`resNotFound`	-192	The resource was not found. Available in Mac OS X v10.0 and later.
`resFNotFound`	-193	The resource file was not found. Available in Mac OS X v10.0 and later.
`addResFailed`	-194	The `AddResource` function failed. Available in Mac OS X v10.0 and later.
`rmvResFailed`	-196	The `RemoveResource` function failed. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`resAttrErr`	-198	The attribute is inconsistent with the operation. Available in Mac OS X v10.0 and later.
`mapReadErr`	-199	The map is inconsistent with the operation. Available in Mac OS X v10.0 and later.

Script Manager Reference (Not Recommended)

Framework: CoreServices/CoreServices.h

Declared in Script.h

Overview

Important: The Script Manager is deprecated as of Mac OS X v10.5. Instead, you should update your application to handle Unicode text using the facilities of the Cocoa system (see *Text System Overview*) or Core Text (see *Core Text Programming Guide*). See also *Internationalization Programming Topics*.

The Script Manager makes script systems available and coordinates the interaction between many parts of the Mac OS and those available script systems. A script system (or script for short) is a collection of resources that provides for the representation of a particular writing system.

The Script Manager also provides several services directly to your application. Through them you can get information about the current text environment, modify that environment, and perform a variety of text-handling tasks.

The Script Manager has evolved through several versions. It started with sole responsibility for all international-compatibility and multilingual text issues, but as more power and features have been added, many of its specific functions have been moved to the other parts of system software.

For many text-related tasks, the Script Manager's role is transparent when you make a script-aware Text Utilities or QuickDraw call while processing text, that routine may get the information it needs through the Script Manager. For example, when you call the QuickDraw function `DrawText` to draw a line of text, `DrawText` in turn calls the Script Manager to determine which script system your text belongs to before drawing it. In other situations you may need to call the Script Manager explicitly, to properly interpret the text you are processing.

Carbon supports most Script Manager functions. However, Apple recommends that whenever possible you should replace Script Manager calls with the appropriate Unicode functionality. For more information, see Unicode Utilities Reference and Supporting Unicode Input.

See also the `KeyScript` function documentation.

Functions by Task

Analyzing Characters

`CharacterByteType` (page 1716) Deprecated in Mac OS X v10.4
Identifies a byte in a text buffer as a single-byte character or as the first or second byte of a double-byte character. (Deprecated. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

`CharacterType` (page 1717) Deprecated in Mac OS X v10.4
Returns a variety of information about the character represented by a given byte, including its type, class, orientation, direction, case, and size (in bytes). (Deprecated. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

`FillParseTable` (page 1720) Deprecated in Mac OS X v10.4
Helps your application to quickly process a buffer of mixed single-byte and double-byte characters. (Deprecated. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

Checking and Setting Script Manager Variables

`GetScriptManagerVariable` (page 1724) Deprecated in Mac OS X v10.5
Retrieves the value of the specified Script Manager variable. (Deprecated. The replacement for this function depends on the selector used with it, as described in the Special Considerations section.)

`SetScriptManagerVariable` (page 1731) Deprecated in Mac OS X v10.5
Sets the specified Script Manager variable to the value of the input parameter. (Deprecated. This is mainly used to set the value of variables that control the internal operation of the Script Manager (selectors `smIntlForce` and `smGenFlags`), and therefore there is no modern replacement.)

Checking and Setting Script Variables

`GetScriptVariable` (page 1726) Deprecated in Mac OS X v10.5
Retrieves the value of the specified script variable from the specified script system. (Deprecated. The replacement for this function depends on the selector used with it, as described in the Special Considerations section.)

`SetScriptVariable` (page 1732) Deprecated in Mac OS X v10.5
Sets the specified script variable for the specified script system to the value of the input parameter. (Deprecated. The replacement for this function depends on the purpose for which it is used, as described in the Special Considerations section.)

Checking and Setting the System Direction

`GetSysDirection` (page 1727) Deprecated in Mac OS X v10.4
Returns the current value of `SysDirection`, the global variable that determines the system direction (primary line direction). (Deprecated. This function does not return anything useful in Mac OS X.)

`SetSysDirection` (page 1733) Deprecated in Mac OS X v10.4
Sets the value of `SysDirection`, the global variable that determines the system direction (primary line direction). (Deprecated. There is no replacement because this function is no longer needed in Mac OS X.)

Determining Script Codes From Font Information

`FontScript` (page 1721) Deprecated in Mac OS X v10.4
Returns the script code for the current script (usually the font script). (Deprecated. Use `ATSFontFamilyGetEncoding` instead.)

`FontToScript` (page 1722) Deprecated in Mac OS X v10.4
Translates a font family ID number into its corresponding script code, if that script system is currently enabled. (Deprecated. Use `ATSFontFamilyGetEncoding` instead.)

`IntlScript` (page 1728) Deprecated in Mac OS X v10.4
Identifies the script system used by the Text Utilities date-formatting, time-formatting, and string-sorting functions. (Deprecated. Use `ATSFontFamilyGetEncoding` instead.)

Directly Accessing International Resources

`GetIntlResource` (page 1722) Deprecated in Mac OS X v10.5
Returns a handle to one of the international resources. (Deprecated. The replacement for this function depends on the purpose for which it is used, as described in the Special Considerations section.)

`ClearIntlResourceCache` (page 1719) Deprecated in Mac OS X v10.4
Clears the application's international resources cache, which contains the resource ID numbers of the string-manipulation (`'itl2'`) and tokens (`'itl4'`) resources for the current script. (Deprecated. There is no replacement because this function is no longer needed in Mac OS X.)

`GetIntlResourceTable` (page 1723) Deprecated in Mac OS X v10.4
Obtains a specific word-selection, line-break, number-parts, untoken, or whitespace table from the appropriate international resource. (Deprecated. There is no replacement because this function is no longer needed in Mac OS X.)

Converting Text

`IntlTokenize` (page 1729) Deprecated in Mac OS X v10.4
Allows your application to convert text into a sequence of language-independent tokens. (Deprecated. There is no replacement because this function is no longer needed in Mac OS X.)

`TransliterateText` (page 1733) Deprecated in Mac OS X v10.4
Converts characters from one subscript to the closest possible approximation in a different subscript within the same double-byte script system. (Deprecated. Use `CFStringUppercase` instead.)

Functions

CharacterByteType

Identifies a byte in a text buffer as a single-byte character or as the first or second byte of a double-byte character. (Deprecated in Mac OS X v10.4. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

```
short CharacterByteType (
   Ptr textBuf,
   short textOffset,
   ScriptCode script
);
```

Parameters

textBuf

A pointer to a text buffer containing the byte to be identified.

textOffset

The offset to the byte to be identified. The offset is measured in bytes; the first byte has an offset of 0.

script

A value that specifies the script system of the text in the buffer. Constants for all defined script codes are listed on "Meta Script Codes" (page 1753). To specify the font script, pass `smCurrentScript` in this parameter.

Return Value

One of three identifications: a single-byte character, the first byte of a double-byte character, or the second byte of a double-byte character. The first byte of a double-byte character—the one at the lower offset in memory—is the high-order byte the second byte of a double-byte character—the one at the higher offset—is the low-order byte. This is the same order in which text is processed and numbers are represented.

Discussion

The script system associated with the character you wish to examine must be enabled in order for the function to provide useful information. For example, if only the Roman script system is available and you attempt to identify a byte in a run of double-byte characters, the `CharacterByteType` function returns 0, indicating that the byte is a single-byte character.

For single-byte script systems, the character-type tables reside in the string-manipulation (`'itl2'`) resource and reflect region-specific or language-specific differences in uppercase conventions.

For double-byte script systems, the character-type tables reside in the encoding/rendering (`'itl5'`) resource, not the string-manipulation resource. Whenever you call `CharacterByteType`, the necessary character-set encoding information is taken from the encoding/rendering resource. You cannot use the `GetIntlResource` function to access double-byte character-type tables directly.

From byte value alone, it is not possible to distinguish the second byte of a double-byte character from a single-byte character. `CharacterByteType` differentiates the second byte of a double-byte character from a single-byte character by assuming that the byte at offset 0 is the first byte of a character. With that assumption, it then sequentially identifies the size and starting position of each character in the buffer up to `textOffset`.

Special Considerations

If you specify `smCurrentScript` for the `script` parameter, the value returned by `CharacterByteType` can be affected by the state of the font force flag. It is unaffected by the state of the international resources selection flag.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Script.h`

CharacterType

Returns a variety of information about the character represented by a given byte, including its type, class, orientation, direction, case, and size (in bytes). (Deprecated in Mac OS X v10.4. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

```
short CharacterType (
   Ptr textBuf,
   short textOffset,
   ScriptCode script
);
```

Parameters

textBuf

A pointer to a text buffer containing the character to be examined.

textOffset

The offset to the location of the character to be examined. (It can be an offset to either the first or the second byte of a double-byte character.) Offset is in bytes; the first byte of the first character has an offset of 0.

script

A value that specifies the script system the byte belongs to. Constants for all defined script codes are listed in "Meta Script Codes" (page 1753). To specify the font script, pass `smCurrentScript` in this parameter.

Return Value

An integer bit field that provides information about the requested character.

Discussion

The `CharacterType` return value is an integer bit field that provides information about the requested character. The field has the following format:

- Bit range 0–3 (Type). The character types.
- Bit range 4–7. Reserved.
- Bit Range 8–11 (Class). Character classes (i.e., subtypes).
- Bit 12 (Orientation). Horizontal or vertical.
- Bit 13 (Direction). Left or right. In double-byte script systems, bit 13 indicates whether or not the character is part of the main character set (not a user-defined character).

- Bit 14 (Case). Uppercase or lowercase.
- Bit 15 (Size). single-byte or double-byte.

The script system associated with the character you wish to examine must be enabled in order for any of these three functions to provide useful information.

For single-byte script systems, the character-type tables reside in the string-manipulation (`'itl2'`) resource and reflect region-specific or language-specific differences in uppercase conventions. The `CharacterType` function gets the tables from the string-manipulation resource using the `GetIntlResource` function.

For double-byte script systems, the character-type tables reside in the encoding/rendering (`'itl5'`) resource, not the string-manipulation resource. Whenever you call `CharacterType`, the necessary character-set encoding information is taken from the encoding/rendering resource. You cannot use the `GetIntlResource` function to access double-byte character-type tables directly.

The Script Manager defines the recognized character types, character classes, and character modifiers (bits 12–15), with constants to describe them. The `CharacterType` field masks are described in "Character Type Field Masks" (page 1746).

The Script Manager also defines a set of masks with which you can isolate each of the fields in the `CharacterType` return value. If you perform an `AND` operation with the `CharacterType` result and the mask for a particular field, you select only the bits in that field. Once you've done that, you can test the result, using the constants that represent the possible results.

The function `CharacterType` calls `CharacterByteType` to determine whether the byte at `textOffset` is a single-byte character or the first byte or second byte of a double-byte character. The larger the text buffer, the longer `CharacterByteType` takes to execute. To be most efficient, place the pointer `textBuf` at the beginning of the character of interest before calling `CharacterType`. (If you want to be compatible with older versions of `CharacterType`, also set `textOffset` to 1, rather than 0, for double-byte characters.)

Special Considerations

The function `CharacterType` may move memory; your application should not call this function at interrupt time.

If you specify `smCurrentScript` for the `script` parameter, `CharacterType` always assumes that the text in the buffer belongs to the font script. It is unaffected by the state of the font force flag or the international resources selection flag.

For single-byte script systems, the character-type tables are in the string-manipulation (`'itl2'`) resource. For double-byte script systems, they are in the encoding/rendering (`'itl5'`) resource. If the appropriate resource does not include these tables, `CharacterType` exits without doing anything.

Some Roman fonts (for example, Symbol) substitute other characters for the standard characters in the Standard Roman character set. Since the Roman script system `CharacterType` function assumes the Standard Roman character set, it may return inappropriate results for nonstandard characters.

Version Notes

In versions of system software earlier than 7.0, the `textOffset` parameter to the `CharacterType` function must point to the second byte of a double-byte character.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Script.h`

ClearIntlResourceCache

Clears the application's international resources cache, which contains the resource ID numbers of the string-manipulation (`'itl2'`) and tokens (`'itl4'`) resources for the current script. (Deprecated in Mac OS X v10.4. There is no replacement because this function is no longer needed in Mac OS X.)

Not recommended

```
void ClearIntlResourceCache (
   void
);
```

Discussion
At application launch, the script management system sets up an international resources cache for the application. The cache contains the resource ID numbers of the string-manipulation and tokens resources for all enabled scripts.

If you provide your own string manipulation or tokens resource to replace the default for a particular script, call `ClearIntlResourceCache` at launch to ensure that your supplied resource is used instead of the script system's `'itl2'` or `'itl4'` resource.

The current default ID numbers for a script system's `'itl2'` and `'itl4'` resources are stored in its script variables. You can read and modify these values with the `GetScriptVariable` and `SetScriptVariable` functions using the selectors `smScriptSort` (for the `'itl2'` resource) and `smScriptToken` (for the `'itl4'` resource). Before calling `ClearIntlResourceCache`, you should set the script's default ID number to the ID of the resource that you are supplying.

If the international resources selection flag is `TRUE`, the ID numbers of your supplied resources must be in the system script range. Otherwise, the IDs must be in the range of the current script.

If you use the `SetScriptVariable` function to change the value of the `'itl2'` or `'itl4'` resource ID and then call `ClearIntlResourceCache` to flush the cache, be sure to restore the original resource ID before your application quits.

Special Considerations

The function `ClearIntlResourceCache` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

FillParseTable

Helps your application to quickly process a buffer of mixed single-byte and double-byte characters. (Deprecated in Mac OS X v10.4. You should update your application to handle Unicode text. There is no replacement function because Unicode handles encoding in a different manner.)

```
Boolean FillParseTable (
   CharByteTable table,
   ScriptCode script
);
```

Parameters

table

A 256-byte table to be filled in by `FillParseTable`.

script

A value that specifies the script system the parse table belongs to. Constants for all defined script codes are listed in "Meta Script Codes" (page 1753). To specify the font script, pass `smCurrentScript` in this parameter.

Return Value

If you specify `smCurrentScript` for the `script` parameter, the value returned by `FillParseTable` can be affected by the state of the font force flag. It is unaffected by the international resources selection flag.

Discussion

Before calling `FillParseTable`, allocate space for a 256-byte table to pass to the function in the table parameter.

This function returns a 256-byte table that distinguishes the character codes of all possible single-byte characters from the first (high-order) byte values of all possible double-byte characters in the specified script system. The script system associated with the character you wish to examine must be enabled in order for any of these three functions to provide useful information.

For single-byte script systems, the character-type tables reside in the string-manipulation (`'itl2'`) resource and reflect region-specific or language-specific differences in uppercase conventions.

For double-byte script systems, the character-type tables reside in the encoding/rendering (`'itl5'`) resource, not the string-manipulation resource. Whenever you call `FillParseTable`, the necessary character-set encoding information is taken from the encoding/rendering resource. You cannot use the `GetIntlResource` function to access double-byte character-type tables directly.In every script system, double-byte characters have distinctive high-order (first) bytes that allow them to be distinguished from single-byte characters. `FillParseTable` fills a 256-byte table, conceptually equivalent to a single-byte character-set table, with values that indicate, byte-for-byte, whether the character-code value represented by that byte index is the first byte of a double-byte character. An entry in the `CharByteTable` is 0 for a single-byte character and 1 for the first byte of a double-byte character.

If your application is processing mixed characters, it can use the table to identify the locations of the double-byte characters as it makes a single pass through the text, rather than having to call `CharacterByteType` or `CharacterType` for each byte of the text buffer in turn. `CharacterByteType` and `CharacterType` start anew at the beginning of the text buffer each time they are called, tracking character positions up to the offset of the byte to be analyzed.

Special Considerations

`FillParseTable` may move memory; your application should not call this function at interrupt time.

The table defined by `CharByteTable` is not dynamic; it does not get updated when the current font changes. You need to call it separately for each script run in your text.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

FontScript

Returns the script code for the current script (usually the font script). (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetEncoding` instead.)

```
short FontScript (
   void
);
```

Parameters

Return Value
A script code. All recognized script codes and their defined constants are listed in "Meta Script Codes" (page 1753). `FontScript` returns only explicit script codes (□). If the font of the active graphics port is Roman and the font force flag is `TRUE`, the script code returned is that of the system script and the script-forced result flag is set to `TRUE`. If the font of the active graphics port is non-Roman, the state of the font force flag is ignored. If the script system corresponding to the font of the active graphics port is not installed and enabled, the script code returned is that of the system script and the script-defaulted result flag is set to `TRUE`.

Discussion
The information about the script code is subject to two control flags—the font force flag and the international resources selection flag. You can test and set these flags with the `GetScriptManagerVariable` and `SetScriptManagerVariable` selectors `smFontForce` and `smIntlForce`.

The function starts by initializing two result flags, the script-forced result flag and the script-defaulted result flag, to `FALSE`. These flags are Script Manager variables, accessed through the `GetScriptManagerVariable` function selectors `smForced` and `smDefault`.

Special Considerations

`FontScript` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

FontToScript

Translates a font family ID number into its corresponding script code, if that script system is currently enabled. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetEncoding` instead.)

```
short FontToScript (
   short fontNumber
);
```

Parameters

fontNumber

A font family ID number.

Return Value

A script code. All recognized script codes and their defined constants are listed in "Meta Script Codes" (page 1753). `FontToScript` returns only explicit script codes (□). If `fontNumber` is in the Roman range and the font force flag is `TRUE`, the script code returned is that of the system script and the script-forced result flag is set to `TRUE`. If `fontNumber` is in the non-Roman range, the state of the font force flag is ignored. If the script system corresponding to `fontNumber` is not enabled, the script code returned is that of the system script and the script-defaulted result flag is set to `TRUE`.

Discussion

The information about the script code is subject to two control flags—the font force flag and the international resources selection flag. You can test and set these flags with the `GetScriptManagerVariable` and `SetScriptManagerVariable` selectors `smFontForce` and `smIntlForce`.

The function starts by initializing two result flags, the script-forced result flag and the script-defaulted result flag, to `FALSE`. These flags are Script Manager variables, accessed through the `GetScriptManagerVariable` function selectors `smForced` and `smDefault`.

Do not use the function `FontToScript` to convert resource IDs to scripts codes.

Special Considerations

`FontToScript` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Script.h`

GetIntlResource

Returns a handle to one of the international resources. (Deprecated in Mac OS X v10.5. The replacement for this function depends on the purpose for which it is used, as described in the Special Considerations section.)

```
Handle GetIntlResource (
   short theID
);
```

Parameters

theID

Contains an integer (0, 1, 2, 4, or 5 respectively for the `'itl0'`, `'itl1'`, `'itl2'`, `'itl4'`, and `'itl5'` resources) to identify the type of the desired international resource.

Return Value

A handle to the correct resource of the requested type. The resource returned is that of the current script, which is either the font script or the system script. The resource is of one of the following types: numeric-format (`'itl0'`), long-date-format (`'itl1'`), string-manipulation (`'itl2'`), tokens (`'itl4'`), or encoding/rendering (`'itl5'`). If `GetIntlResource` cannot return the requested resource, it returns a `NULL` handle and sets the global variable `resErr` to the appropriate error code.

Special Considerations

Depending on the information that this function was called to obtain, it can be replaced by the use of `CFLocaleCopyCurrent` to get an appropriate `CFLocaleRef` followed by one of the following:

- `CFLocaleGetValue` with keys such as `kCFLocaleUsesMetricSystem`, `kCFLocaleDecimalSeparator`, `kCFLocaleCurrencySymbol`.
- `CFDateFormatterCreate` to get an appropriate `CFDateFormatterRef` object, followed by `CFDateFormatterCopyProperty` with keys such as `kCFDateFormatterMonthSymbols`, `kCFDateFormatterWeekdaySymbols`, and `kCFDateFormatterAMSymbol`.
- `CFNumberFormatterCreate` to get an appropriate `CFNumberFormatterRef` object, followed by `CFNumberFormatterCopyProperty` with keys such as `kCFNumberFormatterCurrencyDecimalSeparator`, `kCFNumberFormatterMinusSign`, `kCFNumberFormatterPercentSymbol`, and `kCFNumberFormatterNegativePrefix`.

`GetIntlResource` may move memory; your application should not call this function at interrupt time.

Carbon Porting Notes

While the return type of this function remains a Handle, in Mac OS X it returns an ordinary memory handle instead of a resource handle.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Script.h`

GetIntlResourceTable

Obtains a specific word-selection, line-break, number-parts, untoken, or whitespace table from the appropriate international resource. (Deprecated in Mac OS X v10.4. There is no replacement because this function is no longer needed in Mac OS X.)

```
void GetIntlResourceTable (
   ScriptCode script,
   short tableCode,
   Handle *itlHandle,
   long *offset,
   long *length
);
```

Parameters

script

A script code, the value that specifies a particular script system. Constants for all defined script codes are listed in "Meta Script Codes" (page 1753).

tableCode

A number that specifies which table is requested. The constants for `tableCode` are detailed in "Table Selectors" (page 1778).

itlHandle

On return, a handle to the string-manipulation (`'itl2'`) or tokens (`'itl4'`) resource containing the table specified in the `tableCode` parameter. If the script system whose table is requested is not available, `GetIntlResourceTable` returns a `NULL` handle.

offset

On return, a pointer to the offset (in bytes) to the specified table from the beginning of the resource.

length

On return, a pointer to the size of the table (in bytes).

Discussion

When you provide a script code in the `script` parameter, and a table code in the `tableCode` parameter, `GetIntlResourceTable` returns a handle to the string-manipulation resource or tokens resource containing that table, the offset of the specified table from the beginning of the resource, and the length of the table.

If you wish to manipulate the contents of the table you have requested, use the size returned in the `length` parameter to allocate a buffer, and perform a block move of the table's contents into that buffer.

Special Considerations

`GetIntlResourceTable` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Script.h`

GetScriptManagerVariable

Retrieves the value of the specified Script Manager variable. (Deprecated in Mac OS X v10.5. The replacement for this function depends on the selector used with it, as described in the Special Considerations section.)

```
long GetScriptManagerVariable (
   short selector
);
```

Parameters

selector

A value that specifies a particular Script Manager variable. To specify the Script Manager variable whose value you need, use one of the selector constants listed in "Script Manager Selectors" (page 1768).

Return Value

The current value of the specified Script Manager variable or 0 if the selector is invalid. For some valid selectors, 0 may also be a valid return value. For example, when you call `GetScriptManagerVariable` with a selector value of `smRegionCode` on a version of Macintosh system software that has been localized for the United States, it returns 0. Although `GetScriptManagerVariable` always returns a long integer, the actual value may be a long integer, standard integer, or signed byte. If the value is not a long integer, it is stored in the low-order word or byte of the long integer returned by `GetScriptManagerVariable`; the remaining bytes are set to 0.

Discussion

The Script Manager maintains a set of variables that control general settings of the text environment, including the identity of the system script and the keyboard script, and the settings of the font force flag and the international resources selection flag.

You may want access to the Script Manager variables in order to understand the current environment or to modify it.

Special Considerations

The replacement for this function depends on the selector used with it. Many of the selectors refer to information that is not meaningful on a Unicode system or refer to details of the Script Manager itself; in general there are no replacements for these. Selectors that have meaningful replacements are shown in the following list. These are not direct replacements; they provide analogous but more modern functionality.

`smSysScript`. To obtain a text encoding for the legacy Mac OS encoding associated with the user's preferred user interface language or with the application's default text encoding, use `CFStringGetSystemEncoding` or `GetApplicationTextEncoding`. Sometimes `smSysScript` is just used to get a script code to pass to `GetScriptVariable` (page 1726); in this case the replacements for `GetScriptVariable` (page 1726) selectors may provide more information.

`smKeyScript`. To obtain the intended language associated with the user's current keyboard input source (plus other languages that can be input using it), use `TISCopyCurrentKeyboardInputSource` to get that input source, then pass it to `TISGetInputSourceProperty` with the `kTISPropertyInputSourceLanguages` key.

`smKCHRCache`. To obtain the key layout data for the keyboard layout currently in use, use `TISCopyCurrentKeyboardLayoutInputSource` to get that input source, then pass it to `TISGetInputSourceProperty` with the `kTISPropertyUnicodeKeyLayoutData` key (this returns `'uchr'` Unicode ayout data only; it will not return any data for keyboard layouts that only have `'KCHR'` data).

`smRegionCode`. To obtain the locale associated with the user's preferred formats (for dates, times, numbers, and so on) use the following code:

```
CFStringRef curLocaleStringRef = NULL;
localeRef = CFLocaleCopyCurrent();
if (localeRef) {
    curLocaleStringRef = CFLocaleGetIdentifier(localeRef);
    CFRelease(localeRef);
```

```
}
```

To obtain the user's preferred user interface language, use the following line of code:

```
CFArrayRef langArray = (CFArrayRef)CFPreferencesCopyAppValue(CFSTR("AppleLanguages"),
kCFPreferencesCurrentApplication);
```

The first entry in `langArray` indicates the preferred language. See also `CFLocaleCopyPreferredLanguages`.

Selectors that have no meaningful replacement on a Unicode system include `smEnabled`, `smBidirect`, and `smDoubleByte`. Selectors that pertain to internal operation of the Script Manager itself and thus have no meaningful replacement include `smVersion`, `smMunged`, `smPrint`, and `smSysRef`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Script.h`

GetScriptVariable

Retrieves the value of the specified script variable from the specified script system. (Deprecated in Mac OS X v10.5. The replacement for this function depends on the selector used with it, as described in the Special Considerations section.)

```
long GetScriptVariable (
   short script,
   short selector
);
```

Parameters

script

A value that specifies the script system whose variable you are accessing. Use one of the script-code constants listed in "Meta Script Codes" (page 1753).

selector

A value that specifies a particular script variable. Use one of the selector constants listed in "Script Variable Selectors" (page 1773). Valid selector values are defined by each script system.

Return Value
0 if the selector value is invalid or if the specified script system is not installed. For some valid selectors, 0 may also be a valid return value. For example, calling `GetScriptVariable` with a selector of `smScriptLang` on a version of Macintosh system software that has been localized for the United States returns 0. Although `GetScriptVariable` always returns a long integer, the actual value may be a long integer, standard integer, or signed byte. If the value is not a long integer, it is stored in the low-order word or byte of the long integer returned by `GetScriptVariable`; the remaining bytes are set to 0.

Discussion
Each enabled script system maintains a set of variables that control the current settings of that script system, including the ID numbers of its international resources, its preferred fonts and font sizes, and its primary line direction.

Special Considerations

The replacement for this function depends on the selector used with it. Many of the selectors refer to information that is not meaningful on a Unicode system or refer to details of the Script Manager itself; in general there are no replacements for these. Selectors that have meaningful replacements are shown in the following list. These are not direct replacements; they provide analogous but more modern functionality.

`smScriptLang`. This was typically used with the system script to determine the system language. Instead, to obtain the user's preferred user interface language, use the following line of code:

```
CFArrayRef langArray = (CFArrayRef)CFPreferencesCopyAppValue(CFSTR("AppleLanguages"),
kCFPreferencesCurrentApplication);
```

The first entry in `langArray` indicates the preferred language. See also `CFLocaleCopyPreferredLanguages`.

Font selectors `smScriptSysFond`, `smScriptSysFondSize`, `smScriptAppFond`, `smScriptAppFondSize`, `smScriptMonoFondSize`, `smScriptPrefFondSize`, `smScriptSmallFondSize`, and `smScriptHelpFondSize`. On Mac OS X you generally do not need to worry about setting an appropriate font based on character script to ensure that characters are displayed correctly; Unicode encoding and font fallbacks (to automatically find a font that can display a character) take care of this. However, for cases where you do need to do this (such as Carbon applications that handle non-Unicode text), the Core Text function `CTFontCreateUIFontForLanguage` (available in Mac OS X v10.5 and later) provides a way to get a `CTFontRef` object for a specified language and user interface use.

Script resource ID selectors `smScriptNumber`, `smScriptDate`, `smScriptSort`, and `smScriptToken`. These were used in several ways. Sometimes they were used to get a resource ID so specific fields in the resource could be examined (for example, to determine the appropriate decimal separator or time format). For this use `CFLocaleGetValue` can now be used with an appropriate key (for example, `kCFLocaleDecimalSeparator`) to get similar information (much of the information associated with the resource specified by `smScriptToken` is not relevant for a Unicode system). Another use was to get a resource ID (or a handle) to pass to some other system function. For text sorting, this is replaced by the collation functionality in CFString. For formatting of times, dates, and numbers, this is replaced by functionality in CFLocale, CFDateFormatter, CFNumberFormatter.

`smScriptKeys`. To determine an appropriate keyboard input source for a particular language, use `TISCopyInputSourceForLanguage`.

`smScriptIcon`. To obtain an icon for a particular keyboard input source, use `TISGetInputSourceProperty` with the `kTISPropertyIconRef` or `kTISPropertyIconImageURL` key.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Script.h`

GetSysDirection

Returns the current value of `SysDirection`, the global variable that determines the system direction (primary line direction). (Deprecated in Mac OS X v10.4. This function does not return anything useful in Mac OS X.)

```
short GetSysDirection (
   void
);
```

Parameters

Return Value
The current value of `SysDirection`: 0 if the system direction is left-to-right; -1 ($FFFF) if the system direction is right-to-left.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

IntlScript

Identifies the script system used by the Text Utilities date-formatting, time-formatting, and string-sorting functions. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetEncoding` instead.)

```
short IntlScript (
   void
);
```

Parameters

Return Value
A script code. All recognized script codes and their defined constants are listed in "Meta Script Codes" (page 1753). `IntlScript` returns only explicit script codes (□0). If the international resources selection flag is `TRUE`, the script code returned is that of the system script. If the identified script system is not enabled, the script code returned is that of the system script and the script-defaulted result flag is set to `TRUE`.

Discussion
Information about the script system is subject to two control flags—the font force flag and the international resources selection flag. You can test and set these flags with the `GetScriptManagerVariable` and `SetScriptManagerVariable` selectors `smFontForce` and `smIntlForce`.

The function starts by initializing two result flags, the script-forced result flag and the script-defaulted result flag, to `FALSE`. These flags are Script Manager variables, accessed through the `GetScriptManagerVariable` function selectors `smForced` and `smDefault`.

The function also identifies the script system whose resources are returned by the Script Manager function `GetIntlResource`. It is either the font script—the script system corresponding to the current font of the active graphics port—or the system script.

Special Considerations

`IntlScript` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

IntlTokenize

Allows your application to convert text into a sequence of language-independent tokens. (Deprecated in Mac OS X v10.4. There is no replacement because this function is no longer needed in Mac OS X.)

```
TokenResults IntlTokenize (
   TokenBlockPtr tokenParam
);
```

Parameters

tokenParam

A pointer to a token block structure. The structure specifies the text to be converted to tokens, the destination of the token list, a handle to the tokens (`'itl4'`) resource, and a set of options. See the `TokenBlock` (page 1736)data structure for information on what you need to pass in this structure and what you obtain on return.

Return Value
A `TokenResults` value that specifies whether the function executed with errors. See "Token Results" (page 1818) for a list of the values that can be returned.

Discussion
Before calling the `IntlTokenize` function, allocate memory for and set up the following data structures:

- A token block structure (data type `TokenBlock`). The token block structure is a parameter block that holds both input and output parameters for the `IntlTokenize` function.
- A token list to hold the results of the tokenizing operation. To set up the token list, estimate how many tokens will be generated from your text, multiply that by the size of a token structure, and allocate a memory block of that size in bytes. An upper limit to the possible number of tokens is the number of characters in the source text.
- A string list, if you want the `IntlTokenize` function to generate character strings for all the tokens. To set up the string list, multiply the estimated number of tokens by the expected average size of a string, and allocate a memory block of that size in bytes. An upper limit is twice the number of tokens plus the number of bytes in the source text.

The function `IntlTokenize` creates tokens based on information in the tokens (`'itl4'`) resource of the script system under which the source text was created. You must load the tokens resource and place its handle in the token block structure before calling the `IntlTokenize` function.

The token block structure contains both input and output values. At input, you must provide values for the fields that specify the source text location, the token list location, the size of the token list, the tokens (`'itl4'`) resource to use, and several options that affect the operation. You must set reserved locations to 0 before calling `IntlTokenize`.

On output, the token block structure specifies how many tokens have been generated and the size of the string list (if you have selected the option to generate strings).

The results of the tokenizing operation are contained in the token list, an array of token structures (data type `TokenRec` (page 1739)).

Pascal strings are generated if the `doString` parameter in the token block structure is set to `TRUE`. The string is a normalized version of the source text that generated the token; alternate digits are replaced with ASCII numerals, the decimal point is always an ASCII period, and double-byte Roman letters are replaced with low-ASCII equivalents.

To make a series of calls to `IntlTokenize` and append the results of each call to the results of previous calls, set `doAppend` to `FALSE` and initialize `tokenCount` and `stringCount` to 0 before making the first call to `IntlTokenize`. (You can ignore `stringCount` if you set `doString` to `FALSE`.) Upon completion of the call, `tokenCount` and `stringCount` will contain the number of tokens and the length in bytes of the string list, respectively, generated by the call. On subsequent calls, set `doAppend` to `TRUE`, reset the `source` and `sourceLength` parameters (and any other parameters as appropriate) for the new source text, but maintain the output values for `tokenCount` and `stringCount` from each call as input values to the next call. At the end of your sequence of calls, the token list and string list will contain, in order, all the tokens and strings generated from the calls to `IntlTokenize`.

If you are making tokens from text that was created under more than one script system, you must load the proper tokens resource and place its handle in the token block structure separately for each script run in the text, appending the results each time.

Delimiters for quoted literals are passed to `IntlTokenize` in a two-integer array.

The individual delimiters, as specified in the `leftDelims` and `rightDelims` parameters, are paired by position. The first (in storage order) opening delimiter in `leftDelims` is paired with the first closing delimiter in `rightDelims`.

Comment delimiters may be 1 or 2 tokens each and there may be two sets of opening and closing pairs. They are passed to `IntlTokenize` in a `commentType` array.

If only one token is needed for a delimiter, the second token must be specified to be `delimPad`. If only one delimiter of an opening-closing pair is needed, then both of the tokens allocated for the other symbol must be `delimPad`. The first token of a two-token sequence is at the higher position in the `leftComment` or `rightComment` array.

When `IntlTokenize` encounters an escape character within a quoted literal, it places the portion of the literal before the escape character into a single token (of type `tokenLiteral`), places the escape character into another token (`tokenEscape`), places the character following the escape character into another token (whatever token type it corresponds to), and places the portion of the literal following the escape sequence into another token (`tokenLiteral`). Outside of a quoted literal, the escape character has no special significance.

`IntlTokenize` considers the character specified in the `decimalCode` parameter to be a decimal character only when it is flanked by numeric or alternate numeric characters, or when it follows them.

Special Considerations

`IntlTokenize` may move memory; your application should not call this function at interrupt time.

Because each call to `IntlTokenize` must be for a single script run, there can be no change of script within a comment or quoted literal.

Comments and quoted literals must be complete within a single call to `IntlTokenize` in order to avoid syntax errors.

`IntlTokenize` always uses the tokens resource whose handle you pass it in the token block structure. Therefore, it is not directly affected by the state of the font force flag or the international resources selection flag. However, if you use the `GetIntlResource` function to get a handle to the tokens resource to pass to `IntlTokenize`, remember that `GetIntlResource` is affected by the state of the international resources selection flag.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Script.h`

SetScriptManagerVariable

Sets the specified Script Manager variable to the value of the input parameter. (Deprecated in Mac OS X v10.5. This is mainly used to set the value of variables that control the internal operation of the Script Manager (selectors `smIntlForce` and `smGenFlags`), and therefore there is no modern replacement.)

```
OSErr SetScriptManagerVariable (
   short selector,
   long param
);
```

Parameters

`selector`

A value that specifies a particular Script Manager variable. To specify the Script Manager variable whose value you wish to change, use one of the selector constants listed in "Script Manager Selectors" (page 1768).

`param`

The new value for the specified Script Manager variable.

The actual values to be assigned may be long integers, standard integers, or signed bytes. If the value is other than a long integer, you must store it in the low-order word or byte of the `param` parameter and set the unused bytes to 0.

Return Value
A result code. See "Script Manager Result Codes" (page 1821). The value `smBadVerb` if the selector is not valid. Otherwise, the function returns 0 (`noErr`).

Discussion
The Script Manager maintains a set of variables that control general settings of the text environment, including the identity of the system script and the keyboard script, and the settings of the font force flag and the international resources selection flag.

You may want access to the Script Manager variables in order to understand the current environment or to modify it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Script.h`

SetScriptVariable

Sets the specified script variable for the specified script system to the value of the input parameter. (Deprecated in Mac OS X v10.5. The replacement for this function depends on the purpose for which it is used, as described in the Special Considerations section.)

```
OSErr SetScriptVariable (
   short script,
   short selector,
   long param
);
```

Parameters

script

A value that specifies the script system whose variable you are setting. Use one of the script-code constants listed in "Meta Script Codes" (page 1753).

selector

A value that specifies a particular script variable. Use one of the selector constants listed in "Script Variable Selectors" (page 1773).

param

The new value for the specified script variable. The actual value to be assigned may be a long integer, standard integer, or signed byte. If the value is not a long integer, you must store it in the low-order word or byte of the `param` parameter and set the unused bytes to 0.

Return Value
A result code. See "Script Manager Result Codes" (page 1821). The value `smBadVerb` if the selector is not valid, and `smBadScript` if the script is invalid. Otherwise, 0 (`noErr`).

Discussion
Each enabled script system maintains a set of variables that control the current settings of that script system, including the ID numbers of its international resources, its preferred fonts and font sizes, and its primary line direction.

Special Considerations

The replacement for this function depends on whether the goal is to set the keyboard layout globally or for a specific TSM document. To set it globally, use `TISSelectInputSource`. To set it for a specific document, use the TSM document property `kTSMDocumentInputSourceOverridePropertyTag`.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Script.h`

SetSysDirection

Sets the value of `SysDirection`, the global variable that determines the system direction (primary line direction). (Deprecated in Mac OS X v10.4. There is no replacement because this function is no longer needed in Mac OS X.)

```
void SetSysDirection (
   short value
);
```

Parameters

value

The desired value for `SysDirection`:0 if you wish the system direction to be left-to-right and -1 ($FFFF) if you wish the system direction to be right-to-left.

Return Value

Discussion

The value of `SysDirection` is initialized from the system's international configuration resource, and may be controlled by the user. Your application can use the `SetSysDirection` function to change `SysDirection` while drawing, but should restore it when appropriate (such as when your application becomes inactive).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Script.h`

TransliterateText

Converts characters from one subscript to the closest possible approximation in a different subscript within the same double-byte script system. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

```
OSErr TransliterateText (
   Handle srcHandle,
   Handle dstHandle,
   short target,
   long srcMask,
   ScriptCode script
);
```

Parameters

srcHandle

A handle to the source text to be transliterated. The `TransliterateText` function converts all of the text that you pass it in this parameter. It determines the length of the source text (in bytes) from the handle size.

dstHandle

A handle to a buffer that, upon completion of the call, contains the transliterated text.

Before calling `TransliterateText`, allocate a handle (of any size) to pass in the `dstHandle` parameter. The length of the transliterated text may be different (as when converting between single-byte and double-byte characters), and `TransliterateText` sets the size of the destination handle as required. It is your responsibility to dispose of the destination handle when you no longer need it.

target

A value that specifies what kind of text the source text is to be transliterated into.

The low byte of the target is the format to convert to (the target format). It determines what form the text should be transliterated to. In all script systems, there are two currently supported values for target format: `smTransAscii` and `smTransNative`. In double-byte script systems, additional values are recognized.

The high byte is the target modifier; it contains modifiers, whose meanings depend on the script code, providing additional formatting instructions. In all script systems, there are two values for target modifier: `smTransLower` and `smTransUpper`.

srcMask

A bit array that specifies which parts of the source text are to be transliterated. A bit is set for each script system or subscript that should be converted to the target format. In all script systems, the `srcMask` parameter may have the following values: `smMaskAscii`, `smMaskNative`, and `smMaskAll`. In double-byte script systems, additional values are recognized.

script

A value that specifies the script system of the text to be transliterated. Constants for all defined script codes are listed in "Meta Script Codes" (page 1753). To specify the font script, pass `smCurrentScript` in this parameter.

Return Value
A result code. See "Script Manager Result Codes" (page 1821).

Discussion
Transliteration is the conversion of text from one form or subscript to another within a single script system. In the Roman script system, transliteration means case conversion. In double-byte script systems, it is the automatic conversion of characters from one subscript to another. One common use for transliteration is as an initial stage of text conversion for an input method.

`TransliterateText` also performs uppercasing and lowercasing, with consideration for regional variants, in the Roman script system and on Roman text within double-byte script systems.

Because the low-ASCII character set (character codes $20–$7F) is present in all script systems, you could theoretically use the `TransliterateText` function to convert characters from one script system into another completely different script system. You could transliterate from a native subscript into ASCII under one script system, and then transliterate from that ASCII into a native subscript under a different script system. Such a function is not recommended, however, because of the imperfect nature of phonetic translation. Furthermore, many script systems do not support transliteration from native subscripts to ASCII.

Special Considerations

`TransliterateText` may move memory; your application should not call this function at interrupt time.

If you pass `smCurrentScript` in the `script` parameter, the conversion performed by `TransliterateText` can be affected by the state of the font force flag. It is unaffected by the international resources selection flag.

Transliteration of a block of text does not work across script-run boundaries. Because the `TransliterateText` function requires transliteration tables that are in a script system's international resources, you need to call it anew for each script run in your text.

Currently, the Roman version of `TransliterateText` checks the source mask only to ensure that at least one of the bits corresponding to the `smMaskAscii` and `smMaskNative` constants is set.

The Arabic and Hebrew versions of `TransliterateText` perform case conversion only. They allow the target values `smTransAscii` and `smTransNative` only; otherwise, they behave like the Roman version.

The `TransliterateText` tables for single-byte script systems reside in the script's string-manipulation (`'itl2'`) resource, so they can reflect region-specific or language-specific differences in uppercase conventions. If the string-manipulation resource does not include these tables, `TransliterateText` exits without doing anything.

The `TransliterateText` tables for double-byte script systems reside in the script's transliteration (`'trsl'`) resource. If the `'trsl'` resource does not include these tables, `TransliterateText` exits without doing anything.

The Japanese, Traditional Chinese, and Simplified Chinese versions of `TransliterateText` have two modes of operation. If either `smMaskAscii` or `smMaskNative` is specified in the source mask, and if the target is `smTransAscii`, and if either of the target modifiers is specified, `TransliterateText` performs the specified case conversion on both single-byte and double-byte Roman letters. Otherwise, `TransliterateText` performs conversions according to the target format values. Any combination of source masks and target format is permitted.

Availability
Available in Mac OS X v10.0 and later.

TokenBlock

Contains information about text that is to be converted to tokens, the destination of the token list, a handle to the tokens resource, and a set of options.

```
struct TokenBlock {
    Ptr source;
    long sourceLength;
    Ptr tokenList;
    long tokenLength;
    long tokenCount;
    Ptr stringList;
    long stringLength;
    long stringCount;
    Boolean doString;
    Boolean doAppend;
    Boolean doAlphanumeric;
    Boolean doNest;
    ScriptTokenType leftDelims[2];
    ScriptTokenType rightDelims[2];
    ScriptTokenType leftComment[4];
    ScriptTokenType rightComment[4];
    ScriptTokenType escapeCode;
    ScriptTokenType decimalCode;
    Handle itlResource;
    long reserved[8];
};
typedef struct TokenBlock TokenBlock;
typedef TokenBlock * TokenBlockPtr;
```

Fields

`source`
: A pointer to a stream of characters. On input to the function `IntlTokenize` (page 1729), a pointer to the beginning of the source text (not a Pascal string) to be converted.

`sourceLength`
: The length of the source stream. On input, the number of bytes in the source text.

`tokenList`
: A pointer to an array of tokens. On input, a pointer to a buffer you have allocated. On output, a pointer to a list of token structures generated by the `IntlTokenize` function.

`tokenLength`
: The maximum length of `TokenList`. On input, the maximum size of token list (in number of tokens, not bytes) that will fit into the buffer pointed to by the `tokenList` field.

`tokenCount`
: The number of tokens generated by the tokenizer. On input (if `doAppend = TRUE`), must contain the correct number of tokens currently in the token list. (Ignored if `doAppend = FALSE`.) On output, the number of tokens currently in the token list.

`stringList`
: A pointer to a stream of identifiers. On input (if `doString = TRUE`), a pointer to a buffer you have allocated. (Ignored if `doString = FALSE`) On output, a pointer to a list of strings generated by the `IntlTokenize` function.

`stringLength`
: The length of the string list. On input (if `doString = TRUE`), the size in bytes of the string list buffer pointed to by the `stringList` field. (Ignored if `doString = FALSE`.)

`stringCount`
: The number of bytes currently used. On input (if `doString = TRUE` and `doAppend = TRUE`), the correct current size in bytes of the string list. (Ignored if `doString = FALSE` or `doAppend = FALSE`.) On output, the current size in bytes of the string list. (Indeterminate if `doString = FALSE`.)

`doString`
: A Boolean value. On input, if `TRUE`, instructs `IntlTokenize` to create a Pascal string representing the contents of each token it generates. If `FALSE`, `IntlTokenize` generates a token list without an associated string list.

`doAppend`
: A Boolean value. On input, if `TRUE`, instructs `IntlTokenize` to append tokens and strings it generates to the current token list and string list. If `FALSE`, `IntlTokenize` writes over any previous contents of the buffer pointed to by `tokenList` and `stringList`.

`doAlphanumeric`
: A Boolean value. On input, if `TRUE`, instructs `IntlTokenize` to interpret numeric characters as alphabetic when mixed with alphabetic characters. If `FALSE`, all numeric characters are interpreted as numbers.

`doNest`
: A Boolean value. A value of type `Boolean`. On input, if `TRUE`, instructs `IntlTokenize` to allow nested comments (to any depth of nesting). If `FALSE`, comment delimiters may not be nested within other comment delimiters.

`leftDelims`
: A value of type `DelimType`. On input, an array of two integers, each of which contains the token code of the symbol that may be used as an opening delimiter for a quoted literal. If only one opening delimiter is needed, the other must be specified to be `delimPad`.

`rightDelims`
: A value of type `DelimType`. On input, an array of two integers, each of which contains the token code of the symbol that may be used as the matching closing delimiter for the corresponding opening delimiter in the `leftDelims` field.

`leftComment`
: A value of type `CommentType`. On input, an array of two pairs of integers, each pair of which contains codes for the two token types that may be used as opening delimiters for comments.

`rightComment`
: A value of type `CommentType`. On input, an array of two pairs of integers, each pair of which contains codes for the two token types that may be used as closing delimiters for comments.

`escapeCode`
: A value of type `TokenType`. On input, a single integer that contains the token code for the symbol that may be an escape character within a quoted literal.

`decimalCode`
: A value of type `TokenType`. On input, a single integer that contains the token type of the symbol to be used for a decimal point.

`itlResource`
: A value of type `Handle`. On input, a handle to the tokens (`'itl4'`) resource of the script system under which the source text was created.

`reserved`
: An 8-byte array of type `LongInt` . On input, this must be set to 0.

Discussion
The token block structure is a parameter block used to pass information to the `IntlTokenize` (page 1729) function and to retrieve results from it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Script.h

TokenRec

Contains information about the conversion of a sequence of characters to a token.

```
struct TokenRec {
    ScriptTokenType theToken;
    Ptr position;
    long length;
    StringPtr stringPosition;
};
typedef struct TokenRec TokenRec;
typedef TokenRec * TokenRecPtr;
```

Fields

`theToken`
A numeric code that specifies the type of token (such as whitespace, opening parenthesis, alphabetic or numeric sequence) described by this token structure. Constants for all defined token codes are listed in "Obsolete Token Codes" (page 1821).

`position`
A pointer to the first character in the source text that caused this particular token to be generated.

`length`
The length, in bytes, of the source text that caused this particular token to be generated.

`stringPosition`
If `doString` = `TRUE`, a pointer to a null-terminated Pascal string, padded if necessary so that its total number of bytes (length byte + text + null byte + padding) is even. If `doString` = `FALSE`, this field is `NULL`.

The value in the length byte of the null-terminated Pascal string does not include either the terminating zero byte or the possible additional padding byte. There may be as many as two additional bytes beyond the specified length.

Discussion
The token structure holds the results of the conversion of a sequence of characters to a token by the `IntlTokenize` (page 1729) function. When it analyzes text, `IntlTokenize` generates a token list, which is a sequence of token structures.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Script.h

Constants

Assorted Constants

Calendar Codes

Specify constants for various calendars.

```
enum {
    calGregorian = 0,
    calArabicCivil = 1,
    calArabicLunar = 2,
    calJapanese = 3,
    calJewish = 4,
    calCoptic = 5,
    calPersian = 6
};
```

Constants

`calGregorian`
Specifies the Gregorian calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calArabicCivil`
Specifies the Arabic civil calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calArabicLunar`
Specifies the Arabic lunar calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calJapanese`
Specifies the Japanese calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calJewish`
Specifies the Jewish calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calCoptic`
Specifies the Coptic calendar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`calPersian`
Specifies the Persian calendar.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion
These calendar codes are bit numbers, not masks.

Character Byte Types

Specify character byte types.

```
enum {
    smSingleByte = 0,
    smFirstByte = -1,
    smLastByte = 1,
    smMiddleByte = 2
};
```

Constants
`smSingleByte`
Specifes a single byte.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smFirstByte`
Specifies the first byte.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smLastByte`
Specifies the last byte.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smMiddleByte`
Specifies the middle byte.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Character Types

Specify basic character types.

```
enum {
    smCharPunct = 0x0000,
    smCharAscii = 0x0001,
    smCharEuro = 0x0007,
    smCharExtAscii = 0x0007,
    smCharKatakana = 0x0002,
    smCharHiragana = 0x0003,
    smCharIdeographic = 0x0004,
    smCharTwoByteGreek = 0x0005,
    smCharTwoByteRussian = 0x0006,
    smCharBidirect = 0x0008,
    smCharContextualLR = 0x0009,
    smCharNonContextualLR = 0x000A,
    smCharHangul = 0x000C,
    smCharJamo = 0x000D,
    smCharBopomofo = 0x000E,
    smCharGanaKana = 0x000F,
    smCharFISKana = 0x0002,
    smCharFISGana = 0x0003,
    smCharFISIdeo = 0x0004
};
```

Constants

`smCharPunct`
Specifies punctuation characters.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharAscii`
Specifies ASCII characters.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharEuro`
Specifies `smCharEuro`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharExtAscii`
Specifies a more correct synonym for `smCharEuro`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharKatakana`
Specifies additional character types for Japanese Katakana.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharHiragana`
Specifies additional character types for Japanese Hiragana.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharIdeographic`
Specifies additional character types for Hanzi, Kanji, and Hanja.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharTwoByteGreek`
Specifies additional character types for double-byte Greek in Far East systems.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharTwoByteRussian`
Specifies additional character types for double-byte Cyrillic in Far East systems.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharBidirect`
Specifies additional character types for Arabic/Hebrew.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharContextualLR`
Specifies contextual left-right: Thai, Indic scripts.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharNonContextualLR`
Specifies additional character types for non-contextual left-right: Cyrillic, Greek.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharHangul`
Specifies additional character types for Korean Hangul.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharJamo`
Specifies additional character types for Korean Jamo.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharBopomofo`
Specifies additional character types for Chinese Bopomofo.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharGanaKana`
Specifies additional character types shared for Japanese Hiragana and Katakana.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharFISKana`
Specifies obsolete Katakana names, for backward compatibility.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smCharFISGana`
Specifies obsolete Hiragana namde, for backward compatibility.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smCharFISIdeo`
Specifies obsolete Hanzi, Kanji, and Hanja names, for backward compatibility.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Character Type Classes

Specify character-type classes for double-byte script systems.

```
enum {
    smCharFISGreek = 0x0005,
    smCharFISRussian = 0x0006,
    smPunctNormal = 0x0000,
    smPunctNumber = 0x0100,
    smPunctSymbol = 0x0200,
    smPunctBlank = 0x0300,
    smPunctRepeat = 0x0400,
    smPunctGraphic = 0x0500,
    smKanaSmall = 0x0100,
    smKanaHardOK = 0x0200,
    smKanaSoftOK = 0x0300,
    smIdeographicLevel1 = 0x0000,
    smIdeographicLevel2 = 0x0100,
    smIdeographicUser = 0x0200,
    smFISClassLvl1 = 0x0000,
    smFISClassLvl2 = 0x0100,
    smFISClassUser = 0x0200,
    smJamoJaeum = 0x0000,
    smJamoBogJaeum = 0x0100,
    smJamoMoeum = 0x0200,
    smJamoBogMoeum = 0x0300
};
```

Constants

`smCharFISGreek`
Specfies character-type classes for double-byte Greek in Far East systems.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smCharFISRussian`
Specfies character-type classes for double-byte Cyrillic in Far East systems.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctNormal`
Specfies character-type classes for normal punctuation (`smCharPunct`).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctNumber`
Specfies character-type classes for number punctuation (`smCharPunct`).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctSymbol`
Specfies character-type classes for symbol punctuation (`smCharPunct`).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctBlank`
Specfies additional character-type classes for punctuation in double-byte systems.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctRepeat`
Specifies a character-type class for repeat markers.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smPunctGraphic`
Specifies a character-type class forl ine graphics.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKanaSmall`
Specfies character-type classes for Katakana and Hiragana double-byte systems.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKanaHardOK`
Specfies character-type classes for Katakana and Hiragana double-byte systems; can have dakuten.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKanaSoftOK`
Specfies character-type classes for Katakana and Hiragana double-byte systems; can have dakuten or han-dakuten.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smIdeographicLevel1`
Specfies character-type classes for Ideographic double-byte systems; level 1 char.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smIdeographicLevel2`
Specfies character-type classes for Ideographic double-byte systems; level 2 char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smIdeographicUser`
Specfies character-type classes for Ideographic double-byte systems; user char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smFISClassLvl1`
Obsolete, for backward compatibility; level 1 char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smFISClassLvl2`
Obsolete, for backward compatibility; level 2 char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smFISClassUser`
Obsolete, for backward compatibility; user char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smJamoJaeum`
Specfies character-type Jamo classes for Korean systems; simple consonant char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smJamoBogJaeum`
Specfies character-type Jamo classes for Korean systems; complex consonant char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smJamoMoeum`
Specfies character-type Jamo classes for Korean systems; simple vowel char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smJamoBogMoeum`
Specfies character-type Jamo classes for Korean systems; complex vowel char.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Character Type Field Masks

Specify masks used to extract information from the return value of the `CharacterType` function.

```
enum {
    smcTypeMask = 0x000F,
    smcReserved = 0x00F0,
    smcClassMask = 0x0F00,
    smcOrientationMask = 0x1000,
    smcRightMask = 0x2000,
    smcUpperMask = 0x4000,
    smcDoubleMask = 0x8000
};
```

Constants

`smcTypeMask`
Character-type mask.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcReserved`
Reserved.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcClassMask`
Character-class mask.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcOrientationMask`
Character orientation (double-byte scripts).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcRightMask`
Writing direction (bidirectional scripts); main character set or subset (double-byte scripts)
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcUpperMask`
Uppercase or lowercase.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smcDoubleMask`
Size (1 or 2 bytes).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Discussion

These bit masks are used to extract fields from the return value of the `CharacterType` (page 1717) function.

The character type of the character in question is the result of performing an `AND` operation with `smcTypeMask` and the `CharacterType` result.

The character class of the character in question is the result of performing an `AND` operation with `smcClassMask` and the `CharacterType` result. Character classes can be considered as subtypes of character types.

The orientation of the character in question is the result of performing an `AND` operation with `smcOrientationMask` and the `CharacterType` result. The orientation value can be either `smCharHorizontal` or `smCharVertical`.

The direction of the character in question is the result of performing an `AND` operation with `smcRightMask` and the `CharacterType` result. The direction value can be either `smCharLeft` (left-to-right) or `smCharRight` (right-to-left).

The case of the character in question is the result of performing an `AND` operation with `smcUpperMask` and the `CharacterType` result. The case value can be either `smCharLower` or `smCharUpper`.

The size of the character in question is the result of performing an `AND` operation with `smcDoubleMask` and the `CharacterType` result. The size value can be either `smChar1byte` or `smChar2byte`.

Character Set Extensions

Specify extensions to character sets.

```
enum {
    diaeresisUprY = 0xD9,
    fraction = 0xDA,
    intlCurrency = 0xDB,
    leftSingGuillemet = 0xDC,
    rightSingGuillemet = 0xDD,
    fiLigature = 0xDE,
    flLigature = 0xDF,
    dblDagger = 0xE0,
    centeredDot = 0xE1,
    baseSingQuote = 0xE2,
    baseDblQuote = 0xE3,
    perThousand = 0xE4,
    circumflexUprA = 0xE5,
    circumflexUprE = 0xE6,
    acuteUprA = 0xE7,
    diaeresisUprE = 0xE8,
    graveUprE = 0xE9,
    acuteUprI = 0xEA,
    circumflexUprI = 0xEB,
    diaeresisUprI = 0xEC,
    graveUprI = 0xED,
    acuteUprO = 0xEE,
    circumflexUprO = 0xEF,
    appleLogo = 0xF0,
    graveUprO = 0xF1,
    acuteUprU = 0xF2,
    circumflexUprU = 0xF3,
    graveUprU = 0xF4,
    dotlessLwrI = 0xF5,
    circumflex = 0xF6,
    tilde = 0xF7,
    macron = 0xF8,
    breveMark = 0xF9,
    overDot = 0xFA,
    ringMark = 0xFB,
    cedilla = 0xFC,
    doubleAcute = 0xFD,
    ogonek = 0xFE,
    hachek = 0xFF
};
```

Keyboard Script Synchronization

Specifies to disable font and keyboard script synchronization.

```
enum {
    smfDisableKeyScriptSync = 27
};
```

Glyph Orientations

Specify character-type glyph orientation for double-byte systems.

```
enum {
    smCharHorizontal = 0x0000,
    smCharVertical = 0x1000,
    smCharLeft = 0x0000,
    smCharRight = 0x2000,
    smCharLower = 0x0000,
    smCharUpper = 0x4000,
    smChar1byte = 0x0000,
    smChar2byte = 0x8000
};
```

Constants

`smCharHorizontal`
Specifies horizontal character form.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharVertical`
Specifies vertical character form.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharLeft`
Specifies left character direction.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharRight`
Specifies right character direction.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharLower`
Specifies lowercase character modifers.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCharUpper`
Specifies uppercase character modifers.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smChar1byte`
Specifies character size modifiers (single or multiple bytes).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smChar2byte`
Specifies character size modifiers (single or multiple bytes).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Keyboard Script Switching Selectors

Specify a keyboard script switching flag and mask.

```
enum {
    smKeyForceKeyScriptBit = 7,
    smKeyForceKeyScriptMask = 1 << smKeyForceKeyScriptBit
};
```

Constants

`smKeyForceKeyScriptBit`

A flag that specifies to force keyboard script switching.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyForceKeyScriptMask`

A mask that specifies to force keyboard script switching.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Keyboard Script Values

Specify actions for keyboard scripts.

```
enum {
    smKeyNextScript = -1,
    smKeySysScript = -2,
    smKeySwapScript = -3,
    smKeyNextKybd = -4,
    smKeySwapKybd = -5,
    smKeyDisableKybds = -6,
    smKeyEnableKybds = -7,
    smKeyToggleInline = -8,
    smKeyToggleDirection = -9,
    smKeyNextInputMethod = -10,
    smKeySwapInputMethod = -11,
    smKeyDisableKybdSwitch = -12,
    smKeySetDirLeftRight = -15,
    smKeySetDirRightLeft = -16,
    smKeyRoman = -17
};
```

Constants

`smKeyNextScript`

Specifies to switch to the next available script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySysScript`

Specfiies to switch to the system script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySwapScript`
Specifies to switch to the previously-used script

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyNextKybd`
Specifies to switch to the next keyboard in current keyscript.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySwapKybd`
Specfies to switch to a previously-used keyboard in the current keyscript.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyDisableKybds`
Specifies to disable keyboards not in the system or Roman script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyEnableKybds`
Specifies to enable keyboards for all enabled scripts.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyToggleInline`
Specifies to toggle inline input for the current keyscript

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyToggleDirection`
Specifies to toggle the default line direction (`TESysJust`).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyNextInputMethod`
Specfies to switch to the next input method in the current keyscript.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySwapInputMethod`
Specfies to switch to the last-used input method in the current keyscript.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyDisableKybdSwitch`
Specfies to disable switching from the current keyboard.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySetDirLeftRight`
Specfies to set the default line direction to left-right, align left.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeySetDirRightLeft`
Specfies to set the default line direction to right-left, align right.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyRoman`
Specfies to set the keyscript to Roman. Does nothing if on a Roman-only system. This is unlike `KeyScript(smRoman)` which forces an update to current default Roman keyboard. See `KeyScript` documentation for more information.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Keyboard Synchronization Mask

Disables font and keyboard script synchronization mask

```
enum {
    smfDisableKeyScriptSyncMask = 1L << smfDisableKeyScriptSync
};
```

Constants

`smfDisableKeyScriptSyncMask`
Disable font and keyboard script synchronization mask

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion

Meta Script Codes

Specify implicit script codes.

```
enum {
    smSystemScript = -1,
    smCurrentScript = -2,
    smAllScripts = -3
};
```

Constants

`smSystemScript`
Specifies the system script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smCurrentScript`
Specifies the font script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smAllScripts`
Specfies any script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion
You can specify script systems with implicit and explicit script code constants in the `script` parameter of the `GetScriptVariable` (page 1726) and `SetScriptVariable` (page 1732) functions. The implicit script codes `smSystemScript` and `smCurrentScript` are special negative values for the system script and the font script, respectively.

Negative Verbs

Specify special negative verbs that were associated with WorldScript I.

```
enum {
    smLayoutCache = -309,
    smOldVerbSupport = -311,
    smSetKashidas = -291,
    smSetKashProp = -287,
    smScriptSysBase = -281,
    smScriptAppBase = -283,
    smScriptFntBase = -285,
    smScriptLigatures = -263,
    smScriptNumbers = -267
};
```

Constants
`smLayoutCache`
Specifies that `HiWrd(param)` is the number of entries, `LoWrd` is the maximum input length

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smOldVerbSupport`
Specifies that a parameter is added to old verbs to map to WorldScript I verb.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smSetKashidas`
Specifies parameter is on or off; obsolete verb = -36.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smSetKashProp`
Specifies parameter is kashida proportion; obsolete verb = -32.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

`smScriptSysBase`
Specifies parameter is associated font to use with the system font; obsolete verb = -26)
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

`smScriptAppBase`
Specifies parameter is associated font to use with application font; obsolete verb = -28.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

`smScriptFntBase`
Specifies that a parameter is associated font to use with all other fonts; obsolete verb = -30.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

`smScriptLigatures`
Obsolete verb = -8.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

`smScriptNumbers`
Obsolete verb = -12.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Script.h`.

Numeral Codes

Specify the kinds of numerals used by a script.

```
enum {
    intWestern = 0,
    intArabic = 1,
    intRoman = 2,
    intJapanese = 3,
    intEuropean = 4,
    intOutputMask = 0x8000
};
```

Constants

`intWestern`
Specifies Western numerals.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`intArabic`
Specifies Native Arabic numerals.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`intRoman`
Specifies Roman numerals.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`intJapanese`
Specifies Japanese numerals.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`intEuropean`
Specifies European numerals.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`intOutputMask`
Specifies an output mask.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Discussion
These constants specify bit numbers, not masks.

Script Redraw Selectors

Specify values for script redraw flags.

```
enum {
    smRedrawChar = 0,
    smRedrawWord = 1,
    smRedrawLine = -1
};
```

Constants

`smRedrawChar`

Specifies to redraw character only.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smRedrawWord`

Specifies to redraw entire word (double-byte systems).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smRedrawLine`

Specifies to redraw entire line (bidirectional systems).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

Script Codes

Specify Mac OS encodings that are related to a `FOND` ID range.

```
enum {
    smRoman = 0,
    smJapanese = 1,
    smTradChinese = 2,
    smKorean = 3,
    smArabic = 4,
    smHebrew = 5,
    smGreek = 6,
    smCyrillic = 7,
    smRSymbol = 8,
    smDevanagari = 9,
    smGurmukhi = 10,
    smGujarati = 11,
    smOriya = 12,
    smBengali = 13,
    smTamil = 14,
    smTelugu = 15,
    smKannada = 16,
    smMalayalam = 17,
    smSinhalese = 18,
    smBurmese = 19,
    smKhmer = 20,
    smThai = 21,
    smLao = 22,
    smGeorgian = 23,
    smArmenian = 24,
    smSimpChinese = 25,
    smTibetan = 26,
    smMongolian = 27,
    smEthiopic = 28,
    smGeez = 28,
    smCentralEuroRoman = 29,
    smVietnamese = 30,
    smExtArabic = 31,
    smUninterp = 32
};
```

Constants

`smRoman`

Specifies the Roman script system.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smJapanese`

Specifies the Japanese script system.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smTradChinese`

Specifies the traditional Chinese script system.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKorean`
Specifies the Korean script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smArabic`
Specifies the Arabic script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smHebrew`
Specifies the Hebrew script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smGreek`
Specifies the Greek script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCyrillic`
Specifies the Cyrillic script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smRSymbol`
Specifies right-to-left symbols. The script code represented by the constant `smRSymbol` is available as an alternative to `smUninterp`, for representation of special symbols that have a right-to-left line direction. Note, however, that the script management system provides no direct support for representation of text with this script code.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smDevanagari`
Specifies the Devanagari script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smGurmukhi`
Specifies the Gurmukhi script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smGujarati`
Specifies the Gujarati script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smOriya`
Specifies the Oriya script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smBengali`
Specifies the Bengali script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTamil`
Specifies the Tamil script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTelugu`
Specifies the Telugu script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smKannada`
Specifies the Kannada/Kanarese script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smMalayalam`
Specifies the Malayalam script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smSinhalese`
Specifies the Sinhalese script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smBurmese`
Specifies the Burmese script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smKhmer`
Specifies the Khmer script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smThai`
Specifies the Thai script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smLao`
Specifies the Laotian script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smGeorgian`
Specifies the Georgian script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smArmenian`
Specifies the Armenian script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smSimpChinese`
Specifies the simplified Chinese script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTibetan`
Specifies the Tibetan script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smMongolian`
Specifies the Mongolian script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smEthiopic`
Specifies the Geez/Ethiopic script system. This constant is the same as `smGeez`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smGeez`
Specifies the Geez/Ethiopic script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smCentralEuroRoman`
Used for Czech, Slovak, Polish, Hungarian, Baltic languages.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smVietnamese`
Specifies the Extended Roman script system for Vietnamese.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smExtArabic`
Specifies the extended Arabic for Sindhi script system.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smUninterp`
: Uninterpreted symbols. The script code represented by the constant `smUninterp` is available for representation of special symbols, such as items in a tool palette, that must not be considered as part of any actual script system. For manipulating and drawing such symbols, the `smUninterp` constant should be treated as if it indicated the Roman script system rather than the system script; that is, the default behavior of uninterpreted symbols should be Roman.

  Available in Mac OS X v10.0 and later.

  Declared in `Script.h`.

Script Code - Unicode Input

Specifies the extended script code for full Unicode input.

```
enum {
    smUnicodeScript = 0x7E
};
```

Script Constants

Specify constants used to get and set script variables.

```
enum {
    smScriptNumDate = 30,
    smScriptKeys = 32,
    smScriptIcon = 34,
    smScriptPrint = 36,
    smScriptTrap = 38,
    smScriptCreator = 40,
    smScriptFile = 42,
    smScriptName = 44,
    smScriptMonoFondSize = 78,
    smScriptPrefFondSize = 80,
    smScriptSmallFondSize = 82,
    smScriptSysFondSize = 84,
    smScriptAppFondSize = 86,
    smScriptHelpFondSize = 88,
    smScriptValidStyles = 90,
    smScriptAliasStyle = 92
};
```

Constants

`smScriptNumDate`
: (2 bytes) The numeral code and calendar code for the script. The numeral code specifies the kind of numerals the script uses, and is in the high-order byte of the word the calendar code specifies the type of calendar it uses and is in the low-order byte of the word. The value of this variable is initialized from the script system's international bundle resource. It may be changed during execution when the user selects, for example, a new calendar from a script system's control panel. See "Numeral Codes" (page 1755) and "Calendar Codes" (page 1740) for the different codes.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptKeys`
(2 bytes) The resource ID of the script's current keyboard-layout (`'KCHR'`) resource. The keyboard-layout resource is used to map virtual key codes into the correct character codes for the script. The value of this variable is initialized from the script system's international bundle resource. It is updated when the user selects a new keyboard layout, or when the application calls the `KeyScript` function. You can force a particular keyboard layout to be used with your application by setting the value of this variable and then calling `KeyScript`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptIcon`
(2 bytes) The resource ID of the script's keyboard icon family (resource types `'kcs#'`, `'kcs4'`, and `'kcs8'`). The keyboard icon family consists of the keyboard icons displayed in the keyboard menu. The value of this variable is initialized from the script system's international bundle resource. Note that, unlike `smScriptKeys`, the value of this variable is not automatically updated when the keyboard layout changes. (System software assumes that the icon family has an identical ID to the keyboard-layout resource, and usually ignores this variable.)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptPrint`
(4 bytes) The print action function vector, set up by the script system (or by the Script Manager if the `smsfAutoInit` bit is set) when the script is initialized.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptTrap`
(4 bytes) A pointer to the script's script-structure dispatch function (for internal use only).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptCreator`
(4 bytes) The 4-character creator type for the script system's file, that is, the file containing the script system. For the Roman script system, it is `'ZSYS'`, for WorldScript I it is `'univ'`, and for World Script II it is `'doub'`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptFile`
(4 bytes) A pointer to the Pascal string that contains the name of the script system's file, that is, the file containing the script system. For the Roman script system, the string is `'System'`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptName`

(4 bytes) A pointer to a Pascal string that contains the script system's name. For the Roman script system and single-byte simple script systems, the string is `'Roman'`. For single-byte complex script systems, this name is taken from the encoding/rendering (`'itl5'`) resource. For double-byte script systems, it is taken from the WorldScript II extension and is `'WorldScript II'`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptMonoFondSize`

(4 bytes) The default font family ID and size (in points) for monospaced text. The ID is stored in the high-order word, and the size is stored in the low-order word. The value of this variable is taken from the script system's international bundle resource. Note that not all script systems have a monospaced font.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptPrefFondSize`

(4 bytes) Currently not used.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptSmallFondSize`

(4 bytes) The default font family ID and size (in points) for small text, generally the smallest font and size combination that is legible on screen. The ID is stored in the high-order word, and the size is stored in the low-order word. Sizes are important for example, a 9-point font may be too small in Chinese. The value of this variable is taken from the script system's international bundle resource.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptSysFondSize`

(4 bytes) The default font family ID and size (in points) for this script system's preferred system font. The ID is stored in the high-order word, and the size is stored in the low-order word. The value of this variable is taken from the script system's international bundle resource.

This variable holds similar information to the variable accessed through the `smScriptSysFond` selector. If you need font family ID only and don't want size information, it is simpler to use `smScriptSysFond`. Note, however, that changing the value of this variable has no effect on the value accessed through `smScriptSysFond`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptAppFondSize`
: (4 bytes) The default font family ID and size (in points) for this script system's preferred application font. The ID is stored in the high-order word, and the size is stored in the low-order word. The value of this variable is taken from the script system's international bundle resource.

  This variable holds similar information to the variable accessed through the `smScriptAppFond` selector. If you need font family ID only and don't want size information, it is simpler to use `smScriptAppFond`. Note, however, that changing the value of this variable has no effect on the value accessed through `smScriptAppFond`.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptHelpFondSize`
: (4 bytes) The default font family ID and size (in points) for Balloon Help. The ID is stored in the high-order word, and the size is stored in the low-order word. Sizes are important for example, a 9-point font may be too small in Chinese. The value of this variable is taken from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptValidStyles`
: (1 byte) The set of all valid styles for the script. For example, the Extended style is not valid in the Arabic script. When the `GetScriptVariable` function is called with the `smScriptValidStyles` selector, the low-order byte of the returned value is a style code that includes all of the valid styles for the script (that is, the bit corresponding to each QuickDraw style is set if that style is valid for the specified script). The value of this variable is taken from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptAliasStyle`
: (1 byte) The style to use for indicating aliases. When the `GetScriptVariable` function is called with `smScriptAliasStyle`, the low-order byte of the returned value is the style code that should be used in that script for indicating alias names (for example, in the Roman script system, alias names are indicated in italics). The value of this variable is taken from the script system's international bundle resource.

  Some script systems, such as Arabic and Hebrew, have private script-system selectors that are unique to those scripts. Those private selectors are negative, whereas selectors that extend across script systems are positive.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

Script Flag Attributes

Specify bits used to examine attributes in the script flags word.

```
enum {
    smsfIntellCP = 0,
    smsfSingByte = 1,
    smsfNatCase = 2,
    smsfContext = 3,
    smsfNoForceFont = 4,
    smsfBODigits = 5,
    smsfAutoInit = 6,
    smsfUnivExt = 7,
    smsfSynchUnstyledTE = 8,
    smsfForms = 13,
    smsfLigatures = 14,
    smsfReverse = 15,
    smfShowIcon = 31,
    smfDualCaret = 30,
    smfNameTagEnab = 29,
    smfUseAssocFontInfo = 28
};
```

Constants

`smsfIntellCP`
Specifies the script can support intelligent cut and paste (it uses spaces as word delimiters).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfSingByte`
Specifies the script has only single-byte characters.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfNatCase`
Specifies the script has both uppercase and lowercase native characters.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfContext`
Specifies the script is contextual.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfNoForceFont`
Specifies the script does not support font forcing (ignores the font force flag).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfBODigits`
Specifies the script has alternate digits at $B0–$B9. Arabic and Hebrew, for example, have their native numeric forms at this location in their character sets.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smsfAutoInit`
Specifies the script is initialized by the Script Manager. Single-byte simple script systems can set this bit to avoid having to initialize themselves.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smsfUnivExt`
Specifies the script uses the WorldScript I extension.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smsfSynchUnstyledTE`
Specifies the script synchronizes keyboard with font for monostyled TextEdit.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smsfForms`
Specifies to use contextual forms if this bit is set; do not use them if it is cleared.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smsfLigatures`
Specifies to use contextual ligatures if this bit is set; do not use them if it is cleared.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smsfReverse`
Specifies reverse right-to-left text to draw it in (left-to-right) display order if this bit is set; do not reorder text if this bit is cleared.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smfShowIcon`
Specifies to show icon even if only one script; bits in the `smGenFlags` long.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smfDualCaret`
Specifies to use dual caret for mixed direction text; bits in the `smGenFlags` long.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smfNameTagEnab`
Reserved for internal use; bits in the `smGenFlags` long.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smfUseAssocFontInfo`
Specifies to set the associated font info for `FontMetrics` calls; bits in the `smGenFlags` long.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion
These constants are available for examining attributes in the script flags word. Bits above 8 are nonstatic, meaning that they may change during program execution. (Note that the constant values represent bit numbers in the flags word, not masks.)

Script Manager Selectors

Specify selectors you can use with the functions `GetScriptManagerVariable` and `SetScriptManagerVariable`.

```
enum {
    smVersion = 0,
    smMunged = 2,
    smEnabled = 4,
    smBidirect = 6,
    smFontForce = 8,
    smIntlForce = 10,
    smForced = 12,
    smDefault = 14,
    smPrint = 16,
    smSysScript = 18,
    smLastScript = 20,
    smKeyScript = 22,
    smSysRef = 24,
    smKeyCache = 26,
    smKeySwap = 28,
    smGenFlags = 30,
    smOverride = 32,
    smCharPortion = 34,
    smDoubleByte = 36,
    smKCHRCache = 38,
    smRegionCode = 40,
    smKeyDisableState = 42
};
```

Constants
`smVersion`

The Script Manager version number (2 bytes) . This variable has the same format as the version number obtained from calling the `Gestalt` function with the Gestalt selector `gestaltScriptMgrVersion`. The high-order byte contains the major version number, and the low-order byte contains the minor version number.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smMunged`

The modification count for Script Manager variables (2 bytes) . At startup, `smMunged` is initialized to 0, and it is incremented when the `KeyScript` function changes the current keyboard script and updates the variables accessed via `smKeyScript` and `smLastScript`. The `smMunged` selector is also incremented when the `SetScriptManagerVariable` function is used to change a Script Manager variable. You can check this variable at any time to see whether any of your own data structures that may depend on Script Manager variables need to be updated.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smEnabled`

The script count (1 byte) ; the number of currently enabled script systems. At startup time, the Script Manager initializes the script count to 0, then increments it for each installed and enabled script system (including Roman). You can use `smEnabled` to determine whether more than one script system is installed—that is, whether your application needs to handle non-Roman text.

Never call `SetScriptManagerVariable` with the `smEnabled` selector. It could result in inconsistency with other script system values.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smBidirect`

The bidirectional flag, which indicates when at least one bidirectional script system is enabled. This flag is set to `TRUE` ($FF) if the Arabic or Hebrew script system is enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smFontForce`

The font force flag (1 byte). At startup, the Script Manager sets its value from the system script's international configuration (`'itlc'`) resource. The flag returns 0 for `FALSE` and $FF for `TRUE`. If the system script is non-Roman, the font force flag controls whether a font with ID in the Roman script range is interpreted as belonging to the Roman script or to the system script.

When you call `SetScriptManagerVariable` with the `smFontForce` selector, be sure to pass only the value 0 or $FF, or a later call to `GetScriptManagerVariable` may return an unrecognized value.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smIntlForce`

The international resources selection flag (1 byte). At startup, the Script Manager sets its value from the system script's international configuration (`'itlc'`) resource. The flag returns 0 for `FALSE` and `$FF` for `TRUE`. This flag controls whether international resources of the font script or the system script are used for string manipulation.

When you call `SetScriptManagerVariable` with the `smIntlForce` selector, be sure to pass only the value 0 or $FF, or a later call to `GetScriptManagerVariable` may return an unrecognized value.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smForced`

The script-forced result flag (1 byte). If the current script has been forced to the system script, this flag is set to `TRUE`. Use the `smForced` selector to obtain reports of the actions of the `FontScript`, `FontToScript`, and `IntlScript` functions. This variable is for information only; never set its value with `SetScriptManagerVariable`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smDefault`

The script-defaulted result flag (1 byte). If the script system corresponding to a specified font is not available, this flag is set to `TRUE`. Use this selector to obtain reports of the actions of the `FontScript`, `FontToScript`, and `IntlScript` functions. This variable is for information only; never set its value with `SetScriptManagerVariable`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smPrint`

The print action function vector, set up by the Script Manager at startup (4 bytes).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smSysScript`

The system script code (2 bytes) . At startup, the Script Manager initializes this variable from the system script's international configuration (`'itlc'`) resource. This variable is for information only; never set its value with `SetScriptManagerVariable`. Constants for all defined script codes are listed in "Region Codes A" (page 1798).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smLastScript`

The previously used keyboard script (2 bytes). When you change keyboard scripts with the `KeyScript` function, the Script Manager moves the old value of `smKeyScript` into `smLastScript`. `KeyScript` can also swap the current keyboard script with the previous keyboard script, in which case the contents of `smLastScript` and `smKeyScript` are swapped. Constants for all defined script codes are listed in "Region Codes A" (page 1798). Never set the value of this variable with `SetScriptManagerVariable`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smKeyScript`

The current keyboard script (2 bytes) . The `KeyScript` function tests and updates this variable. When you change keyboard scripts with the `KeyScript` function, the Script Manager moves the old value of `smKeyScript` into `smLastScript`. `KeyScript` can also swap the current keyboard script with the previous keyboard script, in which case the contents of `smLastScript` and `smKeyScript` are swapped. The Script Manager also uses this variable to get the proper keyboard icon and to retrieve the proper keyboard-layout (`'KCHR'`) resource. Constants for all defined script codes are listed in "Region Codes A" (page 1798). Never set the value of this variable directly with `SetScriptManagerVariable`; call `KeyScript` to change keyboard scripts.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smSysRef`

The System Folder volume reference number (2 bytes) . Its value is initialized from the system global variable `BootDrive` at startup.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smKeyCache`

An obsolete variable (4 bytes). This variable at one time held a pointer to the keyboard cache. The value it provided was not correct and should not be used.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smKeySwap`

A handle to the keyboard-swap (`'KSWP'`) resource (4 bytes). The Script Manager initializes the handle at startup. The keyboard-swap resource controls the key combinations with which the user can invoke various actions with the `KeyScript` function, such as switching among script systems.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smGenFlags`

The general flags used by the Script Manager (4 bytes). The Script Manager general flags is a long word value its high-order byte is set from the flags byte in the system script's international configuration (`'itlc'`) resource. These constants are available to designate bits in the variable accessed through `smGenFlags`:

- `smfNameTagEnab` (a value of 29)Reserved for internal use.
- `smfDualCaret` (a value of 30)Use a dual caret for mixed-directional text.
- `smfShowIcon` (a value of 31)Show the keyboard menu even if only one keyboard layout or one script (Roman) is available. (This bit is checked only at system startup.)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smOverride`

The script override flags (4 bytes). At present, these flags are not set or used by the Script Manager. They are, however, reserved for future use.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smCharPortion`

A value used by script systems to allocate intercharacter and interword spacing when justifying text (2 bytes). It denotes the weight allocated to intercharacter space versus interword space. The value of this variable is initialized to 10 percent by the Script Manager, although it currently has no effect on text of the Roman script system. The variable is in 4.12 fixed-point format, which is a 16-bit signed number with 4 bits of integer and 12 bits of fraction. (In that format, 10 percent has the hexadecimal value $0199.)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smDoubleByte`

The double-byte flag, a Boolean value that is `TRUE` if at least one double-byte script system is enabled. (1 byte)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smKCHRCache`

(A pointer to the cache that stores a copy of the current keyboard-layout (`'KCHR'`) resource 4 bytes).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smRegionCode`

The region code for this localized version of system software, obtained from the system script's international configuration (`'itlc'`) resource. This variable identifies the localized version of the system script. Constants for all defined region codes are listed in "Region Codes A" (page 1798) (2 bytes).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smKeyDisableState`

The current disable state for keyboards (1 byte). The Script Manager disables some keyboard scripts or keyboard switching when text input must be restricted to certain script systems or when script systems are being moved into or out of the System file. These are the possible values for the variable accessed through `smKeyDisableState`:

- 0All keyboards are enabled; switching is enabled.
- 1Keyboard switching is disabled.
- $FFKeyboards for all non-Roman secondary scripts are disabled

The script management system maintains the keyboard disable state separately for each application. Never set the value of this variable directly with `SetScriptManagerVariable`; call `KeyScript` to change the keyboard disable state for your application.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

Discussion
This section lists and describes the selector constants for accessing the Script Manager variables through calls to the `GetScriptManagerVariable` (page 1724) and `SetScriptManagerVariable` (page 1731) functions. In every case the variable parameter passed to or from the function is a long integer (4 bytes); the number in parentheses indicates how many of the 4 bytes are necessary to hold the input or return value for that variable. If fewer than 4 bytes are needed, the low byte or low word contains the information.

Script Variable Selectors

Specify script variables to get or set using the functions `GetScriptVariable` and `SetScriptVariable`.

```
enum {
    smScriptVersion = 0,
    smScriptMunged = 2,
    smScriptEnabled = 4,
    smScriptRight = 6,
    smScriptJust = 8,
    smScriptRedraw = 10,
    smScriptSysFond = 12,
    smScriptAppFond = 14,
    smScriptBundle = 16,
    smScriptNumber = 16,
    smScriptDate = 18,
    smScriptSort = 20,
    smScriptFlags = 22,
    smScriptToken = 24,
    smScriptEncoding = 26,
    smScriptLang = 28
};
```

Constants

`smScriptVersion`

The script system's version number (2 bytes). When the Script Manager loads the script system, the script system puts its current version number into this variable. The high-order byte contains the major version number, and the low-order byte contains the minor version number.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptMunged`

The modification count for this script system's script variables. (2 bytes)The Script Manager increments the variable accessed by the `smScriptMunged` selector each time the `SetScriptVariable` function is called for this script system. You can check this variable at any time to see whether any of your own data structures that depend on this script system's script variables need to be updated.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptEnabled`

The script-enabled flag, a Boolean value that indicates whether the script has been enabled (1 byte). It is set to $FF when enabled and to 0 when not enabled. Note that this variable is not equivalent to the Script Manager variable accessed by the `smEnabled` selector, which is a count of the total number of enabled script systems.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptRight`

The right-to-left flag, a Boolean value that indicates whether the primary line direction for text in this script is right-to-left or left-to-right (1 byte). It is set to $FF for right-to-left text (used in Arabic and Hebrew script systems) and to 0 for left-to-right (used in Roman and other script systems).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptJust`

The script alignment flag, a byte that specifies the default alignment for text in this script system (1 byte). It is set to $FF for right alignment (common for Arabic and Hebrew), and it is set to 0 for left alignment (common for Roman and other script systems). This flag usually has the same value as the `smScriptRight` flag.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptRedraw`

The script-redraw flag, a byte that provides redrawing recommendations for text of this script system (1 byte). It describes how much of a line should be redrawn when a user adds, inserts, or deletes text. It is set to 0 when only a character should be redrawn (used by the Roman script system), to 1 when an entire word should be redrawn (used by the Japanese script system), and to –1 when the entire line should be redrawn (used by the Arabic and Hebrew script systems). These constants are available for the script-redraw flag:

- `smRedrawChar` (a value of 0)Redraw the character only.
- `smRedrawWord` (a value of 1)Redraw the entire word.
- `smRedrawLine` (a value of –1)Redraw the entire line.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptSysFond`

The preferred system font, the font family ID of the system font preferred for this script (2 bytes). In the Roman script system, this variable specifies Chicago font, whose font family ID is 0 if Roman is the system script. The preferred system font in the Japanese script system is 16384, the font family ID for Osaka.

This variable holds similar information to the variable accessed through the `smScriptSysFondSize` selector. However, changing the value of this variable has no effect on the value accessed through `smScriptSysFondSize`.

Remember that in all localized versions of system software the special value of 0 is remapped to the system font ID. Thus, if an application running under Japanese system software specifies a font family ID of 0 in a function or in the `txFont` field of the current graphics port, Osaka will be used. However, the variable accessed by `smScriptSysFond` will still show the true ID for Osaka (16384).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Script.h`.

`smScriptAppFond`
: The preferred application font (2 bytes); the font family ID of the application font preferred for this script. In the Roman script system, the value of this variable is the font family ID for Geneva.

  This variable holds similar information to the variable accessed through the `smScriptAppFondSize` selector. However, changing the value of this variable has no effect on the value accessed through `smScriptAppFondSize`.

  Remember that in all localized versions of system software the special value of 1 is remapped to the application font ID. For example, if an application running under Arabic system software specifies a font family ID of 1 in a function, Nadeem will be used. However, the variable accessed by `smScriptSysFond` will still show the true ID for Nadeem (17926).

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptBundle`
: The beginning of `itlb` values.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptNumber`
: The resource ID of the script's numeric-format (`'itl0'`) resource (2 bytes). The numeric-format resource includes formatting information for the correct display of numbers, times, and short dates. The value of this variable is initialized from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptDate`
: The resource ID of the script's long-date-format (`'itl1'`) resource (2 bytes). The long-date-format resource includes formatting information for the correct display of long dates (dates that include month or day names). The value of this variable is initialized from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptSort`
: The resource ID of the script's string-manipulation (`'itl2'`) resource (2 bytes). The string-manipulation resource contains functions for sorting and tables for word selection, line breaks, character types, and case conversion of text. The value of this variable is initialized from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptFlags`
: The script flags word, which contains bit flags specifying attributes of the script (2 bytes). The value of this variable is initialized from the script system's international bundle resource. The "Language Codes A" (page 1782) constants are available for examining attributes in the script flags word. Bits above 8 are nonstatic, meaning that they may change during program execution. (Note that the constant values represent bit numbers in the flags word, not masks.)

  The `smsfIntellCP` flag is set if this script system uses spaces as word delimiters. In such a script system it is possible to implement intelligent cut and paste, in which extra spaces are removed when a word is cut from text, and any needed spaces are added when a word is pasted into text. Macintosh Human Interface Guidelines recommends that you implement intelligent cut and paste in script systems that support it.

  If you use the `CharToPixel` function to determine text widths, such as for line breaking, you need to clear the `smsfReverse` bit first.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptToken`
: The resource ID of the script's tokens (`'itl4'`) resource (2 bytes). The tokens resource contains information for tokenizing and number formatting. The value of this variable is initialized from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptEncoding`
: The resource ID of the script's (optional) encoding/rendering (`'itl5'`) resource (2 bytes)For single-byte scripts, the encoding/rendering resource specifies text-rendering behavior for double-byte scripts, it specifies character-encoding information. The value of this variable is taken from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

`smScriptLang`
: The language code for this version of the script. A language is a specialized variation of a specific script system (2 bytes). Constants for all defined language codes are listed in "Language Codes A" (page 1782). The value of this variable is initialized from the script system's international bundle resource.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `Script.h`.

Discussion
This section lists and describes the selector constants for accessing script variables through calls to the `GetScriptManagerVariable` (page 1724) and `SetScriptManagerVariable` (page 1731) functions. In every case the variable parameter passed to or from the function is a long integer (4 bytes); the number in parentheses indicates how many of the 4 bytes are necessary to hold the input or return value for that variable. If fewer than 4 bytes are needed, the low byte or low word contains the information.

In many cases the value of a script variable is taken from the script system's international bundle (`'itlb'`) resource.

Script Token Types

Specify script token types.

```
enum {
    tokenIntl = 4,
    tokenEmpty = -1
};
```

Constants

`tokenIntl`

The `'itl'` resource number of the tokenizer.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`tokenEmpty`

Represents an empty flag.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Source Masks

Specify general transliterate text source masks.

```
enum {
    smMaskAll = 0xFFFFFFFF,
    smMaskAscii = 0x00000001,
    smMaskNative = 0x00000002,
    smMaskAscii1 = 0x00000004,
    smMaskAscii2 = 0x00000008,
    smMaskKana1 = 0x00000010,
    smMaskKana2 = 0x00000020,
    smMaskGana2 = 0x00000080,
    smMaskHangul2 = 0x00000100,
    smMaskJamo2 = 0x00000200,
    smMaskBopomofo2 = 0x00000400
};
```

Table Selectors

Specify selectors for the international table

```
enum {
    smWordSelectTable = 0,
    smWordWrapTable = 1,
    smNumberPartsTable = 2,
    smUnTokenTable = 3,
    smWhiteSpaceList = 4,
    iuWordSelectTable = 0,
    iuWordWrapTable = 1,
    iuNumberPartsTable = 2,
    iuUnTokenTable = 3,
    iuWhiteSpaceList = 4
};
```

Constants

`smWordSelectTable`
Specifies to get the word select break table from `'itl2'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smWordWrapTable`
Specifies to get the word wrap break table from `'itl2'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smNumberPartsTable`
Specifies to get the default number parts table from `'itl4'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smUnTokenTable`
Specifies to get the `unToken` table from `'itl4'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smWhiteSpaceList`
Specifies to get the white space list from `'itl4'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`iuWordSelectTable`
Obsolete; specifies to get the word select break table from `'itl2'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`iuWordWrapTable`
Obsolete; specifies to get the word wrap break table from `'itl2'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`iuNumberPartsTable`
Obsolete; specifies to get the default number parts table from `''itl4'`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`iuUnTokenTable`
Obsolete; specifies to get the `unToken` table from `'itl4'`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`iuWhiteSpaceList`
Obsolete; specifies to get the white space list from `'itl4'`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion
These constants can be used as the value of the `tableCode` variable, passed as a parameter to the `GetIntlResourceTable` (page 1723) function.

Transliteration Target Types 1

Specify transliterate text target types for Roman or for double-byte scripts

```
enum {
    smTransAscii = 0,
    smTransNative = 1,
    smTransCase = 0xFE,
    smTransSystem = 0xFF,
    smTransAscii1 = 2,
    smTransAscii2 = 3,
    smTransKana1 = 4,
    smTransKana2 = 5
};
```

Constants
`smTransAscii`
Specifies to convert to ASCII.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smTransNative`
Specifies to convert to the font script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smTransCase`
Specifies to convert case for all text.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smTransSystem`
Specifies to convert to the system script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`smTransAscii1`
Specifies to single-byte Roman.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransAscii2`
Specifies to double-byte Roman.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransKana1`
Specifies to single-byte Japanese Katakana.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransKana2`
Specifies to double-byte Japanese Katakana.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Transliteration Target Types 2

Specify transliteration targets for double-byte script systems.

```
enum {
    smTransGana2 = 7,
    smTransHangul2 = 8,
    smTransJamo2 = 9,
    smTransBopomofo2 = 10,
    smTransLower = 0x4000,
    smTransUpper = 0x8000,
    smTransRuleBaseFormat = 1,
    smTransHangulFormat = 2,
    smTransPreDoubleByting = 1,
    smTransPreLowerCasing = 2
};
```

Constants

`smTransGana2`
Specifies double-byte Japanese Hiragana (no single-byte Hiragana).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransHangul2`
Specfies double-byte Korean Hangul.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransJamo2`
Specifies double-byte Korean Jamo.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransBopomofo2`
Specifies double-byte Chinese Bopomofo.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransLower`
Specifies target becomes lowercase.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransUpper`
Specifies target becomes uppercase .
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransRuleBaseFormat`
Specifies rule-based `trsl` resource format.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransHangulFormat`
Specifies table-based Hangul `trsl` resource format.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransPreDoubleByting`
Specifies to convert all text to double byte before transliteration.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`smTransPreLowerCasing`
Specifies to convert all text to lower case before transliteration.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Language Codes

Language Codes A

Specify language codes (values 0 though 23).

```
enum {
    langEnglish = 0,
    langFrench = 1,
    langGerman = 2,
    langItalian = 3,
    langDutch = 4,
    langSwedish = 5,
    langSpanish = 6,
    langDanish = 7,
    langPortuguese = 8,
    langNorwegian = 9,
    langHebrew = 10,
    langJapanese = 11,
    langArabic = 12,
    langFinnish = 13,
    langGreek = 14,
    langIcelandic = 15,
    langMaltese = 16,
    langTurkish = 17,
    langCroatian = 18,
    langTradChinese = 19,
    langUrdu = 20,
    langHindi = 21,
    langThai = 22,
    langKorean = 23
};
```

Constants

`langEnglish`
Represents the English language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langFrench`
Represents the French language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGerman`
Represents the German language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langItalian`
Represents the Italian language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langDutch`
Represents the Dutch language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSwedish`
Represents the Swedish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSpanish`
Represents the Spanish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langDanish`
Represents the Danish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langPortuguese`
Represents the Portuguese language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langNorwegian`
Represents the Norwegian language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langHebrew`
Represents the Hebrew language. The associated script code is `smHebrew`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langJapanese`
Represents the Japanese language. The associated script code is `smJapanese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langArabic`
Represents the Arabic language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langFinnish`
Represents the Finnish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGreek`
Represents the Greek language. The associated script code is `smGreek`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langIcelandic`
Represents the Icelandic language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMaltese`
Represents the Maltese language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTurkish`
Represents the Turkish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langCroatian`
Represents the Croatian language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTradChinese`
Represents the Chinese (traditional chararacters) language. The associated script code is `smTradChinese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langUrdu`
Represents the Urdu language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langHindi`
Represents the Hindi language. The associated script code is `smDevanagari`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langThai`
Represents the Thai language. The associated script code is `smThai`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKorean`
Represents the Korean language. The associated script code is `smKorean`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Language Codes B

Specify language codes (values 24 though 46).

```
enum {
    langLithuanian = 24,
    langPolish = 25,
    langHungarian = 26,
    langEstonian = 27,
    langLatvian = 28,
    langSami = 29,
    langFaroese = 30,
    langFarsi = 31,
    langPersian = 31,
    langRussian = 32,
    langSimpChinese = 33,
    langFlemish = 34,
    langIrishGaelic = 35,
    langAlbanian = 36,
    langRomanian = 37,
    langCzech = 38,
    langSlovak = 39,
    langSlovenian = 40,
    langYiddish = 41,
    langSerbian = 42,
    langMacedonian = 43,
    langBulgarian = 44,
    langUkrainian = 45,
    langByelorussian = 46,
    langBelorussian = 46
};
```

Constants

`langLithuanian`
Represents the Lithuanian language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langPolish`
Represents the Polish language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langHungarian`
Represents the Hungarian language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langEstonian`
Represents the Estonian language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langLatvian`
Represents the Lettish language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSami`
Represents the language of the Sami people of northern Scandinavia.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langFaroese`
Modified `smRoman`/Icelandic script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langFarsi`
Represents the Farsi language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langPersian`
Represents the Farsi language. The associated script code is `smArabic`. This is the same as the language code `langFarsi`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langRussian`
Represents the Russian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSimpChinese`
Represents the Chinese (simplified chararacters) language. The associated script code is `smSimpChinese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langFlemish`
Represents the Flemish language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langIrishGaelic`
Represents Irish Gaelic. The associated script code is `smRoman` or modified `smRoman`/Celtic script (without dot above).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAlbanian`
Represents the Albanian language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langRomanian`
Represents the Romanian language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langCzech`
Represents the Czech language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSlovak`
Represents the Slovak language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSlovenian`
Represents the Slovenian language. The associated script code is `smEastEurRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langYiddish`
Represents the Yiddish language. The associated script code is `smHebrew`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSerbian`
Represents the Serbian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMacedonian`
Represents the Macedonian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langBulgarian`
Represents the Bulgarian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langUkrainian`
Represents the Ukrainian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langByelorussian`
Represents the Byelorussian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langBelorussian`
Represents a synonym for `langByelorussian`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Language Codes C

Specify language codes (values 47 though 70).

```
enum {
    langUzbek = 47,
    langKazakh = 48,
    langAzerbaijani = 49,
    langAzerbaijanAr = 50,
    langArmenian = 51,
    langGeorgian = 52,
    langMoldavian = 53,
    langKirghiz = 54,
    langTajiki = 55,
    langTurkmen = 56,
    langMongolian = 57,
    langMongolianCyr = 58,
    langPashto = 59,
    langKurdish = 60,
    langKashmiri = 61,
    langSindhi = 62,
    langTibetan = 63,
    langNepali = 64,
    langSanskrit = 65,
    langMarathi = 66,
    langBengali = 67,
    langAssamese = 68,
    langGujarati = 69,
    langPunjabi = 70
};
```

Constants

`langUzbek`

Represents the Uzbek language. The associated script code is `smCyrillic`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langKazakh`

Represents the Kazakh language. The associated script code is `smCyrillic`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langAzerbaijani`

Represents the Azerbaijani language. The associated script code is `smCyrillic`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langAzerbaijanAr`

Represents the Azerbaijani language. The associated script code is `smArabic`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langArmenian`
Represents the Armenian language. The associated script code is `smArmenian`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGeorgian`
Represents the Georgian language. The associated script code is `smGeorgian`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMoldavian`
Represents the Moldovan language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKirghiz`
Represents the Kirghiz language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTajiki`
Represents the Tajiki language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTurkmen`
Represents the Turkmen language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMongolian`
Represents the Mongolian language. The associated script code is `smMongolian`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMongolianCyr`
Represents the Mongolian language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langPashto`
Represents the Pashto language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKurdish`
Represents the Kurdish language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKashmiri`
Represents the Kashmiri language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSindhi`
Represents the Sindhi language. The associated script code is `smExtArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTibetan`
Represents the Tibetan language. The associated script code is `smTibetan`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langNepali`
Represents the Nepali language. The associated script code is `smDevanagari`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSanskrit`
Represents the Sanskrit language. The associated script code is `smDevanagari`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMarathi`
Represents the Marathi language. The associated script code is `smDevanagari`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langBengali`
Represents the Bengali language. The associated script code is `smBengali`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAssamese`
Represents the Assamese language. The associated script code is `smBengali`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGujarati`
Represents the Gujarati language. The associated script code is `smGujarati`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langPunjabi`
Represents the Punjabi language. The associated script code is `smGurmukhi`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Language Codes D

Specify language codes (values 71 though 94).

```
enum {
    langOriya = 71,
    langMalayalam = 72,
    langKannada = 73,
    langTamil = 74,
    langTelugu = 75,
    langSinhalese = 76,
    langBurmese = 77,
    langKhmer = 78,
    langLao = 79,
    langVietnamese = 80,
    langIndonesian = 81,
    langTagalog = 82,
    langMalayRoman = 83,
    langMalayArabic = 84,
    langAmharic = 85,
    langTigrinya = 86,
    langOromo = 87,
    langSomali = 88,
    langSwahili = 89,
    langKinyarwanda = 90,
    langRuanda = 90,
    langRundi = 91,
    langNyanja = 92,
    langChewa = 92,
    langMalagasy = 93,
    langEsperanto = 94
};
```

Constants

`langOriya`
Represents the Oriya language. The associated script code is `smOriya`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMalayalam`
Represents the Malayalam language. The associated script code is `smMalayalam`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKannada`
Represents the Kannada language. The associated script code is `smKannada`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTamil`
Represents the Tamil language. The associated script code is `smTamil`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTelugu`
Represents the Telugu language. The associated script code is `smTelugu`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSinhalese`
Represents the Sinhalese language. The associated script code is `smSinhalese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langBurmese`
Represents the Burmese language. The associated script code is `smBurmese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKhmer`
Represents the Khmer language. The associated script code is `smKhmer`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langLao`
Represents the Lao language. The associated script code is `smLaotian`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langVietnamese`
Represents the Vietnamese language. The associated script code is `smVietnamese`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langIndonesian`
Represents the Indonesian language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTagalog`
Represents the Tagalog language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMalayRoman`
Represents the Malay language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMalayArabic`
Represents the Malay language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAmharic`
Represents the Amharic language. The associated script code is `smEthiopic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTigrinya`
Represents the Tigrinya language. The associated script code is `smEthiopic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langOromo`
Represents the Galla language. The associated script code is `smEthiopic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSomali`
Represents the Somali language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSwahili`
Represents the Swahili language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langKinyarwanda`
The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langRuanda`
Represents the Ruanda language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langRundi`
Represents the Rundi language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langNyanja`
The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langChewa`
Represents the Chewa language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langMalagasy`
Represents the Malagasy language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langEsperanto`
Represents the Esperanto language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Language Codes E

Specify lanaguage codes (values 128 though 141).

```
enum {
    langWelsh = 128,
    langBasque = 129,
    langCatalan = 130,
    langLatin = 131,
    langQuechua = 132,
    langGuarani = 133,
    langAymara = 134,
    langTatar = 135,
    langUighur = 136,
    langDzongkha = 137,
    langJavaneseRom = 138,
    langSundaneseRom = 139,
    langGalician = 140,
    langAfrikaans = 141
};
```

Constants

`langWelsh`
Represents the Welsh language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langBasque`
Represents the Basque language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langCatalan`
Represents the Catalan language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langLatin`
Represents the Latin language. The associated script code is `smRoman`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`langQuechua`
Represents the Quechua language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGuarani`
Represents the Guarani language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAymara`
Represents the Aymara language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTatar`
Represents the Tatar language. The associated script code is `smCyrillic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langUighur`
Represents the Uighar language. The associated script code is `smArabic`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langDzongkha`
Represents the Bhutanese language. The associated script code is `smTibetan`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langJavaneseRom`
Represents the Javanese language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langSundaneseRom`
Represents the Sundanese language. The associated script code is `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGalician`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAfrikaans`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Language Codes F

Specify language codes (values 142 through 150).

```
enum {
    langBreton = 142,
    langInuktitut = 143,
    langScottishGaelic = 144,
    langManxGaelic = 145,
    langIrishGaelicScript = 146,
    langTongan = 147,
    langGreekPoly = 148,
    langGreenlandic = 149,
    langAzerbaijanRoman = 150
};
```

Constants

`langBreton`
The associated script code is `smRoman` or modified `smRoman`/Celtic script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langInuktitut`
Inuit script using `smEthiopic` script code
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langScottishGaelic`
The associated script code is smRoman or modified `smRoman`/Celtic script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langManxGaelic`
The associated script code is `smRoman` or modified `smRoman`/Celtic script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langIrishGaelicScript`
The associated script code is modified `smRoman`/Gaelic script (using dot above).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langTongan`
The associated script code is `smRoman` script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGreekPoly`
The associated script code is `smGreek` script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langGreenlandic`
The associated script code is `smRoman` script
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`langAzerbaijanRoman`
Represents the Azerbaijani language. The associated script code is `Roman` script.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Language Code - Unspecified

Indicates the language is not specified.

```
enum {
    langUnspecified = 32767
};
```

Region Codes

Range Checking Region Code

Specify values for the the minimum and maximum defined region codes.

```
enum {
    minCountry = verUS,
    maxCountry = verGreenland
};
```

Constants

`minCountry`
The lowest defined region code (for range-checking); currently this is equal to the region code `verUS`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`maxCountry`
The highest defined region code (for range-checking); currently this is equal to the region code `verThailand`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Region Codes A

Specify codes for a variety of regions (values 0 - 25).

```
enum {
    verUS = 0,
    verFrance = 1,
    verBritain = 2,
    verGermany = 3,
    verItaly = 4,
    verNetherlands = 5,
    verFlemish = 6,
    verSweden = 7,
    verSpain = 8,
    verDenmark = 9,
    verPortugal = 10,
    verFrCanada = 11,
    verNorway = 12,
    verIsrael = 13,
    verJapan = 14,
    verAustralia = 15,
    verArabic = 16,
    verFinland = 17,
    verFrSwiss = 18,
    verGrSwiss = 19,
    verGreece = 20,
    verIceland = 21,
    verMalta = 22,
    verCyprus = 23,
    verTurkey = 24,
    verYugoCroatian = 25
};
```

Constants

`verUS`
Represents the region of the United States.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFrance`
Represents the region of France.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verBritain`
Represents the region of Great Britain.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verGermany`
Represents the region of Germany.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verItaly`
Represents the region of Italy.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verNetherlands`
Represents the region of the Netherlands.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFlemish`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verSweden`
Represents the region of Sweden.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verSpain`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verDenmark`
Represents the region of Denmark.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verPortugal`
Represents the region of Portugal.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFrCanada`
Represents the French Canadian region.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verNorway`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verIsrael`
Represents the region of Israel.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verJapan`
Represents the region of Japan.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verAustralia`
Represents the region of Australia.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verArabic`
Represents the Arabic world. This is the same as the region code `verArabia`.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFinland`
Represents the region of Finland.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFrSwiss`
Represents French for the region of Switzerland.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verGrSwiss`
Represents German for the region of Switzerland.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verGreece`
Represents the region of Greece.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verIceland`
Represents the region of Iceland.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verMalta`
Represents the region of Malta.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verCyprus`
Represents the region of Cyprus.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verTurkey`
Represents the region of Turkey.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verYugoCroatian`
Represents the Croatian system for the region of Yugoslavia.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Discussion
Each region is associated with a particular language code and script code (not shown). The existence of a defined region code does not necessarily imply the existence of a version of Macintosh system software localized for that region.

Region Codes B

Specify region codes (values 26 though 32).

```
enum {
    verNetherlandsComma = 26,
    verBelgiumLuxPoint = 27,
    verCanadaComma = 28,
    verCanadaPoint = 29,
    vervariantPortugal = 30,
    vervariantNorway = 31,
    vervariantDenmark = 32
};
```

Constants

`verNetherlandsComma`
Specifies Dutch.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verBelgiumLuxPoint`
Specifies Belgium.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verCanadaComma`
Specifies Canadian ISO.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verCanadaPoint`
Specifies Canadian; now unused.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`vervariantPortugal`
Unused.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`vervariantNorway`
Unused.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`vervariantDenmark`
Specifies Danish Mac Plus.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Region Codes C

Specify region codes (values 33 through 61).

```
enum {
    verIndiaHindi = 33,
    verPakistanUrdu = 34,
    verTurkishModified = 35,
    verItalianSwiss = 36,
    verInternational = 37,
    verRomania = 39,
    verGreecePoly = 40,
    verLithuania = 41,
    verPoland = 42,
    verHungary = 43,
    verEstonia = 44,
    verLatvia = 45,
    verSami = 46,
    verFaroeIsl = 47,
    verIran = 48,
    verRussia = 49,
    verIreland = 50,
    verKorea = 51,
    verChina = 52,
    verTaiwan = 53,
    verThailand = 54,
    verScriptGeneric = 55,
    verCzech = 56,
    verSlovak = 57,
    verFarEastGeneric = 58,
    verMagyar = 59,
    verBengali = 60,
    verByeloRussian = 61
};
```

Constants

`verIndiaHindi`
The Hindi system for the region of India; hi_IN..

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verPakistanUrdu`
Urdu for Pakistan; ur_PK.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verTurkishModified`
Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verItalianSwiss`
Italian Swiss; it_CH.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verInternational`
English for international use; Z en.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verRomania`
Romaniza; ro_RO
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verGreecePoly`
Polytonic Greek (classical); grc.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verLithuania`
Lithuania; lt_LT.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verPoland`
Poland; pl_PL.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verHungary`
Represents the region of Hungary; hu_HU.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verEstonia`
Represents the region of Estonia; et_EE.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verLatvia`
Represents the region of Latvia; lv_LV.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verSami`
se.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verFaroeIsl`
fo_FO.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verIran`
Persian/Farsi Represents the region of Iran; fa_IR .
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verRussia`
Represents the region of Russia; ru_RU.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verIreland`
Represents Irish Gaelic for Ireland (without dot above); ga_IE.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verKorea`
Represents the region of Korea; ko_KR.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verChina`
Simplified Chinese; zh_CN.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verTaiwan`
Traditional Chinese; zh_TW.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verThailand`
Represents the region of Thailand; th_TH.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verScriptGeneric`
Generic script system (no language or script).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verCzech`
cs_CZ.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`verSlovak`
sk_SK.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verFarEastGeneric`
Generic Far East system (no language or script).

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verMagyar`
Unused; see `verHungary`.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verBengali`
Bangladesh or India; bn.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`verByeloRussian`
be_B,

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Region Codes D

Specify region codes (values 62 through 97).

```
enum {
    verUkraine = 62,
    verGreeceAlt = 64,
    verSerbian = 65,
    verSlovenian = 66,
    verMacedonian = 67,
    verCroatia = 68,
    verGermanReformed = 70,
    verBrazil = 71,
    verBulgaria = 72,
    verCatalonia = 73,
    verMultilingual = 74,
    verScottishGaelic = 75,
    verManxGaelic = 76,
    verBreton = 77,
    verNunavut = 78,
    verWelsh = 79,
    verIrishGaelicScript = 81,
    verEngCanada = 82,
    verBhutan = 83,
    verArmenian = 84,
    verGeorgian = 85,
    verSpLatinAmerica = 86,
    verTonga = 88,
    verFrenchUniversal = 91,
    verAustria = 92,
    verGujarati = 94,
    verPunjabi = 95,
    verIndiaUrdu = 96,
    verVietnam = 97
};
```

Regions Codes E

Specify region codes (values 98 through 109).

```
enum {
    verFrBelgium = 98,
    verUzbek = 99,
    verSingapore = 100,
    verNynorsk = 101,
    verAfrikaans = 102,
    verEsperanto = 103,
    verMarathi = 104,
    verTibetan = 105,
    verNepal = 106,
    verGreenland = 107,
    verIrelandEnglish = 108
};
```

Token Constants

Tokens - Mathematical

Specify tokens used in mathematical operations.

```
enum {
    tokenLeftCurly = 20,
    tokenRightCurly = 21,
    tokenLeftEnclose = 22,
    tokenRightEnclose = 23,
    tokenPlus = 24,
    tokenMinus = 25,
    tokenAsterisk = 26,
    tokenDivide = 27,
    tokenPlusMinus = 28,
    tokenSlash = 29,
    tokenBackSlash = 30,
    tokenLess = 31,
    tokenGreat = 32,
    tokenEqual = 33,
    tokenLessEqual2 = 34,
    tokenLessEqual1 = 35,
    tokenGreatEqual2 = 36,
    tokenGreatEqual1 = 37,
    token2Equal = 38,
    tokenColonEqual = 39
};
```

Constants

`tokenLeftCurly`

Represents an opening curly bracket.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`tokenRightCurly`

Represents a closing curly bracket.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`tokenLeftEnclose`
Represents an opening European double quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightEnclose`
Represents a closing European double quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPlus`
Represents a plus sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenMinus`
Represents a minus sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAsterisk`
Represents a times/multiply sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenDivide`
Represents a divide.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPlusMinus`
Represents a plus-or-minus symbol.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenSlash`
Represents a slash.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenBackSlash`
Represents a backslash.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLess`
Represents a less than sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenGreat`
Represents a greater than sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenEqual`
Represents an equal.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLessEqual2`
Represents a less than or equal to sign (2 symbols).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLessEqual1`
Represents a less than or equal to sign (1 symbol).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenGreatEqual2`
Represents a greater than or equal to sign (2 symbols).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenGreatEqual1`
Represents a greater-than-or-equal-to sign (1 symbol).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`token2Equal`
Represents a double equal sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenColonEqual`
Represents a colon equal sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Tokens - Punctuation

Specify tokens for various punctuation marks.

```
enum {
    tokenNotEqual = 40,
    tokenLessGreat = 41,
    tokenExclamEqual = 42,
    tokenExclam = 43,
    tokenTilde = 44,
    tokenComma = 45,
    tokenPeriod = 46,
    tokenLeft2Quote = 47,
    tokenRight2Quote = 48,
    tokenLeft1Quote = 49,
    tokenRight1Quote = 50,
    token2Quote = 51,
    token1Quote = 52,
    tokenSemicolon = 53,
    tokenPercent = 54,
    tokenCaret = 55,
    tokenUnderline = 56,
    tokenAmpersand = 57,
    tokenAtSign = 58,
    tokenBar = 59
};
```

Constants

`tokenNotEqual`
Represents a not equal sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLessGreat`
Represents a less/greater sign (not equal in Pascal).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenExclamEqual`
Represents an exclamation equal sign (not equal in C).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenExclam`
Represents as exclamation point.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenTilde`
Represents a centered tilde.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenComma`
Represents a comma.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPeriod`
Represents a period.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeft2Quote`
Represents an opening double quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRight2Quote`
Represents a closing double quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeft1Quote`
Represents an opening single quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRight1Quote`
Represents a closing single quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`token2Quote`
Represents a double quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`token1Quote`
Represents a single quote.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenSemicolon`
Represents a semicolon.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPercent`
Represents a percent sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenCaret`
Represents a caret.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenUnderline`
Represents an underline.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAmpersand`
Represents an ampersand.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAtSign`
Represents an at sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenBar`
Represents a vertical bar.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Tokens for Symbols

Specify tokens for various symbols.

```
enum {
    tokenQuestion = 60,
    tokenPi = 61,
    tokenRoot = 62,
    tokenSigma = 63,
    tokenIntegral = 64,
    tokenMicro = 65,
    tokenCapPi = 66,
    tokenInfinity = 67,
    tokenColon = 68,
    tokenHash = 69,
    tokenDollar = 70,
    tokenNoBreakSpace = 71,
    tokenFraction = 72,
    tokenIntlCurrency = 73,
    tokenLeftSingGuillemet = 74,
    tokenRightSingGuillemet = 75,
    tokenPerThousand = 76,
    tokenEllipsis = 77,
    tokenCenterDot = 78,
    tokenNil = 127
};
```

Constants

`tokenQuestion`
Represents a question mark.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPi`
Represents a Pi token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRoot`
Represents a square root sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenSigma`
Represents a capital sigma.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenIntegral`
Represents an integral sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenMicro`
Represents a micro.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenCapPi`
Represents a capital pi.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenInfinity`
Represents an infinity sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenColon`
Represents a colon.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenHash`
Represents a pound sign (U.S. weight).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenDollar`
Represents a dollar sign.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenNoBreakSpace`
Represents a nonbreaking space.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenFraction`
Represents a fraction.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenIntlCurrency`
Represents an international currency token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeftSingGuillemet`
Represents an opening single guillemet.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightSingGuillemet`
Represents a closing single guillemet.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenPerThousand`
Represents a per thousands token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenEllipsis`
Represents an ellipsis character.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenCenterDot`
Represents a center dot.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenNil`
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Token Types

Specify types of tokens.

```
enum {
    tokenUnknown = 0,
    tokenWhite = 1,
    tokenLeftLit = 2,
    tokenRightLit = 3,
    tokenAlpha = 4,
    tokenNumeric = 5,
    tokenNewLine = 6,
    tokenLeftComment = 7,
    tokenRightComment = 8,
    tokenLiteral = 9,
    tokenEscape = 10,
    tokenAltNum = 11,
    tokenRealNum = 12,
    tokenAltReal = 13,
    tokenReserve1 = 14,
    tokenReserve2 = 15,
    tokenLeftParen = 16,
    tokenRightParen = 17,
    tokenLeftBracket = 18,
    tokenRightBracket = 19
};
```

Constants

`tokenUnknown`
Has no existing token type.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenWhite`
Represents a whitespace character.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeftLit`
Represents an opening literal marker.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightLit`
Represents a closing literal marker.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAlpha`
Represents an alphabetic token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenNumeric`
Represents a numeric token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenNewLine`
Represents a new line.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeftComment`
Represents an opening comment marker.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightComment`
Represents a closing comment marker.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLiteral`
Represents a literal token.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenEscape`
Represents an escape character.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAltNum`
Represents an alternate number (such as at $B0–$B9).
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRealNum`
Represents a real number.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenAltReal`
Represents an alternate real number.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenReserve1`
Reserved.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenReserve2`
Reserved.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeftParen`
Represents an opening parenthesis.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightParen`
Represents a closing parenthesis.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenLeftBracket`
Represents an opening square bracket.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenRightBracket`
Represents a closing square bracket.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

Token Results

Specify token conditions returned by the function `IntlTokenize`.

```
enum {
    tokenOK = 0,
    tokenOverflow = 1,
    stringOverflow = 2,
    badDelim = 3,
    badEnding = 4,
    crash = 5
};
typedef SInt8 TokenResults;
```

Constants

`tokenOK`
Indicates the function exectured without error.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`tokenOverflow`
Indicates a token overflow.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`stringOverflow`
Indicates a string overflow.
Available in Mac OS X v10.0 and later.
Declared in `Script.h`.

`badDelim`
Indicates a bad delimiter,

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`badEnding`
Indicates a bad ending.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

`crash`
Indicates a crash.

Available in Mac OS X v10.0 and later.

Declared in `Script.h`.

Discussion
Token results are returned by the function `IntlTokenize` (page 1729).

Obsolete Constants

Obsolete Language Codes

Specify obsolete language codes provided for backward compatibility.

```
enum {
    langPortugese = 8,
    langMalta = 16,
    langYugoslavian = 18,
    langChinese = 19,
    langLettish = 28,
    langLapponian = 29,
    langLappish = 29,
    langSaamisk = 29,
    langFaeroese = 30,
    langIrish = 35,
    langGalla = 87,
    langAfricaans = 141
};
```

Discussion
These are obsolete language code names kept for backward compatibility. They have one or more of the following problems: misspelled, ambiguous, misleading, archaic, inappropriate.

Obsolete Regions Codes

Specfiy obsolete region code names provided for backward compatibility.

```
enum {
    verFrBelgiumLux = 6,
    verBelgiumLux = 6,
    verArabia = 16,
    verYugoslavia = 25,
    verIndia = 33,
    verPakistan = 34,
    verRumania = 39,
    verGreekAncient = 40,
    verLapland = 46,
    verFaeroeIsl = 47,
    verGenericFE = 58,
    verBelarus = 61,
    verUkrania = 62,
    verAlternateGr = 64,
    verSerbia = 65,
    verSlovenia = 66,
    verMacedonia = 67,
    verBrittany = 77,
    verWales = 79,
    verArmenia = 84,
    verGeorgia = 85,
    verAustriaGerman = 92,
    verTibet = 105
};
```

Discussion
Obsolete region code names (kept for backward compatibility): Misspelled or alternate form, ambiguous, misleading, considered pejorative, archaic, etc.

Obsolete Roman Script Constants

Specify obsolete constants provided for backward compatibility.

```
enum {
    romanSysFond = 0x3FFF,
    romanAppFond = 3,
    romanFlags = 0x0007,
    smFondStart = 0x4000,
    smFondEnd = 0xC000,
    smUprHalfCharSet = 0x80
};
```

Discussion
You should use the function `GetScriptVariable` (page 1726) to obtain the information specified by these constants.

Obsolete Script Codes

Specify obsolete script code names provided for backward compatibility.

```
enum {
    smChinese = 2,
    smRussian = 7,
    smLaotian = 22,
    smAmharic = 28,
    smSlavic = 29,
    smEastEurRoman = 29,
    smSindhi = 31,
    smKlingon = 32
};
```

Obsolete System Script Codes

Specify obsolete script code values for International Utilities provided for backward compatibility.

```
enum {
    iuSystemScript = -1,
    iuCurrentScript = -2
};
```

Obsolete Token Codes

Specify obsolete token names provided for backward compatibility.

```
enum {
    delimPad = -2,
    tokenTilda = 44,
    tokenCarat = 55
};
```

Result Codes

The most common result codes returned by Script Manager are listed below.

Result Code	Value	Description
`smNotInstalled`	0	Routine not available in script. Available in Mac OS X v10.0 and later.
`smBadVerb`	-1	Bad verb passed to a routine. Available in Mac OS X v10.0 and later.
`smBadScript`	-2	Bad script code passed to a routine. Available in Mac OS X v10.0 and later.

SCSI Manager Reference (Not Recommended)

Framework: CoreServices/CoreServices.h

Declared in SCSI.h

Overview

Carbon supports only the `SCSIAction` function in the SCSI Manager, although this function is no longer recommended. For Mac OS X, the I/O Kit should be used to support more complex SCSI devices.

Important: The SCSI Manager is deprecated in Mac OS X v10.2 and later. You should use I/O Kit to support SCSI devices instead. For more information, see *SCSI Architecture Model Device Interface Guide*.

Functions

DisposeSCSICallbackUPP

Disposes of a UPP to a completion routine. (Deprecated in Mac OS X v10.2. There is no replacement function. For details about communicating with SCSI devices in Mac OS X v10.2 and later, see *SCSI Architecture Model Device Interface Guide*.)

Not recommended

```
void DisposeSCSICallbackUPP (
   SCSICallbackUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.2.
Not available to 64-bit applications.

Declared In
`SCSI.h`

InvokeSCSICallbackUPP

Calls your completion routine. (Deprecated in Mac OS X v10.2. There is no replacement function. For details about communicating with SCSI devices in Mac OS X v10.2 and later, see *SCSI Architecture Model Device Interface Guide*.)

Not recommended

```
void InvokeSCSICallbackUPP (
   void *scsiPB,
   SCSICallbackUPP userUPP
);
```

Discussion
You should not have to call the `InvokeSCSICallbackUPP` function as the system calls your completion routine for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.2.
Not available to 64-bit applications.

Declared In
`SCSI.h`

NewSCSICallbackUPP

Creates a new universal procedure pointer (UPP) to a completion routine. (Deprecated in Mac OS X v10.2. There is no replacement function. For details about communicating with SCSI devices in Mac OS X v10.2 and later, see *SCSI Architecture Model Device Interface Guide*.)

Not recommended

```
SCSICallbackUPP NewSCSICallbackUPP (
   SCSICallbackProcPtr userRoutine
);
```

Return Value
See the description of the `SCSICallbackUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.2.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSIAction

Initiates a SCSI transaction or request a service from the XPT or SIM. (Deprecated in Mac OS X v10.2. There is no replacement function. For details about communicating with SCSI devices in Mac OS X v10.2 and later, see *SCSI Architecture Model Device Interface Guide*.)

Not recommended

```
OSErr SCSIAction (
   SCSI_PB *parameterBlock
);
```

Parameters

parameterBlock

A pointer to a SCSI Manager parameter block.

Return Value

A result code. See "SCSI Manager Result Codes" (page 1863).

Discussion

The `SCSIAction` function initiates the request specified by the `scsiFunctionCode` field of the parameter block. Certain types of requests are handled by the XPT, but most are handled by the SIM.

When called asynchronously, `SCSIAction` normally returns the `NoErr` result code, indicating that the request was queued successfully. The result of the SCSI transaction is returned in the `scsiResult` field upon completion. If the `SCSIAction` function returns an error code, the request was not queued and the completion routine will not be called.

When the completion routine is called, it receives the A5 world that existed when the `SCSIAction` request was received. If A5 was invalid when the request was made, it is also invalid in the completion routine.

Your completion routine should use the following function prototype:

```
pascal void (*CallbackProc) (void * scsiPB);
```

There is no implied ordering of asynchronous requests made to different devices. An earlier request may be started later, and a later request may complete earlier. However, a series of requests to the same device is issued to that device in the order received, except when the `scsiSIMQHead` flag is set in the `scsiFlags` field of the parameter block.

When called synchronously, the `SCSIAction` function returns the actual result of the operation. It also places this result in the `scsiResult` field.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.2.

Not available to 64-bit applications.

Declared In

`SCSI.h`

Callbacks

SCSICallbackProcPtr

Defines a pointer to a completion routine.

```
typedef void (*SCSICallbackProcPtr) (
    void * scsiPB
);
```

If you name your function `MySCSICallbackProc`, you would declare it like this:

```
void MySCSICallbackProc (
    void * scsiPB
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

Data Types

CDB

You use the command descriptor block record to pass SCSI commands to the `SCSIAction` function.

```
union CDB {
    BytePtr cdbPtr;
    UInt8 cdbBytes[16];
};
typedef union CDB CDB;
typedef CDB * CDBPtr;
```

Fields

`cdbPtr`
A pointer to a buffer containing a CDB.

`cdbBytes`
A buffer in which you can place a CDB.

Discussion
The SCSI commands can be stored within this structure, or you can provide a pointer to them. You set the `scsiCDBIsPointer` flag in the SCSI parameter block if this record contains a pointer.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

DeviceIdent

You use the device identification record to specify a target device by its bus, SCSI ID, and logical unit number (LUN).

```
struct DeviceIdent {
    UInt8 diReserved;
    UInt8 bus;
    UInt8 targetID;
    UInt8 LUN;
};
typedef struct DeviceIdent DeviceIdent;
```

Fields

`diReserved`
Reserved.

`bus`
The bus number of the SIM/HBA for the target device.

`targetID`
The SCSI ID number of the target device.

`LUN`
The target LUN, or 0 if the device does not support logical units.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

DeviceIdentATA

```
struct DeviceIdentATA {
    UInt8 diReserved;
    UInt8 busNum;
    UInt8 devNum;
    UInt8 diReserved2;
};
typedef struct DeviceIdentATA DeviceIdentATA;
```

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSI_PB

You use the SCSI Manager parameter block to pass information to the `SCSIAction` function.

```
struct SCSI_PB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    BytePtr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
};
typedef struct SCSI_PB SCSI_PB;
```

Fields

`qLink`
: A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
: Reserved.

`scsiPBLength`
: The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
: A function selector code that specifies the service being requested.

`scsiReserved2`
: Reserved.

`scsiResult`
: The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
: A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
: A pointer to a completion routine.

`scsiFlags`
: Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
: A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
: Private field for use in XPT.

`scsiReserved3`
: Reserved.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
SCSI.h

SCSICallbackUPP

Defines a universal procedure pointer (UPP) to a completion routine.

```
typedef SCSICallbackProcPtr SCSICallbackUPP;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
SCSI.h

SCSI_IO

Defines the SCSI I/O parameter block.

```
struct SCSI_IO {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    BytePtr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    UInt16 scsiResultFlags;
    UInt16 scsiReserved3pt5;
    BytePtr scsiDataPtr;
    UInt32 scsiDataLength;
    BytePtr scsiSensePtr;
    UInt8 scsiSenseLength;
    UInt8 scsiCDBLength;
    UInt16 scsiSGListCount;
    UInt32 scsiReserved4;
    UInt8 scsiSCSIstatus;
    SInt8 scsiSenseResidual;
    UInt16 scsiReserved5;
    long scsiDataResidual;
    CDB scsiCDB;
    long scsiTimeout;
    BytePtr scsiReserved5pt5;
    UInt16 scsiReserved5pt6;
    UInt16 scsiIOFlags;
    UInt8 scsiTagAction;
    UInt8 scsiReserved6;
    UInt16 scsiReserved7;
    UInt16 scsiSelectTimeout;
    UInt8 scsiDataType;
    UInt8 scsiTransferType;
    UInt32 scsiReserved8;
    UInt32 scsiReserved9;
    UInt16 scsiHandshake[8];
    UInt32 scsiReserved10;
    UInt32 scsiReserved11;
    SCSI_IO * scsiCommandLink;
    UInt8 scsiSIMpublics[8];
    UInt8 scsiAppleReserved6[8];
    UInt16 scsiCurrentPhase;
    short scsiSelector;
    OSErr scsiOldCallResult;
    UInt8 scsiSCSImessage;
    UInt8 XPTprivateFlags;
    UInt8 XPTextras[12];
};
typedef struct SCSI_IO SCSI_IO;
typedef SCSI_IO SCSIExecIOPB;
```

Fields

`qLink`
A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
Reserved.

`scsiPBLength`
The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
A function selector code that specifies the service being requested.

`scsiReserved2`
Reserved.

`scsiResult`
The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
A pointer to a completion routine.

`scsiFlags`
Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
Private field for use in XPT.

`scsiReserved3`
Reserved.

`scsiResultFlags`
Output flags that modify the `scsiResult` field.

`scsiReserved3pt5`
Reserved.

`scsiDataPtr`
A pointer to a data buffer or scatter/gather list. You specify the data type using the `scsiDataType` field.

`scsiDataLength`
The amount of data to be transferred, in bytes.

`scsiSensePtr`
A pointer to the autosense data buffer. If autosense is enabled (the `scsiDisableAutosense` flag is not set), the SCSI Manager returns `REQUEST SENSE` information in this buffer.

`scsiSenseLength`
The size of the autosense data buffer, in bytes.

`scsiCDBLength`
The length of the SCSI command descriptor block, in bytes.

`scsiSGListCount`
The number of elements in the scatter/gather list.

`scsiReserved4`
Reserved.

`scsiSCSIstatus`
The status returned by the SCSI device.

`scsiSenseResidual`
The automatic `REQUEST SENSE` residual length (that is, the number of bytes that were expected but not transferred). This number is negative if extra bytes had to be transferred to force the target off of the bus.

`scsiReserved5`
Reserved for output.

`scsiDataResidual`
The data transfer residual length (that is, the number of bytes that were expected but not transferred). This number is negative if extra bytes had to be transferred to force the target off the bus.

`scsiCDB`
This field can contain either the actual CDB or a pointer to the CDB. You set the `scsiCDBIsPointer` flag if this field contains a pointer.

`scsiTimeout`
The length of time the SIM should allow before reporting a timeout of the SCSI bus. The time value is represented in Time Manager format (positive values for milliseconds, negative values for microseconds). The timer is started when the I/O request is sent to the target. If the request does not complete within the specified time, the SIM attempts to issue an `ABORT` message, either by reselecting the device or by asserting the attention (/ATN) signal. A value of 0 specifies the default timeout for the SIM. The default timeout for the SCSI Manager 4.3 SIM is infinite (that is, no timeout).

`scsiReserved5pt5`
Reserved.

`scsiReserved5pt6`
Reserved.

`scsiIOFlags`
Additional I/O flags describing the data transfer.

`scsiTagAction`
Reserved.

`scsiReserved6`
Reserved for input.

`scsiReserved7`
Reserved for input.

`scsiSelectTimeout`
An optional SELECT timeout value, in milliseconds. The default is 250 ms, as specified by SCSI-2. The accuracy of this period is dependent on the HBA.A value of 0 specifies the default timeout. Some SIMs ignore this parameter and always use a value of 250 ms.

`scsiDataType`
The data type pointed to by the `scsiDataPtr` field.

`scsiTransferType`
The type of transfer mode to use during the data phase.

`scsiReserved8`
Reserved for input.

`scsiReserved9`
Reserved for input.

`scsiHandshake`
Handshaking instructions for blind transfers, consisting of an array of word values, terminated by 0. The SIM polls for data ready after transferring the amount of data specified in each successive `scsiHandshake` entry. When it encounters a 0 value, the SIM starts over at the beginning of the list. Handshaking always starts from the beginning of the list every time a device transitions to data phase.

`scsiReserved10`
Reserved for input.

`scsiReserved11`
Reserved for input.

`scsiCommandLink`
A pointer to a linked parameter block. This field provides support for SCSI linked commands. This optional feature ensures that a set of commands sent to a device are executed in sequential order without interference from other applications. You create a list of commands using this pointer to link additional parameter blocks. Each parameter block except the last should have the `scsiCDBLinked` flag set in the `scsiFlags` field. A `CHECK CONDITION` status from the device will abort linked command execution. Linked commands may not be supported by all SIMs.

`scsiSIMpublics`
An additional input field available for use by SIM developers.

`scsiCurrentPhase`
The current SCSI bus phase reported by the SIM after handling an original SCSI Manager function. This field is used only by the XPT and SIM during original SCSI Manager emulation.

`scsiSelector`
The function selector code that was passed to the `_SCSIDispatch` trap during original SCSI Manager emulation. The SIM uses this field to determine which original SCSI Manager function to perform.

`scsiOldCallResult`
The result code from an emulated original SCSI Manager function. The SIM returns results to all original SCSI Manager functions in this field, except for the `SCSIComplete` result, which it returns in `scsiResult`.

`scsiSCSImessage`
The message byte returned by an emulated `SCSIComplete` function. This field is only used by the XPT and SIM during original SCSI Manager emulation.

`XPTprivateFlags`
Reserved.

`XPTextras`
Reserved.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`SCSI.h`

SCSIBusInquiryPB

Defines a SCSI bus inquiry parameter block.

```
struct SCSIBusInquiryPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    BytePtr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    UInt16 scsiEngineCount;
    UInt16 scsiMaxTransferType;
    UInt32 scsiDataTypes;
    UInt16 scsiIOpbSize;
    UInt16 scsiMaxIOpbSize;
    UInt32 scsiFeatureFlags;
    UInt8 scsiVersionNumber;
    UInt8 scsiHBAInquiry;
    UInt8 scsiTargetModeFlags;
    UInt8 scsiScanFlags;
    UInt32 scsiSIMPrivatesPtr;
    UInt32 scsiSIMPrivatesSize;
    UInt32 scsiAsyncFlags;
    UInt8 scsiHiBusID;
    UInt8 scsiInitiatorID;
    UInt16 scsiBIReserved0;
    UInt32 scsiBIReserved1;
    UInt32 scsiFlagsSupported;
    UInt16 scsiIOFlagsSupported;
    UInt16 scsiWeirdStuff;
    UInt16 scsiMaxTarget;
    UInt16 scsiMaxLUN;
    char scsiSIMVendor[16];
    char scsiHBAVendor[16];
    char scsiControllerFamily[16];
    char scsiControllerType[16];
    char scsiXPTversion[4];
    char scsiSIMversion[4];
    char scsiHBAversion[4];
    UInt8 scsiHBAslotType;
    UInt8 scsiHBAslotNumber;
    UInt16 scsiSIMsRsrcID;
    UInt16 scsiBIReserved3;
    UInt16 scsiAdditionalLength;
};
typedef struct SCSIBusInquiryPB SCSIBusInquiryPB;
```

Fields

`qLink`

A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`

Reserved.

`scsiPBLength`
The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
A function selector code that specifies the service being requested.

`scsiReserved2`
Reserved.

`scsiResult`
The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
A pointer to a completion routine.

`scsiFlags`
Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
Private field for use in XPT.

`scsiReserved3`
Reserved.

`scsiEngineCount`
The number of engines on the HBA. This value is 0 for a built-in SCSI bus.

`scsiMaxTransferType`
The number of data transfer types available on the HBA.

`scsiDataTypes`
A bit mask describing the data types supported by the SIM/HBA. Bits 3 through 15 and bit 31 are reserved by Apple Computer, Inc. Bits 16 through 30 are available for use by SIM developers.

`scsiIOpbSize`
The minimum size of a SCSI I/O parameter block for this SIM.

`scsiMaxIOpbSize`
The minimum size of a SCSI I/O parameter block for all currently registered SIMs. That is, the largest registered `scsiIOpbSize`.

`scsiFeatureFlags`
These flags describe various physical characteristics of the SCSI bus.

`scsiVersionNumber`
The version number of the SIM/HBA.

`scsiHBAInquiry`
Flags describing the capabilities of the bus.

`scsiTargetModeFlags`
Reserved.

`scsiScanFlags`
Reserved.

`scsiSIMPrivatesPtr`
A pointer to the SIM's private storage.

`scsiSIMPrivatesSize`
The size of the SIM's private storage, in bytes.

`scsiAsyncFlags`
Reserved.

`scsiHiBusID`
The highest bus number currently registered with the XPT. If no buses are registered, this field contains 0xFF (the ID of the XPT).

`scsiInitiatorID`
The SCSI ID of the HBA. This value is 7 for a built-in SCSI bus.

`scsiBIReserved0`
`scsiBIReserved1`
`scsiFlagsSupported`
A bit mask that defines which `scsiFlags` bits are supported.

`scsiIOFlagsSupported`
A bit mask that defines which `scsiIOFlags` bits are supported.

`scsiWeirdStuff`
Flags that identify unusual aspects of a SIM's operation.

`scsiMaxTarget`
The highest SCSI ID value supported by the HBA.

`scsiMaxLUN`
The highest logical unit number supported by the HBA.

`scsiSIMVendor`
An ASCII text string that identifies the SIM vendor. This field returns `'Apple Computer'` for a built-in SCSI bus.

`scsiHBAVendor`
An ASCII text string that identifies the HBA vendor. This field returns `'Apple Computer'` for a built-in SCSI bus.

`scsiControllerFamily`
An optional ASCII text string that identifies the family of parts to which the SCSI controller chip belongs. This information is provided at the discretion of the HBA vendor.

`scsiControllerType`
An optional ASCII text string that identifies the specific type of SCSI controller chip. This information is provided at the discretion of the HBA vendor.

`scsiXPTversion`
An ASCII text string that identifies the version number of the XPT. You should use the other fields of this parameter block to check for specific features, rather than relying on this value.

`scsiSIMversion`
An ASCII text string that identifies the version number of the SIM. You should use the other fields of this parameter block to check for specific features, rather than relying on this value.

`scsiHBAversion`
An ASCII text string that identifies the version number of the HBA. You should use the other fields of this parameter block to check for specific features, rather than relying on this value.

`scsiHBAslotType`
The slot type, if any, used by this HBA.

`scsiHBAslotNumber`
: The slot number for the SIM. Device drivers should copy this value into the `dCtlSlot` field of the device control entry. This value is 0 for a built-in SCSI bus.

`scsiSIMsRsrcID`
: The ID for the SIM. Device drivers should copy this value into the `dCtlSlotID` field of the device control entry. This value is 0 for a built-in SCSI bus.

`scsiAdditionalLength`
: The additional size of this parameter block, in bytes. If this structure includes extra fields to return additional information, this field contains the number of additional bytes.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSIAbortCommandPB

Defines a SCSI abort command parameter block.

```
struct SCSIAbortCommandPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    BytePtr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    SCSI_IO * scsiIOptr;
};
typedef struct SCSIAbortCommandPB SCSIAbortCommandPB;
```

Fields
`qLink`
: A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
: Reserved.

`scsiPBLength`
: The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
: A function selector code that specifies the service being requested.

`scsiReserved2`
: Reserved.

`scsiResult`
: The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
: A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
: A pointer to a completion routine.

`scsiFlags`
: Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
: A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
: Private field for use in XPT.

`scsiReserved3`
: Reserved.

`scsiIOptr`
: A pointer to the parameter block to be canceled.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSITerminateIOPB

Defines a SCSI terminate I/O parameter block.

```
struct SCSITerminateIOPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    BytePtr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    SCSI_IO * scsiIOptr;
};
typedef struct SCSITerminateIOPB SCSITerminateIOPB;
```

Fields

`qLink`
: A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
: Reserved.

`scsiPBLength`
: The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
: A function selector code that specifies the service being requested.

`scsiReserved2`
: Reserved.

`scsiResult`
: The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
: A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
: A pointer to a completion routine.

`scsiFlags`
: Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
: A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
: Private field for use in XPT.

`scsiReserved3`
: Reserved.

`scsiIOptr`
: A pointer to the parameter block to be canceled.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`SCSI.h`

SCSIGetVirtualIDInfoPB

Defines a SCSI virtual ID information parameter block.

```
struct SCSIGetVirtualIDInfoPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    Ptr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    UInt16 scsiOldCallID;
    Boolean scsiExists;
    SInt8 filler;
};
typedef struct SCSIGetVirtualIDInfoPB SCSIGetVirtualIDInfoPB;
```

Fields

`qLink`
A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
Reserved.

`scsiPBLength`
The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
A function selector code that specifies the service being requested.

`scsiReserved2`
Reserved.

`scsiResult`
The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
A pointer to a completion routine.

`scsiFlags`
: Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
: A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
: Private field for use in XPT.

`scsiReserved3`
: Reserved.

`scsiOldCallID`
: The virtual SCSI ID of the device you are searching for.

`scsiExists`
: The XPT returns true in this field if the `scsiDevice` field contains a valid device identification record.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSILoadDriverPB

Defines a SCSI load driver parameter block.

```
struct SCSILoadDriverPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    Ptr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    short scsiLoadedRefNum;
    Boolean scsiDiskLoadFailed;
    SInt8 filler;
};
typedef struct SCSILoadDriverPB SCSILoadDriverPB;
```

Fields
`qLink`
: A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
: Reserved.

`scsiPBLength`
: The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
: A function selector code that specifies the service being requested.

`scsiReserved2`
: Reserved.

`scsiResult`
: The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
: A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
: A pointer to a completion routine.

`scsiFlags`
: Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
: A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
: Private field for use in XPT.

`scsiReserved3`
: Reserved.

`scsiLoadedRefNum`
: If the driver is successfully loaded, this field contains the driver reference number returned by the SIM.

`scsiDiskLoadFailed`
: If this field is set to true, the SIM should attempt to load its own driver regardless of whether there is one on the device. If this field is set to false, the SIM has the option of loading a driver from the device or using one of its own.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

SCSIDriverPB

Defines a SCSI driver identification parameter block.

```
struct SCSIDriverPB {
    SCSIHdr * qLink;
    short scsiReserved1;
    UInt16 scsiPBLength;
    UInt8 scsiFunctionCode;
    UInt8 scsiReserved2;
    volatile OSErr scsiResult;
    DeviceIdent scsiDevice;
    SCSICallbackUPP scsiCompletion;
    UInt32 scsiFlags;
    Ptr scsiDriverStorage;
    Ptr scsiXPTprivate;
    long scsiReserved3;
    short scsiDriver;
    UInt16 scsiDriverFlags;
    DeviceIdent scsiNextDevice;
};
typedef struct SCSIDriverPB SCSIDriverPB;
```

Fields

`qLink`
A pointer to the next entry in the request queue. This field is used internally by the SCSI Manager and must be set to 0 when the parameter block is initialized. The SCSI Manager functions always set this field to 0 before returning, so you do not need to set it to 0 again before reusing a parameter block.

`scsiReserved1`
Reserved.

`scsiPBLength`
The size of the parameter block, in bytes, including the parameter block header.

`scsiFunctionCode`
A function selector code that specifies the service being requested.

`scsiReserved2`
Reserved.

`scsiResult`
The result code returned by the XPT or SIM when the function completes. The value `scsiRequestInProgress` indicates that the request is still in progress or queued.

`scsiDevice`
A 4-byte value that uniquely identifies the target device for a request. The `DeviceIdent` data type designates the bus number, target SCSI ID, and logical unit number (LUN).

`scsiCompletion`
A pointer to a completion routine.

`scsiFlags`
Flags indicating the transfer direction and any special handling required for this request.

`scsiDriverStorage`
A pointer to the device driver's private storage. This field is not affected or used by the SCSI Manager.

`scsiXPTprivate`
`scsiReserved3`
Reserved.

`scsiDriver`
The driver reference number of the device driver associated with this device identification record.

`scsiDriverFlags`
: Driver information flags. These flags are not interpreted by the XPT but can be used to provide information about the driver to other clients.

`scsiNextDevice`
: The device identification record of the next device in the driver registration list.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`SCSI.h`

Constants

SCSI Flags

Used in the `scsiFlags` field of the `SCSI_PB` structure.

```
enum {
    scsiDirectionMask = 0xC0000000,
    scsiDirectionNone = 0xC0000000,
    scsiDirectionReserved = 0x00000000,
    scsiDirectionOut = 0x80000000,
    scsiDirectionIn = 0x40000000,
    scsiDisableAutosense = 0x20000000,
    scsiFlagReservedA = 0x10000000,
    scsiFlagReserved0 = 0x08000000,
    scsiCDBLinked = 0x04000000,
    scsiQEnable = 0x02000000,
    scsiCDBIsPointer = 0x01000000,
    scsiFlagReserved1 = 0x00800000,
    scsiInitiateSyncData = 0x00400000,
    scsiDisableSyncData = 0x00200000,
    scsiSIMQHead = 0x00100000,
    scsiSIMQFreeze = 0x00080000,
    scsiSIMQNoFreeze = 0x00040000,
    scsiDoDisconnect = 0x00020000,
    scsiDontDisconnect = 0x00010000,
    scsiDataReadyForDMA = 0x00008000,
    scsiFlagReserved3 = 0x00004000,
    scsiDataPhysical = 0x00002000,
    scsiSensePhysical = 0x00001000,
    scsiFlagReserved5 = 0x00000800,
    scsiFlagReserved6 = 0x00000400,
    scsiFlagReserved7 = 0x00000200,
    scsiFlagReserved8 = 0x00000100
};
```

Constants

`scsiDirectionMask`

A bit field that specifies transfer direction, using these constants: `scsiDirectionIn`, `scsiDirectionOut`, and `scsiDirectionNone`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDirectionNone`

No data phase expected.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDirectionOut`

Data out.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDirectionIn`
Data in.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDisableAutosense`
Disable the automatic REQUEST SENSE feature.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiCDBLinked`
The parameter block contains a linked CDB. This option may not be supported by all SIMs.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiQEnable`
Enable target queue actions. This option may not be supported by all SIMs.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiCDBIsPointer`
Set if the `scsiCDB` field of a SCSI I/O parameter block contains a pointer. If clear, the `scsiCDB` field contains the actual CDB. In either case, the `scsiCDBLength` field contains the number of bytes in the SCSI command descriptor block.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiInitiateSyncData`
Set if the SIM should attempt to initiate a synchronous data transfer by sending the SDTR message. If successful, the device normally remains in the synchronous transfer mode until it is reset or until you specify asynchronous mode by setting the `scsiDisableSyncData` flag. Because SDTR negotiation occurs every time this flag is set, you should set it only when negotiation is actually needed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDisableSyncData`
Disable synchronous data transfer. The SIM sends an SDTR message with a REQ/ACK offset of 0 to indicate asynchronous data transfer mode. You should set this flag only when negotiation is actually needed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiSIMQHead`
: Place the parameter block at the head of the SIM queue. This can be used to insert error handling at the head of a frozen queue.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiSIMQFreeze`
: Freeze the SIM queue after completing this transaction.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiSIMQNoFreeze`
: Disable SIM queue freezing for this transaction.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDoDisconnect`
: Explicitly allow device to disconnect.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDontDisconnect`
: Explicitly prohibit device disconnection. If this flag and the `scsiDoDisconnect` flag are both 0, the SIM determines whether to allow or prohibit disconnection, based on performance criteria.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDataReadyForDMA`
: Data buffer is locked and non-cacheable.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDataPhysical`
: Data buffer address is physical.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiSensePhysical`
: Autosense data pointer is physical.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

SCSIAction function selector codes

Used in the `scsiFunctionCode` field of the parameter block passed to the `SCSIAction` function.

```
enum {
    SCSINop = 0x00,
    SCSIExecIO = 0x01,
    SCSIBusInquiry = 0x03,
    SCSIReleaseQ = 0x04,
    SCSIAbortCommand = 0x10,
    SCSIResetBus = 0x11,
    SCSIResetDevice = 0x12,
    SCSITerminateIO = 0x13
};
enum {
    SCSIGetVirtualIDInfo = 128,
    SCSILoadDriver = 130,
    SCSIOldCall = 132,
    SCSICreateRefNumXref = 133,
    SCSILookupRefNumXref = 134,
    SCSIRemoveRefNumXref = 135,
    SCSIRegisterWithNewXPT = 136
};
```

Constants

`SCSINop`
No operation.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`SCSIExecIO`
Execute a SCSI I/O transaction.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`SCSIBusInquiry`
Bus inquiry.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`SCSIReleaseQ`
Release a frozen SIM queue.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`SCSIAbortCommand`
: Abort a SCSI command.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`SCSIResetBus`
: Reset the SCSI bus.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`SCSIResetDevice`
: Reset a SCSI device.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`SCSITerminateIO`
: Terminate I/O transaction.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`SCSIGetVirtualIDInfo`
: Return `DeviceIdent` of a virtual SCSI ID.

`SCSILoadDriver`
: Load a driver from a SCSI device.

`SCSIOldCall`
: SIM support function for original SCSI Manager emulation.

`SCSICreateRefNumXref`
: Register a device driver.

`SCSILookupRefNumXref`
: Find a driver reference number.

`SCSIRemoveRefNumXref`
: Deregister a device driver.

`SCSIRegisterWithNewXPT`
: XPT was replaced; SIM needs to reregister.

kBusTypeSCSI

Used in the `diReserved` field of the `DeviceIdent` structure to identify the type of device described by the structure.

```
enum {
    kBusTypeSCSI = 0,
    kBusTypeATA = 1,
    kBusTypePCMCIA = 2,
    kBusTypeMediaBay = 3
};
```

Constants

`kBusTypeSCSI`
`DeviceIdent` holds information about a SCSI device.
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`kBusTypeATA`
`DeviceIdent` holds information about an ATA device.
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`kBusTypePCMCIA`
Not recommended.
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`kBusTypeMediaBay`
Not recommended.
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

SCSI Result Flags

Used in `scsiResultFlags` field of the `SCSI_IO` structure.

```
enum {
    scsiSIMQFrozen = 0x0001,
    scsiAutosenseValid = 0x0002,
    scsiBusNotFree = 0x0004
};
```

Constants

`scsiSIMQFrozen`
The SIM queue for this LUN is frozen because of an error. You must call the `SCSIReleaseQ` function to release the queue and resume processing requests.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiAutosenseValid`
: An automatic `REQUEST SENSE` was performed after this I/O because of a `CHECK CONDITION` status message from the device. The data contained in the `scsiSensePtr` buffer is valid.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`scsiBusNotFree`
: The SCSI Manager was unable to clear the bus after an error. You may need to call the `SCSIResetBus` function to restore operation.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

SCSI IO Flags

Used in the `scsiIOFlags` field of the `SCSI_IO` structure.

```
enum {
    scsiNoParityCheck = 0x0002,
    scsiDisableSelectWAtn = 0x0004,
    scsiSavePtrOnDisconnect = 0x0008,
    scsiNoBucketIn = 0x0010,
    scsiNoBucketOut = 0x0020,
    scsiDisableWide = 0x0040,
    scsiInitiateWide = 0x0080,
    scsiRenegotiateSense = 0x0100,
    scsiDisableDiscipline = 0x0200,
    scsiIOFlagReserved0080 = 0x0080,
    scsiIOFlagReserved8000 = 0x8000
};
```

Constants

`scsiNoParityCheck`
: Disable parity error detection for this transaction.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`scsiDisableSelectWAtn`
: Do not send the IDENTIFY message for LUN selection. The LUN is still required in the `scsiDevice` field so that the request can be placed in the proper queue. The LUN field in the CDB is untouched. The purpose is to provide compatibility with older devices that do not support this aspect of the SCSI-2 specification.

  Available in Mac OS X v10.0 and later.

  Not available to 64-bit applications.

  Declared in `SCSI.h`.

`scsiSavePtrOnDisconnect`

Perform a SAVE DATA POINTER operation automatically in response to a DISCONNECT message from the target. The purpose of this flag is to provide compatibility with devices that do not properly implement this aspect of the SCSI-2 specification.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiNoBucketIn`

Prohibit bit-bucketing during the data-in phase of the transaction. Bit-bucketing is the practice of throwing away excess data bytes when a target tries to supply more data than the initiator expects. For example, if the CDB requests more data than you specified in the `scsiDataLength` field, the SCSI Manager normally throws away the excess and returns the `scsiDataRunError` result code. If this flag is set, the SCSI Manager refuses any extra data, terminates the I/O request, and leaves the bus in the data-in phase. You must reset the bus to restore operation. This flag is intended only for debugging purposes.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiNoBucketOut`

Prohibit bit-bucketing during the data-out phase of the transaction. If a target requests more data than you specified in the `scsiDataLength` field, the SCSI Manager normally sends an arbitrary number of meaningless bytes (0xEE) until the target releases the bus. If this flag is set, the SCSI Manager terminates the I/O request when the last byte is sent and leaves the bus in the data-out phase. You must reset the bus to restore operation. This flag is intended only for debugging purposes.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDisableWide`

Disable wide data transfer negotiation for this transaction if it had been previously enabled. This option may not be supported by all SIMs.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiInitiateWide`

Attempt wide data transfer negotiation for this transaction if it is not already enabled. This option may not be supported by all SIMs.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiRenegotiateSense`
Attempt to renegotiate synchronous or wide transfers before issuing a REQUEST SENSE. This is necessary when the error was caused by problems operating in synchronous or wide transfer mode. It is optional because some devices flush sense data after performing negotiation.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

SCSI_IO Data Types

Used in the `scsiDataType` field of the `SCSI_IO` parameter block.

```
enum {
    scsiDataBuffer = 0,
    scsiDataTIB = 1,
    scsiDataSG = 2,
    scsiDataIOTable = 3
};
```

Constants

`scsiDataBuffer`
The `scsiDataPtr` field contains a pointer to a contiguous data buffer, and the `scsiDataLength` field contains the length of the buffer, in bytes.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDataTIB`
The `scsiDataPtr` field contains a pointer to a transfer instruction block. This is used by the XPT during original SCSI Manager emulation, when communicating with a SIM that supports this.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDataSG`
The `scsiDataPtr` field contains a pointer to a scatter/gather list. The `scsiDataLength` field contains the total number of bytes to be transferred, and the `scsiSGListCount` field contains the number of elements in the scatter/gather list.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

SCSIBusInquiryPB Data Types

Used in the `scsiDataTypes` field of the `SCSIBusInquiryPB` structure.

```
enum {
    scsiBusDataTIB = (1 << scsiDataTIB),
    scsiBusDataBuffer = (1 << scsiDataBuffer),
    scsiBusDataSG = (1 << scsiDataSG),
    scsiBusDataIOTable = (1 << scsiDataIOTable),
    scsiBusDataReserved = 0x80000000
};
```

Discussion
These types correspond to the `scsiDataType` field of the SCSI I/O parameter block.

SCSI Transfer Types

Used in the `scsiTransferType` field of the `SCSI_IO` structure.

```
enum {
    scsiTransferBlind = 0,
    scsiTransferPolled = 1
};
```

Constants

`scsiTransferBlind`
Use DMA, if available; otherwise, perform a blind transfer using the handshaking information contained in the `scsiHandshake` field.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiTransferPolled`
Use polled transfer mode. The `scsiHandshake` field is not required for this mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

SCSIBusInquiryPB Feature Flags

Used in the `featureFlags` field of the `SCSIBusInquiryPB` structure.

```
enum {
    scsiBusLVD = 0x00000400,
    scsiBusUltra3SCSI = 0x00000200,
    scsiBusUltra2SCSI = 0x00000100,
    scsiBusInternalExternalMask = 0x000000C0,
    scsiBusInternalExternalUnknown = 0x00000000,
    scsiBusInternalExternal = 0x000000C0,
    scsiBusInternal = 0x00000080,
    scsiBusExternal = 0x00000040,
    scsiBusCacheCoherentDMA = 0x00000020,
    scsiBusOldCallCapable = 0x00000010,
    scsiBusUltraSCSI = 0x00000008,
    scsiBusDifferential = 0x00000004,
    scsiBusFastSCSI = 0x00000002,
    scsiBusDMAavailable = 0x00000001
};
```

Constants

`scsiBusInternalExternalUnknown`
The internal/external state of the bus is unknown.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusInternalExternal`
The bus is both internal and external.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusInternal`
The bus is at least partly internal to the computer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusExternal`
The bus extends outside of the computer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusCacheCoherentDMA`
DMA is cache coherent.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusOldCallCapable`
The SIM supports the original SCSI Manager interface.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusDifferential`
The bus uses a differential SCSI interface.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusFastSCSI`
The bus supports SCSI-2 fast data transfers.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusDMAavailables`
DMA is available.

scsiBusMDP

Used in the `scsiHBAInquiry` field of the `SCSIBusInquiryPB` parameter block.

```
enum {
    scsiBusMDP = 0x80,
    scsiBusWide32 = 0x40,
    scsiBusWide16 = 0x20,
    scsiBusSDTR = 0x10,
    scsiBusLinkedCDB = 0x08,
    scsiBusTagQ = 0x02,
    scsiBusSoftReset = 0x01
};
```

Constants

`scsiBusMDP`
Supports the `MODIFY DATA POINTER` message.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusWide32`
Supports 32-bit wide transfers.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusWide16`
Supports 16-bit wide transfers.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusSDTR`
Supports synchronous transfers.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusLinkedCDB`
Supports linked commands.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusTagQ`
Supports tagged queuing.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiBusSoftReset`
Supports soft reset.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

scsiOddDisconnectUnsafeRead1

Used in the `scsiWeirdStuff` field of the `SCSIBusInquiryPB` parameter block.

```
enum {
    scsiOddDisconnectUnsafeRead1 = 0x0001,
    scsiOddDisconnectUnsafeWrite1 = 0x0002,
    scsiBusErrorsUnsafe = 0x0004,
    scsiRequiresHandshake = 0x0008,
    scsiTargetDrivenSDTRSafe = 0x0010,
    scsiOddCountForPhysicalUnsafe = 0x0020,
    scsiAbortCmdFixed = 0x0040,
    scsiMeshACKTimingFixed = 0x0080
};
```

Constants

`scsiOddDisconnectUnsafeRead1`
Indicates that a disconnect or other phase change on a odd byte boundary during a read operation will result in inaccurate residual counts or data loss. If your device can disconnect on odd bytes, use polled transfers instead of blind.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiOddDisconnectUnsafeWrite1`
Indicates that a disconnect or other phase change on a odd byte boundary during a write operation will result in inaccurate residual counts or data loss. If your device can disconnect on odd bytes, use polled transfers instead of blind.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiBusErrorsUnsafe`
Indicates that a delay of more than 16 microseconds or a phase change during a blind transfer on a non-handshaked boundary may cause a system crash. If you cannot predict where delays or disconnects will occur, use polled transfers.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiRequiresHandshake`
Indicates that a delay of more than 16 microseconds or a phase change during a blind transfer on a non-handshaked boundary may result in inaccurate residual counts or data loss. If you cannot predict where delays or disconnects will occur, use polled transfers.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiTargetDrivenSDTRSafe`
Indicates that the SIM supports target-initiated synchronous data transfer negotiation. If your device supports this feature and this bit is not set, you must set the `scsiDisableSelectWAtn` flag in the `scsiIOFlags` field.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

scsiMotherboardBus

Used in the `scsiHBAslotType` field of the `SCSIBusInquiryPB` parameter block.

```
enum {
    scsiMotherboardBus = 0x00,
    scsiNuBus = 0x01,
    scsiPDSBus = 0x03,
    scsiPCIBus = 0x04,
    scsiPCMCIABus = 0x05,
    scsiFireWireBridgeBus = 0x06,
    scsiUSBBus = 0x07
};
```

Constants

`scsiMotherboardBus`
A built-in SCSI bus.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiNuBus`
A NuBus slot.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiPDSBus`
A processor-direct slot.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiPCIBus`
A SIM on a PCI bus card.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiPCMCIABus`
A SIM on a PCMCIA card.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiFireWireBridgeBus`
A SIM connected through a FireWire bridge.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `SCSI.h`.

`scsiUSBBus`

A SIM connected on a USB bus.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

kDataOutPhase

Used in the `scsiCurrentPhase` field of the `SCSI_IO` structure.

```
enum {
    kDataOutPhase = ,
    kDataInPhase = 1,
    kCommandPhase = 2,
    kStatusPhase = 3,
    kPhaseIllegal0 = 4,
    kPhaseIllegal1 = 5,
    kMessageOutPhase = 6,
    kMessageInPhase = 7,
    kBusFreePhase = 8,
    kArbitratePhase = 9,
    kSelectPhase = 10,
    kMessageInPhaseNACK = 11
};
```

scsiErrorBase

```
enum {
    scsiErrorBase = -7936
};
```

scsiExecutionErrors

```
enum {
    scsiExecutionErrors = scsiErrorBase,
    scsiNotExecutedErrors = scsiTooManyBuses,
    scsiParameterErrors = scsiPBLengthError
};
```

scsiVERSION

```
enum {
    scsiVERSION = 43
};
```

vendorUnique

```
enum {
    vendorUnique = 0xC0
};
```

scsiDeviceSensitive

Used in the `scsiDriverFlags` field of the `SCSIDriverPB` parameter block.

```
enum {
    scsiDeviceSensitive = 0x0001,
    scsiDeviceNoOldCallAccess = 0x0002
};
```

Constants

`scsiDeviceSensitive`

Only the device driver should access this device. SCSI utilities and other applications that bypass drivers should check this flag before accessing a device.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

`scsiDeviceNoOldCallAccess`

This driver or device does not accept original SCSI Manager requests.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `SCSI.h`.

Result Codes

The table below shows the result codes most commonly returned by the SCSI Manager.

Result Code	Value	Description
`scsiRequestInProgress`	1	Parameter block request is in progress Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scCommErr`	2	Communications error, operation timeout.
`scArbNBErr`	3	Bus busy, arbitration timeout.
`scBadParmsErr`	4	Unrecognized TIB instruction.
`scPhaseErr`	5	Phase error on the SCSI bus.
`scCompareErr`	6	Comparison error from `scComp` instruction.
`scMgrBusyErr`	7	SCSI Manager busy.
`scSequenceErr`	8	Attempted operation is out of sequence.
`scBusTOErr`	9	Bus timeout during blind transfer.
`scComplPhaseErr`	10	SCSI bus was not in status phase on entry to `SCSIComplete`.

Result Code	Value	Description
`scsiPluginInternalError`	-7848	Internal consistency check failed Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiFamilyInternalError`	-7849	Internal consistency check failed Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiCannotLoadPlugin`	-7849	No matching service category Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiBadConnType`	-7850	Bad connection type Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiTargetReserved`	-7853	Target already reserved Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiIOInProgress`	-7854	Can't close connection, I/O in progress Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiBadConnID`	-7856	Bad connection ID Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiInvalidMsgType`	-7858	Invalid message type Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiPartialPrepared`	-7859	Could not do full prepare mem for I/O Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiBadDataLength`	-7860	A zero data length in the parameter block. Available in Mac OS X v10.0 and later. Not available to 64-bit applications.

Result Code	Value	Description
`scsiCDBLengthInvalid`	-7863	The CDB length supplied is not supported by this SIM; typically this means it was too big Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiTransferTypeInvalid`	-7864	The `scsiTransferType` requested is not supported by this SIM Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiDataTypeInvalid`	-7865	SIM does not support the requested `scsiDataType` Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiIDInvalid`	-7866	The initiator ID is invalid Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiLUNInvalid`	-7867	The logical unit number is invalid Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiTIDInvalid`	-7868	The target ID is invalid Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiBusInvalid`	-7869	The bus ID is invalid Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiRequestInvalid`	-7870	The parameter block request is invalid Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiFunctionNotAvailable`	-7871	The requested function is not supported by this SIM Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiPBLengthError`	-7872	The parameter block length supplied was too small for this SIM Available in Mac OS X v10.0 and later. Not available to 64-bit applications.

Result Code	Value	Description
scsiQLinkInvalid	-7881	The qLink field was not 0 Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiNoSuchXref	-7882	No driver has been cross-referenced with this device Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiDeviceConflict	-7883	Attempt to register more than one driver to a device Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiNoHBA	-7884	No HBA detected Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiDeviceNotThere	-7885	SCSI device not installed or available Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiProvideFail	-7886	Unable to provide the requested service Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiBusy	-7887	SCSI subsystem is busy Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiTooManyBuses	-7888	SIM registration failed because the XPT registry is full Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiCDBReceived	-7910	The SCSI CDB was received Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
scsiNoNexus	-7911	Nexus is not established Available in Mac OS X v10.0 and later. Not available to 64-bit applications.

Result Code	Value	Description
`scsiTerminated`	-7912	Parameter block request terminated by the host Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiBDRsent`	-7913	A SCSI bus device reset (BDR) message was sent to the target Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiWrongDirection`	-7915	Data phase was in an unexpected direction Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiSequenceFailed`	-7916	Target bus phase sequence failure Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiUnexpectedBusFree`	-7917	Unexpected bus free phase Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiDataRunError`	-7918	Data overrun/underrun error Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiAutosenseFailed`	-7920	Automatic `REQUEST SENSE` command failed Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiParityError`	-7921	An uncorrectable parity error occurred Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiSCSIBusReset`	-7922	Execution of this parameter block was halted because of a SCSI bus reset Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiMessageRejectReceived`	-7923	`REJECT` message received Available in Mac OS X v10.0 and later. Not available to 64-bit applications.

Result Code	Value	Description
`scsiIdentifyMessageRejected`	-7924	The target issued a `REJECT` message in response to the `IDENTIFY` message; the LUN probably does not exist Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiCommandTimeout`	-7925	The timeout value for this parameter block was exceeded and the parameter block was aborted Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiSelectTimeout`	-7926	Target selection timeout Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiUnableToTerminate`	-7927	Unable to terminate I/O parameter block request Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiNonZeroStatus`	-7932	The target returned non-zero status upon completion of the request Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiUnableToAbort`	-7933	Unable to abort parameter block request Available in Mac OS X v10.0 and later. Not available to 64-bit applications.
`scsiRequestAborted`	-7934	Parameter block request aborted by the host Available in Mac OS X v10.0 and later. Not available to 64-bit applications.

Text Encoding Conversion Manager Reference

Framework: CoreServices/CoreServices.h

Declared in UnicodeConverter.h
TextCommon.h
Unicode.h
TextEncodingConverter.h
TextEncodingPlugin.h

Overview

The Text Encoding Conversion (TEC) Manager provides two facilities—the Text Encoding Converter and the Unicode Converter—that your application can use to handle text encoding conversion on the Mac OS. You will find the Text Encoding Conversion Manager helpful if you develop Internet applications, such as Web browsers or e-mail applications, applications that transfer text across different platforms, or applications based in Unicode.

Functions by Task

Creating a Text Encoding Specification

`CreateTextEncoding` (page 1890)
Creates and returns a text encoding specification.

Obtaining Information From a Text Encoding Specification

`GetTextEncodingBase` (page 1899)
Returns the base encoding of the specified text encoding.

`GetTextEncodingFormat` (page 1899)
Returns the format value of the specified text encoding.

`GetTextEncodingName` (page 1899)
Returns the localized name for a specified text encoding.

`GetTextEncodingVariant` (page 1901)
Returns the variant from the specified text encoding.

`ResolveDefaultTextEncoding` (page 1906)
Returns a text encoding specification in which any meta-values have been resolved to real values. Currently, this affects only the base encoding values packed into the text encoding specification.

Converting Between Script Manager Values and Text Encodings

`RevertTextEncodingToScriptInfo` (page 1907)
Converts the given Mac OS text encoding specification to the corresponding script code and, if possible, language code and font name.

`UpgradeScriptInfoToTextEncoding` (page 1937)
Converts any combination of a Mac OS script code, a language code, a region code, and a font name to a text encoding.

Obtaining Information About Available Text Encodings

`TECCountAvailableTextEncodings` (page 1914)
Counts and returns the number of text encodings currently configured in the Text Encoding Converter.

`TECCountSubTextEncodings` (page 1917)
Counts and returns the number of subencodings a text encoding supports.

`TECGetAvailableTextEncodings` (page 1926)
Returns the text encoding specifications currently configured in the Text Encoding Converter.

`TECGetSubTextEncodings` (page 1930)
Returns the text encoding specifications for the subencodings the encoding scheme supports.

`NearestMacTextEncodings` (page 1902)
Obtains the best and alternate Mac text encoding.

Identifying Direct Encoding Conversions

`TECCountDirectTextEncodingConversions` (page 1916)
Counts and returns the number of direct conversions currently configured in the Text Encoding Converter.

`TECGetDirectTextEncodingConversions` (page 1927)
Returns the types of direct conversions currently configured in the Text Encoding Converter.

Identifying Possible Destination Encodings

`TECCountDestinationTextEncodings` (page 1915)
Counts and returns the number of destination encodings to which a specified source encoding can be converted in one step.

`TECGetDestinationTextEncodings` (page 1926)
Returns the encoding specifications for all the destination text encodings to which the Text Encoding Converter can directly convert the specified source encoding.

Obtaining Converter Information

`TECGetInfo` (page 1929)
Allocates a converter information structure of type `TECInfo` in the application heap using `NewHandle`, fills it out, and returns a handle.

Creating and Deleting Converter Objects

`TECCreateConverter` (page 1918)
Determines a conversion path for a source and destination encoding, then creates a text encoding converter object and returns a pointer to it.

`TECCreateConverterFromPath` (page 1919)
Creates a converter object for a specific conversion path—from a source encoding through intermediate encodings to a destination encoding—and returns a pointer to it.

`TECClearConverterContextInfo` (page 1910)
Resets a converter object to its initial state so you can reuse it.

`TECDisposeConverter` (page 1921)
Disposes of a converter object.

Converting Text Between Encodings

`TECConvertText` (page 1911)
Converts a stream of text from a source encoding to a destination encoding. It uses the conversion path specified by the converter object you supply.

`TECFlushText` (page 1924)
Flushes out any data in a converter object's temporary buffers and resets the converter object.

Converting to Multiple Encoding Runs

`TECConvertTextToMultipleEncodings` (page 1912)
Converts text in the source encoding to runs of text in multiple destination encodings. It uses the conversion path specified in the converter object you supply.

`TECCreateOneToManyConverter` (page 1920)
Determines a conversion path for the source encoding and destinations encodings you specify, creates a text encoding converter object, and returns a reference to it.

`TECFlushMultipleEncodings` (page 1922)
Flushes out any encodings that may be stored in a converter object's temporary buffers and shifts encodings back to their default state, if any.

`TECGetEncodingList` (page 1928)
Gets the list of destination encodings from a converter object.

Using Sniffers to Investigate Encodings

`TECCreateSniffer` (page 1920)
Creates a sniffer object and returns a reference to it.

`TECClearSnifferContextInfo` (page 1910)
Resets a sniffer object to its initial settings so you can reuse it.

`TECDisposeSniffer` (page 1922)
Disposes of a sniffer object.

`TECCountAvailableSniffers` (page 1914)
Counts and returns the number of sniffers available in all installed plug-ins.

`TECGetAvailableSniffers` (page 1925)
Returns the list of sniffers available in all installed plug-ins.

`TECSniffTextEncoding` (page 1933)
Analyzes a text stream and returns the probable encodings in a ranked list, based on an array of possible encodings you supply. It also returns the number of errors and features for each encoding.

Getting Information About Internet and Regional Text Encoding Names

`TECCountMailTextEncodings` (page 1916)
Counts and returns the number of currently supported e-mail encodings for a specified region.

`TECCountWebTextEncodings` (page 1918)
Counts and returns the number of currently supported text encodings for a region code.

`TECGetMailTextEncodings` (page 1929)
Returns the currently supported mail encoding specifications for a region code.

`TECGetTextEncodingFromInternetName` (page 1931)
Returns the Mac OS text encoding specification that corresponds to an Internet encoding name.

`TECGetTextEncodingInternetName` (page 1931)
Returns the Internet encoding name that corresponds to a Mac OS text encoding.

`TECGetWebTextEncodings` (page 1932)
Returns the currently supported text encoding specifications for a region code.

Converting to Unicode

`ChangeTextToUnicodeInfo` (page 1875)
Changes the mapping information for the specified Unicode converter object used to convert text to Unicode to the new mapping you provide.

`ConvertFromTextToUnicode` (page 1877)
Converts a string from any encoding to Unicode.

`CreateTextToUnicodeInfo` (page 1890)
Creates and returns a Unicode converter object containing information required for converting strings from a non-Unicode encoding to Unicode.

`CreateTextToUnicodeInfoByEncoding` (page 1891)
Based on the given text encoding specification, creates and returns a Unicode converter object containing information required for converting strings from the specified non-Unicode encoding to Unicode.

`DisposeTextToUnicodeInfo` (page 1897)
Releases the memory allocated for the specified Unicode converter object.

`ResetTextToUnicodeInfo` (page 1905)
Reinitializes all state information kept by the context objects.

Converting From Unicode

`ChangeUnicodeToTextInfo` (page 1875)
Changes the mapping information contained in the specified Unicode converter object used to convert Unicode text to a non-Unicode encoding.

`ConvertFromUnicodeToText` (page 1883)
Converts a Unicode text string to the destination encoding you specify.

`CreateUnicodeToTextInfo` (page 1892)
Creates and returns a Unicode converter object containing information required for converting strings from Unicode to a non-Unicode encoding.

`CreateUnicodeToTextInfoByEncoding` (page 1893)
Based on the given text encoding specification for the converted text, creates and returns a Unicode converter object containing information required for converting strings from Unicode to the specified non-Unicode encoding.

`DisposeUnicodeToTextInfo` (page 1898)
Releases the memory allocated for the specified Unicode converter object.

`ResetUnicodeToTextInfo` (page 1905)
Reinitializes all state information kept by a Unicode converter object.

Converting From Unicode to Multiple Encodings

`ConvertFromUnicodeToTextRun` (page 1885)
Converts a string from Unicode to one or more encodings.

`ConvertFromUnicodeToScriptCodeRun` (page 1880)
Converts a string from Unicode to one or more scripts.

`CreateUnicodeToTextRunInfo` (page 1894)
Creates and returns a Unicode converter object containing the information required for converting a Unicode text string to strings in one or more non-Unicode encodings.

`CreateUnicodeToTextRunInfoByEncoding` (page 1895)
Based on the given text encoding specifications for the converted text runs, creates and returns a Unicode converter object containing information required for converting strings from Unicode to one or more specified non-Unicode encodings.

`CreateUnicodeToTextRunInfoByScriptCode` (page 1896)
Based on the given script codes for the converted text runs, creates and returns a Unicode converter object containing information required for converting strings from Unicode to one or more specified non-Unicode encodings.

`DisposeUnicodeToTextRunInfo` (page 1898)
Releases the memory allocated for the specified Unicode converter object.

`ResetUnicodeToTextRunInfo` (page 1906)
Reinitializes all state information kept by the context objects in TextRun conversions.

Converting Between Unicode and Pascal Strings

`ConvertFromPStringToUnicode` (page 1876)
Converts a Pascal string in a Mac OS text encoding to a Unicode string.

`ConvertFromUnicodeToPString` (page 1879)
Converts a Unicode string to Pascal in a Mac OS text encoding.

Obtaining Unicode Mapping Information

`CountUnicodeMappings` (page 1889)
Counts available mappings that meet the specified matching criteria.

`QueryUnicodeMappings` (page 1903)
Returns a list of the conversion mappings available on the system that meet specified matching criteria and returns the number of mappings found.

Truncating Strings Before Converting Them

`TruncateForTextToUnicode` (page 1934)
Identifies where your application can safely break a multibyte string to be converted to Unicode so that the string is not broken in the middle of a multibyte character.

`TruncateForUnicodeToText` (page 1935)
Identifies where your application can safely break a Unicode string to be converted to any encoding so that the string is broken in a way that preserves the text element integrity.

Setting the Fallback Handler

`SetFallbackUnicodeToText` (page 1908)
Specifies a fallback handler to be used for converting a Unicode text segment to another encoding when the Unicode Converter cannot convert the text using the mapping table specified by the Unicode converter object.

`SetFallbackUnicodeToTextRun` (page 1909)
Specifies a fallback handler to be used for converting a Unicode text segment to another encoding when the Unicode Converter cannot convert the text using the mapping table specified by a Unicode converter object.

Working With Universal Procedure Pointers

`NewUnicodeToTextFallbackUPP` (page 1903)
Creates a new universal procedure pointer (UPP) to a Unicode-to-text fallback callback.

`DisposeUnicodeToTextFallbackUPP` (page 1897)
Disposes of a a new universal procedure pointer (UPP) to a Unicode-to-text fallback callback.

`InvokeUnicodeToTextFallbackUPP` (page 1901)
Calls your Unicode-to-text fallback callback.

Getting UniChar Property Values

`UCGetCharProperty` (page 1936)
Obtains the value associated with a property type for the specified `UniChar` characters.

Functions

ChangeTextToUnicodeInfo

Changes the mapping information for the specified Unicode converter object used to convert text to Unicode to the new mapping you provide.

```
OSStatus ChangeTextToUnicodeInfo (
   TextToUnicodeInfo ioTextToUnicodeInfo,
   ConstUnicodeMappingPtr iUnicodeMapping
);
```

Parameters

ioTextToUnicodeInfo
The Unicode converter object of type `TextToUnicodeInfo` (page 1966) containing the mapping to be modified. You use the function `CreateTextToUnicodeInfo` (page 1890) to obtain one.

iUnicodeMapping
A structure of type `UnicodeMapping` (page 1967) identifying the new mapping to be used. This is the mapping that replaces the existing mapping in the Unicode converter object.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
The function replaces the mapping table information that currently exists in the Unicode converter object pointed to by the `ioTextToUnicodeInfo` parameter with the information contained in the `UnicodeMapping` structure you supply as the `iUnicodeMapping` parameter.

`ChangeTextToUnicodeInfo` resets the Unicode converter object's fields as necessary.

If an error is returned, the Unicode converter object is invalid.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ChangeUnicodeToTextInfo

Changes the mapping information contained in the specified Unicode converter object used to convert Unicode text to a non-Unicode encoding.

```
OSStatus ChangeUnicodeToTextInfo (
   UnicodeToTextInfo ioUnicodeToTextInfo,
   ConstUnicodeMappingPtr iUnicodeMapping
);
```

Parameters

ioUnicodeToTextInfo

The Unicode converter object of type `UnicodeToTextInfo` (page 1969) to be modified. You use the function `CreateUnicodeToTextInfo` (page 1892) or `CreateUnicodeToTextInfoByEncoding` (page 1893) to obtain a Unicode converter object of this type.

iUnicodeMapping

The structure of type `UnicodeMapping` (page 1967) to be used. This is the new mapping that replaces the existing mapping in the Unicode converter object.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

The function replaces the mapping table information that currently exists in the specified Unicode converter object with the information contained in the new Unicode mapping structure you provide.

`ChangeUnicodeToTextInfo` resets the Unicode converter object's fields as necessary. However, it does not initialize or reset the conversion state maintained by the Unicode converter object.

This function is especially useful for converting a string from Unicode if the Unicode string contains characters that require multiple destination encodings and you know the next destination encoding.

For example, you can change the other (destination) encoding of the Unicode mapping structure pointed to by the `iUnicodeMapping` parameter before you call the function `ConvertFromUnicodeToText` (page 1883) to convert the next character or sequence of characters that require a different destination encoding.

If an error is returned, the Unicode converter object is invalid.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

ConvertFromPStringToUnicode

Converts a Pascal string in a Mac OS text encoding to a Unicode string.

```
OSStatus ConvertFromPStringToUnicode (
   TextToUnicodeInfo iTextToUnicodeInfo,
   ConstStr255Param iPascalStr,
   ByteCount iOutputBufLen,
   ByteCount *oUnicodeLen,
   UniChar oUnicodeStr[]
);
```

Parameters

iTextToUnicodeInfo

A Unicode converter object of type `TextToUnicodeInfo` (page 1966) for the Pascal string to be converted. You can use the function `CreateTextToUnicodeInfo` (page 1890) or `CreateTextToUnicodeInfoByEncoding` (page 1891) to create the Unicode converter object.

iPascalStr

The Pascal string to be converted to Unicode.

iOutputBufLen

The length in bytes of the output buffer pointed to by the `oUnicodeStr` parameter. Your application supplies this buffer to hold the returned converted string. The `oUnicodeLen` parameter may return a byte count that is less than this value if the converted string is smaller than the buffer size you allocated.

oUnicodeLen

On return, a pointer to the length in bytes of the converted Unicode string returned in the `oUnicodeStr` parameter.

oUnicodeStr

A pointer to a Unicode character array. On return, this array holds the converted Unicode string.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

The `ConvertFromPStringToUnicode` function provides an easy and efficient way to convert a short Pascal string to a Unicode string without incurring the overhead associated with the function `ConvertFromTextToUnicode` (page 1877).

If necessary, this function automatically uses fallback characters to map the text elements of the string.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

ConvertFromTextToUnicode

Converts a string from any encoding to Unicode.

```
OSStatus ConvertFromTextToUnicode (
   TextToUnicodeInfo iTextToUnicodeInfo,
   ByteCount iSourceLen,
   ConstLogicalAddress iSourceStr,
   OptionBits iControlFlags,
   ItemCount iOffsetCount,
   const ByteOffset iOffsetArray[],
   ItemCount *oOffsetCount,
   ByteOffset oOffsetArray[],
   ByteCount iOutputBufLen,
   ByteCount *oSourceRead,
   ByteCount *oUnicodeLen,
   UniChar oUnicodeStr[]
);
```

Parameters

iTextToUnicodeInfo

A Unicode converter object of type `TextToUnicodeInfo` containing mapping and state information used for the conversion. The contents of this Unicode converter object are modified by the function. Your application obtains a Unicode converter object using the function `CreateTextToUnicodeInfo` (page 1890).

iSourceLen

The length in bytes of the source string to be converted.

iSourceStr

The address of the source string to be converted.

iControlFlags

Conversion control flags. You can use "Conversion Masks" (page 1972) to set the `iControlFlags` parameter.

iOffsetCount

The number of offsets in the `iOffsetArray` parameter. Your application supplies this value. The number of entries in `iOffsetArray` must be fewer than the number of bytes specified in `iSourceLen`. If you don't want offsets returned to you, specify `0` (zero) for this parameter.

iOffsetArray

An array of type `ByteOffset`. On input, you specify the array that contains an ordered list of significant byte offsets pertaining to the source string. These offsets may identify font or style changes, for example, in the source string. All array entries must be less than the length in bytes specified by the `iSourceLen` parameter. If you don't want offsets returned to your application, specify `NULL` for this parameter and `0` (zero) for `iOffsetCount`.

oOffsetCount

On return, a pointer to the number of offsets that were mapped in the output stream.

oOffsetArray

An array of type `ByteOffset`. On return, this array contains the corresponding new offsets for the Unicode string produced by the converter.

iOutputBufLen

The length in bytes of the output buffer pointed to by the `oUnicodeStr` parameter. Your application supplies this buffer to hold the returned converted string. The `oUnicodeLen` parameter may return a byte count that is less than this value if the converted byte string is smaller than the buffer size you allocated. The relationship between the size of the source string and the Unicode string is complex and depends on the source encoding and the contents of the string.

oSourceRead

On return, a pointer to the number of bytes of the source string that were converted. If the function returns a `kTECUnmappableElementErr` result code, this parameter returns the number of bytes that were converted before the error occurred.

oUnicodeLen

On return, a pointer to the length in bytes of the converted stream.

oUnicodeStr

A pointer to an array used to hold a Unicode string. On input, this value points to the beginning of the array for the converted string. On return, this buffer holds the converted Unicode string. (For guidelines on estimating the size of the buffer needed, see the discussion.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026). The function returns a `noErr` result code if it has completely converted the input string to Unicode without using fallback characters.

Discussion
You specify the source string's encoding in the Unicode mapping structure that you pass to the function `CreateTextToUnicodeInfo` (page 1890) to obtain a Unicode converter object for the conversion. You pass the Unicode converter object returned by `CreateTextToUnicodeInfo` to `ConvertFromTextToUnicode` as the `iTextToUnicodeInfo` parameter.

In addition to converting a text string in any encoding to Unicode, the `ConvertFromTextToUnicode` function can map offsets for style or font information from the source text string to the returned converted string. The converter reads the application-supplied offsets, which apply to the source string, and returns the corresponding new offsets in the converted string. If you do not want the offsets at which font or style information occurs mapped to the resulting string, you should pass `NULL` for `iOffsetArray` and `0` (zero) for `iOffsetCount`.

Your application must allocate a buffer to hold the resulting converted string and pass a pointer to the buffer in the `oUnicodeStr` parameter. To determine the size of the output buffer to allocate, you should consider the size of the source string, its encoding type, and its content in relation to the resulting Unicode string.

For example, for 1-byte encodings, such as MacRoman, the Unicode string will be at least double the size (more if it uses noncomposed Unicode) for MacArabic and MacHebrew, the corresponding Unicode string could be up to six times as big. For most 2-byte encodings, for example Shift-JIS, the Unicode string will be less than double the size. For international robustness, your application should allocate a buffer three to four times larger than the source string. If the output Unicode text is actually UTF-8—which could occur beginning with the current release of the Text Encoding Conversion Manager, version 1.2.1—the UTF-8 buffer pointer must be cast to `UniCharArrayPtr` before it can be passed as the `oUnicodeStr` parameter. Also, the output buffer length will have a wider range of variation than for UTF-16; for ASCII input, the output will be the same size; for Han input, the output will be twice as big, and so on.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ConvertFromUnicodeToPString

Converts a Unicode string to Pascal in a Mac OS text encoding.

```
OSStatus ConvertFromUnicodeToPString (
   UnicodeToTextInfo iUnicodeToTextInfo,
   ByteCount iUnicodeLen,
   const UniChar iUnicodeStr[],
   Str255 oPascalStr
);
```

Parameters

iUnicodeToTextInfo

A Unicode converter object. You use the `CreateUnicodeToTextInfo` or `CreateUnicodeToTextInfoByEncoding` function to obtain the Unicode converter object for the conversion.

iUnicodeLen

The length in bytes of the Unicode string to be converted. This is the string your application provides in the `iUnicodeStr` parameter.

iUnicodeStr

A pointer to an array containing the Unicode string to be converted.

oPascalStr

A buffer. On return, the converted Pascal string returned by the function.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

The `ConvertFromUnicodeToPString` function provides an easy and efficient way to convert a Unicode string to a Pascal string in a Mac OS text encoding without incurring the overhead associated with use of the function `ConvertFromUnicodeToText` (page 1883) or `ConvertFromUnicodeToScriptCodeRun` (page 1880).

If necessary, this function uses the loose mapping and fallback characters to map the text elements of the string. For fallback mappings, it uses the handler associated with the Unicode converter object.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

ConvertFromUnicodeToScriptCodeRun

Converts a string from Unicode to one or more scripts.

```
OSStatus ConvertFromUnicodeToScriptCodeRun (
   UnicodeToTextRunInfo iUnicodeToTextInfo,
   ByteCount iUnicodeLen,
   const UniChar iUnicodeStr[],
   OptionBits iControlFlags,
   ItemCount iOffsetCount,
   const ByteOffset iOffsetArray[],
   ItemCount *oOffsetCount,
   ByteOffset oOffsetArray[],
   ByteCount iOutputBufLen,
   ByteCount *oInputRead,
   ByteCount *oOutputLen,
   LogicalAddress oOutputStr,
   ItemCount iScriptRunBufLen,
   ItemCount *oScriptRunOutLen,
   ScriptCodeRun oScriptCodeRuns[]
);
```

Parameters

iUnicodeToTextInfo

You use the function `CreateUnicodeToTextRunInfoByScriptCode` (page 1896) to obtain a Unicode converter object to specify for this parameter.

iUnicodeLen

The length in bytes of the Unicode string to be converted.

iUnicodeStr

A pointer to the Unicode string to be converted.

iControlFlags

Conversion control flags. The following constants define the masks for control flags valid for this parameter. You can use "Conversion Masks" (page 1972) and "Directionality Masks" (page 1976) to set the `iControlFlags` parameter.

If the text-run control flag is clear, `ConvertFromUnicodeToScriptCodeRun` attempts to convert the Unicode text to the single script from the list of scripts in the Unicode converter object that produces the best result, that is, that provides for the greatest amount of source text conversion. If the complete source text can be converted into more than one of the scripts specified in the array, then the converter chooses among them based on their order in the array. If this flag is clear, the `oScriptCodeRuns` parameter always points to a value equal to 1.

If you set the use-fallbacks control flag, the converter uses the default fallback characters for the current script. If the converter cannot handle a character using the current encoding, even using fallbacks, the converter attempts to convert the character using the other scripts, beginning with the first one specified in the list and skipping the one where it failed.

If you set the `kUnicodeTextRunBit` control flag, the converter attempts to convert the complete Unicode text string into the first script specified in the Unicode mapping structures array you passed to `CreateUnicodeToTextRunInfo`, `CreateUnicodeToTextRunInfoByEncoding`, or `CreateUnicodeToTextRunInfoByScriptCode` to create the Unicode converter object used for this conversion. If it cannot do this, the converter then attempts to convert the first text element that failed to the remaining scripts, in their specified order in the array. What the converter does with the next text element depends on the setting of the keep-same-encoding control flag:

If the keep-same-encoding control flag is clear, the converter returns to the original script and attempts to continue conversion with that script; this is equivalent to converting each text element to the first one that works, in the order specified.

If the Unicode-keep-same-encoding control flag is set, the converter continues with the new destination script until it encounters a text element that cannot be converted using the new script. This attempts to minimize the number of script code changes in the output text. When the converter cannot convert a text element using any of the scripts in the list and the Unicode-keep-same-encoding control flag is set, the converter uses the fallbacks default characters for the current script.

iOffsetCount

The number of offsets in the array pointed to by the `iOffsetArray` parameter. Your application supplies this value. The number of entries in `iOffsetArray` must be fewer than half the number of bytes specified in `iUnicodeLen`. If you don't want offsets returned to you, specify `0` (zero) for this parameter.

iOffsetArray

An array of type `ByteOffset`. On input, you specify the array that contains an ordered list of significant byte offsets pertaining to the source Unicode string. These offsets may identify font or style changes, for example, in the Unicode string. If you don't want offsets returned to your application, specify `NULL` for this parameter and `0` (zero) for `iOffsetCount`.

oOffsetCount

On return, a pointer to the number of offsets that were mapped in the output stream.

oOffsetArray

An array of type `ByteOffset`. On return, this array contains the corresponding new offsets for the resulting converted string.

iOutputBufLen

The length in bytes of the output buffer pointed to by the `oOutputStr` parameter. Your application supplies this buffer to hold the returned converted string. The `oOutputLen` parameter may return a byte count that is less than this value if the converted byte string is smaller than the buffer size you allocated.

oInputRead

On return, a pointer to the number of bytes of the Unicode source string that were converted. If the function returns a result code other than `noErr`, then this parameter returns the number of bytes that were converted before the error occurred.

oOutputLen

On return, a pointer to the length in bytes of the converted string.

oOutputStr

A buffer address. On input, this value points to the beginning of the buffer for the converted string. On return, this buffer contains the converted string in one or more encodings. When an error occurs, the `ConvertFromUnicodeToScriptCodeRun` function returns the converted string up to the character that caused the error.

iScriptRunBufLen

The number of script code run elements you allocated for the script code run array pointed to by the `oScriptCodeRuns` parameter. The converter returns the number of valid script code runs in the location pointed to by `oScriptRunOutLen`. Each entry in the script code run array specifies the beginning offset in the converted text and its associated script code.

oScriptRunOutLen

A pointer to a value of type `ItemCount`. On output, this value contains the number of valid script code runs returned in the `oScriptCodeRuns` parameter.

oScriptCodeRuns

An array of elements of type `ScriptCodeRun`. Your application should allocate an array with the number of elements you specify in the `iScriptRunBufLen` parameter. On return, this array contains the script code runs for the converted text string. Each entry in the array specifies the beginning offset in the converted text string and the associated script code specification.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
To use the `ConvertFromUnicodeToScriptCodeRun` function, you must first set up an array of script codes containing in order of precedence the scripts to be used for the conversion. To create a Unicode converter object, you call the function `CreateUnicodeToTextRunInfoByScriptCode` (page 1896). You pass the returned Unicode converter object as the `iUnicodeToTextInfo` parameter when you call the `ConvertFromUnicodeToScriptCodeRun` function.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ConvertFromUnicodeToText

Converts a Unicode text string to the destination encoding you specify.

```
OSStatus ConvertFromUnicodeToText (
   UnicodeToTextInfo iUnicodeToTextInfo,
   ByteCount iUnicodeLen,
   const UniChar iUnicodeStr[],
   OptionBits iControlFlags,
   ItemCount iOffsetCount,
   const ByteOffset iOffsetArray[],
   ItemCount *oOffsetCount,
   ByteOffset oOffsetArray[],
   ByteCount iOutputBufLen,
   ByteCount *oInputRead,
   ByteCount *oOutputLen,
   LogicalAddress oOutputStr
);
```

Parameters

iUnicodeToTextInfo

A Unicode converter object of type `UnicodeToTextInfo` for converting text from Unicode. You use the function `CreateUnicodeToTextInfo` (page 1892) or `CreateUnicodeToTextInfoByEncoding` (page 1893) to obtain a Unicode converter object to specify for this parameter. This function modifies the contents of the `iUnicodeToTextInfo` parameter.

iUnicodeLen

The length in bytes of the Unicode string to be converted.

iUnicodeStr

A pointer to the Unicode string to be converted. If the input text is UTF-8, which is supported for versions 1.2.1 or later of the converter, you must cast the UTF-8 buffer pointer to `ConstUniCharArrayPtr` before you can pass it as this parameter.

iControlFlags

Conversion control flags. You can use "Conversion Masks" (page 1972) and "Directionality Masks" (page 1976) to set the `iControlFlags` parameter.

iOffsetCount

The number of offsets contained in the array provided by the `iOffsetArray` parameter. Your application supplies this value. If you don't want offsets returned to you, specify `0` (zero) for this parameter.

iOffsetArray

An array of type `ByteOffset`. On input, you specify the array that gives an ordered list of significant byte offsets pertaining to the Unicode source string to be converted. These offsets may identify font or style changes, for example, in the source string. If you don't want offsets returned to your application, specify `NULL` for this parameter and `0` (zero) for `iOffsetCount`. All offsets must be less than `iUnicodeLen`.

oOffsetCount

On return, a pointer to the number of offsets that were mapped in the output stream.

oOffsetArray

An array of type `ByteOffset`. On return, this array contains the corresponding new offsets for the converted string in the new encoding.

iOutputBufLen

The length in bytes of the output buffer pointed to by the `oOutputStr` parameter. Your application supplies this buffer to hold the returned converted string. The `oOutputLen` parameter may return a byte count that is less than this value if the converted byte string is smaller than the buffer size you allocated.

oInputRead

On return, a pointer to a the number of bytes of the Unicode string that were converted. If the function returns a `kTECUnmappableElementErr` result code, this parameter returns the number of bytes that were converted before the error occurred.

oOutputLen

On return, a pointer to the length in bytes of the converted text stream.

oOutputStr

A value of type `LogicalAddress`. On input, this value points to a buffer for the converted string. On return, the buffer holds the converted text string. (For guidelines on estimating the size of the buffer needed, see the following discussion.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function can also map offsets for style or font information from the source text string to the returned converted string. The converter reads the application-supplied offsets and returns the corresponding new offsets in the converted string. If you do not want font or style information offsets mapped to the resulting string, you should pass `NULL` for `iOffsetArray` and `0` (zero) for `iOffsetCount`.

Your application must allocate a buffer to hold the resulting converted string and pass a pointer to the buffer in the `oOutputStr` parameter. To determine the size of the output buffer to allocate, you should consider the size and content of the Unicode source string in relation to the type of encoding to which it will be converted. For example, for many encodings, such as MacRoman and Shift-JIS, the size of the returned string will be between half the size and the same size as the source Unicode string. However, for some encodings that are not Mac OS ones, such as EUC-JP, which has some 3-byte characters for Kanji, the returned string could be larger than the source Unicode string. For MacArabic and MacHebrew, the result will usually be less than half the size of the Unicode string.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ConvertFromUnicodeToTextRun

Converts a string from Unicode to one or more encodings.

```
OSStatus ConvertFromUnicodeToTextRun (
   UnicodeToTextRunInfo iUnicodeToTextInfo,
   ByteCount iUnicodeLen,
   const UniChar iUnicodeStr[],
   OptionBits iControlFlags,
   ItemCount iOffsetCount,
   const ByteOffset iOffsetArray[],
   ItemCount *oOffsetCount,
   ByteOffset oOffsetArray[],
   ByteCount iOutputBufLen,
   ByteCount *oInputRead,
   ByteCount *oOutputLen,
   LogicalAddress oOutputStr,
   ItemCount iEncodingRunBufLen,
   ItemCount *oEncodingRunOutLen,
   TextEncodingRun oEncodingRuns[]
);
```

Parameters

iUnicodeToTextInfo

You use the function `CreateUnicodeToTextRunInfo` (page 1894), `CreateUnicodeToTextRunInfoByEncoding` (page 1895), or `CreateUnicodeToTextRunInfoByScriptCode` (page 1896) to obtain a Unicode converter object to specify for this parameter.

iUnicodeLen

The length in bytes of the Unicode string to be converted.

iUnicodeStr

A pointer to the Unicode string to be converted.

iControlFlags

Conversion control flags. The following constants define the masks for control flags valid for this parameter. You can use "Conversion Masks" (page 1972) and "Directionality Masks" (page 1976) to set the `iControlFlags` parameter.

If the text-run control flag is clear, `ConvertFromUnicodeToTextRun` attempts to convert the Unicode text to the single encoding it chooses from the list of encodings in the Unicode mapping structures array that you provide when you create the Unicode converter object. This is the encoding that produces the best result, that is, that provides for the greatest amount of source text conversion. If the complete source text can be converted into more than one of the encodings specified in the Unicode mapping structures array, then the converter chooses among them based on their order in the array. If this flag is clear, the `oEncodingRuns` parameter always points to a value equal to 1.

If you set the use-fallbacks control flag, the converter uses the default fallback characters for the current encoding. If the converter cannot handle a character using the current encoding, even using fallbacks, the converter attempts to convert the character using the other encodings, beginning with the first encoding specified in the list and skipping the encoding where it failed.

If you set the `kUnicodeTextRunBit` control flag, the converter attempts to convert the complete Unicode text string into the first encoding specified in the Unicode mapping structures array you passed to `CreateUnicodeToTextRunInfo`, `CreateUnicodeToTextRunInfoByEncoding`, or `CreateUnicodeToTextRunInfoByScriptCod`e when you created the Unicode converter object for this conversion. If it cannot do this, the converter then attempts to convert the first text element that failed to the remaining encodings, in their specified order in the array. What the converter does with the next text element depends on the setting of the keep-same-encoding control flag.

If the keep-same-encoding control flag is clear, the converter returns to the original encoding and attempts to continue conversion with that encoding; this is equivalent to converting each text element to the first encoding that works, in the order specified.

If the keep-same-encoding control flag is set, the converter continues with the new destination encoding until it encounters a text element that cannot be converted using the new encoding. This attempts to minimize the number of encoding changes in the output text. When the converter cannot convert a text element using any of the encodings in the list and the Unicode-keep-same-encoding control flag is set, the converter uses the fallbacks default characters for the current encoding.

iOffsetCount

The number of offsets in the array pointed to by the `iOffsetArray` parameter. Your application supplies this value. If you don't want offsets returned to you, specify `0` (zero) for this parameter.

iOffsetArray

An array of type `ByteOffset`. On input, you specify the array that contains an ordered list of significant byte offsets pertaining to the source Unicode string. These offsets may identify font or style changes, for example, in the Unicode string. If you don't want offsets returned to your application, specify `NULL` for this parameter and `0` (zero) for `iOffsetCount`. All offsets must be less than `iUnicodeLen`.

oOffsetCount

On return, a pointer to the number of offsets that were mapped in the output stream.

oOffsetArray

An array of type `ByteOffset`. On return, this array contains the corresponding new offsets for the resulting converted string.

iOutputBufLen

The length in bytes of the output buffer pointed to by the `oOutputStr` parameter. Your application supplies this buffer to hold the returned converted string. The `oOutputLen` parameter may return a byte count that is less than this value if the converted byte string is smaller than the buffer size you allocated.

oInputRead

On return, a pointer to the number of bytes of the Unicode source string that were converted. If the function returns a result code other than `noErr`, then this parameter returns the number of bytes that were converted before the error occurred.

oOutputLen

On return, a pointer to the length in bytes of the converted string.

oOutputStr

A value of type `LogicalAddress`. On input, this value points to the start of the buffer for the converted string. On output, this buffer contains the converted string in one or more encodings. When an error occurs, the `ConvertFromUnicodeToTextRun` function returns the converted string up to the character that caused the error. (For guidelines on estimating the size of the buffer needed, see the discussion following the parameter descriptions.

iEncodingRunBufLen

The number of text encoding run elements you allocated for the encoding run array pointed to by the `oEncodingRuns` parameter. The converter returns the number of valid encoding runs in the location pointed to by `oEncodingRunOutLen`. Each entry in the encoding runs array specifies the beginning offset in the converted text and its associated text encoding.

oEncodingRunOutLen

On return, a pointer to a the number of valid encoding runs returned in the `oEncodingRuns` parameter.

oEncodingRuns

On input, an array of structures of type `TextEncodingRun`. Your application should allocate an array with the number of elements you specify in the `iEncodingRunBufLen` parameter. On return, this array contains the encoding runs for the converted text string. Each entry in the encoding run array specifies the beginning offset in the converted text string and the associated encoding specification.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

To use the `ConvertFromUnicodeToTextRun` function, you must first set up an array of structures of type `UnicodeMapping` (page 1967) containing, in order of precedence, the mapping information for the conversion. To create a Unicode converter object, you call the `CreateUnicodeToTextRunInfo` function passing it the Unicode mapping array, or you can the `CreateUnicodeToTextRunInfoByEncoding` or `CreateUnicodeToTextRunInfoByScriptCode` functions, which take arrays of text encodings or script codes instead of an array of Unicode mappings. You pass the returned Unicode converter object as the `iUnicodeToTextInfo` parameter when you call the `ConvertFromUnicodeToTextRun` function.

Two of the control flags that you can set for the `iControlFlags` parameter allow you to control how the Unicode Converter uses the multiple encodings in converting the text string. These flags are explained in the description of the `iControlFlags` parameter. Here is a summary of how to use these two control flags:

- To keep the converted text in a single encoding, clear the text-run control flag.
- To keep as much contiguous converted text as possible in one encoding, set the text-run control flag and clear the keep-same-encoding control flag.
- To minimize the number of resulting encoding runs and the changes of destination encoding, set both the text-run and keep-same-encoding control flags.

The `ConvertFromUnicodeToTextRun` function returns the converted string in the array pointed to by the `oOutputStr` parameter. Beginning with the first text element in the `oOutputStr` array, the elements of the array pointed to by the `oEncodingRuns` parameter identify the encodings of the converted string. The

number of elements in the `oEncodingRuns` array may not correspond to the number of elements in the `oOutputStr` array. This is because the `oEncodingRuns` array includes only elements for the beginning of each new encoding run in the converted string.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CountUnicodeMappings

Counts available mappings that meet the specified matching criteria.

```
OSStatus CountUnicodeMappings (
   OptionBits iFilter,
   ConstUnicodeMappingPtr iFindMapping,
   ItemCount *oActualCount
);
```

Parameters

iFilter

Filter control flags representing the six subfields of the Unicode mapping structure that this function uses to match against in determining which mappings on the system to return to your application. The filter control enumeration, described in "Unicode Matching Masks" (page 1980), define the constants for the subfield's flags and their masks. You can include in the search criteria any of the three text encoding subfields for both the Unicode encoding and the other specified encoding. For any flag not turned on, the subfield value is ignored and the function does not check the corresponding subfield of the mappings on the system.

iFindMapping

A structure of type `UnicodeMapping` (page 1967) containing the text encodings whose field values are to be matched.

oActualCount

On return, a pointer to the number of matching mappings found.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You can filter on any of the three text encoding subfields of the Unicode mapping structure's `unicodeEncoding` specification and on any of the three text encoding subfields of the structure's `otherEncoding` specification. The `iFilter` parameter consists of a set of six control flags that you set to identify which of the corresponding six subfields to include in the match count. No filtering is performed on fields for which you do not set the corresponding filter control flag.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CreateTextEncoding

Creates and returns a text encoding specification.

```
TextEncoding CreateTextEncoding (
   TextEncodingBase encodingBase,
   TextEncodingVariant encodingVariant,
   TextEncodingFormat encodingFormat
);
```

Parameters

encodingBase

A base text encoding.

encodingVariant

A variant of the base text encoding. To specify the default variant for the base encoding given in the `encodingBase` parameter, you can use the `kTextEncodingDefaultVariant` constant.

encodingFormat

A format for the base text encoding. To specify the default format for the base encoding, you can use the `kTextEncodingDefaultFormat` constant. If you want to obtain a `TextEncoding` value that references UTF-16 or UTF-8, pass `kUnicode16BitFormat` or `kUnicodeUTF8Format`.

Return Value

The text encoding specification that the function creates from the values you pass it.

Discussion

When you create a text encoding specification, the three values that you specify are packed into an unsigned integer, which you can then pass by value to the functions that use text encodings. See the data type `TextEncodingRun` (page 1965).

Availability

Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In

`TextCommon.h`

CreateTextToUnicodeInfo

Creates and returns a Unicode converter object containing information required for converting strings from a non-Unicode encoding to Unicode.

```
OSStatus CreateTextToUnicodeInfo (
   ConstUnicodeMappingPtr iUnicodeMapping,
   TextToUnicodeInfo *oTextToUnicodeInfo
);
```

Parameters

iUnicodeMapping

A pointer to a structure of type `UnicodeMapping`. Your application provides this structure to identify the mapping to use for the conversion. You must supply a value of type `TextEncoding` in the `unicodeEncoding` field of this structure. A `TextEncoding` is a triple composed of an encoding base, an encoding variant, and a format. You can obtain a `UnicodeMapping` (page 1967) value by calling the function `CreateTextEncoding`.

oTextToUnicodeInfo

On return, the Unicode converter object holds mapping table information you supplied as the `UnicodeMapping` parameter and state information related to the conversion. This information is required for conversion of a text stream in a non-Unicode encoding to Unicode.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

You pass a Unicode converter object returned from the function CreateTextToUnicodeInfo to the function `ConvertFromTextToUnicode` (page 1877) or `ConvertFromPStringToUnicode` (page 1876) to identify the information to be used for the conversion. These two functions modify the contents of the object.

You pass a Unicode converter object returned from `CreateTextToUnicodeInfo` to the function `TruncateForTextToUnicode` (page 1934) to identify the information to be used to truncate the string. This function does not modify the contents of the Unicode converter object.

If an error is returned, the Unicode converter object is invalid.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

CreateTextToUnicodeInfoByEncoding

Based on the given text encoding specification, creates and returns a Unicode converter object containing information required for converting strings from the specified non-Unicode encoding to Unicode.

```
OSStatus CreateTextToUnicodeInfoByEncoding (
   TextEncoding iEncoding,
   TextToUnicodeInfo *oTextToUnicodeInfo
);
```

Parameters

iEncoding

The text encoding specification for the source text.

oTextToUnicodeInfo

The Unicode converter object of type `TextToUnicodeInfo` (page 1966) returned by the function.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You can use this function instead of the `CreateTextToUnicodeInfo` (page 1890) function when you do not need to create a Unicode mapping structure. You simply specify the text encoding of the source text. However, this method is less efficient because the text encoding parameter must be resolved internally into a Unicode mapping.

You cannot specify a version of Unicode. The function uses a 16-bit form of Unicode as the default.

You pass a Unicode converter object returned from `CreateTextToUnicodeInfoByEncoding` to the function `ConvertFromTextToUnicode` (page 1877) or `ConvertFromPStringToUnicode` (page 1876) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

You pass a Unicode converter object returned from `CreateTextToUnicodeInfoByEncoding` to the function `TruncateForTextToUnicode` (page 1934) to identify the information to be used to truncate the string. This function does not modify the contents of the Unicode converter object.

If you are converting the text stream to Unicode as an intermediary encoding, and then from Unicode to the final destination encoding, you use the function `CreateUnicodeToTextInfo` (page 1892) to create a Unicode converter object for the second part of the process.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`UnicodeConverter.h`

CreateUnicodeToTextInfo

Creates and returns a Unicode converter object containing information required for converting strings from Unicode to a non-Unicode encoding.

```
OSStatus CreateUnicodeToTextInfo (
   ConstUnicodeMappingPtr iUnicodeMapping,
   UnicodeToTextInfo *oUnicodeToTextInfo
);
```

Parameters

iUnicodeMapping

A pointer to a structure of type `UnicodeMapping` (page 1967). Your application provides this structure to identify the mapping to be used for the conversion. The `unicodeEncoding` field of this structure can specify a Unicode format of `kUnicode16BitFormat` or `kUnicodeUTF8Format`. Note that the versions of the Unicode Converter prior to 1.2.1 do not support `kUnicodeUTF8Format`.

oUnicodeToTextInfo

On return, a pointer to a Unicode converter object that holds the mapping table information you supply as the `iUnicodeMapping` parameter and the state information related to the conversion. The information contained in the Unicode converter object is required for the conversion of a Unicode string to a non-Unicode encoding.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You pass the Unicode converter object returned from `CreateUnicodeToTextInfo` to the function `ConvertFromUnicodeToText` (page 1883) or `ConvertFromUnicodeToPString` (page 1879) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

If an error is returned, the Unicode converter object is invalid.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CreateUnicodeToTextInfoByEncoding

Based on the given text encoding specification for the converted text, creates and returns a Unicode converter object containing information required for converting strings from Unicode to the specified non-Unicode encoding.

```
OSStatus CreateUnicodeToTextInfoByEncoding (
   TextEncoding iEncoding,
   UnicodeToTextInfo *oUnicodeToTextInfo
);
```

Parameters

iEncoding

The text encoding specification for the destination, or converted, text.

oUnicodeToTextInfo

A pointer to a Unicode converter object of type `UnicodeToTextInfo` (page 1969).

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You can use this function instead of the `CreateUnicodeToTextInfo` (page 1892) function to create a Unicode converter. However, this method is less efficient internally because the destination text encoding you specify must be resolved into a Unicode mapping. Using this function, you cannot specify a version of Unicode, so a default version of Unicode is used; 16-bit format is assumed.

You pass a Unicode converter object returned from the function `CreateUnicodeToTextInfoByEncoding` to the function `ConvertFromUnicodeToText` (page 1883) or `ConvertFromUnicodeToPString` (page 1879) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

You pass a Unicode converter object returned from `CreateUnicodeToTextInfoByEncoding` to the function `TruncateForUnicodeToText` (page 1935) to identify the information to be used to truncate the string. This function does not modify the contents of the Unicode converter object.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CreateUnicodeToTextRunInfo

Creates and returns a Unicode converter object containing the information required for converting a Unicode text string to strings in one or more non-Unicode encodings.

```
OSStatus CreateUnicodeToTextRunInfo (
   ItemCount iNumberOfMappings,
   const UnicodeMapping iUnicodeMappings[],
   UnicodeToTextRunInfo *oUnicodeToTextInfo
);
```

Parameters

iNumberOfMappings

The number of mappings specified by your application for converting from Unicode to any other encoding types, including other forms of Unicode. If you pass 0 for this parameter, the converter will use all of the scripts installed in the system. The primary script is the one with highest priority; `ScriptOrder` (`'itlm'` resource) determines the priority of the rest. If you set the high-order bit for this parameter, the Unicode converter assumes that the `iEncodings` parameter contains a single element specifying the preferred encoding. This feature is supported for versions 1.2 or later of the converter.

iUnicodeMappings

A pointer to an array of structures of type `UnicodeMapping` (page 1967). Your application provides this structure to identify the mappings to be used for the conversion. The order in which you specify the mappings determines the priority of the destination encodings. For this function, the Unicode mapping structure can specify a Unicode format of `kUnicode16BitFormat` or `kUnicodeUTF8Format`. Note that the versions of the Unicode Converter prior to the Text Encoding Conversion Manager 1.2.1 do not support `kUnicodeUTF8Format`. Also, note that the `unicodeEncoding` field should be the same for all of the entries in `iUnicodeMappings`. If you pass `NULL` for the `iUnicodeMappings` parameter, the converter uses all of the scripts installed in the system, assuming the default version of Unicode with 16-bit format. The primary script is the one with the highest priority and `ScriptOrder`(`'itlm'` resource) determines the priority of the rest. This is supported beginning with version 1.2 of the Text Encoding Conversion Manager.

oUnicodeToTextInfo

A pointer to a Unicode converter object for converting Unicode text strings to strings in one or more non-Unicode encodings. On return, a pointer to a Unicode converter object that holds the mapping table information you supply as the `iUnicodeMappings` parameter and the state information related to the conversion.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You pass a Unicode converter object returned from the function `CreateUnicodeToTextRunInfo` to the function `ConvertFromUnicodeToTextRun` (page 1885) or `ConvertFromUnicodeToScriptCodeRun` (page 1880) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CreateUnicodeToTextRunInfoByEncoding

Based on the given text encoding specifications for the converted text runs, creates and returns a Unicode converter object containing information required for converting strings from Unicode to one or more specified non-Unicode encodings.

```
OSStatus CreateUnicodeToTextRunInfoByEncoding (
   ItemCount iNumberOfEncodings,
   const TextEncoding iEncodings[],
   UnicodeToTextRunInfo *oUnicodeToTextInfo
);
```

Parameters

iNumberOfEncodings

The number of desired encodings. If you pass 0 for this parameter, the converter will use all of the scripts installed in the system. The primary script is the one with highest priority; `ScriptOrder`('itlm' resource) determines the priority of the rest. If you set the high-order bit for this parameter, the Unicode converter assumes that the `iEncodings` parameter contains a single element specifying the preferred encoding. This feature is supported for versions 1.2 or later of the converter.

iEncodings

An array of text encoding specifications for the desired encodings. Your application provides this structure to identify the encodings to be used for the conversion. The order in which you specify the encodings determines the priority of the destination encodings. If you pass `NULL` for this parameter, the converter will use all of the scripts installed in the system. The primary script is the one with highest priority and `ScriptOrder`('itlm' resource) determines the priority of the rest.This feature is supported for versions 1.2 or later of the converter.

oUnicodeToTextInfo

A pointer to a Unicode converter object for converting Unicode text strings to strings in one or more non-Unicode encodings. On return, a pointer to a Unicode converter object that holds the encodings you supply as the `iEncodings` parameter and the state information related to the conversion.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You pass a Unicode converter object returned from `CreateUnicodeToTextRunInfoByEncoding` to the function `ConvertFromUnicodeToTextRun` (page 1885) or `ConvertFromUnicodeToScriptCodeRun` (page 1880) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

If an error is returned, the converter object is invalid.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

CreateUnicodeToTextRunInfoByScriptCode

Based on the given script codes for the converted text runs, creates and returns a Unicode converter object containing information required for converting strings from Unicode to one or more specified non-Unicode encodings.

```
OSStatus CreateUnicodeToTextRunInfoByScriptCode (
   ItemCount iNumberOfScriptCodes,
   const ScriptCode iScripts[],
   UnicodeToTextRunInfo *oUnicodeToTextInfo
);
```

Parameters

iNumberOfScriptCodes

The number of desired scripts. If you pass 0 for this parameter, the converter uses all the scripts installed in the system. In this case, the primary script is the one with highest priority; `ScriptOrder` (`'itlm'` resource) determines the priority of the rest. If you set the high-order bit for this parameter, the Unicode converter assumes that the `iScripts` parameter contains a single element specifying the preferred script. This feature is supported beginning with the Text Encoding Conversion Manager 1.2.

iScripts

An array of script codes for the desired scripts. Your application provides this structure to identify the scripts to be used for the conversion. The order in which you specify the scripts determines their priority. If you pass `NULL` for this parameter, the converter uses all of the scripts installed in the system. In this case, the primary script is the one with the highest priority and the priority order of the remaining scripts is defined by the `ScriptOrder(itlm resource)` resource. This feature is supported for versions 1.2 or later of the converter.

oUnicodeToTextInfo

A pointer to a Unicode converter object for converting Unicode text strings to strings in one or more non-Unicode encodings. On return, a pointer to Unicode converter object that holds the scripts you supply as the `iScripts` parameter and the state information related to the conversion.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You pass a Unicode converter object returned from `CreateUnicodeToTextRunInfoByScriptCode` to the function `ConvertFromUnicodeToTextRun` (page 1885) or `ConvertFromUnicodeToScriptCodeRun` (page 1880) to identify the information to be used for the conversion. These two functions modify the contents of the Unicode converter object.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`UnicodeConverter.h`

DisposeTextToUnicodeInfo

Releases the memory allocated for the specified Unicode converter object.

```
OSStatus DisposeTextToUnicodeInfo (
   TextToUnicodeInfo *ioTextToUnicodeInfo
);
```

Parameters

ioTextToUnicodeInfo

A pointer to a Unicode converter object of type `TextToUnicodeInfo` (page 1966), used for converting text to Unicode. On input, you specify the object to dispose. It must be an object which your application created using the function `CreateTextToUnicodeInfo` (page 1890) or `CreateTextToUnicodeInfoByEncoding` (page 1891). You must not point to any other type of Unicode converter object. Your application should not use this function with the same structure more than once.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026). If your application specifies an invalid Unicode converter object, such as `NULL`, the function returns a `paramErr` result code.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

DisposeUnicodeToTextFallbackUPP

Disposes of a a new universal procedure pointer (UPP) to a Unicode-to-text fallback callback.

```
void DisposeUnicodeToTextFallbackUPP (
   UnicodeToTextFallbackUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `UnicodeToTextFallbackProcPtr` (page 1953) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

DisposeUnicodeToTextInfo

Releases the memory allocated for the specified Unicode converter object.

```
OSStatus DisposeUnicodeToTextInfo (
   UnicodeToTextInfo *ioUnicodeToTextInfo
);
```

Parameters

ioUnicodeToTextInfo

A pointer to a Unicode converter object for converting from Unicode to a non-Unicode encoding. You specify a Unicode converter object that your application created using the function `CreateUnicodeToTextInfo` (page 1892) or `CreateUnicodeToTextInfoByEncoding` (page 1893). You must not point to any other type of Unicode converter object. Your application should not attempt to dispose of the same Unicode converter object more than once.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). The function returns `noErr` if it disposes of the Unicode converter object successfully. If your application specifies an invalid Unicode converter object, such as `NULL`, the function returns a `paramErr` result code.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

DisposeUnicodeToTextRunInfo

Releases the memory allocated for the specified Unicode converter object.

```
OSStatus DisposeUnicodeToTextRunInfo (
   UnicodeToTextRunInfo *ioUnicodeToTextRunInfo
);
```

Parameters

ioUnicodeToTextRunInfo

A pointer to a Unicode converter object. On input, you specify a Unicode converter object that points to the conversion information to dispose. It must be an object which your application created using the function `CreateUnicodeToTextRunInfo` (page 1894), `CreateUnicodeToTextRunInfoByEncoding` (page 1895), or `CreateUnicodeToTextRunInfoByScriptCode` (page 1896). You must point to any other type of Unicode converter object. Your application should not use this function with the same structure more than once.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). If your application specifies an invalid Unicode converter object, such as `NULL`, the function returns `paramErr`.

Availability

Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
UnicodeConverter.h

GetTextEncodingBase

Returns the base encoding of the specified text encoding.

```
TextEncodingBase GetTextEncodingBase (
   TextEncoding encoding
);
```

Parameters

encoding
A text encoding specification whose base encoding you want to obtain.

Return Value
The base encoding portion of the specified text encoding.

Discussion
See the data type TextEncodingRun (page 1965)

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
TextCommon.h

GetTextEncodingFormat

Returns the format value of the specified text encoding.

```
TextEncodingFormat GetTextEncodingFormat (
   TextEncoding encoding
);
```

Parameters

encoding
A text encoding specification.

Return Value
The text encoding format value contained in the text encoding you specified.

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
TextCommon.h

GetTextEncodingName

Returns the localized name for a specified text encoding.

```
OSStatus GetTextEncodingName (
   TextEncoding iEncoding,
   TextEncodingNameSelector iNamePartSelector,
   RegionCode iPreferredRegion,
   TextEncoding iPreferredEncoding,
   ByteCount iOutputBufLen,
   ByteCount *oNameLength,
   RegionCode *oActualRegion,
   TextEncoding *oActualEncoding,
   TextPtr oEncodingName
);
```

Parameters

iEncoding

A text encoding specification whose name you want to obtain.

iNamePartSelector

The portion of the encoding name you want to obtain. See "Text Encoding Name Selectors" (page 2012) for a list of possible values.

iPreferredRegion

The preferred region to use for the name. You can specify a Mac OS region code (which also implies a language) for this parameter. If the function cannot return the name for the preferred region, it returns the name using a region code with the same language or in a default language (for example, English).

iPreferredEncoding

The preferred encoding to use for the name. For example, ASCII, Mac OS Roman, or Shift-JIS. If the function cannot return the name using the preferred encoding, it returns the name using another encoding, such as Unicode or ASCII.

iOutputBufLen

The length in bytes of the output buffer that your application provides for the returned encoding name.

oNameLength

A pointer to a value of type `ByteCount`. On return, this parameter holds the actual length, in bytes, of the text encoding name. The value represents the full length of the name, which might be greater than the size of the output buffer, specified by the `iOutputBufLen` parameter. The length of the portion of the name actually contained in the output buffer is the smaller of `oNameLength` and `iOutputBufLen`.

oActualRegion

A pointer to a value of type `RegionCode`. On return, this parameter holds the actual region associated with the returned encoding name.

oActualEncoding

A pointer to a value of type `TextEncoding`. On return, this parameter holds the actual encoding associated with the returned encoding name.

oEncodingName

A pointer to a buffer you provide. On return, this parameter holds the text encoding name.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Names returned by `GetTextEncodingName` (in the buffer referred to by `oEncodingName`) can contain parentheses and other menu item meta characters, and so cannot be used with `AppendMenu` or `InsertMenuItem`. You can use them with `SetMenuItemText`.

This function can return resources and memory errors, and the following result codes:

- `kTextUnsupportedEncodingErr`, which indicates that the encoding whose name you want to obtain is not supported.
- `kTECMissingTableErr`, which indicates the name resource associated with the encoding is missing.
- `kTECTableFormatErr` or `kTECTableCheckSumErr`, which indicates that the name resource associated with that encoding is invalid.

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextCommon.h`

GetTextEncodingVariant

Returns the variant from the specified text encoding.

```
TextEncodingVariant GetTextEncodingVariant (
   TextEncoding encoding
);
```

Parameters
encoding
A text encoding specification.

Return Value
The text encoding variant portion of the specified text encoding.

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`TextCommon.h`

InvokeUnicodeToTextFallbackUPP

Calls your Unicode-to-text fallback callback.

```
OSStatus InvokeUnicodeToTextFallbackUPP (
   UniChar *iSrcUniStr,
   ByteCount iSrcUniStrLen,
   ByteCount *oSrcConvLen,
   TextPtr oDestStr,
   ByteCount iDestStrLen,
   ByteCount *oDestConvLen,
   LogicalAddress iInfoPtr,
   ConstUnicodeMappingPtr iUnicodeMappingPtr,
   UnicodeToTextFallbackUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeUnicodeToTextFallbackUPP`, as the system calls your Unicode-to-text fallback callback for you. See the callback `UnicodeToTextFallbackProcPtr` (page 1953) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

NearestMacTextEncodings

Obtains the best and alternate Mac text encoding.

```
OSStatus NearestMacTextEncodings (
   TextEncoding generalEncoding,
   TextEncoding *bestMacEncoding,
   TextEncoding *alternateMacEncoding
);
```

Parameters

`generalEncoding`
The text encoding for which you want to obtain a Mac text encoding.

`bestMacEncoding`
On return, the Mac text encoding that best matches the encoding specified by the `generalEncoding` parameter.

`alternateMacEncoding`
On return, the Mac text encoding that is the second best match for the encoding specified by the `generalEncoding` parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Text Common 1.5 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextCommon.h`

NewUnicodeToTextFallbackUPP

Creates a new universal procedure pointer (UPP) to a Unicode-to-text fallback callback.

```
UnicodeToTextFallbackUPP NewUnicodeToTextFallbackUPP (
   UnicodeToTextFallbackProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your Unicode-to-text fallback callback.

Return Value

On return, a UPP to the Unicode-to-text fallback callback.

Discussion

See the callback `UnicodeToTextFallbackProcPtr` (page 1953) for more information.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeConverter.h`

QueryUnicodeMappings

Returns a list of the conversion mappings available on the system that meet specified matching criteria and returns the number of mappings found.

```
OSStatus QueryUnicodeMappings (
   OptionBits iFilter,
   ConstUnicodeMappingPtr iFindMapping,
   ItemCount iMaxCount,
   ItemCount *oActualCount,
   UnicodeMapping oReturnedMappings[]
);
```

Parameters

iFilter

Filter control flags representing the six values given in the Unicode mapping structure that this function uses to match against in determining which mappings on the system to return to your application. The filter control flag enumerations, described in "Unicode Matching Masks" (page 1980), define the constants for the flags and their masks. You can include in the search criteria any of the three text encoding values—base, variant, and format—for both the Unicode encoding and the other specified encoding. For any flag not turned on, the value is ignored the function does not check the corresponding value of the mapping tables on the system.

iFindMapping

A structure of type `UnicodeMapping` (page 1967) containing the text encodings whose values are to be matched.

iMaxCount

The maximum number of mappings that can be returned. You provide this value to identify the number of elements in the array pointed to by the `oReturnedMappings` parameter that your application allocated. If the function identifies more matching mappings than the array can hold, it returns as many of them as fit. The function also returns a `kTECArrayFullErr` in this case.

oActualCount

On return, a pointer to the number of matching mappings found. This number may be greater than the number of mappings specified by `iMaxCount` if more matching mappings are found than can fit in the `oReturnedMappings` array.

oReturnedMappings

A pointer to an array of structures of type `UnicodeMapping` (page 1967). On input, this pointer refers to an array for the matching mappings returned by the function. To allocate sufficient elements for the array, you can use the function `CountUnicodeMappings` (page 1889) to determine the number of mappings returned for given values of the `iFilter` and `iFindMapping` parameters. On return, a pointer to an array that holds the matching mappings. If there are more matches than the array can hold, the function returns as many of them as will fit and a `kTECBufferBelowMinimumSizeErr` error result. The `oActualCount` parameter identifies the number of matching mappings actually found, which may be greater than the number returned.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). If the function returns a `noErr` result code, the value retuned in the `oActualCount` parameter is less than or equal to the value returned in the `iMaxCount` parameter and the `oReturnedMappings` parameter contains all of the matching mappings found. If the function returns a `kTECArrayFullErr`, the function found more mappings than your `oReturnedMappings` array could accommodate.

Discussion

You can use the `QueryUnicodeMappings` function to obtain all mappings on the system up to the number allowed by your `oReturnedMappings` array by specifying a value of zero for the `iFilter` field.

You can use the function to obtain very specific mappings by setting individual filter control flags. You can filter on any of the three text encoding subfields of the Unicode mapping structure's `unicodeEncoding` specification and on any of the three text encoding subfields of the mapping's `otherEncoding` specification. The `iFilter` parameter consists of a set of six control flags that you set to identify which of the corresponding six subfields to include in the match. The list provided in the `oReturnedMappings` parameter will contain only mappings that match the fields of the Unicode mapping structure whose text encodings subfields you identify in the filter control flags. No filtering is performed on subfields for which you do not set the corresponding filter control flag.

For example, to obtain a list of all mappings in which one of the encodings is the default variant and default format of the Unicode 1.1 base encoding and the other encoding is the default variant and default format of a base encoding other than Unicode, you would set up the `iFilter` and `iFindMappings` parameter as follows. To set up these parameters, you use the constants defined for the text encoding bases, the text encoding default variants, the text encoding default formats, and the filter control flag bitmasks. In this example, the text encoding base field of the Unicode mapping structure's `otherEncoding` field is ignored, so you can specify any value for it. When you call `QueryUnicodeMappings`, passing it these parameters, the function will return a list of mappings between the Unicode encoding you specified and every other available encoding in which each non-Unicode base encoding shows up once because you specified its default variant and default format.

```
iFindMapping.unicodeMapping = CreateTextEncoding(
kTextEncodingUnicodeV1_1,
kTextEncodingDefaultVariant,
kTextEncodingDefaultFormat);
```

```
iFindMapping.otherEncoding = CreateTextEncoding(
kTextEncodingMacRoman,
kTextEncodingDefaultVariant,
kTextEncodingDefaultFormat);
iFilter = kUnicodeMatchUnicodeBaseMask |
kUnicodeMatchUnicodeVariantMask |
kUnicodeMatchUnicodeFormatMask |
kUnicodeMatchOtherVariantMask |
kUnicodeMatchOtherFormatMask;
```

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ResetTextToUnicodeInfo

Reinitializes all state information kept by the context objects.

```
OSStatus ResetTextToUnicodeInfo (
   TextToUnicodeInfo ioTextToUnicodeInfo
);
```

Parameters
ioTextToUnicodeInfo

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.3 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ResetUnicodeToTextInfo

Reinitializes all state information kept by a Unicode converter object.

```
OSStatus ResetUnicodeToTextInfo (
   UnicodeToTextInfo ioUnicodeToTextInfo
);
```

Parameters
ioUnicodeToTextInfo

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`UnicodeConverter.h`

ResetUnicodeToTextRunInfo

Reinitializes all state information kept by the context objects in TextRun conversions.

```
OSStatus ResetUnicodeToTextRunInfo (
   UnicodeToTextRunInfo ioUnicodeToTextRunInfo
);
```

Parameters

ioUnicodeToTextRunInfo

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

ResolveDefaultTextEncoding

Returns a text encoding specification in which any meta-values have been resolved to real values. Currently, this affects only the base encoding values packed into the text encoding specification.

```
TextEncoding ResolveDefaultTextEncoding (
   TextEncoding encoding
);
```

Parameters

encoding

A text encoding specification possibly containing meta-values that you want to resolve to a text encoding specification containing only real values.

Return Value
A text encoding specification containing only real base encoding values.

Discussion
This function is useful for application developers who are providing APIs that take text encoding specifications as parameters. All APIs in the Unicode Converter and Text Encoding Converter perform this translation automatically.

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextCommon.h`

RevertTextEncodingToScriptInfo

Converts the given Mac OS text encoding specification to the corresponding script code and, if possible, language code and font name.

```
OSStatus RevertTextEncodingToScriptInfo (
   TextEncoding iEncoding,
   ScriptCode *oTextScriptID,
   LangCode *oTextLanguageID,
   Str255 oTextFontname
);
```

Parameters

iEncoding

The text encoding specification to be converted.

oTextScriptID

A pointer to a value of type `ScriptCode`. On return, a Mac OS script code that corresponds to the text encoding specification you identified in the `iEncoding` parameter. If you do not pass a pointer for this parameter, the function returns a `paramErr` result code.

oTextLanguageID

A pointer to a value of type `LangCode`. On input, if you do not want the function to return the language code, specify `NULL` as the value of this parameter. On return, the appropriate language code, if the language can be unambiguously derived from the text encoding specification, for example, Japanese, and you did not set the parameter to `NULL`.

If you do not specify `NULL` on input and the language is ambiguous—that is, the function cannot accurately derive it from the text encoding specification—the function returns a value of `kTextLanguageDontCare`.

oTextFontname

A Pascal string. On input, if you do not want the function to return the font name, specify `NULL` as the value of this parameter. On return, the name of the appropriate font if the font can be unambiguously derived from the text encoding specification, for example, Symbol, and you did not set the parameter to `NULL`.

If you do not specify `NULL` on input and the font is ambiguous—that is, the function cannot accurately derive it from the text encoding specification—the function returns a zero-length string.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). The function returns `paramErr` if the text encoding specification input parameter value is invalid. The function returns a `kTECTableFormatErr` result code if the internal mapping tables used for translation are invalid. For a list of other possible result codes, see "Data Types".

Discussion

If you have applications that use Mac OS Script Manager and Font Manager functions, you can use the `RevertTextEncodingToScriptInfo` function to convert information in a text encoding specification into the appropriate Mac OS script code, language code, and font name, if they can be unambiguously derived. Your application can then use this information to display text to a user on the screen.

For more information see the `UpgradeScriptInfoToTextEncoding` (page 1937) function and "Base Text Encodings" (page 1982).

Availability

Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
TextCommon.h

SetFallbackUnicodeToText

Specifies a fallback handler to be used for converting a Unicode text segment to another encoding when the Unicode Converter cannot convert the text using the mapping table specified by the Unicode converter object.

```
OSStatus SetFallbackUnicodeToText (
   UnicodeToTextInfo iUnicodeToTextInfo,
   UnicodeToTextFallbackUPP iFallback,
   OptionBits iControlFlags,
   LogicalAddress iInfoPtr
);
```

Parameters

iUnicodeToTextInfo

\The Unicode converter object to which the fallback handler is to be associated. You use the function CreateUnicodeToTextInfo (page 1892) or CreateUnicodeToTextInfoByEncoding (page 1893) to obtain a Unicode converter object of this type.

iFallback

A universal procedure pointer to the application-defined fallback routine. For a description of the function prototype that your fallback handler must adhere to and how to create your own fallback handler, see UnicodeToTextFallbackProcPtr (page 1953). You should use the NewUnicodeToTextFallbackProc macro to convert a pointer to your fallback handler into a UnicodeToTextFallbackUPP.

iControlFlags

Control flags that stipulate which fallback handler the Unicode Converter should call—the application-defined fallback handler or the default handler—if a fallback handler is required, and the sequence in which the Unicode Converter should call the fallback handlers if either can be used when the other fails or is unavailable. See "Fallback Handler Selectors" (page 1982).

iInfoPtr

A point to a block of memory to be passed to the application-defined fallback handler. The Unicode Converter passes this pointer to the application-defined fallback handler as the last parameter when it calls the fallback handler. Your application can use this memory block to store data required by your fallback handler whenever it is called. This is similar in use to a reference constant (refcon). If you don't need to use a memory block, specify NULL for this parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You can define multiple fallback handlers and associate them with different Unicode converter objects, depending on your requirements. See UnicodeToTextFallbackProcPtr (page 1953) for a description of how to create and install an application-defined fallback handler.

You can use a fallback handler when one of the Unicode conversion functions, ConvertFromUnicodeToText (page 1883) , ConvertFromUnicodeToTextRun (page 1885) , ConvertFromUnicodeToPString (page 1879) , and ConvertFromUnicodeToScriptCodeRun (page 1880) , cannot convert the text using the mapping table specified by the Unicode converter object passed to the function.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

SetFallbackUnicodeToTextRun

Specifies a fallback handler to be used for converting a Unicode text segment to another encoding when the Unicode Converter cannot convert the text using the mapping table specified by a Unicode converter object.

```
OSStatus SetFallbackUnicodeToTextRun (
   UnicodeToTextRunInfo iUnicodeToTextRunInfo,
   UnicodeToTextFallbackUPP iFallback,
   OptionBits iControlFlags,
   LogicalAddress iInfoPtr
);
```

Parameters

iUnicodeToTextRunInfo

The Unicode converter object to which the fallback handler is to be associated. You use the function `CreateUnicodeToTextRunInfo` (page 1894), `CreateUnicodeToTextRunInfoByEncoding` (page 1895), or `CreateUnicodeToTextRunInfoByScriptCode` (page 1896) to obtain a Unicode converter object to specify for this parameter.

iFallback

A universal procedure pointer to the application-defined fallback routine. For a description of the function prototype to which your fallback handler must adhere and how to create your own fallback handler, see `UnicodeToTextFallbackProcPtr` (page 1953). You should use the `NewUnicodeToTextFallbackProc` macro described in the discussion of the function `SetFallbackUnicodeToText` (page 1908).

iControlFlags

Control flags that stipulate which fallback handler the Unicode Converter should call—the application-defined fallback handler or the default handler—if a fallback handler is required, and the sequence in which the Unicode Converter should call the fallback handlers if either can be used when the other fails or is unavailable. See "Fallback Handler Selectors" (page 1982).

iInfoPtr

A pointer to a block of memory to be passed to the application-defined fallback handler. The Unicode Converter passes this pointer to the application-defined fallback handler as the last parameter when it calls the fallback handler. Your application can use this block to store data required by your fallback handler whenever it is called. This is similar in use to a reference constant (refcon). If you don't need to use a memory block, specify `NULL` for this parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You can define multiple fallback handlers and associate them with different Unicode converter objects, depending on your requirements. See `UnicodeToTextFallbackProcPtr` (page 1953) for a description of how to create and install an application-defined fallback handler.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

TECClearConverterContextInfo

Resets a converter object to its initial state so you can reuse it.

```
OSStatus TECClearConverterContextInfo (
   TECObjectRef encodingConverter
);
```

Parameters

encodingConverter

A reference to the text encoding converter object you want to reset. It can be a reference returned by the `TECCreateConverter` (page 1918), `TECCreateOneToManyConverter` (page 1920), or `TECCreateConverterFromPath` (page 1919) functions.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
It is more efficient to reuse an existing converter object than to create a new one that contains the same conversion information. This function clears the text string, but does not alter the source and destination encodings.

If you are converting multiple segments of a text string, you should not clear the converter object until you have converted all the text segments.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECClearSnifferContextInfo

Resets a sniffer object to its initial settings so you can reuse it.

```
OSStatus TECClearSnifferContextInfo (
   TECSnifferObjectRef encodingSniffer
);
```

Parameters

encodingSniffer

A pointer to the sniffer object you want to reset.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Sniffers maintain state information about the input encoding buffer and the number of errors and features found for each encoding; this information allows a caller to progressively sniff an input buffer in sequential chunks. Before sniffing a buffer that contains completely new information you must clear any state information by calling `TECClearSnifferContextInfo`.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECConvertText

Converts a stream of text from a source encoding to a destination encoding. It uses the conversion path specified by the converter object you supply.

```
OSStatus TECConvertText (
   TECObjectRef encodingConverter,
   ConstTextPtr inputBuffer,
   ByteCount inputBufferLength,
   ByteCount *actualInputLength,
   TextPtr outputBuffer,
   ByteCount outputBufferLength,
   ByteCount *actualOutputLength
);
```

Parameters

encodingConverter
A reference to the text encoding converter object you want to use for the conversion. It can be a reference returned by the `TECCreateConverter` (page 1918) or `TECCreateConverterFromPath` (page 1919) functions.

inputBuffer
The stream of text you want to convert.

inputBufferLength
The length in bytes (`UInt8` or `unsigned char`) of the stream of text.

actualInputLength
On return, a pointer to the number of source text bytes that were converted from the input buffer.

outputBuffer
A pointer to a buffer for a byte stream. On output, the buffer holds the converted text.

outputBufferLength
The length in bytes of the `outputBuffer` parameter.

actualOutputLength
On return, a pointer to the number of bytes of converted text returned in the `outputBuffer` parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026). If there is not enough memory available for `TECConvertText` to convert the text when allocating internal buffers, the function returns the appropriate Memory Manager result code.

Discussion
If the output buffer you allocate is too small to accommodate any of the converted text, the function fails. For best results, you should follow these guidelines when you allocate an output buffer:

- Base the buffer length on an estimate of the byte requirements of the destination encoding. Make sure you account for additional bytes needed by the destination encoding (for example, an escape sequence) in addition to the actual text.
- Always allocate a buffer at least 32 bytes long.
- If size is a concern, make sure the output buffer is at least large enough to hold a portion of the converted text. You can convert part of the text, then use the value of the `actualInputLength` parameter to identify the next byte to be taken and to determine how many bytes remain. To convert the remaining text, you simply call the function again with the remaining text and a new output buffer.
- If the destination encoding is a character encoding scheme—such as ISO-2022-JP, which begins in ASCII and switches to other coded character sets through limited combinations of escape sequences—then you need to allocate enough space to accommodate escape sequences that signal switches. ISO-2022-JP requires 3 to 5 bytes for an escape sequence preceding the 1-byte or 2-byte character it introduces. If you allocate a buffer that is less than 5 bytes, the TECConvertText function could fail, depending on the text being converted.

To make sure that you receive all of the converted text, you should call the function `TECFlushText` (page 1924) when you are finished converting all the text in a text stream.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECConvertTextToMultipleEncodings

Converts text in the source encoding to runs of text in multiple destination encodings. It uses the conversion path specified in the converter object you supply.

```
OSStatus TECConvertTextToMultipleEncodings (
   TECObjectRef encodingConverter,
   ConstTextPtr inputBuffer,
   ByteCount inputBufferLength,
   ByteCount *actualInputLength,
   TextPtr outputBuffer,
   ByteCount outputBufferLength,
   ByteCount *actualOutputLength,
   TextEncodingRun outEncodingsBuffer[],
   ItemCount maxOutEncodingRuns,
   ItemCount *actualOutEncodingRuns
);
```

Parameters

encodingConverter

The reference to the text encoding converter object to be used for the conversion. This is the reference returned by the function `TECCreateOneToManyConverter` (page 1920).

inputBuffer
The stream of text to be converted.

inputBufferLength
The length in bytes of the stream of text specified in the `inputBuffer` parameter.

actualInputLength
On return, a pointer to a the number of source text bytes that were converted.

outputBuffer
On return, a pointer to a buffer that holds the converted text.

outputBufferLength
The length in bytes of the `outputBuffer` parameter.

actualOutputLength
On return, a pointer to the number of bytes of the converted text returned in the `outputBuffer` parameter.

outEncodingsBuffer
An array of text encoding runs for output. Note that the actual byte size of this buffer should be `actualOutEncodingRuns * sizeof(TextEncodingRun)`.

maxOutEncodingRuns
The maximum number of runs that can fit in the `outEncodingsBuffer` array.

actualOutEncodingRuns
On return, a pointer to the number of runs in `outEncodingsBuffer` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026). If there is not enough memory available to convert the text when allocating internal buffers, the function returns the appropriate Memory Manager result code.

Discussion
For the function to return successfully, the output buffer you allocate must be large enough to accommodate the converted text. If the output buffer is too small to accommodate any converted text, the function will fail. For best results, you should follow these guidelines when you allocate an output buffer:

- Base the buffer length on an estimate of the byte requirements of the destination encoding. Make sure you account for additional bytes needed by the destination encoding (for example, an escape sequence) in addition to the actual text.
- Always allocate a buffer at least 32 bytes long.
- If size is a concern, make sure the output buffer is at least large enough to hold a portion of the converted text. You can convert part of the text, then use the value of the `actualInputLength` parameter to identify the next byte to be taken and to determine how many bytes remain. To convert the remaining text, you simply call the function again with the remaining text and a new output buffer.
- If the destination encoding is a character encoding scheme—such as ISO-2022-JP, which begins in ASCII and switches to other coded character sets through limited combinations of escape sequences—then you need to allocate enough space to accommodate escape sequences that signal switches. ISO-2022-JP requires 3 to 5 bytes for an escape sequence preceding the 1-byte or 2-byte character it introduces. If you allocate a buffer that is less than 5 bytes, the `TECConvertText` function could fail, depending on the text being converted.

The Text Encoding Converter creates internal buffers that hold intermediate results for indirect conversions

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCountAvailableSniffers

Counts and returns the number of sniffers available in all installed plug-ins.

```
OSStatus TECCountAvailableSniffers (
   ItemCount *numberOfEncodings
);
```

Parameters

numberOfEncodings

On return, a pointer to the number of sniffers in all installed plug-ins. You can use this number to determine what size array to allocate for a parameter of the `TECGetAvailableSniffers` (page 1925) function.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function counts every instance of a sniffer. If different conversion plug-ins support a sniffer for the same encoding, the sniffer is counted more than once. Since the `TECGetAvailableSniffers` function ignores duplicate sniffers, `TECCountAvailableSniffers` may return a number greater than the number of array elements needed for the `availableSniffers[]` parameter of the `TECGetAvailableSniffers` function.

Availability
Supported in Carbon. Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCountAvailableTextEncodings

Counts and returns the number of text encodings currently configured in the Text Encoding Converter.

```
OSStatus TECCountAvailableTextEncodings (
   ItemCount *numberEncodings
);
```

Parameters

numberEncodings

On return, a pointer to the number of currently supported text encodings. You use this value to determine the array size for a parameter of the `TECGetAvailableTextEncodings` (page 1926) function.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
The number of text encodings includes every instance of a text encoding. If different conversion plug-ins support the same text encoding, the text encoding will be counted more than once. For example, the Japanese Encodings plug-in supports Mac OS Japanese, and so does the Unicode Encodings plug-in. Since the `TECGetAvailableTextEncodings` function ignores duplicate text encoding specifications, `TECCountAvailableTextEncodings` may return a number greater than the number of array elements needed for the `availableEncodings []` parameter.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCountDestinationTextEncodings

Counts and returns the number of destination encodings to which a specified source encoding can be converted in one step.

```
OSStatus TECCountDestinationTextEncodings (
   TextEncoding inputEncoding,
   ItemCount *numberOfEncodings
);
```

Parameters

`inputEncoding`
The text encoding specification describing the source text.

`numberOfEncodings`
On return, a pointer to the number of text encodings to which the source encoding can be converted in one step. You should use this to determine how large to make the array you pass to the `TECGetDestinationTextEncodings` (page 1926) function.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function counts every instance of an encoding. If different conversion plug-ins support the same direct text encoding, the direct text encoding is counted more than once.

Since the `TECGetDestinationTextEncodings` function ignores duplicate text encoding specifications, `TECCountDestinationTextEncodings` may return a number greater than the number of array elements needed for the `destinationEncodings[]` parameter.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`TextEncodingConverter.h`

TECCountDirectTextEncodingConversions

Counts and returns the number of direct conversions currently configured in the Text Encoding Converter.

```
OSStatus TECCountDirectTextEncodingConversions (
   ItemCount *numberOfEncodings
);
```

Parameters

numberOfEncodings

On return, a pointer to the number of direct conversions. You should use this value to determine the array size for a parameter of the `TECGetDirectTextEncodingConversions` (page 1927) function.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

The number of direct conversions includes every instance of a conversion. If different conversion plug-ins support the same direct conversion, the direct conversion is counted more than once.

Since the `TECGetDirectTextEncodingConversions` (page 1927) function ignores duplicate direct conversions, `TECCountDirectTextEncodingConversions` may return a number greater than the number of array elements needed for the `directConversions` parameter.

Availability

Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`TextEncodingConverter.h`

TECCountMailTextEncodings

Counts and returns the number of currently supported e-mail encodings for a specified region.

```
OSStatus TECCountMailTextEncodings (
   RegionCode locale,
   ItemCount *numberEncodings
);
```

Parameters

locale

A Mac OS region code. A region code designates a combination of language, writing system, and geographic region; the region may not correspond to a particular country (for example, Swiss French or Arabic).

numberEncodings

On return, a pointer to the number of currently supported e-mail encodings for the region code. You use this number to determine what size array to allocate for a parameter of the `TECGetMailTextEncodings` (page 1929) function.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function counts every instance of an encoding. If different conversion plug-ins support the same direct text encoding, the direct text encoding is counted more than once. Since the `TECGetMailTextEncodings` function ignores duplicate text encoding specifications, `TECCountMailTextEncodings` may return a number greater than the number of array elements needed.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCountSubTextEncodings

Counts and returns the number of subencodings a text encoding supports.

```
OSStatus TECCountSubTextEncodings (
   TextEncoding inputEncoding,
   ItemCount *numberOfEncodings
);
```

Parameters

inputEncoding
The text encoding specification that contains the subencodings.

numberOfEncodings
On return, a pointer to the number of currently supported subencodings. You use this value to determine the array size for a parameter of the `TECGetSubTextEncodings` (page 1930) function.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Subencodings are text encodings that are embedded as part of a larger text encoding specification. For example, EUC-JP contains JIS Roman or ASCII, JIS X0208, JIS X0212, and half-width Katakana from JIS X0201. Not every encoding that can be broken into multiple encodings necessarily supports this routine. It's up to the plug-in developer to decide which encodings might be useful to break up. Subencodings are not the same as text encoding variants.

If an encoding can be converted to multiple runs of encodings (as indicated by a destination base encoding of `kTextEncodingMultiRun`), you can call the `TECGetSubTextEncodings` function to get the list of output encodings. See the `TECCreateOneToManyConverter` (page 1920) and `TECGetDestinationTextEncodings` (page 1926) functions for information.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCountWebTextEncodings

Counts and returns the number of currently supported text encodings for a region code.

```
OSStatus TECCountWebTextEncodings (
   RegionCode locale,
   ItemCount *numberEncodings
);
```

Parameters

locale

A Mac OS region code indicating the locale for which you want to count encodings. A region code designates a combination of language, writing system, and geographic region; the region may not correspond to a particular country (for example, Swiss French or Arabic).

numberEncodings

On return, a pointer to the number of currently supported text encodings for a region code. You should use this number to determine how large to make the array you pass to the `TECGetWebTextEncodings` (page 1932) function.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

This function counts every instance of the same encoding. That is, if different conversion plug-ins support the same text encoding for a conversion process, the text encoding is counted more than once. Since the `TECGetWebTextEncodings` function ignores duplicate text encoding specifications, `TECCountWebTextEncodings` may return a number greater than the number of array elements needed for the `availableEncodings[]` parameter.

Availability

Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`TextEncodingConverter.h`

TECCreateConverter

Determines a conversion path for a source and destination encoding, then creates a text encoding converter object and returns a pointer to it.

```
OSStatus TECCreateConverter (
   TECObjectRef *newEncodingConverter,
   TextEncoding inputEncoding,
   TextEncoding outputEncoding
);
```

Parameters

newEncodingConverter

A pointer to a converter object. On return, this reference points to a newly created text converter object.

inputEncoding

The text encoding specification for the source text encoding.

outputEncoding
The text encoding specification for the destination text encoding.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You use this converter object reference with conversion functions such as `TECConvertText` (page 1911) to convert text. This converter object describes the source, destination, and intermediate encodings; state information; and references to required plug-ins.

If the function does not find a direct conversion path, it creates an indirect conversion path. You can use the function `TECCreateConverterFromPath` (page 1919) to specify an explicit conversion path.

You must use the `TECDisposeConverter` (page 1921) function to remove a converter object.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCreateConverterFromPath

Creates a converter object for a specific conversion path—from a source encoding through intermediate encodings to a destination encoding—and returns a pointer to it.

```
OSStatus TECCreateConverterFromPath (
   TECObjectRef *newEncodingConverter,
   const TextEncoding inPath[],
   ItemCount inEncodings
);
```

Parameters
newEncodingConverter
A pointer to a converter object reference. On return, the reference points to a newly created text converter object.

inPath
An ordered array of text encoding specifications, beginning with the source encoding specification and ending with the destination encoding specification. Each adjacent pair of text encodings must represent a conversion that is supported by the Text Encoding Converter.

inEncodings
The number of text encoding specifications in the `inPath` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function is faster than the function `TECCreateConverter` (page 1918) since it does not need to search for a conversion path. You can use the `TECGetDestinationTextEncodings` (page 1926) function to determine each step in the sequence from the source to the destination encoding.

To remove a converter object, you must call the function `TECDisposeConverter` (page 1921).

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCreateOneToManyConverter

Determines a conversion path for the source encoding and destinations encodings you specify, creates a text encoding converter object, and returns a reference to it.

```
OSStatus TECCreateOneToManyConverter (
   TECObjectRef *newEncodingConverter,
   TextEncoding inputEncoding,
   ItemCount numOutputEncodings,
   const TextEncoding outputEncodings[]
);
```

Parameters

newEncodingConverter
A pointer to a converter object. On return, this points to a newly created one-to-many converter object.

inputEncoding
The text encoding specification for the source text encoding.

numOutputEncodings
The number of text encoding specifications in the `outputEncoding` array.

outputEncodings
An ordered array of text encoding specifications for the destination text encodings.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You use this converter object reference with conversion functions such as `TECConvertTextToMultipleEncodings` (page 1912). The converter object describes the source, destination, and intermediate encodings; state information; and references to required plug-ins.

To remove a converter object, you must call the function `TECDisposeConverter` (page 1921).

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECCreateSniffer

Creates a sniffer object and returns a reference to it.

```
OSStatus TECCreateSniffer (
   TECSnifferObjectRef *encodingSniffer,
   TextEncoding testEncodings[],
   ItemCount numTextEncodings
);
```

Parameters

encodingSniffer

A pointer to a sniffer object reference, which is of type `TECSnifferObjectRef` (page 1964). On return, the reference pertains to the newly created sniffer object.

testEncodings

An array of text encoding specifications supplied by the caller; `TECCreateSniffer` creates a sniffer that can detect each of these encodings.

numTextEncodings

The number of text encoding specifications in the `testEncodings[]` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
The `TECCreateSniffer` function polls plug-ins for available sniffers, creates a sniffer object capable of sniffing each of the specified encodings that it can find a sniffer function for, and returns a reference to it. You use this sniffer object reference with sniffer functions such as `TECSniffTextEncoding` (page 1933). If no sniffer function is available for an encoding, no error is returned and `TECSniffTextEncoding` indicates later that the encoding was not examined.

To remove a sniffer object, you must call the function `TECDisposeSniffer` (page 1922).

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECDisposeConverter

Disposes of a converter object.

```
OSStatus TECDisposeConverter (
   TECObjectRef newEncodingConverter
);
```

Parameters

newEncodingConverter

A reference to the text encoding converter object you want to remove. This can be the reference returned by the `TECCreateConverter` (page 1918), `TECCreateConverterFromPath` (page 1919), or `TECCreateOneToManyConverter` (page 1920) functions.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
If you want to reuse the converter object for a different text stream with the same source and destination encoding, you should clear the converter object using the `TECClearConverterContextInfo` (page 1910) function rather than disposing of it and then creating a new converter object.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECDisposeSniffer

Disposes of a sniffer object.

```
OSStatus TECDisposeSniffer (
   TECSnifferObjectRef encodingSniffer
);
```

Parameters
encodingSniffer
The sniffer object reference you want to remove.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function releases all memory allocated to the sniffer object created by the `TECCreateSniffer` (page 1920) function.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECFlushMultipleEncodings

Flushes out any encodings that may be stored in a converter object's temporary buffers and shifts encodings back to their default state, if any.

```
OSStatus TECFlushMultipleEncodings (
   TECObjectRef encodingConverter,
   TextPtr outputBuffer,
   ByteCount outputBufferLength,
   ByteCount *actualOutputLength,
   TextEncodingRun outEncodingsBuffer[],
   ItemCount maxOutEncodingRuns,
   ItemCount *actualOutEncodingRuns
);
```

Parameters

encodingConverter

The reference to the text encoding converter object whose contents are to be flushed. This is the reference returned by the function `TECCreateOneToManyConverter` (page 1920).

outputBuffer

On return, a pointer to a buffer that holds the converted text. An error is returned is the buffer is not large enough to hold the entire converted text stream.

outputBufferLength

The length in bytes of the `outputBuffer` parameter.

actualOutputLength

On return, a pointer to a the actual number of bytes of the converted text returned in the `outputBuffer` parameter.

outEncodingsBuffer

An ordered array of text encoding runs for the destination text encoding. Note that the actual byte size of this buffer should be `actualOutEncodingRuns * sizeof(TextEncodingRun)`.

maxOutEncodingRuns

The maximum number of encoding runs that can fit in `outEncodingsBuffer[]`.

actualOutEncodingRuns

On return, a pointer to a the number of runs in the buffer during conversion.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

You should always call `TECFlushMultipleEncodings` at the end of the conversion process to flush out any data that may be stored in the temporary buffers of the text encoding converter object or to perform other end-of-encoding conversion tasks. Encodings such as ISO-2022-JP are reset to a default state when you use this function.

For the function to return successfully, the output buffer you allocate must be large enough to accommodate the converted text. If the output buffer is too small to accommodate any converted text, the function will fail. For best results, you should follow these guidelines when you allocate an output buffer:

- Base the buffer length on an estimate of the byte requirements of the destination encoding. Make sure you account for additional bytes needed by the destination encoding (for example, an escape sequence) in addition to the actual text.
- Always allocate a buffer at least 32 bytes long.
- If size is a concern, make sure the output buffer is at least large enough to hold a portion of the converted text. You can convert part of the text, then use the value of the `actualInputLength` parameter to identify the next byte to be taken and to determine how many bytes remain. To convert the remaining text, you simply call the function again with the remaining text and a new output buffer.

- If the destination encoding is a character encoding scheme—such as ISO-2022-JP, which begins in ASCII and switches to other coded character sets through limited combinations of escape sequences—then you need to allocate enough space to accommodate escape sequences that signal switches. ISO-2022-JP requires 3 to 5 bytes for an escape sequence preceding the 1-byte or 2-byte character it introduces. If you allocate a buffer that is less than 5 bytes, the `TECConvertText` function could fail, depending on the text being converted.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECFlushText

Flushes out any data in a converter object's temporary buffers and resets the converter object.

```
OSStatus TECFlushText (
   TECObjectRef encodingConverter,
   TextPtr outputBuffer,
   ByteCount outputBufferLength,
   ByteCount *actualOutputLength
);
```

Parameters

`encodingConverter`
A reference to the text converter object whose contents are to be flushed. This can be a reference returned by the `TECCreateConverter` (page 1918) or `TECCreateConverterFromPath` (page 1919) functions.

`outputBuffer`
On return, a pointer to a buffer that holds the converted text.

`outputBufferLength`
The length in bytes of the buffer provided by the `outputBuffer` parameter.

`actualOutputLength`
On return, a pointer to the number of bytes of converted text returned in the buffer specified by the `outputBuffer` parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
You should always call `TECFlushText` when you finish converting a text stream. If you are converting a single stream in multiple chunks using multiple calls to `TECConvertText`, you only need to call `TECFlushText` after the last call to `TECConvertText` for that stream. The function uses the conversion path specified in the converter object you supply.

For the function to return successfully, the output buffer you allocate must be large enough to accommodate the flushed text. If the output buffer is too small to accommodate any flushed text, the function will fail. For best results, you should follow these guidelines when you allocate an output buffer:

- Base the buffer length on an estimate of the byte requirements of the destination encoding. Make sure you account for additional bytes needed by the destination encoding (for example, an escape sequence) in addition to the actual text.
- Always allocate a buffer at least 32 bytes long.

Encodings such as ISO-2022 that need to shift back to a certain default state at the end of a conversion can do so when this function is called.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetAvailableSniffers

Returns the list of sniffers available in all installed plug-ins.

```
OSStatus TECGetAvailableSniffers (
   TextEncoding availableSniffers[],
   ItemCount maxAvailableSniffers,
   ItemCount *actualAvailableSniffers
);
```

Parameters

availableSniffers
On return, an array of text encoding specifications that the available sniffers currently support. You should use the `TECCountAvailableSniffers` (page 1914) function to determine what size array to allocate.

maxAvailableSniffers
The number of text encoding specifications the `availableSniffers` array can contain.

actualAvailableSniffers
On return, a pointer to the number of text encodings in the `availableSniffers` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function ignores duplicate text encoding specifications. If you used the `TECCountAvailableSniffers` (page 1914) function to determine the size of the `TECGetAvailableSniffers` array, the number of available encodings may be fewer than the number of array elements, because `TECCountAvailableSniffers` includes duplicate text encoding specifications in its count.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetAvailableTextEncodings

Returns the text encoding specifications currently configured in the Text Encoding Converter.

```
OSStatus TECGetAvailableTextEncodings (
   TextEncoding availableEncodings[],
   ItemCount maxAvailableEncodings,
   ItemCount *actualAvailableEncodings
);
```

Parameters

availableEncodings

On return, an array of text encoding specifications. You should use the `TECCountAvailableTextEncodings` (page 1914) function to determine what size array to allocate.

maxAvailableEncodings

The number of text encoding specifications the `availableEncodings` array can contain.

actualAvailableEncodings

On return, a pointer to the number of text encodings returned in the `availableEncodings` array.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

This function ignores duplicate text encoding specifications. If you used the `TECCountAvailableTextEncodings` (page 1914) function to determine the size of the `availableEncodings` [] array, the number of encodings may be fewer than the number of array elements, because `TECCountAvailableTextEncodings` includes duplicate text encodings in its count.

Availability

Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`TextEncodingConverter.h`

TECGetDestinationTextEncodings

Returns the encoding specifications for all the destination text encodings to which the Text Encoding Converter can directly convert the specified source encoding.

```
OSStatus TECGetDestinationTextEncodings (
   TextEncoding inputEncoding,
   TextEncoding destinationEncodings[],
   ItemCount maxDestinationEncodings,
   ItemCount *actualDestinationEncodings
);
```

Parameters

inputEncoding

The text encoding specification describing the source text.

destinationEncodings

On return, an array of specifications for the destination encodings to which the converter can directly convert the source encoding. You should use the `TECCountDestinationTextEncodings` (page 1915) function to determine how large an array to allocate.

maxDestinationEncodings
The maximum number of destination text encodings that the array can contain.

actualDestinationEncodings
On return, a pointer to the number of text encoding specifications in the destination encodings array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function ignores duplicate direct text encoding specifications. If you used the `TECCountDestinationTextEncodings` (page 1915) function to determine the size of the `destinationEncodings[]` array, the number of available encodings may be fewer than the number of array elements, because `TECCountDestinationTextEncodings` includes duplicates in its count.

You can display the names of these destination encodings to the user.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetDirectTextEncodingConversions

Returns the types of direct conversions currently configured in the Text Encoding Converter.

```
OSStatus TECGetDirectTextEncodingConversions (
   TECConversionInfo availableConversions[],
   ItemCount maxAvailableConversions,
   ItemCount *actualAvailableConversions
);
```

Parameters

availableConversions
An array composed of text encoding conversion information structures, each of which specifies a set of source and destination encodings for a type of conversion. See `TECConversionInfo` (page 1959) for more information. You should use the `TECGetDirectTextEncodingConversions` (page 1927) function to determine how large to make the array.

maxAvailableConversions
The maximum number of text encoding conversion information structures that the `directConversions` array can contain.

actualAvailableConversions
On return, a pointer to the number of text encoding conversion information structures returned in the `directConversions` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function ignores duplicate text encoding conversion information structures. If you used the `TECCountDirectTextEncodingConversions` (page 1916) function to determine the size of the `directConversions[]` array, the number of text encoding conversion information structures may be fewer than the number of array elements, because `TECCountDirectTextEncodingConversions` counts duplicate text encoding conversion information structures.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetEncodingList

Gets the list of destination encodings from a converter object.

```
OSStatus TECGetEncodingList (
   TECObjectRef encodingConverter,
   ItemCount *numEncodings,
   Handle *encodingList
);
```

Parameters

`encodingConverter`
A reference to the text encoding conversion object returned by the `TECCreateOneToManyConverter` (page 1920) function.

`numEncodings`
On return, a pointer to the number of encodings specified by the `encodingList` handle.

`encodingList`
A handle to an array of text encoding specifications. On return, it contains an array of text encoding specifications to which the converter object can convert. The memory for the array is allocated automatically by the Text Encoding Converter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
The `TECDisposeConverter` function automatically disposes of the pointer for you. This means you should not reference the pointer after you have disposed of the converter object.

Plug-ins that perform one-to-many conversions use the `TECGetEncodingList` function to get the output encoding list from the converter object reference.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`TextEncodingConverter.h`

TECGetInfo

Allocates a converter information structure of type `TECInfo` in the application heap using `NewHandle`, fills it out, and returns a handle.

```
OSStatus TECGetInfo (
   TECInfoHandle *tecInfo
);
```

Parameters

tecInfo

A handle to a structure of type `TECInfo` (page 1961) containing information about the converter.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). This function can return memory errors.

Discussion

When you are finished with the handle, your application must dispose of it using `DisposeHandle`. You must also perform any required preflighting or memory rearrangement before calling `TECGetInfo`.

Availability

Available in CarbonLib 1.0 and later when Text Common 1.2.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`TextCommon.h`

TECGetMailTextEncodings

Returns the currently supported mail encoding specifications for a region code.

```
OSStatus TECGetMailTextEncodings (
   RegionCode locale,
   TextEncoding availableEncodings[],
   ItemCount maxAvailableEncodings,
   ItemCount *actualAvailableEncodings
);
```

Parameters

locale

A Mac OS region code. A region code designates a combination of language, writing system, and geographic region; the region may not correspond to a particular country (for example, Swiss French or Arabic).

availableEncodings

An array of text encoding specifications. On return, the array contains specifications for the e-mail text encodings for a region code. You should use the function `TECCountMailTextEncodings` (page 1916) function to determine what size array to allocate.

maxAvailableEncodings

The number of text encoding specifications the `availableEncodings` array can contain.

actualAvailableEncodings

On return, a pointer to the number of text encodings in the `availableEncodings` array.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function ignores duplicate text encoding specifications. If you used the `TECCountMailTextEncodings` (page 1916) function to determine the size of the `availableEncodings[]` array the number of available encodings may be fewer than the number of array elements, because `TECCountMailTextEncodings` includes duplicate text encoding specifications in its count.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetSubTextEncodings

Returns the text encoding specifications for the subencodings the encoding scheme supports.

```
OSStatus TECGetSubTextEncodings (
   TextEncoding inputEncoding,
   TextEncoding subEncodings[],
   ItemCount maxSubEncodings,
   ItemCount *actualSubEncodings
);
```

Parameters

inputEncoding
A text encoding specification.

subEncodings
On return, the array contains the specifications for the subencodings of the `inputEncoding` parameter. You should use the function `TECCountSubTextEncodings` (page 1917) function to determine what size an array to allocate.

maxSubEncodings
The number of text encoding specifications the `subEncodings` array can contain.

actualSubEncodings
On return, a pointer to number of subencodings in the `subEncodings` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Subencodings are text encodings that are embedded as part of a larger text encoding specification. For example, EUC-JP contains JIS Roman or ASCII, JIS X0208, JIS X0212, and half-width Katakana from JIS X0201. Not every encoding that can be broken into multiple encodings necessarily supports this routine. It's up to the plug-in developer to decide which encodings might be useful to break up. Subencodings are not the same as text encoding variants

If an encoding can be converted to multiple runs of encodings (as indicated by a destination base encoding of `kTextEncodingMultiRun`), you can call the `TECGetSubTextEncodings` (page 1930) function to get the list of output encodings. See the `TECCreateOneToManyConverter` (page 1920) and `TECGetDestinationTextEncodings` (page 1926) functions for information about multiple output encoding run conversions.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetTextEncodingFromInternetName

Returns the Mac OS text encoding specification that corresponds to an Internet encoding name.

```
OSStatus TECGetTextEncodingFromInternetName (
   TextEncoding *textEncoding,
   ConstStr255Param encodingName
);
```

Parameters

textEncoding
On return, a pointer to a structure that contains a Mac OS text encoding specification.

encodingName
An Internet encoding name, in 7-bit US ASCII.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Internet encoding names are stored as strings, while the Text Encoding Converter uses numeric values.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetTextEncodingInternetName

Returns the Internet encoding name that corresponds to a Mac OS text encoding.

```
OSStatus TECGetTextEncodingInternetName (
   TextEncoding textEncoding,
   Str255 encodingName
);
```

Parameters

textEncoding
A Mac OS text encoding specification.

encodingName
On return, the Internet encoding name, in 7-bit US ASCII. If there are several Internet encoding names for the same text encoding, the `encodingName` parameter contains the preferred name.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECGetWebTextEncodings

Returns the currently supported text encoding specifications for a region code.

```
OSStatus TECGetWebTextEncodings (
   RegionCode locale,
   TextEncoding availableEncodings[],
   ItemCount maxAvailableEncodings,
   ItemCount *actualAvailableEncodings
);
```

Parameters

locale
A Mac OS region code. A region code designates a combination of language, writing system, and geographic region and may not correspond to a particular country (for example, Swiss French or Arabic).

availableEncodings
On return, an array that contains specifications for the currently supported text encodings in the specified region. You should use the `TECCountWebTextEncodings` (page 1918) function to determine how large an array to allocate.

maxAvailableEncodings
The number of text encodings specifications the `availableEncodings` array can contain.

actualAvailableEncodings
On return, a pointer to the number of text encodings specifications in the `availableEncodings` array.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
This function ignores duplicate text encoding specifications. If you used the `TECCountWebTextEncodings` (page 1918) function to determine the size of the `availableEncodings[]` array the number of available encodings may be fewer than the number of array elements, because `TECCountWebTextEncodings` includes duplicate text encoding specifications in its count.

You can use the list of available encodings to create an encoding selection menu for a Web browser.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextEncodingConverter.h`

TECSniffTextEncoding

Analyzes a text stream and returns the probable encodings in a ranked list, based on an array of possible encodings you supply. It also returns the number of errors and features for each encoding.

```
OSStatus TECSniffTextEncoding (
   TECSnifferObjectRef encodingSniffer,
   ConstTextPtr inputBuffer,
   ByteCount inputBufferLength,
   TextEncoding testEncodings[],
   ItemCount numTextEncodings,
   ItemCount numErrsArray[],
   ItemCount maxErrs,
   ItemCount numFeaturesArray[],
   ItemCount maxFeatures
);
```

Parameters

encodingSniffer
: A reference to a sniffer object.

inputBuffer
: The text to be sniffed.

inputBufferLength
: The length of the input buffer.

testEncodings
: An array of text encoding specifications. You must fill the array with the text encodings for which you want to sniff. On output, the array elements are reordered from the most likely to the least likely text encodings.

numTextEncodings
: The number of entries in the `testEncodings[]` parameter.

numErrsArray
: An array that must contain at least `numTextEncodings` elements. On return, an array of the number of errors found for each possible text encoding. The array elements are in the same order as the `testEncodings[]` array elements at output.

maxErrs
: The maximum number of errors a sniffer can encounter. The sniffer stops looking for an encoding after this number is reached.

numFeaturesArray
: An array of that must contain at least `numTextEncodings` elements. On return, an array of the number of features found for each possible text encoding. The array elements are in the same order as the `testEncodings[]` array elements at output.

maxFeatures
: The maximum number of features a sniffer can encounter. The sniffer stops looking for a features after this number is reached.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Discussion

An error indicates a code point or sequence that is illegal in the specified encoding. A feature indicates the presence of a sequence that is characteristic of that encoding.

For example, the byte sequence which is interpreted in Mac OS Roman as "é" could legally be interpreted either as Mac OS Roman text or as Mac OS Japanese text. Both sniffers would return zero errors, but the Mac OS Japanese sniffer would also return two features of Mac OS Japanese (representing two legal 2-byte characters.)

The arrays are returned in a ranked list with the most likely text encodings first. The results are sorted first by number of errors (fewest to most), then by number of features (most to fewest), and then by the original order in the list. On return, the most likely encoding is in `testEncodings[0]` or `testEncodings[1]`.

If an encoding is not examined, its number of errors and features are set to 0xFFFFFFFF, and the encoding is sorted to the end of the list.

Availability
Available in CarbonLib 1.0 and later when Text Encoding Convertor 1.2 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Declared In
`TextEncodingConverter.h`

TruncateForTextToUnicode

Identifies where your application can safely break a multibyte string to be converted to Unicode so that the string is not broken in the middle of a multibyte character.

```
OSStatus TruncateForTextToUnicode (
   ConstTextToUnicodeInfo iTextToUnicodeInfo,
   ByteCount iSourceLen,
   ConstLogicalAddress iSourceStr,
   ByteCount iMaxLen,
   ByteCount *oTruncatedLen
);
```

Parameters

iTextToUnicodeInfo
The Unicode converter object of type `TextToUnicodeInfo` (page 1966) for the text string to be divided up with each segment properly truncated. The `TruncateForTextToUnicode` function does not modify the object's contents.

iSourceLen
The length in bytes of the multibyte string to be divided up.

iSourceStr
The address of the multibyte string to be divided up.

iMaxLen
The maximum allowable length of the string to be truncated. This must be less than or equal to `iSourceLen`.

oTruncatedLen
A pointer to a value of type `ByteCount`. On return, this value contains the length of the longest portion of the multibyte string, pointed to by `iSourceStr`, that is less than or equal to the length specified by `iMaxLen`. This identifies the byte after which you can break the string.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Your application can use this function to break a string properly before you call the function `ConvertFromTextToUnicode` (page 1877) so that the string you pass it is terminated with complete characters. You can call this function repeatedly to properly divide up a text segment, each time identifying the new beginning of the string, until the last portion of the text is less than or equal to the maximum allowable length. Each time you use the function, you get a properly terminated string within the allowable length range.

Because the `TruncateForTextToUnicode` function does not modify the contents of the Unicode converter object, you can call this function safely between calls to the function `ConvertFromTextToUnicode` (page 1877).

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

TruncateForUnicodeToText

Identifies where your application can safely break a Unicode string to be converted to any encoding so that the string is broken in a way that preserves the text element integrity.

```
OSStatus TruncateForUnicodeToText (
   ConstUnicodeToTextInfo iUnicodeToTextInfo,
   ByteCount iSourceLen,
   const UniChar iSourceStr[],
   OptionBits iControlFlags,
   ByteCount iMaxLen,
   ByteCount *oTruncatedLen
);
```

Parameters

iUnicodeToTextInfo
A Unicode converter object `UnicodeToTextInfo` (page 1969) for the Unicode string to be divided up. The `TruncateForUnicodeToText` function does not modify the contents of this private structure.

iSourceLen
The length in bytes of the Unicode string to be divided up.

iSourceStr
A pointer to the Unicode string to be divided up.

iControlFlags
Truncation control flags. Specify the flag `kUnicodeStringUnterminatedMask` if truncating a buffer of text that belongs to a longer stream containing a subsequent buffer of text that could have characters belonging to a text element that begins at the end of the current buffer. If you set this flag, typically you would set the `iMaxLen` parameter equal to `iSourceLen`.

iMaxLen
The maximum allowable length of the string to be truncated. This must be less than or equal to `iSourceLen`.

oTruncatedLen

A pointer to a value of type `ByteCount`. On return, this value contains the length of the longest portion of the Unicode source string, pointed to by the `iSourceStr` parameter, that is less than or equal to the value of the `iMaxLen` parameter. This returned parameter identifies the byte after which you can truncate the string.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Discussion
Your application can use this function to divide up a Unicode string properly truncating each portion before you call `ConvertFromUnicodeToText` or `ConvertFromUnicodeToScriptCodeRun` to convert the string. You can call this function repeatedly to properly truncate a text segment, each time identifying the new beginning of the string, until the last portion of the text is less than or equal to the maximum allowable length. Each time you use the function, you get a properly terminated string within the allowable length range.

Because this function does not modify the contents of the Unicode converter object, you can call this function between conversion calls.

Availability
Available in CarbonLib 1.0 and later when Unicode Utilities 1.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeConverter.h`

UCGetCharProperty

Obtains the value associated with a property type for the specified `UniChar` characters.

```
OSStatus UCGetCharProperty (
   const UniChar *charPtr,
   UniCharCount textLength,
   UCCharPropertyType propType,
   UCCharPropertyValue *propValue
);
```

Parameters

charPtr

A pointer to the Unicode text whose property value you want to obtain.

textLength

The length of the text pointed to by `charPtr`.

propType

The property type for the `UniChar` character whose value you want to obtain. See "Unicode Character Property Types" (page 2020) for a list of the constants you can supply.

propValue

On return, the value associated with the property type specified by the `propType` parameter. See "Unicode Character Property Values" (page 2020) for a list of the constants that can be returned.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in CarbonLib 1.0 and later when Text Common 1.5 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextCommon.h`

UpgradeScriptInfoToTextEncoding

Converts any combination of a Mac OS script code, a language code, a region code, and a font name to a text encoding.

```
OSStatus UpgradeScriptInfoToTextEncoding (
   ScriptCode iTextScriptID,
   LangCode iTextLanguageID,
   RegionCode iRegionID,
   ConstStr255Param iTextFontname,
   TextEncoding *oEncoding
);
```

Parameters

iTextScriptID
A valid Script Manager script code. The Mac OS Script Manager defines constants for script codes using this format: `sm`Xxx. To designate the system script, specify the meta-value of `smSystemScript`. To designate the current script based on the font specified in the graphics port (`grafPort`), specify the metavalue of `smCurrentScript`. To indicate that you do not want to provide a script code for this parameter, specify the constant `kTextScriptDontCare`.

iTextLanguageID
A valid Script Manager language code. The Mac OS Script Manager defines constants for language codes using this format: `lang`Xxx. To indicate that you do not want to provide a language code for this parameter, specify the constant `kTextLanguageDontCare`.

iRegionID
A valid Script Manager region code. The Mac OS Script Manager defines constants for region codes using this format: `ver`Xxx. To indicate that you do not want to provide a region code for this parameter, specify the constant `kTextRegionDontCare`.

iTextFontname
The name of a font associated with a particular text encoding specification, such as Symbol or Zapf Dingbats, or the name of any font that is currently installed on the system. To indicate that you do not want to provide a font name, specify a value of `NULL`.

oEncoding
A pointer to a value of type `TextEncoding`. On return, this value holds the text encoding specification that the function created from the other values you provided.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026). This function returns `paramErr` if two or more of the input parameter values conflict in some way—for example, the Mac OS language code does not belong to the script whose script code you specified, or if the input parameter values are invalid. The function returns a `kTECTableFormatErr` result code if the internal mapping tables used for translation are invalid.

Discussion
The `UpgradeScriptInfoToTextEncoding` function allows you to derive a text encoding specification from script codes, language codes, region codes, and font names. A one-to-one correspondence exists between many of the Script Manager's script codes and a particular Mac OS text encoding base value. However, because text encodings are a superset of script codes, some combinations of script code, language code, region code, and font name might result in a different text encoding base value than would be the case if the translation were based on the script code alone.

When you call the `UpgradeScriptInfoToTextEncoding` function, you can specify any combination of its parameters, but you must specify at least one.

If you don't specify an explicit value for a script, language, or region code parameter, you must pass the do-not-care constant appropriate to that parameter. If you do not specify an explicit value for `iTextFontName`, you must pass `NULL`. `UpgradeScriptInfoToTextEncoding` uses as much information as you supply to determine the equivalent text encoding or the closest approximation. If you provide more than one parameter, all parameters are checked against one another to ensure that they are valid in combination.

A font name, such as `'Symbol'` or `'Zapf Dingbats,'` can indicate a particular text encoding base. Other font names can indicate particular variants associated with a particular text encoding base. Otherwise, the font name is used to obtain a script code, and this script code will be checked against any script code you supply (in this case, the font must be installed; if it is not, the function returns a `paramErr` result code). If you do not supply either a language code or a region code and the script code you supply or the one that is derived matches the system script, then the system's localization is used to determine the appropriate region and language code. This is used for deriving text encoding base values that depend on region and language, such as `kTextEncodingMacTurkish`.

For more information see the `RevertTextEncodingToScriptInfo` (page 1907) function and "Base Text Encodings" (page 1982).

Availability
Available in CarbonLib 1.0 and later when Text Common 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`TextCommon.h`

Callbacks by Task

Setting Up a Fallback Handler

`UnicodeToTextFallbackProcPtr` (page 1953)
Defines a pointer to a function that converts a Unicode text element for which there is no destination encoding equivalent in the appropriate mapping table to the fallback character sequence defined by your fallback handler, and returns the converted character sequence to the Unicode Converter.

Setting Up a TEC Plug-in

`TECPluginGetPluginDispatchTablePtr` (page 1949)
Defines a pointer to a function that returns a pointer to a plug-in dispatch table.

`TECPluginNewEncodingConverterPtr` (page 1951)
Defines a pointer to a function that determines a conversion path for a source and destination encoding, then creates a text encoding converter object and returns a pointer to it.

`TECPluginClearContextInfoPtr` (page 1940)
Defines a pointer to a function that resets a converter object to its initial state.

`TECPluginConvertTextEncodingPtr` (page 1941)
Defines a pointer to a function that converts stream of text from a source encoding to a destination encoding, using the conversion path specified by the converter object you supply.

`TECPluginFlushConversionPtr` (page 1943)
Defines a pointer to a function that flushes out any data in a converter object's temporary buffers and resets the converter object.

`TECPluginDisposeEncodingConverterPtr` (page 1941)
Defines a pointer to a function that disposes of a converter object.

`TECPluginNewEncodingSnifferPtr` (page 1952)
Defines a pointer to a function that creates a sniffer object and returns a reference to it.

`TECPluginClearSnifferContextInfoPtr` (page 1940)
Defines a pointer to a function that resets a sniffer object to its initial settings.

`TECPluginSniffTextEncodingPtr` (page 1952)
Defines a pointer to a function that analyzes a text stream and returns the probable encodings in a ranked list, based on an array of possible encodings you supply; it also returns the number of errors and features for each encoding.

`TECPluginDisposeEncodingSnifferPtr` (page 1942)
Defines a pointer to a function that disposes of a sniffer object.

`TECPluginGetCountAvailableTextEncodingsPtr` (page 1945)
Defines a pointer to a function that obtains the available text encodings.

`TECPluginGetCountAvailableTextEncodingPairsPtr` (page 1944)
Defines a pointer to a function that obtains the available text encoding pairs.

`TECPluginGetCountDestinationTextEncodingsPtr` (page 1946)
Defines a pointer to a function that counts and returns the number of destination encodings to which a specified source encoding can be converted in one step.

`TECPluginGetCountSubTextEncodingsPtr` (page 1947)
Defines a pointer to a function that obtains the text encoding specifications for the subencodings the encoding scheme supports.

`TECPluginGetCountAvailableSniffersPtr` (page 1943)
Defines a pointer to a function that counts and returns the number of sniffers available in all installed plug-ins.

`TECPluginGetCountWebEncodingsPtr` (page 1948)
Defines a pointer to a function that obtains the available web text encodings.

`TECPluginGetCountMailEncodingsPtr` (page 1947)
Defines a pointer to a function that obtains the text encodings available for email.

`TECPluginGetTextEncodingInternetNamePtr` (page 1950)
Defines a pointer to a function that obtains the Internet text encoding name for a text encoding specification.

`TECPluginGetTextEncodingFromInternetNamePtr` (page 1949)
Defines a pointer to a function that obtains the text encoding for an Internet text encoding name.

Callbacks

TECPluginClearContextInfoPtr

Defines a pointer to a function that resets a converter object to its initial state.

```
typedef OSStatus (*TECPluginClearContextInfoPtr)
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

If you name your function `MyTECPluginClearContextInfo`, you would declare it like this:

```
OSStatus MyTECPluginClearContextInfoPtr
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

Parameters

encodingConverter
A reference to the text encoding converter object that needs to be reset.

plugContext
A pointer to a TEC converter context record.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginClearSnifferContextInfoPtr

Defines a pointer to a function that resets a sniffer object to its initial settings.

```
typedef OSStatus (*TECPluginClearSnifferContextInfoPtr)
(
    TECSnifferObjectRef encodingSniffer,
    TECSnifferContextRec * snifContext
);
```

If you name your function `MyTECPluginClearSnifferContextInfo`, you would declare it like this:

```
OSStatus MyTECPluginClearSnifferContextInfoPtr
(
    TECSnifferObjectRef encodingSniffer,
    TECSnifferContextRec * snifContext
);
```

Parameters

encodingSniffer

A reference to the sniffer object that needs to be reset.

snifContext

A pointer to a TEC sniffer context record.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginConvertTextEncodingPtr

Defines a pointer to a function that converts stream of text from a source encoding to a destination encoding, using the conversion path specified by the converter object you supply.

```
typedef OSStatus (*TECPluginConvertTextEncodingPtr)
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

If you name your function `MyTECPluginConvertTextEncoding`, you would declare it like this:

```
OSStatus MyTECPluginConvertTextEncodingPtr
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

Parameters

encodingConverter

A reference to the text encoding converter object to use for the conversion.

plugContext

A pointer to a TEC converter context record that contains the text and other information needed for the conversion.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginDisposeEncodingConverterPtr

Defines a pointer to a function that disposes of a converter object.

```
typedef OSStatus (*TECPluginDisposeEncodingConverterPtr)
(
    TECObjectRef newEncodingConverter,
    TECConverterContextRec * plugContext
);
```

If you name your function `MyTECPluginDisposeEncodingConverter`, you would declare it like this:

```
OSStatus MyTECPluginDisposeEncodingConverterPtr
(
    TECObjectRef newEncodingConverter,
    TECConverterContextRec * plugContext
);
```

Parameters

newEncodingConverter

A reference to the converter object to dispose of.

plugContext

A pointer to a TEC converter context record.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginDisposeEncodingSnifferPtr

Defines a pointer to a function that disposes of a sniffer object.

```
typedef OSStatus (*TECPluginDisposeEncodingSnifferPtr)
(
    TECSnifferObjectRef encodingSniffer,
    TECSnifferContextRec * snifContext
);
```

If you name your function `MyTECPluginDisposeEncodingSniffer`, you would declare it like this:

```
OSStatus MyTECPluginDisposeEncodingSnifferPtr
(
    TECSnifferObjectRef encodingSniffer,
    TECSnifferContextRec * snifContext
);
```

Parameters

encodingSniffer

A reference to the sniffer object you want to dispose.

snifContext

A pointer to a TEC sniffer context record.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginFlushConversionPtr

Defines a pointer to a function that flushes out any data in a converter object's temporary buffers and resets the converter object.

```
typedef OSStatus (*TECPluginFlushConversionPtr)
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

If you name your function `MyTECPluginFlushConversion`, you would declare it like this:

```
OSStatus MyTECPluginFlushConversionPtr
(
    TECObjectRef encodingConverter,
    TECConverterContextRec * plugContext
);
```

Parameters

`encodingConverter`
A reference to the text converter object whose contents are to be flushed.

`plugContext`
A pointer to a TEC converter context record.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetCountAvailableSniffersPtr

Defines a pointer to a function that counts and returns the number of sniffers available in all installed plug-ins.

```
typedef OSStatus (*TECPluginGetCountAvailableSniffersPtr)
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

If you name your function `MyTECPluginGetCountAvailableSniffers`, you would declare it like this:

```
OSStatus MyTECPluginGetCountAvailableSniffersPtr
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

Parameters

availableEncodings

On return, a pointer to the currently available sniffer text encoding specifications.

maxAvailableEncodings

The number of text encoding specifications the `availableEncodings` array can contain.

actualAvailableEncodings

On the return, the number of text encoding specifications the `availableEncodings` array actually contains.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginGetCountAvailableTextEncodingPairsPtr

Defines a pointer to a function that obtains the available text encoding pairs.

```
typedef OSStatus (*TECPluginGetCountAvailableTextEncodingPairsPtr)
(
    TECConversionInfo * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

If you name your function `MyTECPluginGetCountAvailableTextEncodingPairs`, you would declare it like this:

```
OSStatus MyTECPluginGetCountAvailableTextEncodingPairsPtr
(
    TECConversionInfo * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
```

```
);
```

Parameters

availableEncodings

On return, an array of text encoding conversion information structures, each of which specifies a set of source and destination encodings for a type of conversion.

maxAvailableEncodings

The number of text encoding information structures the `availableEncodings` array can contain.

actualAvailableEncodings

On the return, the number of text encoding information structures the `availableEncodings` array actually contains.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetCountAvailableTextEncodingsPtr

Defines a pointer to a function that obtains the available text encodings.

```
typedef OSStatus (*TECPluginGetCountAvailableTextEncodingsPtr)
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

If you name your function `MyTECPluginGetCountAvailableTextEncodings`, you would declare it like this:

```
OSStatus MyTECPluginGetCountAvailableTextEncodingsPtr
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

Parameters

availableEncodings

On return, a pointer to the currently available text encoding specifications.

maxAvailableEncodings

The number of text encoding specifications the `availableEncodings` array can contain.

actualAvailableEncodings

On the return, the number of text encoding specifications the `availableEncodings` array actually contains.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetCountDestinationTextEncodingsPtr

Defines a pointer to a function that counts and returns the number of destination encodings to which a specified source encoding can be converted in one step.

```
typedef OSStatus (*TECPluginGetCountDestinationTextEncodingsPtr)
(
    TextEncoding inputEncoding,
    TextEncoding * destinationEncodings,
    ItemCount maxDestinationEncodings,
    ItemCount * actualDestinationEncodings
);
```

If you name your function `MyTECPluginGetCountDestinationTextEncodings`, you would declare it like this:

```
OSStatus MyTECPluginGetCountDestinationTextEncodingsPtr
(
    TextEncoding inputEncoding,
    TextEncoding * destinationEncodings,
    ItemCount maxDestinationEncodings,
    ItemCount * actualDestinationEncodings
);
```

Parameters

inputEncoding
The text encoding specification describing the source text.

destinationEncodings
On return, a pointer to text encodings to which the source encoding can be converted in one step.

maxDestinationEncodings
The maximum number of text encodings that can be specified by the `destinationEncodings` parameter.

actualDestinationEncodings
On return, the actual number of text encodings specified by the `destinationEncodings` parameter.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetCountMailEncodingsPtr

Defines a pointer to a function that obtains the text encodings available for email.

```
typedef OSStatus (*TECPluginGetCountMailEncodingsPtr)
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

If you name your function `MyTECPluginGetCountMailEncodings`, you would declare it like this:

```
OSStatus MyTECPluginGetCountMailEncodingsPtr
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

Parameters

availableEncodings
: On return, a pointer to the text encodings available for email.

maxAvailableEncodings
: The maximum number of text encodings that can be specified by the `availableEncodings` parameter.

actualAvailableEncodings
: On return, the number of text encoding specifications `availableEncodings` actually contains.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginGetCountSubTextEncodingsPtr

Defines a pointer to a function that obtains the text encoding specifications for the subencodings the encoding scheme supports.

```
typedef OSStatus (*TECPluginGetCountSubTextEncodingsPtr)
(
    TextEncoding inputEncoding,
    TextEncoding subEncodings[],
    ItemCount maxSubEncodings,
    ItemCount * actualSubEncodings
);
```

If you name your function `MyTECPluginGetCountSubTextEncodings`, you would declare it like this:

```
OSStatus MyTECPluginGetCountSubTextEncodingsPtr
(
```

```
    TextEncoding inputEncoding,
    TextEncoding subEncodings[],
    ItemCount maxSubEncodings,
    ItemCount * actualSubEncodings
);
```

Parameters

inputEncoding

A text encoding specification.

subEncodings

On return, the array contains the specifications for the subencodings of the `inputEncoding` parameter.

maxSubEncodings

The number of text encoding specifications the `subEncodings` array can contain.

actualSubEncodings

On return, a pointer to number of subencodings in the `subEncodings` array.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginGetCountWebEncodingsPtr

Defines a pointer to a function that obtains the available web text encodings.

```
typedef OSStatus (*TECPluginGetCountWebEncodingsPtr)
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

If you name your function `MyTECPluginGetCountWebEncodings`, you would declare it like this:

```
OSStatus MyTECPluginGetCountWebEncodingsPtr
(
    TextEncoding * availableEncodings,
    ItemCount maxAvailableEncodings,
    ItemCount * actualAvailableEncodings
);
```

Parameters

availableEncodings

On return, points to the currently supported text encodings available for the web.

maxAvailableEncodings

The number of text encodings specifications that `availableEncodings` can specify.

actualAvailableEncodings
On return, the number of text encodings specifications `availableEncodings` actually contains.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetPluginDispatchTablePtr

Defines a pointer to a function that returns a pointer to a plug-in dispatch table.

```
typedef TECPluginDispatchTable * (*TECPluginGetPluginDispatchTablePtr)
(
);
```

If you name your function `ConverterPluginGetPluginDispatchTable`, you would declare it like this:

```
TECPluginDispatchTable * ConverterPluginGetPluginDispatchTable();
```

Parameters

Return Value
A pointer to the function dispatch table for the plug-in.

Discussion
You need this callback only for Mac OS X plug-ins. When you create a TEC plug-in in Mac OS X you must export a function named `ConverterPluginGetPluginDispatchTable` with the following prototype:

```
extern TECPluginDispatchTable *ConverterPluginGetPluginDispatchTable (void)
```

This function must return a pointer to the function dispatch table for the plug-in. It is important you name the function `ConverterPluginGetPluginDispatchTable` because `TECPluginGetPluginDispatchTablePtr` is a function pointer to a function of this exact name.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginGetTextEncodingFromInternetNamePtr

Defines a pointer to a function that obtains the text encoding for an Internet text encoding name.

```
typedef OSStatus (*TECPluginGetTextEncodingFromInternetNamePtr)
(
    TextEncoding * textEncoding,
    ConstStr255Param encodingName
);
```

If you name your function `MyTECPluginGetTextEncodingFromInternetName`, you would declare it like this:

```
OSStatus MyTECPluginGetTextEncodingFromInternetNamePtr
(
    TextEncoding * textEncoding,
    ConstStr255Param encodingName
);
```

Parameters

textEncoding

On return, a pointer to a structure that contains a text encoding specification for the text encoding name specified by the `encodingName` parameter.

encodingName

An Internet encoding name, in 7-bit US ASCII.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginGetTextEncodingInternetNamePtr

Defines a pointer to a function that obtains the Internet text encoding name for a text encoding specification.

```
typedef OSStatus (*TECPluginGetTextEncodingInternetNamePtr)
(
    TextEncoding textEncoding,
    Str255 encodingName
);
```

If you name your function `MyTECPluginGetTextEncodingInternetName`, you would declare it like this:

```
OSStatus MyTECPluginGetTextEncodingInternetNamePtr
(
    TextEncoding textEncoding,
    Str255 encodingName
);
```

Parameters

textEncoding

A text encoding specification.

encodingName
On return, the Internet encoding name, in 7-bit US ASCII. If there are several Internet encoding names for the same text encoding, the `encodingName` parameter contains the preferred name.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginNewEncodingConverterPtr

Defines a pointer to a function that determines a conversion path for a source and destination encoding, then creates a text encoding converter object and returns a pointer to it.

```
typedef OSStatus (*TECPluginNewEncodingConverterPtr)
(
    TECObjectRef * newEncodingConverter,
    TECConverterContextRec * plugContext,
    TextEncoding inputEncoding,
    TextEncoding outputEncoding
);
```

If you name your function `MyTECPluginNewEncodingConverter`, you would declare it like this:

```
OSStatus MyTECPluginNewEncodingConverterPtr
(
    TECObjectRef * newEncodingConverter,
    TECConverterContextRec * plugContext,
    TextEncoding inputEncoding,
    TextEncoding outputEncoding
);
```

Parameters

newEncodingConverter
A pointer to a converter object. On return, this points to a newly created text converter object.

plugContext
A pointer to a TEC converter context record.

inputEncoding
The text encoding specification for the source text.

outputEncoding
The text encoding specification for the destination text.

Return Value
A result code. See "TEC Manager Result Codes" (page 2026).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECPluginNewEncodingSnifferPtr

Defines a pointer to a function that creates a sniffer object and returns a reference to it.

```
typedef OSStatus (*TECPluginNewEncodingSnifferPtr)
(
    TECSnifferObjectRef * encodingSniffer,
    TECSnifferContextRec * snifContext,
    TextEncoding inputEncoding
);
```

If you name your function `MyTECPluginNewEncodingSniffer`, you would declare it like this:

```
OSStatus MyTECPluginNewEncodingSnifferPtr
(
    TECSnifferObjectRef * encodingSniffer,
    TECSnifferContextRec * snifContext,
    TextEncoding inputEncoding
);
```

Parameters

encodingSniffer

A pointer to a sniffer object reference, which is of type `TECSnifferObjectRef` (page 1964). On return, the reference pertains to the newly created sniffer object.

snifContext

A pointer to a TEC sniffer context record.

inputEncoding

The text encoding specification to be detected by the sniffer object.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECPluginSniffTextEncodingPtr

Defines a pointer to a function that analyzes a text stream and returns the probable encodings in a ranked list, based on an array of possible encodings you supply; it also returns the number of errors and features for each encoding.

```
typedef OSStatus (*TECPluginSniffTextEncodingPtr)
(
    TECSnifferObjectRef encodingSniffer,
    TECSnifferContextRec * snifContext
);
```

If you name your function `MyTECPluginSniffTextEncoding`, you would declare it like this:

```
OSStatus MyTECPluginSniffTextEncodingPtr
(
    TECSnifferObjectRef encodingSniffer,
```

```
    TECSnifferContextRec * snifContext
);
```

Parameters

encodingSniffer

A reference to a sniffer object.

snifContext

A pointer to a TEC sniffer context record.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

UnicodeToTextFallbackProcPtr

Defines a pointer to a function that converts a Unicode text element for which there is no destination encoding equivalent in the appropriate mapping table to the fallback character sequence defined by your fallback handler, and returns the converted character sequence to the Unicode Converter.

```
typedef OSStatus (*UnicodeToTextFallbackProcPtr)
(
    UniChar * iSrcUniStr,
    ByteCount iSrcUniStrLen,
    ByteCount * oSrcConvLen,
    TextPtr oDestStr,
    ByteCount iDestStrLen,
    ByteCount * oDestConvLen,
    LogicalAddress iInfoPtr,
    ConstUnicodeMappingPtr iUnicodeMappingPtr
);
```

If you name your function `MyUnicodeToTextFallbackProc`, you would declare it like this:

```
OSStatus MyUnicodeToTextFallbackProcPtr
(
    UniChar * iSrcUniStr,
    ByteCount iSrcUniStrLen,
    ByteCount * oSrcConvLen,
    TextPtr oDestStr,
    ByteCount iDestStrLen,
    ByteCount * oDestConvLen,
    LogicalAddress iInfoPtr,
    ConstUnicodeMappingPtr iUnicodeMappingPtr
);
```

Parameters

iSrcUniStr

A pointer to a single UTF-16 character to be mapped by the fallback handler.

iSrcUniStrLen

The length in bytes of the UTF-16 character indicated by the `iSrcUniStr` parameter. Usually this is 2 bytes, but it could be 4 bytes for a non-BMP character.

oSrcConvLen

On return, a pointer to the length in bytes of the portion of the Unicode character that was actually processed by your fallback handler. Your fallback handler returns this value. It should set this to 0 if none of the text was handled, or 2 or 4 if the Unicode character was handled. This value is initialized to 0 before the fallback handler is called.

oDestStr

A pointer to the output buffer where your handler should place any converted text.

iDestStrLen

The maximum size in bytes of the buffer provided by the `oDestStr` parameter.

oDestConvLen

On return, a pointer to the length in bytes of the fallback character sequence generated by your fallback handler. Your handler should return this length. It is initialized to 0 (zero) before the fallback handler is called.

iInfoPtr

A pointer to a block of memory allocated by your application, which can be used by your fallback handler in any way that you like. This is the same pointer passed as the last parameter of `SetFallbackUnicodeToText` or `SetFallbackUnicodeToTextRun`. How you use the data passed to you in this memory block is particular to your handler. This is similar in use to a reference constant (refcon).

iUnicodeMappingPtr

A constant pointer to a structure of type `UnicodeMapping` (page 1967). This structure identifies a Unicode encoding specification and a particular base encoding specification.

Return Value

A result code. See "TEC Manager Result Codes" (page 2026). Your handler should return `noErr` if it can handle the fallback, or `kTECUnmappableElementErr` if it cannot. It can return other errors for exceptional conditions, such as when the output buffer is too small. If your handler returns `kTECUnmappableElementErr`, then `oSrcConvLen` and `oDestConvLen` are ignored because either the default handler will be called or the default fallback sequence will be used.

Discussion

The Unicode Converter calls your fallback handler when it cannot convert a text string using the mapping table specified by the Unicode converter object passed to either `ConvertFromUnicodeToText` or `ConvertFromUnicodeToPString`. The control flags you set for the `controlFlags` parameter of the function `SetFallbackUnicodeToText` (page 1908) or the `SetFallbackUnicodeToTextRun` (page 1909) stipulate which fallback handler the Unicode Converter should call and which one to try first if both can be used.

When the Unicode Converter calls your handler, it passes to it the Unicode character to be converted and its length, a buffer for the converted string you return and the buffer length, and a pointer to a block of memory containing the data your application supplied to be passed on to your fallback handler.

After you convert the Unicode text segment to fallback characters, you return the fallback character sequence of the converted text in the buffer provided to you and the length in bytes of this fallback character sequence. You also return the length in bytes of the portion of the source Unicode text element that your handler actually processed.

You provide a fallback-handler function for use with the function `CreateUnicodeToTextInfoByEncoding` (page 1893), `ConvertFromUnicodeToPString` (page 1879), `ConvertFromUnicodeToTextRun` (page 1885), or `ConvertFromUnicodeToScriptCodeRun` (page 1880). You associate an application-defined fallback handler with a particular Unicode converter object you intend to pass to the conversion function when you call it.

Text converted from UTF-8 will already have been converted to UTF-16 before the fallback handler is called to process it. Your fallback handler should do all of its processing on text encoded in UTF-16.

Your application-defined fallback handler should not move memory or call any toolbox function that would move memory. If it needs memory, the memory should be allocated before the call to `SetFallbackUnicodeToText` or `SetFallbackUnicodeToTextRun`, and a memory reference should be passed either directly as `iInfoPtr` or in the data referenced by `iInfoPtr`.

To associate a fallback-handler function with a Unicode converter object you use the `SetFallbackUnicodeToText` (page 1908) and `SetFallbackUnicodeToTextRun` (page 1909) functions. For these functions, you must pass a universal procedure pointer (`UniversalProcPtr`). This is derived from a pointer to your function by using the predefined macro `NewUnicodeToTextFallbackProc`.

For versions of the Unicode Converter prior to 1.2, the fallback handler may receive a multiple character text element, so the source string length value could be greater than 2 and the fallback handler may set `srcConvLen` to a value greater than 2. In versions earlier than 1.2.1, the `srcConvLen` and `destConvLen` variables are not initialized to 0; both values are ignored unless the fallback handler returns `noErr`.

The following example shows how to install an application-defined fallback handler. You can name your application-defined fallback handler anything you choose. The name, `MyUnicodeToTextFallbackProc`, used in this example is not significant. However, you must adhere to the parameters, the return type, and the calling convention as expressed in this example, which follows the prototype, because a pointer to this function must be of type `UnicodeToTextFallbackProcPtr` as defined in the `UnicodeConverter.h` header file.

The `UnicodeConverter.h` header file also defines the `UnicodeToTextFallbackUPP` type and the `NewUnicodeToTextFallbackProc` macro.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

Data Types

ConstScriptCodeRunPtr

Defines a constant script code run pointer.

```
typedef const ScriptCodeRun * ConstScriptCodeRunPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextCommon.h

ConstTextEncodingRunPtr

Defines a constant text encoding run pointer.

```
typedef const TextEncodingRun * ConstTextEncodingRunPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextCommon.h

ConstTextPtr

Defines a constant text pointer.

```
typedef const UInt8 * ConstTextPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextCommon.h

ConstTextToUnicodeInfo

Defines a constant text to Unicode converter object.

```
typedef TextToUnicodeInfo ConstTextToUnicodeInfo;
```

Discussion
The `TruncateForTextToUnicode` (page 1934) function requires a Unicode converter object as a parameter. This function does not modify the contents of the private structure to which the Unicode converter object refers, so it uses the constant Unicode converter object defined by the `ConstTextToUnicodeInfo` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
UnicodeConverter.h

ConstUniCharArrayPtr

Defines a constant Unicode character array pointer.

```
typedef const UniChar * ConstUniCharArrayPtr;
```

Discussion
You specify a constant Unicode character array pointer for Unicode strings used within the scope of a function whose contents are not modified by that function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextCommon.h`

ConstUnicodeMappingPtr

Defines a constant Unicode mapping pointer.

```
typedef const UnicodeMapping *     ConstUnicodeMappingPtr;
```

Discussion
Many Unicode Converter functions take a pointer to a Unicode mapping structure as a parameter. For functions that do not modify the Unicode mapping contents, the Unicode Converter provides a constant pointer to a Unicode mapping structure defined by the `ConstUnicodeMappingPtr` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

ConstUnicodeToTextInfo

Defines a constant Unicode to text converter object.

```
typedef UnicodeToTextInfo ConstUnicodeToTextInfo;
```

Discussion
The `TruncateForUnicodeToText` (page 1935) function requires a Unicode converter object as a parameter. This function does not modify the contents of the private structure to which the Unicode converter object refers, so it uses the constant Unicode converter object defined by the `ConstUnicodeToTextInfo` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

ScriptCodeRun

Contains script code information for a text run.

```
struct ScriptCodeRun {
    ByteOffset offset;
    ScriptCode script;
};
typedef struct ScriptCodeRun ScriptCodeRun;
typedef ScriptCodeRun * ScriptCodeRunPtr;
```

Fields

`offset`

The beginning character position of a text run and its script code in the converted text.

`script`

The script code for the text that begins at the position specified.

Discussion

To return the result of a multiple encoding conversion, the `ConvertFromUnicodeToScriptCodeRun` (page 1880) function uses a script code run structure.

The script code run structure uses an extended script code with values in the range 0–254, which are the text encoding base equivalents to Mac OS encodings. Values 0–32 correspond directly to traditional script codes. This allows a script code run to distinguish Icelandic, Turkish, Symbol, Zapf Dingbats, and so on.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextCommon.h`

TECBufferContextRec

Contains buffers for text and text encoding runs.

```
struct TECBufferContextRec {
    TextPtr textInputBuffer;
    TextPtr textInputBufferEnd;
    TextPtr textOutputBuffer;
    TextPtr textOutputBufferEnd;
    TextEncodingRunPtr encodingInputBuffer;
    TextEncodingRunPtr encodingInputBufferEnd;
    TextEncodingRunPtr encodingOutputBuffer;
    TextEncodingRunPtr encodingOutputBufferEnd;
};
typedef struct TECBufferContextRec TECBufferContextRec;
```

Discussion

This structure is used in the `TECConverterContextRec` (page 1959) data structure that is used for a TEC plug-in.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECConversionInfo

Contains text encoding conversion information.

```
struct TECConversionInfo {
    TextEncoding sourceEncoding;
    TextEncoding destinationEncoding;
    UInt16 reserved1;
    UInt16 reserved2;
};
typedef struct TECConversionInfo TECConversionInfo;
```

Fields

`sourceEncoding`
The text encoding specification for the source text.

`destinationEncoding`
The text encoding specification for the destination text.

`reserved1`
Reserved.

`reserved2`
Reserved.

Discussion

When you call the function `TECGetDirectTextEncodingConversions` (page 1927), you pass an array of text encoding conversion information structures. The function fills these structures with information about each type of supported conversion.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingConverter.h`

TECConverterContextRec

Contains converter information used by a Text Encoding Converter plug-in.

```
struct TECConverterContextRec {
    Ptr pluginRec;
    TextEncoding sourceEncoding;
    TextEncoding destEncoding;
    UInt32 reserved1;
    UInt32 reserved2;
    TECBufferContextRec bufferContext;
    UInt32 contextRefCon;
    ProcPtr conversionProc;
    ProcPtr flushProc;
    ProcPtr clearContextInfoProc;
    UInt32 options1;
    UInt32 options2;
    TECPluginStateRec pluginState;
};
typedef struct TECConverterContextRec TECConverterContextRec;
```

Fields

`pluginRec`

`sourceEncoding`

The text encoding specification for the source text.

`destEncoding`

The text encoding specification for the destination text.

`reserved1`

Reserved.

`reserved2`

Reserved.

`bufferContext`

`contextRefCon`

A 32-bit value containing or referring to plug-in-specific data.

`conversionProc`

A pointer to a callback for your conversion procedure.

`flushProc`

A pointer to a callback for your reset procedure.

`clearContextInfoProc`

A pointer to a callback for our clear procedure.

`options1`

A 32-bit value that specfies options needed by your plug-in.

`options2`

A 32-bit value that specfies options needed by your plug-in.

`pluginState`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEncodingPlugin.h`

TECInfo

Contains information about the Unicode Converter, the Text Encoding Converter, and Basic Text Types.

```
struct TECInfo {
    UInt16 format;
    UInt16 tecVersion;
    UInt32 tecTextConverterFeatures;
    UInt32 tecUnicodeConverterFeatures;
    UInt32 tecTextCommonFeatures;
    Str31 tecTextEncodingsFolderName;
    Str31 tecExtensionFileName;
    UInt16 tecLowestTEFileVersion;
    UInt16 tecHighestTEFileVersion;
};
typedef struct TECInfo TECInfo;
typedef TECInfo * TECInfoPtr;
```

Fields

`format`

The current format of the returned structure. The format of the structure is indicated by the `kTECInfoCurrentFormat` constant. Any future changes to the format will always be backwardly compatible; any new fields will be added to the end of the structure.

`tecVersion`

The current version of the Text Encoding Conversion Manager extension in BCD (binary coded decimal), with the first byte indicating the major version; for example, 0x0121 for 1.2.1.

`tecTextConverterFeatures`

New features or bug fixes in the Text Encoding Converter. No bits are currently defined.

`tecUnicodeConverterFeatures`

Bit flags indicating new features or bug fixes in the Unicode Converter. See "Unicode Converter Flags" (page 1977) for the currently defined bit flags.

`tecTextCommonFeatures`

Bit flags indicating new features or bug fixes in Basic Text Types (the Text Common static library). No bits are currently defined.

`tecTextEncodingsFolderName`

A Pascal string with the (possibly localized) name of the Text Encodings folder.

`tecExtensionFileName`

A Pascal string with the (possibly localized) name of the Text Encoding Conversion Manager extension file.

`tecLowestTEFileVersion`

`tecHighestTEFileVersion`

Discussion

The converter information structure is used by the function `TECGetInfo` (page 1929) to hold returned information about the Unicode Converter, the Text Encoding Converter, and Basic Text Types.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextCommon.h`

TECObjectRef

Defines an opaque reference to a converter object.

```
typedef struct OpaqueTECObjectRef * TECObjectRef;
```

Discussion
When making a text conversion, the Text Encoding Converter requires a reference to a converter object that indicates how to accomplish the conversion. Functions, such as `TECCreateConverter` (page 1918), that create a converter object return this reference, which you can then pass to other functions when converting text. A converter object reference is defined by the `TECObjectRef` data type.

The structure of the `OpaqueTECObjectRef` data type is private, and a converter object is not accessible directly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingConverter.h`

TECPluginDispatchTable

Contains version and signature information and pointers to the callback functions used by a text encoding converter plug-in.

```
struct TECPluginDispatchTable {
    TECPluginVersion version;
    TECPluginVersion compatibleVersion;
    TECPluginSignature PluginID;
    TECPluginNewEncodingConverterPtr PluginNewEncodingConverter;
    TECPluginClearContextInfoPtr PluginClearContextInfo;
    TECPluginConvertTextEncodingPtr PluginConvertTextEncoding;
    TECPluginFlushConversionPtr PluginFlushConversion;
    TECPluginDisposeEncodingConverterPtr PluginDisposeEncodingConverter;
    TECPluginNewEncodingSnifferPtr PluginNewEncodingSniffer;
    TECPluginClearSnifferContextInfoPtr PluginClearSnifferContextInfo;
    TECPluginSniffTextEncodingPtr PluginSniffTextEncoding;
    TECPluginDisposeEncodingSnifferPtr PluginDisposeEncodingSniffer;
   TECPluginGetCountAvailableTextEncodingsPtr PluginGetCountAvailableTextEncodings;
    TECPluginGetCountAvailableTextEncodingPairsPtr
PluginGetCountAvailableTextEncodingPairs;
    TECPluginGetCountDestinationTextEncodingsPtr
PluginGetCountDestinationTextEncodings;
    TECPluginGetCountSubTextEncodingsPtr PluginGetCountSubTextEncodings;
    TECPluginGetCountAvailableSniffersPtr PluginGetCountAvailableSniffers;
    TECPluginGetCountWebEncodingsPtr PluginGetCountWebTextEncodings;
    TECPluginGetCountMailEncodingsPtr PluginGetCountMailTextEncodings;
    TECPluginGetTextEncodingInternetNamePtr PluginGetTextEncodingInternetName;
    TECPluginGetTextEncodingFromInternetNamePtr
PluginGetTextEncodingFromInternetName;
};
typedef struct TECPluginDispatchTable TECPluginDispatchTable;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEncodingPlugin.h

TECPluginSig

Defines a data type for a Text Encoding Converter plug-in signature.

```
typedef OSType TECPluginSig;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEncodingConverter.h

TECPluginSignature

Defines a data type for a Text Encoding Converter plug-in signature.

```
typedef OSType TECPluginSignature;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEncodingConverter.h

TECPluginStateRec

Contains state information for a Text Encoding Converter plug-in.

```
struct TECPluginStateRec {
    UInt8 state1;
    UInt8 state2;
    UInt8 state3;
    UInt8 state4;
    UInt32 longState1;
    UInt32 longState2;
    UInt32 longState3;
    UInt32 longState4;
};
typedef struct TECPluginStateRec TECPluginStateRec;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEncodingPlugin.h

TECPluginVersion

Defines a data type for Text Encoding Converter plug-in version.

```
typedef UInt32 TECPluginVersion;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingConverter.h`

TECSnifferContextRec

Contains infomation used by a sniffer object.

```
struct TECSnifferContextRec {
    Ptr pluginRec;
    TextEncoding encoding;
    ItemCount maxErrors;
    ItemCount maxFeatures;
    TextPtr textInputBuffer;
    TextPtr textInputBufferEnd;
    ItemCount numFeatures;
    ItemCount numErrors;
    UInt32 contextRefCon;
    ProcPtr sniffProc;
    ProcPtr clearContextInfoProc;
    TECPluginStateRec pluginState;
};
typedef struct TECSnifferContextRec TECSnifferContextRec;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingPlugin.h`

TECSnifferObjectRef

Defines a reference to an opaque sniffer object.

```
typedef struct OpaqueTECSnifferObjectRef * TECSnifferObjectRef;
```

Discussion
When analyzing text for possible encodings, the Text Encoding Converter requires a reference to a sniffer object that specifies what types of encodings can be detected. You receive this reference when calling the function `TECCreateSniffer` (page 1920). A sniffer object reference is defined by the `TECSnifferObjectRef` data type. The structure of the `OpaqueTECObjectRef` data type is private, and a sniffer object is not accessible directly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEncodingConverter.h`

TextEncoding

Defines a data type for a text encoding value.

```
typedef UInt32 TextEncoding;
```

Discussion
A `TextEncoding` value is specified by a text encoding base, a text encoding variant, and a text encoding format. You can obtain a `TextEncoding` value by calling the function `CreateTextEncoding` (page 1890). When you call this function, you can provide the `TextEncodingBase`, `TextEncodingVariant`, and `TextEncodingFormat` data types.

A `TextEncoding` value is used, for example, to identify the encoding of text passed to a text converter. Two `TextEncoding` values are needed—for source and destination encoding—when calling the Text Encoding Converter or the Unicode Converter to convert text.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextCommon.h`

TextEncodingRun

Contains text encoding information for a text run.

```
struct TextEncodingRun {
    ByteOffset offset;
    TextEncoding textEncoding;
};
typedef struct TextEncodingRun TextEncodingRun;
typedef TextEncodingRun * TextEncodingRunPtr;
```

Fields
`offset`
The beginning character position of a run of text in the converted text string.
`textEncoding`
The encoding of the text run that begins at the position specified.

Discussion
It is not always possible to convert text expressed in Unicode to another single encoding because no other single encoding encompasses the Unicode character encoding range. To adjust for this, you can create a Unicode mapping structure array that specifies the target encodings the Unicode text should be converted to when multiple encodings must be used.

If the `kUnicodeTextRunMask` flag is set, `ConvertFromUnicodeToTextRun` (page 1885) and `ConvertFromUnicodeToScriptCodeRun` (page 1880) may convert Unicode text to a string of text containing multiple text encoding runs. Each run contains text expressed in a different encoding from that of the preceding or following text segment. For each text encoding run in the string, a `TextEncodingRun` structure indicates the beginning offset and the text encoding for that run.

Functions that convert text from Unicode to a text run return the converted text in an array of text encoding run structures. A text encoding run structure is defined by the `TextEncodingRun` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextCommon.h`

TextEncodingVariant

Defines a data type for a text encoding variant.

```
typedef UInt32 TextEncodingVariant;
```

Discussion
The following enumerations define text encoding variant constants: "Encoding Variants for Big-5" (page 1988), "Encoding Variants for MacArabic" (page 1989), "Encoding Variants for MacCroatian" (page 1990), "Encoding Variants for MacCyrillic" (page 1991), "Encoding Variants for MacFarsi" (page 1991), "Encoding Variants for MacHebrew" (page 1992), "Encoding Variants for MacIcelandic" (page 1992), "Encoding Variants for MacJapanese" (page 1993), "Encoding Variants for MacRoman Related to Currency" (page 1996), "Encoding Variants for MacRomanian" (page 1997), "Encoding Variants for MacRomanLatin1" (page 1997), "Encoding Variants for MacRoman" (page 1994), and "Encoding Variants for MacVT100" (page 1998).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextCommon.h`

TextToUnicodeInfo

Defines reference to an opaque Unicode converter object.

```
typedef struct OpaqueTextToUnicodeInfo * TextToUnicodeInfo;
```

Discussion
A Unicode converter object is a private object containing mapping and state information. Many of the Unicode Converter functions that perform conversions require a Unicode converter object containing information used for the conversion process. There are three types of Unicode converter objects, all serving the same purpose but used for different types of conversions. You use the `TextToUnicodeInfo` type, described here, for converting from non-Unicode text to Unicode text.

Because your application cannot directly create or modify the contents of the private Unicode converter object, the Unicode Converter provides functions to create and dispose of it. To create a Unicode converter object for converting from non-Unicode text to Unicode text, your application must first call either the function `CreateTextToUnicodeInfo` (page 1890) or the function `CreateTextToUnicodeInfoByEncoding` (page 1891) to provide the mapping information required for the conversion. You can then pass this object to the function `ConvertFromTextToUnicode` (page 1877) or `ConvertFromPStringToUnicode` (page 1876) to identify the information to be used in performing the actual conversion. After you have finished using the object, you should release the memory allocated for it by calling the function `DisposeTextToUnicodeInfo` (page 1897). The `TextToUnicodeInfo` data type defines the Unicode converter object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
UnicodeConverter.h

UniCharArrayOffset

Represents the boundary between two characters.

```
typedef UInt32 UniCharArrayOffset;
```

Discussion
A UniCharArrayOffset represents the boundary between two characters. For example, the first character in a buffer lies between offsets 0 and 1. So the first character in the buffer can be referred to as either "offset 0, leading" or "offset 1, trailing." This distinction is useful when you deal with caret positions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextCommon.h

UnicodeMapping

Contains information for mapping to or from Unicode encoding.

```
struct UnicodeMapping {
    TextEncoding unicodeEncoding;
    TextEncoding otherEncoding;
    UnicodeMapVersion mappingVersion;
};
typedef struct UnicodeMapping UnicodeMapping;
typedef UnicodeMapping * UnicodeMappingPtr;
```

Fields
unicodeEncoding
: A Unicode text encoding specification of type TextEncoding.

otherEncoding
: A text encoding specification for the text to be converted to or from Unicode.

mappingVersion
: The version of the Unicode mapping table to be used.

Discussion
A Unicode mapping structure contains a complete text encoding specification for a Unicode encoding, a complete non-Unicode text encoding specification giving the encoding for the text to be converted to or from Unicode, and the version of the mapping table to be used for conversion. You use a structure of this type to specify the text encodings to and from which the text string is to be converted. A Unicode mapping structure is defined by the UnicodeMapping data type.

You can specify a variety of normalization options by setting up the Unicode mapping structure as described in the following.

To specify normal canonical decomposition according to Unicode 3.2 rules, with no exclusions ("Canonical decomposition 3.2"), set up the UnicodeMapping structure as follows:

```
mapping.unicodeEncoding (in) = Unicode 2.x-3.x, kUnicodeNoSubset,
kUnicode16BitFormat
mapping.otherEncoding (out) = Unicode 2.x-3.x, kUnicodeCanonicalDecompVariant,
  kUnicode16BitFormat
mapping.mappingVersion = kUnicodeUseLatestMapping
```

Examples:

```
u00E0 -> u0061 + u0300
u0061 + u0300 -> u0061 + u0300
u03AC ->  u03B1 + u0301 (3.2 rules)
uF900 -> u8C48
u00E0 + u0323 -> u0061 + u0323 + u0300  (correct)
```

To specify canonical decomposition according to Unicode 3.2 rules, with HFS+ exclusions ("HFS+ decomposition 3.2"), set up the `UnicodeMapping` structure in one of the following ways. The second method is for compatibility with the old method of using `mappingVersion = kUnicodeUseHFSPlusMapping`.

```
// Method 1
mapping.unicodeEncoding (in) = Unicode 2.x-3.x, kUnicodeNoSubset,
kUnicode16BitFormat
mapping.otherEncoding (out) = Unicode 2.x-3.x, kUnicodeHFSPlusDecompVariant,
kUnicode16BitFormat
mapping.mappingVersion = kUnicodeUseLatestMapping
// Method 2
mapping.unicodeEncoding (in) = Unicode 2.x-3.x, kUnicode16BitFormat,
kUnicode16BitFormat
mapping.otherEncoding (out) = Unicode 2.x, kUnicodeCanonicalDecompVariant,
kUnicode16BitFormat
mapping.mappingVersion = kUnicodeUseHFSPlusMapping
```

Examples:

```
u00E0 -> u0061 + u0300
u0061 + u0300 -> u0061 + u0300
u03AC ->  u03B1 + u0301 (3.2 rules)
uF900 -> uF900 (decomposition excluded for HFS+)
u00E0 + u0323 -> u0061 + u0323 + u0300  (correct)
```

To specify normal canonical composition according to Unicode 3.2 rules, set up the `UnicodeMapping` structure as follows:

```
mapping.unicodeEncoding (in) = Unicode 2.x-3.x, kUnicodeNoSubset,
kUnicode16BitFormat
mapping.otherEncoding (out) = Unicode 2.x-3.x, kUnicodeCanonicalCompVariant,
kUnicode16BitFormat
mapping.mappingVersion = kUnicodeUseLatestMapping
```

Examples:

```
u00E0 -> u00E0
u0061 + u0300 -> u00E0
u03AC ->  u03AC
uF900 -> u8C48
u00E0 + u0323 -> u1EA1 u0300 (correct)
```

To specify canonical composition according to Unicode 3.2 rules, but using the HFS+ decomposition exclusions, set up the `UnicodeMapping` structure as follows. This is the form to use if you want to obtain a composed form that dervide from the decomposed form used for HFS+ filenames.

```
mapping.unicodeEncoding (in) = Unicode 2.x-3.x, kUnicodeNoSubset,
kUnicode16BitFormat
mapping.otherEncoding (out) = Unicode 2.x-3.x, kUnicodeHFSPlusCompVariant,
kUnicode16BitFormat
mapping.mappingVersion = kUnicodeUseLatestMapping
```

Examples:

```
u00E0 -> u00E0
u0061 + u0300 -> u00E0
u03AC ->  u03AC
uF900 -> uF900
u00E0 + u0323 -> u1EA1 u0300 (correct)
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

UnicodeToTextFallbackUPP

Defines a universal procedure pointer to a Unicode-to-text-fallback callback function.

```
typedef UnicodeToTextFallbackProcPtr UnicodeToTextFallbackUPP;
```

Discussion
For more information, see the description of the `UnicodeToTextFallbackProcPtr` (page 1953) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

UnicodeToTextInfo

Defines a reference to an opaque Unicode to text converter object.

```
typedef struct OpaqueUnicodeToTextInfo * UnicodeToTextInfo;
```

Discussion
Many of the Unicode Converter functions that perform conversions require a Unicode converter object containing information used for the conversion process. There are three types of Unicode converter objects used for different types of conversions. You use the `UnicodeToTextInfo` type, described here, for converting from Unicode to text.

Because your application cannot directly create or modify the contents of the private Unicode converter object, the Unicode Converter provides functions to create and dispose of it. To create a Unicode converter object for converting from Unicode to text, your application must first call either the function `CreateUnicodeToTextInfo` (page 1892) or `CreateUnicodeToTextInfoByEncoding` (page 1893).

You can then pass this object to the function `ConvertFromUnicodeToText` (page 1883) or `ConvertFromUnicodeToPString` (page 1879) to identify the information used to perform the actual conversion. After you have finished using the object, you should release the memory allocated for it by calling the function `DisposeUnicodeToTextInfo` (page 1898).

A Unicode converter object for this purpose is defined by the `UnicodeToTextInfo` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

UnicodeToTextRunInfo

Defines a reference to an opaque Unicode to text run information converter object.

```
typedef struct OpaqueUnicodeToTextRunInfo * UnicodeToTextRunInfo;
```

Discussion
Many of the Unicode Converter functions that perform conversions require a Unicode converter object containing information used for the conversion process. There are three types of Unicode converter objects used for different types of conversions. You use the `UnicodeToTextRunInfo` type, described here, for converting from Unicode to multiple encodings.

Because your application cannot directly create or modify the contents of the private Unicode converter object, the Unicode Converter provides functions to create and dispose of it. You can use any of three functions to create a Unicode converter object for converting from Unicode to multiple encodings. You can use `CreateUnicodeToTextRunInfo` (page 1894), `CreateUnicodeToTextRunInfoByEncoding` (page 1895), or `CreateUnicodeToTextRunInfoByScriptCode` (page 1896).

You can then pass this object to the function `ConvertFromUnicodeToTextRun` (page 1885) or `ConvertFromUnicodeToScriptCodeRun` (page 1880) to identify the information used to perform the actual conversion. After you have finished using the object, you should release the memory allocated for it by calling the function `DisposeUnicodeToTextRunInfo` (page 1898).

A Unicode converter object for this purpose is defined by the `UnicodeToTextRunInfo` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeConverter.h`

Constants

Feature Selectors

Conversion Flags

Specify how to perform conversion of text from one encoding to another.

```
enum {
    kUnicodeUseFallbacksBit = 0,
    kUnicodeKeepInfoBit = 1,
    kUnicodeDirectionalityBits = 2,
    kUnicodeVerticalFormBit = 4,
    kUnicodeLooseMappingsBit = 5,
    kUnicodeStringUnterminatedBit = 6,
    kUnicodeTextRunBit = 7,
    kUnicodeKeepSameEncodingBit = 8,
    kUnicodeForceASCIIRangeBit = 9,
    kUnicodeNoHalfwidthCharsBit = 10,
    kUnicodeTextRunHeuristicsBit = 11,
    kUnicodeMapLineFeedToReturnBit = 12
};
```

Constants

`kUnicodeUseFallbacksBit`
Enables use of fallback mappings.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeKeepInfoBit`
Sets the keep-information control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeDirectionalityBits`
Sets directionality.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeVerticalFormBit`
Sets the vertical form control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeLooseMappingsBit`
Enables use of the loose-mapping portion of a character mapping table.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeStringUnterminatedBit`
Sets the string-unterminated control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeTextRunBit`
Sets the text-run control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeKeepSameEncodingBit`
Sets the keep-same-encoding control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeForceASCIIRangeBit`
Sets the force ASCII range control flag.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeNoHalfwidthCharsBit`
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeTextRunHeuristicsBit`
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeMapLineFeedToReturnBit`
Available in Mac OS X v10.2 and later.
Declared in `UnicodeConverter.h`.

Conversion Masks

Set or text for conversion flags.

```
enum {
    kUnicodeUseFallbacksMask = 1L << kUnicodeUseFallbacksBit,
    kUnicodeKeepInfoMask = 1L << kUnicodeKeepInfoBit,
    kUnicodeDirectionalityMask = 3L << kUnicodeDirectionalityBits,
    kUnicodeVerticalFormMask = 1L << kUnicodeVerticalFormBit,
    kUnicodeLooseMappingsMask = 1L << kUnicodeLooseMappingsBit,
    kUnicodeStringUnterminatedMask = 1L << kUnicodeStringUnterminatedBit,
    kUnicodeTextRunMask = 1L << kUnicodeTextRunBit,
    kUnicodeKeepSameEncodingMask = 1L << kUnicodeKeepSameEncodingBit,
    kUnicodeForceASCIIRangeMask = 1L << kUnicodeForceASCIIRangeBit,
    kUnicodeNoHalfwidthCharsMask = 1L << kUnicodeNoHalfwidthCharsBit,
    kUnicodeTextRunHeuristicsMask = 1L << kUnicodeTextRunHeuristicsBit,
    kUnicodeMapLineFeedToReturnMask = 1L << kUnicodeMapLineFeedToReturnBit
};
```

Constants

`kUnicodeUseFallbacksMask`

A mask for setting the Unicode-use-fallbacks conversion flag. The Unicode Converter uses fallback mappings when it encounters a source text element for which there is no equivalent destination encoding. Fallback mappings are mappings that do not preserve the meaning or identity of the source character but represent a useful approximation of it. See the function `SetFallbackUnicodeToText` (page 1908).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeKeepInfoMask`

A mask for setting the keep-information control flag which governs whether the Unicode Converter keeps the current state stored in the Unicode converter object before converting the text string.

If you clear this flag, the converter will initialize the Unicode converter object before converting the text string and assume that subsequent calls do not need any context, such as direction state for the current call.

If you set the flag, the converter uses the current state. This is useful if your application must convert a stream of text in pieces that are not block delimited. You should set this flag for each call in a series of calls on the same text stream.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeDirectionalityMask`

A mask for setting the directionality control flag

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeVerticalFormMask`

A mask for setting the vertical form control flag. The vertical form control flag tells the Unicode Converter how to map text elements for which there are both abstract and vertical presentation forms in the destination encoding.

If set, the converter maps these text elements to their vertical forms, if they are available.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeLooseMappingsMask`

A mask that determines whether the Unicode Converter should use the loose-mapping portion of a mapping table for character mapping if the strict mapping portion of the table does not include a destination encoding equivalent for the source text element.

If you clear this flag, the converter will use only the strict equivalence portion.

If set this flag and a conversion for the source text element does not exist in the strict equivalence portion of the mapping table, then the converter uses the loose mapping section.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeStringUnterminatedMask`

A mask for setting the string-unterminated control flag. Determines how the Unicode Converter handles text-element boundaries and direction resolution at the end of an input buffer.

If you clear this bit, the converter treats the end of the buffer as the end of text.

If you set this bit, the converter assumes that the next call you make using the current context will supply another buffer of text that should be treated as a continuation of the current text. For example, if the last character in the input buffer is `'A'`, `ConvertFromUnicodeToText` stops conversion at the `'A'` and returns `kTECIncompleteElementErr`, because the next buffer could begin with a combining diacritical mark that should be treated as part of the same text element. If the last character in the input buffer is a control character, `ConvertFromUnicodeToText` does not return `kTECIncompleteElementErr` because a control character could not be part of a multiple character text element.

In attempting to analyze the text direction, when the Unicode Converter reaches the end of the current input buffer and the direction of the current text element is still unresolved, if you clear this flag, the converter treats the end of the buffer as a block separator for direction resolution. If you set this flag, it sets the direction as undetermined

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeTextRunMask`

A mask for setting the text-run control flag which determines how the Unicode Converter converts Unicode text to a non-Unicode encoding when more than one possible destination encoding exists.

If you clear this flag, the function `ConvertFromUnicodeToTextRun` (page 1885) or `ConvertFromUnicodeToScriptCodeRun` (page 1880) attempts to convert the Unicode text to the single encoding from the list of encodings in the Unicode converter object that produces the best result, that is, that provides for the greatest amount of source text conversion.

If you set this flag, `ConvertFromUnicodeToTextRun` or `ConvertFromUnicodeToScriptCodeRun`, which are the only functions to which it applies, may generate a destination string that combines text in any of the encodings specified by the Unicode converter object.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeKeepSameEncodingMask`

A mask for setting the keep-same-encoding control flag. Determines how the Unicode Converter treats the conversion of Unicode text following a text element that could not be converted to the first destination encoding when multiple destination encodings exist. This control flag applies only if the `kUnicodeTextRunMask` control flag is set.

If you set this flag, the function `ConvertFromUnicodeToTextRun` (page 1885) attempts to minimize encoding changes in the conversion of the source text string; that is, once it is forced to make an encoding change, it attempts to use that encoding as the conversion destination for as long as possible.

If you clear this flag, `ConvertFromUnicodeToTextRun` attempts to keep most of the converted string in one encoding, switching to other encodings only when necessary.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeForceASCIIRangeMask`

A mask for setting the force ASCII range control flag. If an encoding normally treats 1-byte code points `0x00–0x7F` as an ISO 646 national variant that is different from ASCII, setting this flag forces `0x00–0x7F` to be treated as ASCII. For example, Japanese encodings such as Shift-JIS generally treat `0x00–0x7F` as JIS Roman, with `0x5C` as YEN SIGN instead of REVERSE SOLIDUS, but when converting a DOS file path you may want to set this flag so that `0x5C` is mapped as REVERSE SOLIDUS.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeNoHalfwidthCharsMask`

Sets the no halfwidth characters control flag.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeTextRunHeuristicsMask`

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMapLineFeedToReturnMask`

Specifies mapping o the LF (LineFeed) character used in Unix to represent new lines to the CR (CarriageReturn) used in Mac encodings. This option has an effect only when used with the constant `kUnicodeLooseMappingsMask`. You can pass both constants as `iControlFlags` parameters to the functions `ConvertFromUnicodeToText`, `ConvertFromUnicodeToTextRun`, and `ConvertFromUnicodeToScriptCodeRun`.

Available in Mac OS X v10.2 and later.

Declared in `UnicodeConverter.h`.

Discussion

You use these constants to specify how the conversion of text from one encoding to another is performed. You use these masks as the `controlFlags` parameter in the `ConvertFromTextToUnicode` (page 1877), `ConvertFromUnicodeToText` (page 1883), `ConvertFromUnicodeToScriptCodeRun` (page 1880), `ConvertFromUnicodeToTextRun` (page 1885), and `TruncateForUnicodeToText` (page 1935) functions. A different subset of control masks applies to each of these functions. Using the bitmask constants, you can perform a bitwise `OR` operation to set the pertinent flags for a particular function's parameters. For example, when you call a function, you might pass the following `controlFlags` parameter setting:

```
controlflags=kUnicodeUseFallbacksMask |kUnicodeLooseMappingsMask;
```

Directionality Flags

Specify a text direction.

```
enum {
    kUnicodeDefaultDirection = 0,
    kUnicodeLeftToRight = 1,
    kUnicodeRightToLeft = 2
};
```

Constants

`kUnicodeDefaultDirection`
Use the default direction.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeLeftToRight`
Indicates left to right direction.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeRightToLeft`
Indicates right to left direction.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

Directionality Masks

Set or text for directionality bits.

```
enum {
    kUnicodeDefaultDirectionMask = kUnicodeDefaultDirection <<
kUnicodeDirectionalityBits,
    kUnicodeLeftToRightMask = kUnicodeLeftToRight << kUnicodeDirectionalityBits,
    kUnicodeRightToLeftMask = kUnicodeRightToLeft << kUnicodeDirectionalityBits
};
```

Constants

`kUnicodeDefaultDirectionMask`
A mask for setting the global, or base, line direction for the text being converted. The value `kUnicodeDefaultDirectionMask` tells the converter to use the value of the first strong direction character in the string. This determines which direction the converter should use for resolution of neutral coded characters, such as spaces that occur between sets of coded characters having different directions—for example, between Latin and Arabic characters—rendering ambiguous the direction of the space character.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeLeftToRightMask`
: A mask for setting the global, or base, line direction for the text being converted. The value `kUnicodeLeftToRightMask` tells the converter that the base paragraph direction is left to right. This determines which direction the converter should use for resolution of neutral coded characters, such as spaces that occur between sets of coded characters having different directions—for example, between Latin and Arabic characters—rendering ambiguous the direction of the space character.

  Available in Mac OS X v10.0 and later.

  Declared in `UnicodeConverter.h`.

`kUnicodeRightToLeftMask`
: The value `kUnicodeRightToLeftMask` tells the converter that the base paragraph direction is right to left. This determines which direction the converter should use for resolution of neutral coded characters, such as spaces that occur between sets of coded characters having different directions—for example, between Latin and Arabic characters—rendering ambiguous the direction of the space character.

  Available in Mac OS X v10.0 and later.

  Declared in `UnicodeConverter.h`.

Unicode Converter Flags

Specify features for bug fixes in the Unicode Converter.

```
enum {
    kTECKeepInfoFixBit = 0,
    kTECFallbackTextLengthFixBit = 1,
    kTECTextRunBitClearFixBit = 2,
    kTECTextToUnicodeScanFixBit = 3,
    kTECAddForceASCIIChangesBit = 4,
    kTECPreferredEncodingFixBit = 5,
    kTECAddTextRunHeuristicsBit = 6,
    kTECAddFallbackInterruptBit = 7
};
```

Constants

`kTECKeepInfoFixBit`
: This is set if the Unicode Converter has a bug fix to stop ignoring certain control flags

  Available in Mac OS X v10.0 and later.

  Declared in `TextCommon.h`.

`kTECFallbackTextLengthFixBit`
: This is set if the Unicode Converter has a bug fix to use the source length (`srcConvLen`) and destination length (`destConvLen`) returned by a caller-supplied fall-back handler for any status it returns except `kTECUnmappableElementErr`. Previously it honored only these values if `noErr` was returned.

  Available in Mac OS X v10.0 and later.

  Declared in `TextCommon.h`.

`kTECTextRunBitClearFixBit`
: This is set if `ConvertFromUnicodeToTextRun` and `ConvertFromUnicodeToScriptCodeRun` function correctly if the `kUnicodeTextRunBit` is clear.

  Available in Mac OS X v10.0 and later.

  Declared in `TextCommon.h`.

`kTECTextToUnicodeScanFixBit`
: This is set if `ConvertFromTextToUnicode` is enhanced so mappings can depend on context and saved state. The consequences of this are (1) malformed input results in `kTextMalformedInputErr`; (2) `ConvertFromTextToUnicode` accepts the control flags `kUnicodeLooseMappingsMask`, `kUnicodeKeepInfoMask`, and `kUnicodeStringUnterminatedMask`; (3) elimination of redundant direction overrides when converting Mac OS Arabic and Hebrew to Unicode; and (4) improved mapping of 0x30-0x39 digits in Mac OS Arabic when loose mappings are used.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTECAddForceASCIIChangesBit`
: This is set if the new control flag bits `kUnicodeForceASCIIRangeBit` and `kUnicodeNoHalfwidthCharsBit` are supported for use with the functions `ConvertFromTextToUnicode`, `ConvertFromUnicodeToText`, and so forth.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTECPreferredEncodingFixBit`
: This is set to indicate that if a preferred encoding is specified for `CreateUnicodeToTextRunInfo` and related functions, they handle it correctly even if it does not match the system script.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTECAddTextRunHeuristicsBit`
: Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTECAddFallbackInterruptBit`
: Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
These are bit flags to indicate new features for bug fixes in the Unicode Converter. They are used by the `TECInfo` (page 1961) data type.

Unicode Converter Masks

Set or test for Unicode converter flags.

```
enum {
  kTECKeepInfoFixMask           = 1L << kTECKeepInfoFixBit,
  kTECFallbackTextLengthFixMask = 1L << kTECFallbackTextLengthFixBit,
  kTECTextRunBitClearFixMask    = 1L << kTECTextRunBitClearFixBit,
  kTECTextToUnicodeScanFixMask  = 1L << kTECTextToUnicodeScanFixBit,
  kTECAddForceASCIIChangesMask  = 1L << kTECAddForceASCIIChangesBit,
  kTECPreferredEncodingFixMask  = 1L << kTECPreferredEncodingFixBit,
  kTECAddTextRunHeuristicsMask  = 1L << kTECAddTextRunHeuristicsBit,
  kTECAddFallbackInterruptMask  = 1L << kTECAddFallbackInterruptBit
};
```

Unicode Fallback Sequencing Flag

Specifies options for setting fallback sequencing.

```
enum {
    kUnicodeFallbackSequencingBits = 0
};
```

Unicode Fallback Sequencing Masks

Set or text for Unicode sequencing flag.

```
enum {
    kUnicodeFallbackSequencingMask = 3L << kUnicodeFallbackSequencingBits,
    kUnicodeFallbackInterruptSafeMask = 1L << 2
};
```

Constants

`kUnicodeFallbackSequencingMask`

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeFallbackInterruptSafeMask`

Indicate that the caller's fallback routine doesn't move memory.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

Unicode Matching Flags

Specify matching criteria for Unicode mappings.

```
enum {
    kUnicodeMatchUnicodeBaseBit = 0,
    kUnicodeMatchUnicodeVariantBit = 1,
    kUnicodeMatchUnicodeFormatBit = 2,
    kUnicodeMatchOtherBaseBit = 3,
    kUnicodeMatchOtherVariantBit = 4,
    kUnicodeMatchOtherFormatBit = 5
};
```

Constants

`kUnicodeMatchUnicodeBaseBit`
Excludes mappings that do not match the text encoding base of the `unicodeEncoding` field of the structure `UnicodeMapping` (page 1967).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchUnicodeVariantBit`
Excludes mappings that do not match the text encoding variant of the `unicodeEncoding` field of the specified Unicode mapping structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchUnicodeFormatBit`
Excludes mappings that do not match the text encoding format of the `unicodeEncoding` field of the specified Unicode mapping structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherBaseBit`
Excludes mappings that do not match the text encoding base of the `otherEncoding` field of the structure `UnicodeMapping` (page 1967).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherVariantBit`
Excludes mappings that do not match the text encoding variant of the `otherEncoding` field of the specified Unicode mapping structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherFormatBit`
Excludes mappings that do not match the text encoding format of the `otherEncoding` field of the specified Unicode mapping structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

Unicode Matching Masks

Used to set or test for Unicode matching flags.

```
enum {
    kUnicodeMatchUnicodeBaseMask = 1L << kUnicodeMatchUnicodeBaseBit,
    kUnicodeMatchUnicodeVariantMask = 1L << kUnicodeMatchUnicodeVariantBit,
    kUnicodeMatchUnicodeFormatMask = 1L << kUnicodeMatchUnicodeFormatBit,
    kUnicodeMatchOtherBaseMask = 1L << kUnicodeMatchOtherBaseBit,
    kUnicodeMatchOtherVariantMask = 1L << kUnicodeMatchOtherVariantBit,
    kUnicodeMatchOtherFormatMask = 1L << kUnicodeMatchOtherFormatBit
};
```

Constants

`kUnicodeMatchUnicodeBaseMask`
If set, excludes mappings that do not match the text encoding base of the `unicodeEncoding` field of the structure `UnicodeMapping` (page 1967). If not set, the function ignores the text encoding base of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchUnicodeVariantMask`
If set, excludes mappings that do not match the text encoding variant of the `unicodeEncoding` field of the specified Unicode mapping structure. If not set, the function ignores the text encoding variant of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchUnicodeFormatMask`
If set, excludes mappings that do not match the text encoding format of the `unicodeEncoding` field of the specified Unicode mapping structure. If not set, the function ignores the text encoding format of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherBaseMask`
If set, excludes mappings that do not match the text encoding base of the `otherEncoding` field of the structure `UnicodeMapping` (page 1967). If not set, the function ignores the text encoding base of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherVariantMask`
If set, excludes mappings that do not match the text encoding variant of the `otherEncoding` field of the specified Unicode mapping structure. If not set, the function ignores the text encoding variant of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeMatchOtherFormatMask`
If set, excludes mappings that do not match the text encoding format of the `otherEncoding` field of the specified Unicode mapping structure. If not set, the function ignores the text encoding format of that field.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

Fallback Handler Selectors

Specify a fallback handler for the Unicode Converter to use.

```
enum {
    kUnicodeFallbackDefaultOnly = 0,
    kUnicodeFallbackCustomOnly = 1,
    kUnicodeFallbackDefaultFirst = 2,
    kUnicodeFallbackCustomFirst = 3
};
```

Constants

`kUnicodeFallbackDefaultOnly`
Use the default fallback handler only.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeFallbackCustomOnly`
Use the custom fallback handler only.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeFallbackDefaultFirst`
Use the default fallback handler first, then the custom one.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

`kUnicodeFallbackCustomFirst`
Use the custom fallback handler first, then the default one.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeConverter.h`.

Discussion

Used to specify which fallback handler the Unicode Converter should use. If you use both the custom and default handlers, you can set the order in which they are called. You use these constants to set the `controlFlags` parameter of the `SetFallbackUnicodeToText` (page 1908) and `SetFallbackUnicodeToTextRun` (page 1909) functions.

Encodings and Variants

Base Text Encodings

Specify base text encodings.

```
typedef UInt32 TextEncodingBase;
enum {
    kTextEncodingMacRoman = 0,
    kTextEncodingMacJapanese = 1,
    kTextEncodingMacChineseTrad = 2,
    kTextEncodingMacKorean = 3,
    kTextEncodingMacArabic = 4,
    kTextEncodingMacHebrew = 5,
    kTextEncodingMacGreek = 6,
    kTextEncodingMacCyrillic = 7,
    kTextEncodingMacDevanagari = 9,
    kTextEncodingMacGurmukhi = 10,
    kTextEncodingMacGujarati = 11,
    kTextEncodingMacOriya = 12,
    kTextEncodingMacBengali = 13,
    kTextEncodingMacTamil = 14,
    kTextEncodingMacTelugu = 15,
    kTextEncodingMacKannada = 16,
    kTextEncodingMacMalayalam = 17,
    kTextEncodingMacSinhalese = 18,
    kTextEncodingMacBurmese = 19,
    kTextEncodingMacKhmer = 20,
    kTextEncodingMacThai = 21,
    kTextEncodingMacLaotian = 22,
    kTextEncodingMacGeorgian = 23,
    kTextEncodingMacArmenian = 24,
    kTextEncodingMacChineseSimp = 25,
    kTextEncodingMacTibetan = 26,
    kTextEncodingMacMongolian = 27,
    kTextEncodingMacEthiopic = 28,
    kTextEncodingMacCentralEurRoman = 29,
    kTextEncodingMacVietnamese = 30,
    kTextEncodingMacExtArabic = 31,
    kTextEncodingMacSymbol = 33,
    kTextEncodingMacDingbats = 34,
    kTextEncodingMacTurkish = 35,
    kTextEncodingMacCroatian = 36,
    kTextEncodingMacIcelandic = 37,
    kTextEncodingMacRomanian = 38,
    kTextEncodingMacCeltic = 39,
    kTextEncodingMacGaelic = 40,
    kTextEncodingMacKeyboardGlyphs = 41
};
```

Constants

`kTextEncodingMacRoman`

The encoding for Mac OS Roman.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacJapanese`

The encoding for Mac OS Japanese.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacChineseTrad`
The encoding for Mac OS traditional Chinese.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacKorean`
The encoding for Mac OS Korean.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacArabic`
The encoding for Mac OS Arabic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacHebrew`
The encoding for Mac OS Hebrew.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacGreek`
The encoding for Mac OS Greek.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacCyrillic`
The encoding for Mac OS Cyrillic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacDevanagari`
The encoding for Mac OS Devanagari.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacGurmukhi`
The encoding for Mac OS Gurmukhi.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacGujarati`
The encoding for Mac OS Gujurati.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacOriya`
The encoding for Mac OS Oriya.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacBengali`
The encoding for Mac OS Bengali.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacTamil`
The encoding for Mac OS Tamil.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacTelugu`
The encoding for Mac OS Telugu.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacKannada`
The encoding for Mac OS Kannada.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacMalayalam`
The encoding for Mac OS Malayalam.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacSinhalese`
The encoding for Mac OS Sinhalese.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacBurmese`
The encoding for Mac OS Burmese.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacKhmer`
The encoding for Mac OS Khmer.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacThai`
The encoding for Mac OS Thai.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacLaotian`
The encoding for Mac OS Laotian.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacGeorgian`
The encoding for Mac OS Georgian.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacArmenian`
The encoding for Mac OS Armenian.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacChineseSimp`
The encoding for Mac OS simple Chinese.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacTibetan`
The encoding for Mac OS Tibetan.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacMongolian`
The encoding for Mac OS Mongolian.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacEthiopic`
The encoding for Mac OS Ethiopic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacCentralEurRoman`
The encoding for Mac OS Central European Roman.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacVietnamese`
The encoding for Mac OS Vietnamese.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacExtArabic`
The encoding for Mac OS ExtArabic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacSymbol`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacDingbats`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacTurkish`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacCroatian`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacIcelandic`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacRomanian`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacCeltic`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacGaelic`
This Mac OS encoding uses script code 0, `smRoman`.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingMacKeyboardGlyphs`
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

Discussion
You use a base text encoding data type to specify which text encoding or text encoding scheme you have used to express a given text. The text encoding base value is the primary specification of the source or target encoding. Values 0 through 32 correspond directly to Mac OS script codes. Values 33 through 254 are for other Mac OS encodings that do not have their own script codes, such as the Symbol encoding implemented by the Symbol font. You can also specify a meta-value as a base text encoding, such as `kTextEncodingMacHFS` and `kTextEncodingUnicodeDefault`. A meta-value is mapped to a real value.

The function `GetTextEncodingBase` (page 1899) returns the text encoding base of a text encoding specification.

A base text encoding is defined by the `TextEncodingBase` data type.

Compatibility TextEncodings

Specify text encodings that are provided for backward compatibility.

```
enum {
    kTextEncodingMacTradChinese = kTextEncodingMacChineseTrad,
    kTextEncodingMacRSymbol = 8,
    kTextEncodingMacSimpChinese = kTextEncodingMacChineseSimp,
    kTextEncodingMacGeez = kTextEncodingMacEthiopic,
    kTextEncodingMacEastEurRoman = kTextEncodingMacCentralEurRoman,
    kTextEncodingMacUninterp = 32
};
```

EBCDIC and IBM Host Text Encodings

Specify text encodings used by IBM computers.

```
enum {
    kTextEncodingEBCDIC_US = 0x0C01,
    kTextEncodingEBCDIC_CP037 = 0x0C02
};
```

Constants

`kTextEncodingEBCDIC_US`
Basic EBCDIC-US encoding.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingEBCDIC_CP037`
Code page 037, extended EBCDIC-US Latin1.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

Discussion

EBCDIC (Extended Binary- Coded Decimal Interchange Code) is used by IBM computers to represent characters as numbers.

Encoding Variants for Big-5

Specify variants of Big-5 encoding.

```
enum {
    kBig5_BasicVariant = 0,
    kBig5_StandardVariant = 1,
    kBig5_ETenVariant = 2
};
```

Constants

`kBig5_BasicVariant`
The basic encoding variant.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kBig5_StandardVariant`
The standard variant; 0xC6A1-0xC7FC: kana, Cyrillic, enclosed numerics.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kBig5_ETenVariant`
Adds kana, Cyrillic, radicals, and so forth with high-bytes C6-C8, F9.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
Big-5 encoding was developed by five companies as a character set standard in Tawain.

Encoding Variants for Mac OS Encodings

Specify variant Mac OS encodings that use script codes other than 0

```
enum {
    kTextEncodingMacFarsi = 0x8C,
    kTextEncodingMacUkrainian = 0x98,
    kTextEncodingMacInuit = 0xEC,
    kTextEncodingMacVT100 = 0xFC
};
```

Constants
`kTextEncodingMacFarsi`
Uses script code 4, `smArabic`. It is similar to Mac Arabic but uses Farsi digits.]

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacUkrainian`
Uses script code 7, `smCyrillic`.]

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacInuit`
Uses script code 28, `smEthiopic`.]

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacVT100`
Uses script code 32, `smUninterp`; VT100/102 font from the common toolbox; Latin-1 characters plus box drawing.]

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacArabic

Specify variants of MacArabic.

```
enum {
    kMacArabicStandardVariant = 0,
    kMacArabicTrueTypeVariant = 1,
    kMacArabicThuluthVariant = 2,
    kMacArabicAlBayanVariant = 3
};
```

Constants

`kMacArabicStandardVariant`
A Mac OS Arabic variant is supported by the Cairo font (the system font for Arabic) and is the encoding supported by the text processing utilities.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacArabicTrueTypeVariant`
A Mac OS Arabic variant used for most of the Arabic TrueType fonts: Baghdad, Geeza, Kufi, Nadeem.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacArabicThuluthVariant`
A Mac OS Arabic variant used for the Arabic PostScript-only fonts: Thuluth and Thuluth bold.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacArabicAlBayanVariant`
A Mac OS Arabic variant used for the Arabic TrueType font Al Bayan.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacCroatian

Specify variants of MacCroation.

```
enum {
    kMacCroatianDefaultVariant = 0,
    kMacCroatianCurrencySignVariant = 1,
    kMacCroatianEuroSignVariant = 2
};
```

Constants

`kMacCroatianDefaultVariant`
This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacCroatianCurrencySignVariant`
In versions of Mac OS earlier than 8.5, 0xDB is the currency sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacCroatianEuroSignVariant`
In Mac OS version 8.5 and later, 0xDB is the Euro sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacCyrillic

Specify variants of MacCyrillic.

```
enum {
    kMacCyrillicDefaultVariant = 0,
    kMacCyrillicCurrSignStdVariant = 1,
    kMacCyrillicCurrSignUkrVariant = 2,
    kMacCyrillicEuroSignVariant = 3
};
```

Constants

`kMacCyrillicDefaultVariant`
This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacCyrillicCurrSignStdVariant`
In Mac OS versions prior to 9.0 (RU, BG), 0xFF = currency sign, 0xA2/0xB6 = CENT / PARTIAL DIFF.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacCyrillicCurrSignUkrVariant`
In Mac OS version 9.0 and later (UA, LangKit), 0xFF = currency sign, 0xA2/0xB6 = GHE with upturn.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacCyrillicEuroSignVariant`
In Mac OS 9.0 and later, 0xFF is Euro sign, 0xA2/0xB6 = GHE with upturn.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacFarsi

Specify variants of MacFarsi.

```
enum {
    kMacFarsiStandardVariant = 0,
    kMacFarsiTrueTypeVariant = 1
};
```

Constants

`kMacFarsiStandardVariant`
This Mac OS Farsi variant is supported by the Tehran font (the system font for Farsi) and is the encoding supported by the text processing utilities.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacFarsiTrueTypeVariant`
This Mac OS Farsi variant is used for most of the Farsi TrueType fonts: Ashfahan, Amir, Kamran, Mashad, NadeemFarsi.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacHebrew

Specify variants of MacHebrew.

```
enum {
    kMacHebrewStandardVariant = 0,
    kMacHebrewFigureSpaceVariant = 1
};
```

Constants

`kMacHebrewStandardVariant`
The standard Mac OS Hebrew variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacHebrewFigureSpaceVariant`
The Mac OS Hebrew variant in which 0xD4 represents figure space, not left single quotation mark as in the standard variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacIcelandic

Specify variants of MacIcelandic.

```
enum {
    kMacIcelandicStdDefaultVariant = 0,
    kMacIcelandicTTDefaultVariant = 1,
    kMacIcelandicStdCurrSignVariant = 2,
    kMacIcelandicTTCurrSignVariant = 3,
    kMacIcelandicStdEuroSignVariant = 4,
    kMacIcelandicTTEuroSignVariant = 5
};
```

Constants

`kMacIcelandicStdDefaultVariant`
This is a meta value that maps to `kMacIcelandicStdCurrSignVariant` or `kMacIcelandicStdEuroSignVariant`, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicTTDefaultVariant`
This is a meta value that maps to `kMacIcelandicTTCurrSignVariant` or `kMacIcelandicTTEuroSignVariant`, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicStdCurrSignVariant`
In Mac OS versions prior to 8.5, 0xDB is the currency sign; 0xBB/0xBC are fem./masc. ordinal indicators.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicTTCurrSignVariant`
In Mac OS versions prior to 8.5, 0xDB is the currency sign; 0xBB/0xBC are fi/fl ligatures

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicStdEuroSignVariant`
In Mac OS version 8.5 and later , 0xDB is the Euro sign ; 0xBB/0xBC are fem./masc. ordinal indicators.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicTTEuroSignVariant`
In Mac OS versions earlier than 8.5, 0xDB is the Euro sign; 0xBB/0xBC are fi/fl ligatures.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacJapanese

Specify variants of MacJapanese.

```
enum {
    kMacJapaneseStandardVariant = 0,
    kMacJapaneseStdNoVerticalsVariant = 1,
    kMacJapaneseBasicVariant = 2,
    kMacJapanesePostScriptScrnVariant = 3,
    kMacJapanesePostScriptPrintVariant = 4,
    kMacJapaneseVertAtKuPlusTenVariant = 5
};
```

Constants

`kMacJapaneseStandardVariant`
The standard Mac OS Japanese variant. Shift-JIS with JIS Roman modifications, extra 1-byte characters, 2-byte Apple extensions, and some vertical presentation forms in the range 0xEB40—0xEDFE ("ku plus 84").

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacJapaneseStdNoVerticalsVariant`
An artificial Mac OS Japanese variant for callers who don't want to use separately encoded vertical forms (for example, developers using QuickDraw GX).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacJapaneseBasicVariant`
An artificial Mac OS Japanese variant without Apple double-byte extensions.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacJapanesePostScriptScrnVariant`
The Mac OS Japanese variant for the screen bitmap version of the Sai Mincho and Chu Gothic fonts.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacJapanesePostScriptPrintVariant`
The Mac OS Japanese variant for PostScript printing versions of the Sai Mincho and Chu Gothic PostScript fonts. This version includes double-byte half-width characters in addition to single-byte half-width characters.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacJapaneseVertAtKuPlusTenVariant`
The Mac OS Japanese variant for the Hon Mincho and Maru Gothic fonts used in the Japanese localized version of System 7.1. It does not include the standard Apple extensions, and encodes vertical forms at a different location.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacRoman

Specify variants of MacRoman.

```
enum {
    kMacRomanStandardVariant = 0,
    kMacIcelandicStandardVariant = 0,
    kMacIcelandicTrueTypeVariant = 1,
    kJapaneseStandardVariant = 0,
    kJapaneseStdNoVerticalsVariant = 1,
    kJapaneseBasicVariant = 2,
    kJapanesePostScriptScrnVariant = 3,
    kJapanesePostScriptPrintVariant = 4,
    kJapaneseVertAtKuPlusTenVariant = 5,
    kHebrewStandardVariant = 0,
    kHebrewFigureSpaceVariant = 1,
    kUnicodeMaxDecomposedVariant = 2,
    kUnicodeNoComposedVariant = 3,
    kJapaneseNoOneByteKanaOption = 0x20,
    kJapaneseUseAsciiBackslashOption = 0x40
};
```

Constants

`kMacRomanStandardVariant`
The standard variant of Mac OS Roman for Mac OS 8.5 and later; 0xDB is the Euro sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicStandardVariant`
The standard Mac OS Icelandic encoding supported by the bitmap versions of Chicago, Geneva, Monaco, and New York in the Icelandic system. This is also the variant supported by the text processing utilities.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacIcelandicTrueTypeVariant`
The Mac OS Icelandic variant used for the bitmap versions of Courier, Helvetica, Palatino, and Times in the Icelandic system, and for the TrueType versions of Chicago, Geneva, Monaco, New York, Courier, Helvetica, Palatino, and Times.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapaneseStandardVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapaneseStdNoVerticalsVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapaneseBasicVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapanesePostScriptScrnVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapanesePostScriptPrintVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapaneseVertAtKuPlusTenVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kHebrewStandardVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kHebrewFigureSpaceVariant`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeMaxDecomposedVariant`
Replaced by `kUnicodeCanonicalDecompVariant`.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeNoComposedVariant`
Replaced by `kUnicodeCanonicalCompVariant`.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kJapaneseNoOneByteKanaOption`
Replaced by Unicode Converter option `kUnicodeNoHalfwidthCharsBit`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `TextCommon.h`.

`kJapaneseUseAsciiBackslashOption`
Replaced by Unicode Converter option `kUnicodeForceASCIIRangeBit`.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `TextCommon.h`.

Encoding Variants for MacRoman Related to Currency

Specify variants of MacRoman that are related to currency.

```
enum {
    kMacRomanDefaultVariant = 0,
    kMacRomanCurrencySignVariant = 1,
    kMacRomanEuroSignVariant = 2
};
```

Constants

`kMacRomanDefaultVariant`
This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanCurrencySignVariant`
In Mac OS versions earlier than 8.5 0xDB is the currency sign; still used for some older fonts even in Mac OS 8.5.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanEuroSignVariant`
In Mac OS version 8.5 and later, 0xDB is the Euro sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacRomanian

Specify variants of MacRomanian.

```
enum {
    kMacRomanianDefaultVariant = 0,
    kMacRomanianCurrencySignVariant = 1,
    kMacRomanianEuroSignVariant = 2
};
```

Constants

`kMacRomanianDefaultVariant`
This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanianCurrencySignVariant`
In Mac OS versions earlier than 8.5, 0xDB is the currency sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanianEuroSignVariant`
In Mac OS version 8.5 and later, 0xDB is the Euro sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacRomanLatin1

Specify variants of MacRomanLatin1.

```
enum {
    kMacRomanLatin1DefaultVariant = 0,
    kMacRomanLatin1StandardVariant = 2,
    kMacRomanLatin1TurkishVariant = 6,
    kMacRomanLatin1CroatianVariant = 8,
    kMacRomanLatin1IcelandicVariant = 11,
    kMacRomanLatin1RomanianVariant = 14
};
```

Constants

`kMacRomanLatin1DefaultVariant`
This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanLatin1StandardVariant`
Permuted MacRoman, Euro sign variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanLatin1TurkishVariant`
Permuted MacTurkish.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanLatin1CroatianVariant`
Permuted MacCroatian, Euro sign variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanLatin1IcelandicVariant`
Permuted MacIcelandic, standard Euro sign variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacRomanLatin1RomanianVariant`
Permuted MacRomanian, Euro sign variant.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for MacVT100

Specify variants of MacVT100.

```
enum {
    kMacVT100DefaultVariant = 0,
    kMacVT100CurrencySignVariant = 1,
    kMacVT100EuroSignVariant = 2
};
```

Constants

`kMacVT100DefaultVariant`

This is a meta value that maps to one of the following constants, depending on version of the Mac OS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacVT100CurrencySignVariant`

In Mac OS versions earlier than 8.5, 0xDB is the currency sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kMacVT100EuroSignVariant`

In Mac OS version 8.5 and later, 0xDB is the Euro sign.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Encoding Variants for Unicode

Specify variants of Unicode.

```
enum {
    kUnicodeNoSubset = 0,
    kUnicodeCanonicalDecompVariant = 2,
    kUnicodeCanonicalCompVariant = 3,
    kUnicodeHFSPlusDecompVariant = 8,
    kUnicodeHFSPlusCompVariant = 9
};
```

Constants

`kUnicodeNoSubset`

The standard Unicode encoded character set in which the full set of Unicode characters are supported.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeCanonicalDecompVariant`

A variant of Unicode using maximal decomposition with characters in canonical order. This variant does not include most characters which have a canonical decomposition, such as single characters for accented Latin letters or single characters for Korean Hangul syllables (however, this restriction is relaxed for symbol characters in the range U+2000 to U+2FFF). In TEC Manager 1.3, the Unicode Converter supports this variant for converting to and from Mac OS encodings.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeCanonicalCompVariant`
This is the normal canonical composition according to Unicode 3.2 rules.

Available in Mac OS X v10.2 and later.

Declared in `TextCommon.h`.

`kUnicodeHFSPlusDecompVariant`
Specifies canonical decomposition according to Unicode 3.2 rules, with HFS+ exclusions ("HFS+ decomposition 3.2"). That is, it doesn't decompose in 2000-2FFF, F900-FAFF, 2F800-2FAFF. You can use ths option when converting HFS file names.

Available in Mac OS X v10.2 and later.

Declared in `TextCommon.h`.

`kUnicodeHFSPlusCompVariant`
Specifies canonical composition according to Unicode 3.2 rules, but using the HFS+ decomposition exclusions. You can use ths option when converting HFS file names. You should use this form when you want to obtain a composed form that can be converted to and from the decomposed form specified by `kUnicodeHFSPlusDecompVariant`. This is the recommended way to request decompositions with HFS+ exclusions, instead of using `mappingVersion = kUnicodeUseHFSPlusMapping`.

Available in Mac OS X v10.2 and later.

Declared in `TextCommon.h`.

EUC Text Encodings

Specify Extendec Unix Code text encodings.

```
enum {
    kTextEncodingEUC_JP = 0x0920,
    kTextEncodingEUC_CN = 0x0930,
    kTextEncodingEUC_TW = 0x0931,
    kTextEncodingEUC_KR = 0x0940
};
```

Constants

`kTextEncodingEUC_JP`
ISO 646,1-byte katakana,JIS 208 ,JIS 212.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingEUC_CN`
ISO 646, GB 2312-80.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingEUC_TW`
ISO 646, CNS 11643-1992 Planes 1-16.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingEUC_KR`
ISO 646, KS C 5601-1987.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

HFS Text Encoding

Specifies a Mac OS HFS text encoding.

```
enum {
    kTextEncodingMacHFS = 0xFF
};
```

Constants

`kTextEncodingMacHFS`
This is a metavalue for a special Mac OS encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

ISO 2022 Text Encodings

Specify text encodings for ISO 2002.

```
enum {
    kTextEncodingISO_2022_JP = 0x0820,
    kTextEncodingISO_2022_JP_2 = 0x0821,
    kTextEncodingISO_2022_JP_1 = 0x0822,
    kTextEncodingISO_2022_JP_3 = 0x0823,
    kTextEncodingISO_2022_CN = 0x0830,
    kTextEncodingISO_2022_CN_EXT = 0x0831,
    kTextEncodingISO_2022_KR = 0x0840
};
```

Constants

`kTextEncodingISO_2022_JP`
See RFC 1468.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_JP_2`
See RFC 1554.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_JP_1`
See RFC 2237.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_JP_3`
JIS X0213

Available in Mac OS X v10.1 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_CN`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_CN_EXT`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISO_2022_KR`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

ISO 8-bit and 7-bit Text Encodings

Specify text encodings for ISO 8-bit and 7-bit.

```
enum {
    kTextEncodingISOLatin1 = 0x0201,
    kTextEncodingISOLatin2 = 0x0202,
    kTextEncodingISOLatin3 = 0x0203,
    kTextEncodingISOLatin4 = 0x0204,
    kTextEncodingISOLatinCyrillic = 0x0205,
    kTextEncodingISOLatinArabic = 0x0206,
    kTextEncodingISOLatinGreek = 0x0207,
    kTextEncodingISOLatinHebrew = 0x0208,
    kTextEncodingISOLatin5 = 0x0209,
    kTextEncodingISOLatin6 = 0x020A,
    kTextEncodingISOLatin7 = 0x020D,
    kTextEncodingISOLatin8 = 0x020E,
    kTextEncodingISOLatin9 = 0x020F
};
```

Constants

`kTextEncodingISOLatin1`
ISO 8859-1.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin2`
ISO 8859-2.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin3`
ISO 8859-3.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin4`
ISO 8859-4.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatinCyrillic`
ISO 8859-5.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatinArabic`
ISO 8859-6; equivalent to ASMO 708 and DOS CP 708.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatinGreek`
ISO 8859-7.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatinHebrew`
ISO 8859-8.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin5`
ISO 8859-9.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin6`
ISO 8859-10.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin7`
ISO 8859-13; Baltic Rim

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin8`
ISO 8859-14; Celtic

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingISOLatin9`
ISO 8859-15, 8859-1; changed for Euro & CP1252 letters

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Mac Unicode Text Encoding

Specifies a script code that should be handled as a special Mac OS script code.

```
enum {
    kTextEncodingMacUnicode = 0x7E
};
```

Constants

`kTextEncodingMacUnicode`

Beginning with Mac OS 8.5, the set of Mac OS script codes has been extended for some Mac OS components to include Unicode. Some of these components have only 7 bits available for script code, so `kTextEncodingUnicodeDefault` cannot be used to indicate Unicode. Instead, `kTextEncodingMacUnicode` is used as a meta-value to indicate that Unicode handles the script code a special Mac OS script code. The Text Encoding Converter handles this value similar to the way it handles the constant `kTextEncodingUnicodeDefault`.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Miscellaneous Text Encoding Standards

Specify miscellaneous text encodings.

```
enum {
    kTextEncodingShiftJIS = 0x0A01,
    kTextEncodingKOI8_R = 0x0A02,
    kTextEncodingBig5 = 0x0A03,
    kTextEncodingMacRomanLatin1 = 0x0A04,
    kTextEncodingHZ_GB_2312 = 0x0A05,
    kTextEncodingBig5_HKSCS_1999 = 0x0A06
};
```

Constants

`kTextEncodingShiftJIS`

Plain Shift-JIS.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingKOI8_R`

Russian Internet standard.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingBig5`

Big-5 encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingMacRomanLatin1`

Mac OS Roman permuted to align with 8859-1.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingHZ_GB_2312`
See RFC 1842; for Chinese mail and news.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingBig5_HKSCS_1999`
Available in Mac OS X v10.1 and later.

Declared in `TextCommon.h`.

MS-DOS and Windows Text Encodings

Specify text encodings for MS-DOS and Windows.

```
enum {
    kTextEncodingDOSLatinUS = 0x0400,
    kTextEncodingDOSGreek = 0x0405,
    kTextEncodingDOSBalticRim = 0x0406,
    kTextEncodingDOSLatin1 = 0x0410,
    kTextEncodingDOSGreek1 = 0x0411,
    kTextEncodingDOSLatin2 = 0x0412,
    kTextEncodingDOSCyrillic = 0x0413,
    kTextEncodingDOSTurkish = 0x0414,
    kTextEncodingDOSPortuguese = 0x0415,
    kTextEncodingDOSIcelandic = 0x0416,
    kTextEncodingDOSHebrew = 0x0417,
    kTextEncodingDOSCanadianFrench = 0x0418,
    kTextEncodingDOSArabic = 0x0419,
    kTextEncodingDOSNordic = 0x041A,
    kTextEncodingDOSRussian = 0x041B,
    kTextEncodingDOSGreek2 = 0x041C,
    kTextEncodingDOSThai = 0x041D,
    kTextEncodingDOSJapanese = 0x0420,
    kTextEncodingDOSChineseSimplif = 0x0421,
    kTextEncodingDOSKorean = 0x0422,
    kTextEncodingDOSChineseTrad = 0x0423,
    kTextEncodingWindowsLatin1 = 0x0500,
    kTextEncodingWindowsANSI = 0x0500,
    kTextEncodingWindowsLatin2 = 0x0501,
    kTextEncodingWindowsCyrillic = 0x0502,
    kTextEncodingWindowsGreek = 0x0503,
    kTextEncodingWindowsLatin5 = 0x0504,
    kTextEncodingWindowsHebrew = 0x0505,
    kTextEncodingWindowsArabic = 0x0506,
    kTextEncodingWindowsBalticRim = 0x0507,
    kTextEncodingWindowsVietnamese = 0x0508,
    kTextEncodingWindowsKoreanJohab = 0x0510
};
```

Constants

`kTextEncodingDOSLatinUS`
Code page 437.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingDOSGreek`
Code page 737, formerly 437G.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSBalticRim`
Code page 775.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSLatin1`
Code page 860. “multilingual.”
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSGreek1`
Code page 851.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSLatin2`
Code page 852, Slavic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSCyrillic`
Code page 855, IBM Cyrillic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSTurkish`
Code page 857, IBM Turkish.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSPortuguese`
Code page 860.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSIcelandic`
Code page 861.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSHebrew`
Code page 862.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSCanadianFrench`
Code page 863.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSArabic`
Code page 864.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSNordic`
Cde page 865.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSRussian`
Code page 866.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSGreek2`
Code page 869, IBM Modern Green.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSThai`
Code page 874, also for Windows.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSJapanese`
Code page 932, also for Windows
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSChineseSimplif`
Code page 936, also for Windows.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSKorean`
Code page 949, also for Windows; unified Hangul.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingDOSChineseTrad`
Code page 950, also for Windows.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsLatin1`
Code page 1252.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsANSI`
Code page 1252 (alternate name).
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsLatin2`
Code page 1250, Central Europe.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsCyrillic`
Code page 1251, Slavic Cyrillic.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsGreek`
Code page 1253.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsLatin5`
Code page 1254, Turkish.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsHebrew`
Code page 1255.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsArabic`
Code page 1256.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsBalticRim`
Code page 1257.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsVietnamese`
Code page 1258.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingWindowsKoreanJohab`
Code page 1361, for Window NT.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

National Standard Text Encodings

Specify text encodings for various national standards.

```
enum {
    kTextEncodingUS_ASCII = 0x0600,
    kTextEncodingJIS_X0201_76 = 0x0620,
    kTextEncodingJIS_X0208_83 = 0x0621,
    kTextEncodingJIS_X0208_90 = 0x0622,
    kTextEncodingJIS_X0212_90 = 0x0623,
    kTextEncodingJIS_C6226_78 = 0x0624,
    kTextEncodingShiftJIS_X0213_00 = 0x0628,
    kTextEncodingGB_2312_80 = 0x0630,
    kTextEncodingGBK_95 = 0x0631,
    kTextEncodingGB_18030_2000 = 0x0632,
    kTextEncodingKSC_5601_87 = 0x0640,
    kTextEncodingKSC_5601_92_Johab = 0x0641,
    kTextEncodingCNS_11643_92_P1 = 0x0651,
    kTextEncodingCNS_11643_92_P2 = 0x0652,
    kTextEncodingCNS_11643_92_P3 = 0x0653
};
```

Constants

`kTextEncodingUS_ASCII`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingJIS_X0201_76`
JIS Roman and 1-byte katakana (halfwidth).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingJIS_X0208_83`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingJIS_X0208_90`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingJIS_X0212_90`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingJIS_C6226_78`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingShiftJIS_X0213_00`
Shift-JIS format encoding of JIS X0213 planes 1 and 2

Available in Mac OS X v10.1 and later.

Declared in `TextCommon.h`.

`kTextEncodingGB_2312_80`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingGBK_95`
Annex to GB13000-93, for Windows 95; EUC-CN extended.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingGB_18030_2000`
Available in Mac OS X v10.1 and later.

Declared in `TextCommon.h`.

`kTextEncodingKSC_5601_87`
This is the same as KSC 5601-92 without Johab annex.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingKSC_5601_92_Johab`
KSC 5601-92 Johab annex.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingCNS_11643_92_P1`
CNS 11643-1992 plane 1.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingCNS_11643_92_P2`
CNS 11643-1992 plane 2.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingCNS_11643_92_P3`
CNS 11643-1992 plane 3 (11643-1986 plane 14).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

NextStep Platform Encodings

Specify text encodings for the NextStep platform.

```
enum {
    kTextEncodingNextStepLatin = 0x0B01,
    kTextEncodingNextStepJapanese = 0x0B02
};
```

Special Text Encoding Values

Specify special cases of text encodings.

```
enum {
    kTextEncodingMultiRun = 0x0FFF,
    kTextEncodingUnknown = 0xFFFF
};
```

Constants

`kTextEncodingMultiRun`

This is a special value for multiple encoded text, external run information.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingUnknown`

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Text Encoding Formats

Specify a text encoding format.

```
typedef UInt32 TextEncodingFormat;
enum {
    kTextEncodingDefaultFormat = 0,
    kUnicode16BitFormat = 0,
    kUnicodeUTF7Format = 1,
    kUnicodeUTF8Format = 2,
    kUnicode32BitFormat = 3
};
```

Constants

`kTextEncodingDefaultFormat`

The standard default format for any base encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicode16BitFormat`

The 16-bit character encoding format specified by the Unicode standard, equivalent to the UCS-2 format for ISO 10646. This includes support for the UTF-16 method of including non-BMP characters in a stream of 16-bit values.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeUTF7Format`
: The Unicode transformation format in which characters encodings are represented by a sequence of 7-bit values. This format cannot be handled by the Unicode Converter, only by the Text Encoding Converter.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeUTF8Format`
: The Unicode transformation format in which characters are represented by a sequence of 8-bit values.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicode32BitFormat`
: The UCS-4 32-bit format defined for ISO 10646. This format is not currently supported.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
A text encoding format specifies a way of formatting or algorithmically transforming a particular base encoding. For example, the UTF-7 format is the Unicode standard formatted for transmission through channels that can handle only 7-bit values. Other text encoding formats for Unicode include UTF-8 and 16-bit or 32-bit formats. These transformations are not viewed as different base encodings. Rather, they are different formats for representing the same base encoding.

Similar to text encoding variant values, text encoding format values are specific to a particular text encoding base value or to a small set of text encoding base values. A text encoding format is defined by the `TextEncodingFormat` data type.

The function `GetTextEncodingFormat` (page 1899) returns the text encoding format of a text encoding specification.

Text Encoding Name Selectors

Specify the part of an encoding name you want to obtain.

```
typedef UInt32 TextEncodingNameSelector;
enum {
    kTextEncodingFullName = 0,
    kTextEncodingBaseName = 1,
    kTextEncodingVariantName = 2,
    kTextEncodingFormatName = 3
};
```

Constants
`kTextEncodingFullName`
: Requests the full name of the text encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingBaseName`
: Requests the name of the base encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingVariantName`
Requests the name of the encoding variant, if available.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextEncodingFormatName`
Requests the name of the encoding format, if available.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
You use a selector for the `GetTextEncodingName` function to indicate which part of an encoding name you want to determine. The text encoding name selector is defined by the `TextEncodingNameSelector` data type.

Text Encoding Variants

Specify minor variants of a base encoding or group of base encodings.

```
enum {
    kTextEncodingDefaultVariant = 0
};
```

Constants
`kTextEncodingDefaultVariant`
The standard default variant for any base encoding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
This enumeration defines constants for the default variant of any base text encoding and for variants of the Mac OS Japanese, Mac OS Arabic, Mac OS Farsi, Mac OS Hebrew, and Unicode base encodings.

A text encoding variant specifies one among possibly several minor variants of a particular base encoding or group of base encodings. Text encoding variants are often used to support special cases such as the following:

- Differences among fonts that are all intended to support the same encoding. For example, different fonts associated with the MacJapanese and MacArabic encodings support slightly different encoding variants. These fonts would typically coexist on the same system without the user being aware of any differences.
- Artificial variants created by excluding some of the characters in an encoding. For example, the MacJapanese encoding includes separately-encoded vertical forms for some characters. In some contexts (such as with QuickDraw GX), it may be desirable to exclude these.
- Different mappings of a particular character or group of characters for different usages.

For a given text encoding base or small set of related text encoding base values, there may be an enumeration of `TextEncodingVariant` values, which always begins with 0, the default variant. In addition, for a possibly larger set of related text encoding base values, there may be bit masks that can be used independently to designate additional artificial variants. For example, there is an enumeration of six variants for the Mac OS

Japanese encoding. In addition, there are bit masks that can also be used as part of the variant for any Japanese encoding to exclude 1-byte kana or to control the mapping of the reverse solidus (backslash) character.

Languages that are dissimilar but use similar character sets are generally not designated as variants of the same base encoding (for example, MacIcelandic and MacTurkish both use a slight modification of the MacRoman character set, but they are considered separate base encodings).

When you create a new text encoding, you can specify an explicit variant of a base encoding or you can specify the default variant of that base. A text encoding variant is defined by the `TextEncodingVariant` data type. The function `GetTextEncodingVariant` (page 1901) returns the text encoding variant of a text encoding specification.

Unicode and ISO UCS Text Encodings

Specify Unicode and IOS UCS text encodings.

```
enum {
    kTextEncodingUnicodeDefault = 0x0100,
    kTextEncodingUnicodeV1_1 = 0x0101,
    kTextEncodingISO10646_1993 = 0x0101,
    kTextEncodingUnicodeV2_0 = 0x0103,
    kTextEncodingUnicodeV2_1 = 0x0103,
    kTextEncodingUnicodeV3_0 = 0x0104,
    kTextEncodingUnicodeV3_1 = 0x0105,
    kTextEncodingUnicodeV3_2 = 0x0106
};
```

Constants

`kTextEncodingUnicodeDefault`
This is a meta value that takes on one of the following values, depending on the system.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV1_1`
This is a Unicode encoding.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingISO10646_1993`
This ISO UCS encoding has code points identical to Unicode 1.1.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV2_0`
This is the new location for Korean Hangul.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV2_1`
For the Text Encoding Converter, Unicode 2.0 is equivalent to Unicode 2.1.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV3_0`
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV3_1`
Adds characters requiring surrogate pairs in UTF-16
Available in Mac OS X v10.1 and later.
Declared in `TextCommon.h`.

`kTextEncodingUnicodeV3_2`
Available in Mac OS X v10.1 and later.
Declared in `TextCommon.h`.

Unsupported Unicode Variants

Represent Unicode variants that are not yet supported or fully defined.

```
enum {
    kUnicodeNoCompatibilityVariant = 1,
    kUnicodeNoCorporateVariant = 4
};
```

Assorted Constants

Bidirectional Character Values

Specify bidirectional character properties.

```
enum {
    kUCBidiCatNotApplicable = 0,
    kUCBidiCatLeftRight = 1,
    kUCBidiCatRightLeft = 2,
    kUCBidiCatEuroNumber = 3,
    kUCBidiCatEuroNumberSeparator = 4,
    kUCBidiCatEuroNumberTerminator = 5,
    kUCBidiCatArabicNumber = 6,
    kUCBidiCatCommonNumberSeparator = 7,
    kUCBidiCatBlockSeparator = 8,
    kUCBidiCatSegmentSeparator = 9,
    kUCBidiCatWhitespace = 10,
    kUCBidiCatOtherNeutral = 11,
    kUCBidiCatRightLeftArabic = 12,
    kUCBidiCatLeftRightEmbedding = 13,
    kUCBidiCatRightLeftEmbedding = 14,
    kUCBidiCatLeftRightOverride = 15,
    kUCBidiCatRightLeftOverride = 16,
    kUCBidiCatPopDirectionalFormat = 17,
    kUCBidiCatNonSpacingMark = 18,
    kUCBidiCatBoundaryNeutral = 19
};
```

Constants

`kUCBidiCatNotApplicable`
Unassigned.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatLeftRight`
Strong types: L left-to-right.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatRightLeft`
Strong types: R right-to-left.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatEuroNumber`
Weak types: EN European number.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatEuroNumberSeparator`
Weak types: ES European number separator.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatEuroNumberTerminator`
Weak types: ET European number terminator.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatArabicNumber`
Weak types: AN Arabic number.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatCommonNumberSeparator`
Weak types: CS common number separator.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatBlockSeparator`
Separators: B paragraph separator (was block separator).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatSegmentSeparator`
Separators: S segment separator.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatWhitespace`
Neutrals: WS whitespace.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatOtherNeutral`
Neutrals: ON other neutrals (unassigned codes could use this).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatRightLeftArabic`
Unicode 3.0; AL right-to-left Arabic (was Arabic letter).

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatLeftRightEmbedding`
Unicode 3.0; LRE eft-to-right embedding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatRightLeftEmbedding`
Unicode 3.0; RLE right-to-left embedding.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatLeftRightOverride`
Unicode 3.0; LRO left-to-right override.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatRightLeftOverride`
Unicode 3.0; RLO right-to-left override.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatPopDirectionalFormat`
Unicode 3.0; PDF pop directional Format.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatNonSpacingMark`
Unicode 3.0; NSM non-spacing mark.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCBidiCatBoundaryNeutral`
Unicode 3.0; BN boundary neutral.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
These values are requested by `kUCCharPropTypeBidiCategory`.

Common and Special Unicode Values

Specify sommon and special Unicode code values.

```
enum {
    kUnicodeByteOrderMark = 0xFEFF,
    kUnicodeObjectReplacement = 0xFFFC,
    kUnicodeReplacementChar = 0xFFFD,
    kUnicodeSwappedByteOrderMark = 0xFFFE,
    kUnicodeNotAChar = 0xFFFF
};
```

Constants
`kUnicodeByteOrderMark`
Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeObjectReplacement`
A placeholder for a non-text object.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeReplacementChar`
Unicode replacement for an input character that cannot be converted.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeSwappedByteOrderMark`
Not a Unicode character; byte-swapped version of FEFF.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUnicodeNotAChar`
Not a Unicode character; may be used as a terminator.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

TEC Plugin Dispatch Table Versions

Specify a version for a TEC plug-in dispatch table.

```
enum {
    kTECPluginDispatchTableVersion1 = 0x00010000,
    kTECPluginDispatchTableVersion1_1 = 0x00010001,
    kTECPluginDispatchTableVersion1_2 = 0x00010002,
    kTECPluginDispatchTableCurrentVersion = kTECPluginDispatchTableVersion1_2
};
```

Constants

`kTECPluginDispatchTableVersion1`
Specifies versions 1.0 through 1.0.3.

Available in Mac OS X v10.0 and later.

Declared in `TextEncodingPlugin.h`.

`kTECPluginDispatchTableVersion1_1`
Specifies version 1.1.

Available in Mac OS X v10.0 and later.

Declared in `TextEncodingPlugin.h`.

`kTECPluginDispatchTableVersion1_2`
Specifies version 1.2.

Available in Mac OS X v10.0 and later.

Declared in `TextEncodingPlugin.h`.

`kTECPluginDispatchTableCurrentVersion`
A meta value that specifies the current version.

Available in Mac OS X v10.0 and later.

Declared in `TextEncodingPlugin.h`.

TEC Plug-in Signatures

Specify a TEC plug-in signature.

```
enum {
    kTECSignature = 'encv',
    kTECUnicodePluginSignature = 'puni',
    kTECJapanesePluginSignature = 'pjpn',
    kTECChinesePluginSignature = 'pzho',
    kTECKoreanPluginSignature = 'pkor'
};
```

Unicode Character Property Types

Specify property types for a Unicode charater.

```
typedef SInt32 UCCharPropertyType;
enum {
    kUCCharPropTypeGenlCategory = 1,
    kUCCharPropTypeCombiningClass = 2,
    kUCCharPropTypeBidiCategory = 3
};
```

Constants

`kUCCharPropTypeGenlCategory`
Requests enumeration value.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kUCCharPropTypeCombiningClass`
Requests numeric value 0 to 255.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

`kUCCharPropTypeBidiCategory`
Requests enumeration value.
Available in Mac OS X v10.0 and later.
Declared in `TextCommon.h`.

Unicode Character Property Values

Specify a propery value for a Unicode character.

```
typedef UInt32 UCCharPropertyValue;
enum {
    kUCGenlCatOtherNotAssigned = 0,
    kUCGenlCatOtherControl = 1,
    kUCGenlCatOtherFormat = 2,
    kUCGenlCatOtherSurrogate = 3,
    kUCGenlCatOtherPrivateUse = 4,
    kUCGenlCatMarkNonSpacing = 5,
    kUCGenlCatMarkSpacingCombining = 6,
    kUCGenlCatMarkEnclosing = 7,
    kUCGenlCatNumberDecimalDigit = 8,
    kUCGenlCatNumberLetter = 9,
    kUCGenlCatNumberOther = 10,
    kUCGenlCatSeparatorSpace = 11,
    kUCGenlCatSeparatorLine = 12,
    kUCGenlCatSeparatorParagraph = 13,
    kUCGenlCatLetterUppercase = 14,
    kUCGenlCatLetterLowercase = 15,
    kUCGenlCatLetterTitlecase = 16,
    kUCGenlCatLetterModifier = 17,
    kUCGenlCatLetterOther = 18,
    kUCGenlCatPunctConnector = 20,
    kUCGenlCatPunctDash = 21,
    kUCGenlCatPunctOpen = 22,
    kUCGenlCatPunctClose = 23,
    kUCGenlCatPunctInitialQuote = 24,
    kUCGenlCatPunctFinalQuote = 25,
    kUCGenlCatPunctOther = 26,
    kUCGenlCatSymbolMath = 28,
    kUCGenlCatSymbolCurrency = 29,
    kUCGenlCatSymbolModifier = 30,
    kUCGenlCatSymbolOther = 31
};
```

Constants

`kUCGenlCatOtherNotAssigned`
Cn other; not assigned.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatOtherControl`
Cc other; control.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatOtherFormat`
Cf other; format.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatOtherSurrogate`
Cs other; surrogate.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatOtherPrivateUse`
Co other; private use.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatMarkNonSpacing`
Mn mark; non-spacing.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatMarkSpacingCombining`
Mc mark; spacing combining.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatMarkEnclosing`
Me mark; enclosing.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatNumberDecimalDigit`
Nd number; decimal digit.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatNumberLetter`
Nl number; letter.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatNumberOther`
No number; other.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSeparatorSpace`
Zs separator; space.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSeparatorLine`
Zl separator; Line.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSeparatorParagraph`
Zp separator; paragraph.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatLetterUppercase`
Lu Letter; uppercase.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatLetterLowercase`
Ll Letter; lowercase.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatLetterTitlecase`
Lt Letter; titlecase.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatLetterModifier`
Lm Letter; modifier.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatLetterOther`
Lo Letter; other.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctConnector`
Pc punctuation; connector.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctDash`
Pd punctuation; dash.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctOpen`
Ps punctuation; open.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctClose`
Pe punctuation; close.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctInitialQuote`
Pi punctuation; initial quote.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctFinalQuote`
Pf punctuation; final quote.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatPunctOther`
Po punctuation; other.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSymbolMath`
Sm symbol; math.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSymbolCurrency`
Sc symbol; currency.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSymbolModifier`
Sk symbol; modifier.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kUCGenlCatSymbolOther`
So symbol; other.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Unicode Mapping Versions

Specify a Unicode mapping version.

```
typedef SInt32 UnicodeMapVersion;
enum {
    kUnicodeUseLatestMapping = -1,
    kUnicodeUseHFSPlusMapping = 4
};
```

Constants

`kUnicodeUseLatestMapping`
Instead of explicitly specifying the mapping version of the Unicode mapping table to be used for conversion of a text string, you can use this constant to specify that the latest version be used.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

`kUnicodeUseHFSPlusMapping`
Indicates the mapping version used by HFS Plus to convert filenames between Mac OS encodings and Unicode. Only one constant is defined so far for a specific mapping version.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeConverter.h`.

Discussion
When performing conversions, you specify the version of the Unicode mapping table to be used for the conversion. You provide the version number in the mapping version field of the structure `UnicodeMapping` (page 1967) that is passed to a function. A Unicode mapping version is defined by the `UnicodeMapVersion` data type.

Unwanted Data Constants

Specify data you don't care about receiving.

```
enum {
    kTextScriptDontCare = -128,
    kTextLanguageDontCare = -128,
    kTextRegionDontCare = -128
};
```

Constants
`kTextScriptDontCare`
Indicates that the code is not provided for the derivation.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextLanguageDontCare`
Indicates that language code is not provided for the derivation.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

`kTextRegionDontCare`
The region code is not provided for the derivation.

Available in Mac OS X v10.0 and later.

Declared in `TextCommon.h`.

Discussion
For backward compatibility with earlier releases of the Mac OS, the Text Encoding Conversion Manager provides the functions `UpgradeScriptInfoToTextEncoding` (page 1937) and `RevertTextEncodingToScriptInfo` (page 1907) that you can use to derive Script Manager values from a text encoding or vice versa.

When using these functions, you can specify a Script Manager language code, script code, and/or font values to derive a text encoding. These three constants are defined to allow you to identify any part of the derivation you don't care about. When reverting from a text encoding to Script Manager values, the Unicode Converter returns these constants for a corresponding value it does not derive: `kTextLanguageDontCare`, `kTextScriptDontCare`, and `kTextRegionDontCare`.

Result Codes

The most common result codes returned by Text Encoding Conversion Manager are listed below.

Result Code	Value	Description
kTextUnsupportedEncodingErr	-8738	The encoding or mapping is not supported for this function by the current set of tables or plug-ins. Available in Mac OS X v10.0 and later.
kTextMalformedInputErr	-8739	The text input contains a sequence that is not legal in the specified encoding, such as a DBCS high byte followed by an invalid low byte (0x8120 in Shift-JIS). Available in Mac OS X v10.0 and later.
kTextUndefinedElementErr	-8740	The text input contains a code point that is undefined in the specified encoding. The function did not completely convert the input string. You can resume conversion from a point beyond the offending character, or take some other action. Available in Mac OS X v10.0 and later.
kTECMissingTableErr	-8745	The specified encoding is partially supported, but a specific table required for this function is missing. Available in Mac OS X v10.0 and later.
kTECTableChecksumErr	-8746	A specific table required for this function has a checksum error, indicating that it has become corrupted. Available in Mac OS X v10.0 and later.
kTECTableFormatErr	-8747	The table format is either invalid or it cannot be handled by the current version of the code. The function did not convert the string Available in Mac OS X v10.0 and later.
kTECCorruptConverterErr	-8748	The converter object is invalid. Returned by the Text Encoding Converter functions only. Available in Mac OS X v10.0 and later.
kTECNoConversionPathErr	-8749	The converter supports both the source and target encodings, but cannot convert between them either directly or indirectly. Returned by the Text Encoding Converter functions only. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kTECBufferBelowMinimumSizeErr	-8750	The output text buffer is too small to accommodate the result of processing of the first input text element. No part of the input string was processed. Available in Mac OS X v10.0 and later.
kTECArrayFullErr	-8751	The supplied TextEncodingRun, ScriptCodeRun, or UnicodeMapping array is too small, and the input was not completely converted. Call the function again with another output buffer—or with the same output buffer after copying its contents—to convert the remainder of the string Available in Mac OS X v10.0 and later.
kTECPartialCharErr	-8753	The input text ends in the middle of a multibyte character and conversion stopped. Append the unconverted input from this call to the beginning of the subsequent input text and call the function again. Available in Mac OS X v10.0 and later.
kTECUnmappableElementErr	-8754	An input text element cannot be mapped to the specified output encoding(s) using the specified options. For the Unicode Converter, this error can occur only if kUnicodeUseFallbacksBit control flag is not set. Available in Mac OS X v10.0 and later.
kTECIncompleteElementErr	-8755	The input text ends with a text element that might be incomplete, or contains a text element that is too long for the internal buffers. Available in Mac OS X v10.0 and later.
kTECDirectionErr	-8756	An error, such as a direction stack overflow, occurred in directionality processing. Available in Mac OS X v10.0 and later.
kTECGlobalsUnavailableErr	-8770	Global variables have already been deallocated, premature termination. The function did not convert the string. Available in Mac OS X v10.0 and later.
kTECItemUnavailableErr	-8771	An item (for example, a name) is not available for the specified region (and encoding, if relevant). Available in Mac OS X v10.0 and later.
kTECUsedFallbacksStatus	-8783	The function has completely converted the input string to the specified target using one or more fallbacks. For the Unicode Converter, this status code can only occur if the kUnicodeUseFallbacksBit control flag is set. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kTECNeedFlushStatus	-8784	The application disposed of a converter object by calling TECDisposeConverter, but there is still text contained in internal buffers. Returned by the Text Encoding Converter functions only. Available in Mac OS X v10.0 and later.
kTECOutputBufferFullStatus	-8785	The converter successfully converted part of the input text, but the output buffer was not large enough to accommodate the entire input text after conversion. Convert the remaining text beginning from the position where the conversion stopped. Available in Mac OS X v10.0 and later.

Text Utilities Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	TextUtils.h StringCompare.h NumberFormatting.h TypeSelect.h

Overview

The Text Utilities provide you with an integrated collection of routines for performing a variety of operations on textual information, ranging from modifying the contents of a string, to sorting strings from different languages, to converting times, dates, and numbers from internal representations to formatted strings and back. These routines work in conjunction with QuickDraw text drawing routines to help you display and modify text in applications that are distributed to an international audience.

The Text Utilities functions are used for numerous text-handling tasks, including

- defining strings–including functions for allocating strings in the heap and for loading strings from resources
- comparing and sorting strings–including functions for testing whether two strings are equal and functions for finding the sorting relationship between two strings
- modifying the contents of strings–including routines for converting the case of characters, stripping diacritical marks, replacing substrings, and truncating strings
- finding breaks and boundaries in text–including routines for finding word and line breaks, and for finding different script runs in a line of text
- converting and formatting date and time strings–including routines that convert numeric and string representations of dates and times into record format, and routines that convert numeric and record representations of dates and times into strings
- converting and formatting numeric strings–including routines that convert string representations of numbers into numeric representations

Carbon supports the majority of Text Utilities. However, Apple recommends that you use the comparison and word breaking utilities supplied by Unicode Utilities instead.

A number of obsolete Text Utilities functions-such as those prefixed with iu or IU-are not supported.

Functions by Task

Comparing Strings for Equality

`EqualString` (page 2038) Deprecated in Mac OS X v10.4
: Compares two Pascal strings for equality, using the comparison rules of the Macintosh file system. (Deprecated. Use `CFStringCompare` instead.)

`IdenticalString` (page 2046) Deprecated in Mac OS X v10.4
: Compares two Pascal strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` instead.)

`IdenticalText` (page 2046) Deprecated in Mac OS X v10.4
: Compares two text strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` instead.)

Converting Between Integers and Strings

`NumToString` (page 2052) Deprecated in Mac OS X v10.4
: Converts a long integer value into a Pascal string. (Deprecated. Use `CFStringCreateWithFormat` instead.)

`StringToNum` (page 2062) Deprecated in Mac OS X v10.4
: Converts the Pascal string representation of a base-10 number into a long integer value. (Deprecated. Use `CFStringGetIntValue` instead.)

Converting Between Strings and Floating-Point Numbers

`ExtendedToString` (page 2039) Deprecated in Mac OS X v10.4
: Converts an internal floating-point representation of a number into a string that can be presented to the user, using a `NumFormatStringRec` structure to specify how the output number string is formatted (Deprecated. Use `CFNumberFormatterCreateNumberFromString` instead.)

`StringToExtended` (page 2059) Deprecated in Mac OS X v10.4
: Converts a string representation of a number into a floating-point number, using a `NumFormatStringRec` structure to specify how the input number string is formatted. (Deprecated. Use `CFNumberFormatterCreateStringWithNumber` instead.)

Converting Between C and Pascal Strings

`c2pstr` (page 2034) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4
: Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`C2PStr` (page 2034) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4
: Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`c2pstrcpy` (page 2034) Deprecated in Mac OS X v10.4
Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`CopyCStringToPascal` (page 2037) Deprecated in Mac OS X v10.4
Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`CopyPascalStringToC` (page 2037) Deprecated in Mac OS X v10.4
Converts a Pascal String to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`p2cstr` (page 2053) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`P2CStr` (page 2053) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4 Deprecated in Mac OS X version 10.4
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`p2cstrcpy` (page 2054) Deprecated in Mac OS X v10.4
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

Defining and Specifying Strings

`GetIndString` (page 2044) Deprecated in Mac OS X v10.4
Loads a string from a string list (`'STR#'`) resource into memory, given the resource ID of the string list and the index of the individual string. (Deprecated. Use `CFBundleCopyLocalizedString` instead.)

`GetString` (page 2045) Deprecated in Mac OS X v10.4
Loads a string from a string (`'STR'`) resource into memory. (Deprecated. Use `CFBundleCopyLocalizedString` instead.)

`NewString` (page 2051) Deprecated in Mac OS X v10.4
Allocates memory in the heap for a string, copies its contents, and produces a handle for the heap version of the string. (Deprecated. Use `CFStringCreateCopy` instead.)

`SetString` (page 2057) Deprecated in Mac OS X v10.4
Changes the contents of a string referenced by a string handle, replacing the previous contents by copying the specified string. (Deprecated. Use `CFStringCreateWithPascalString` and `CFStringReplaceAll`.)

Determining Sorting Order for Strings in Different Languages

`LanguageOrder` (page 2048) Deprecated in Mac OS X v10.4
Determines the order in which strings in two different languages should be sorted. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`ScriptOrder` (page 2057) Deprecated in Mac OS X v10.4
Determines the order in which strings in two different scripts should be sorted. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`StringOrder` (page 2058) Deprecated in Mac OS X v10.4
Compares two Pascal strings, taking into account the script system and language for each of the strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`TextOrder` (page 2064) Deprecated in Mac OS X v10.4
Compares two text strings, taking into account the script and language for each of the strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

Determining Sorting Order for Strings in the Same Language

`CompareString` (page 2035) Deprecated in Mac OS X v10.4
Compares two Pascal strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`CompareText` (page 2036) Deprecated in Mac OS X v10.4
Compares two text strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`RelString` (page 2054) Deprecated in Mac OS X v10.4
Compares two Pascal strings using the string comparison rules of the Macintosh file system and returns a value that indicates the sorting order of the first string relative to the second string. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

`relstring` (page 2055) Deprecated in Mac OS X v10.4
Compares two strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

Modifying Characters and Diacritical Marks

`LowercaseText` (page 2049) Deprecated in Mac OS X v10.4
Converts any uppercase characters in a text string into their lowercase equivalents. (Deprecated. Use `CFStringLowercase` instead.)

`StripDiacritics` (page 2063) Deprecated in Mac OS X v10.4
Strips any diacritical marks from a text string. (Deprecated. Use `CFStringTransform` instead.)

`UppercaseStripDiacritics` (page 2068) Deprecated in Mac OS X v10.4
Converts any lowercase characters in a text string into their uppercase equivalents and strips any diacritical marks from the text. (Deprecated. Use `CFStringTransform` instead.)

`UppercaseText` (page 2069) Deprecated in Mac OS X v10.4
Converts any lowercase characters in a text string into their uppercase equivalents. (Deprecated. Use `CFStringUppercase` instead.)

`UpperString` (page 2070) Deprecated in Mac OS X v10.4
Converts any lowercase letters in a Pascal string to their uppercase equivalents, using the Macintosh file system rules. (Deprecated. Use `CFStringUppercase` instead.)

`upperstring` (page 2071) Deprecated in Mac OS X v10.4
Converts any lowercase letters in a Pascal string to their uppercase equivalents. (Deprecated. Use `CFStringUppercase` instead.)

Searching for and Replacing Strings

`Munger` (page 2049)
Searches text for a specified string pattern and replaces it with another string.

`ReplaceText` (page 2056) Deprecated in Mac OS X v10.4
Searches text on a character-by-character basis, replacing all instances of a string in that text with another string. (Deprecated. Use `CFStringReplace` instead.)

Using Number Format Specification Strings for International Number Formatting

`FormatRecToString` (page 2043) Deprecated in Mac OS X v10.4
Converts an internal representation of number formatting information into a number format specification string, which can be displayed and modified. (Deprecated. Use `CFNumberFormatterGetFormat` instead.)

`StringToFormatRec` (page 2060) Deprecated in Mac OS X v10.4
Creates a number format specification string structure from a number format specification string that you supply in a Pascal string. (Deprecated. Use `CFNumberFormatterSetFormat` instead.)

Working With Word, Script, and Line Boundaries

`FindScriptRun` (page 2040) Deprecated in Mac OS X v10.4
Finds the next block of subscript text within a script run. (Deprecated. There is no replacement function because this capability is no longer needed in Mac OS X.)

`FindWordBreaks` (page 2041) Deprecated in Mac OS X v10.4
Determines the beginning and ending boundaries of a word in a text string. (Deprecated. Use `UCFindTextBreak` (page 2159) instead.)

Working With Universal Procedure Pointers

`DisposeIndexToStringUPP` (page 2038) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer to an index-to-string callback.

`InvokeIndexToStringUPP` (page 2047) Deprecated in Mac OS X v10.4
Call an index-to-string callback.

`NewIndexToStringUPP` (page 2051) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to an index-to-string callback.

Working With Type Select Records

`TypeSelectClear` (page 2065) Deprecated in Mac OS X v10.4
Clears the key list and resets the type select record. (Deprecated. Use `UCTypeSelectFlushSelectorData` instead.)

`TypeSelectCompare` (page 2066) Deprecated in Mac OS X v10.4
Compares a text buffer to the keystroke buffer. (Deprecated. Use `UCTypeSelectCompare` instead.)

`TypeSelectFindItem` (page 2066) Deprecated in Mac OS X v10.4
: Finds the closest match between a specified list of characters and the keystrokes stored in the type select record. (Deprecated. Use `UCTypeSelectFindItem` instead.)

`TypeSelectNewKey` (page 2067) Deprecated in Mac OS X v10.4
: Creates a new type select record. (Deprecated. Use `UCTypeSelectCreateSelector` instead.)

Functions

c2pstr

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
StringPtr c2pstr (
   char *aStr
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

C2PStr

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
StringPtr C2PStr (
    Ptr cString
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

c2pstrcpy

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void c2pstrcpy (
   Str255 dst,
   const char *src
);
```

Parameters

dst

On output, the Pascal string.

src

The C string you want to convert.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code

SoftVDigX

Declared In

`TextUtils.h`

CompareString

Compares two Pascal strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short CompareString (
    ConstStr255Param aStr,
    ConstStr255Param bStr,
    Handle itl2Handle
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

itl2Handle

The handle to the string-manipulation resource that contains string comparison information. If the value of this parameter is `NULL`, `CompareString` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value

Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates the sorting order of the first string relative to the second string.

Special Considerations

`CompareString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

CompareText

Compares two text strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short CompareText (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   Handle itl2Handle
);
```

Parameters

aPtr
A pointer to the first character of the first text string.

bPtr
A pointer to the first character of the second text string.

aLen
The length, in bytes, of the first text string.

bLen
The length, in bytes, of the second text string.

itl2Handle
A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information. If the value of this parameter is `NULL`, `CompareText` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value
Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates the sorting order of the first string relative to the second string.

Special Considerations

`CompareText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

CopyCStringToPascal

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void CopyCStringToPascal (
   const char *src,
   Str255 dst
);
```

Parameters

src

The C string you want to convert.

dst

On output, the Pascal string.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

Declared In

`TextUtils.h`

CopyPascalStringToC

Converts a Pascal String to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void CopyPascalStringToC (
   ConstStr255Param src,
   char *dst
);
```

Parameters

src

The Pascal string you want to convert.

dst

On output, the C string.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

DisposeIndexToStringUPP

Disposes of a universal procedure pointer to an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
void DisposeIndexToStringUPP (
   IndexToStringUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `IndexToStringProcPtr` (page 2071) for more information.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

EqualString

Compares two Pascal strings for equality, using the comparison rules of the Macintosh file system. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
Boolean EqualString (
   ConstStr255Param str1,
   ConstStr255Param str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters

str1

One of the Pascal strings to be compared.

str2

The other Pascal string to be compared.

caseSensitive

A flag that indicates how to handle case-sensitive information during the comparison. If the value of `caseSens` is `TRUE`, uppercase characters are distinguished from the corresponding lowercase characters. If it is `FALSE`, case information is ignored.

diacSensitive

A flag that indicates how to handle information about diacritical marks during the string comparison. If the value of `diacSens` is `TRUE`, characters with diacritical marks are distinguished from the corresponding characters without diacritical marks during the comparison. If it is `FALSE`, diacritical marks are ignored.

Return Value

`TRUE` if the two strings are equal and `FALSE` if they are not equal. If its value is `TRUE`, `EqualString` distinguishes uppercase characters from the corresponding lowercase characters. If its value is `FALSE`, `EqualString` ignores diacritical marks during the comparison.

Discussion

The comparison is a simple, character-by-character value comparison. This function does not make use of any script or language information (i.e., is not localizable); it assumes the use of a Roman script system.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

ExtendedToString

Converts an internal floating-point representation of a number into a string that can be presented to the user, using a `NumFormatStringRec` structure to specify how the output number string is formatted (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterCreateNumberFromString` instead.)

```
FormatStatus ExtendedToString (
   const extended80 *x,
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   Str255 outString
);
```

Parameters

x

A pointer to a floating-point value in 80-bit SANE representation.

myCanonical

A pointer to the internal representation of the formatting information for numbers, as produced by the `StringToFormatRec` function.

partsTable

A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString

On output, contains the number formatted according to the information in `myFormatRec`.

Return Value

A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `ExtendedToString` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion

`ExtendedToString` creates a string representation of a floating-point number, using the formatting information in the `myFormatRec` parameter (which was created by a previous call to `StringToFormatRec`) to determine how the number should be formatted for output. It uses the number parts table to determine the component parts of the number string.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

FindScriptRun

Finds the next block of subscript text within a script run. (Deprecated in Mac OS X v10.4. There is no replacement function because this capability is no longer needed in Mac OS X.)

```
ScriptRunStatus FindScriptRun (
   Ptr textPtr,
   long textLen,
   long *lenUsed
);
```

Parameters

textPtr

A pointer to the text string to be analyzed.

textLen

The number of bytes in the text string.

lenUsed

On output, a pointer to the length, in bytes, of the script run that begins with the first character in the string; this length is always greater than or equal to 1, unless the string passed in is of length 0.

Return Value

Identifies the run as either native text, Roman, or one of the defined subscripts of the script system and returns a structure of type `ScriptRunStatus` (page 2078). See the description of the `ScriptRunStatus` data type.

Discussion

The `FindScriptRun` function is used to identify blocks of subscript text in a string, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. Some script systems include subscripts, which are character sets that are subsidiary to the main character set. One useful subscript is the set of all character codes that have the same meaning in Roman as they do in a non-Roman script. For other scripts such as Japanese, there are additional useful subscripts. For example, a Japanese script system might include some Hiragana characters that are useful for input methods.

`FindScriptRun` computes the length of the current run of subscript text in the text string specified by `textPtr` and `textLen`. It assigns the length, in bytes, to the `lenUsed` parameter and returns a status code. You can advance the text pointer by the value of `lenUsed` to make subsequent calls to this function. You can use this function to identify runs of subscript characters so that you can treat them separately.

Word processors and other applications can call `FindScriptRun` to separate style runs of native text from non-native text. You can use this capability to extract those characters and apply a different font to them.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

FindWordBreaks

Determines the beginning and ending boundaries of a word in a text string. (Deprecated in Mac OS X v10.4. Use `UCFindTextBreak` (page 2159) instead.)

```
void FindWordBreaks (
   Ptr textPtr,
   short textLength,
   short offset,
   Boolean leadingEdge,
   BreakTablePtr breaks,
   OffsetTable offsets,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be examined.

textLength

The number of bytes in the text string.

offset

A byte offset into the text. This parameter plus the `leadingEdge` parameter determine the position of the character at which to start the search.

leadingEdge

A flag that specifies which character should be used to start the search. If `leadingEdge` is `TRUE`, the search starts with the character specified in the `offset` parameter; if it is `FALSE`, the search starts with the character preceding the offset.

breaks

A pointer to a word-break table of type `NBreakTable` or `BreakTable`. If the value of this pointer is 0, the default word-break table of the script system specified by the `script` parameter is used. If the value of this pointer is –1, the default line-break table of the specified script system is used.

offsets

On output, the values in this table indicate the boundaries of the word that has been found.

script

The script code for the script system whose tables are used to determine where word boundaries occur.

Discussion

`FindWordBreaks` searches for a word in a text string, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. The `textPtr` and `textLength` parameters specify the text string that you want searched. The `offset` parameter and `leadingEdge` parameter together indicate where the search begins.

`FindWordBreaks` searches backward through the text string for one of the word boundaries and forward through the text string for its other boundary. It uses the definitions in the table specified by `nbreaks` to determine what constitutes the boundaries of a word. Each script system's word-break table is part of its string-manipulation (`'itl2'`) resource.

`FindWordBreaks` returns its results in an `OffsetTable` structure. `FindWordBreaks` uses only the first element of this three-element table. Each element is a pair of integers: `offFirst` and `offSecond`.

`FindWordBreaks` places the offset from the beginning of the text string to just before the leading edge of the character of the word that it finds in the `offFirst` field.

`FindWordBreaks` places the offset from the beginning of the text string to just after the trailing edge of the last character of the word that it finds in the `offSecond` field. For example, if the text "This is it" is passed with `offset` set to 0 and `leadingEdge` set to `TRUE`, then `FindWordBreaks` returns the offset pair (0,4).

If `leadingEdge` is `TRUE` and the value of `offset` is 0, then `FindWordBreaks` returns the offset pair (0,0). If `leadingEdge` is `FALSE` and the value of `offset` equals the value of `textLength`, then `FindWordBreaks` returns the offset pair with values (`textLength`, `textLength`).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

FormatRecToString

Converts an internal representation of number formatting information into a number format specification string, which can be displayed and modified. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterGetFormat` instead.)

```
FormatStatus FormatRecToString (
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   Str255 outString,
   TripleInt positions
);
```

Parameters

myCanonical
A pointer to the internal representation of number formatting information, as created by a previous call to the `StringToFormatRec` function.

partsTable
A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString
On output, contains the number format specification string.

positions
An array that specifies the starting position and length of each of the three possible format strings (positive, negative, or zero) in the number format specification string. Semicolons are used as separators in the string.

Return Value
A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `FormatRecToString` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion
`FormatRecToString` is the inverse operation of `StringToFormatRec` (page 2060). The internal representation of the formatting information in `myFormatRec` must have been created by a prior call to the `StringToFormatRec` function. The information in the number parts table specifies how to build the string representation.

The output number format specification string in `outString` specifies how numbers appear. This string contains three parts, which are separated by semicolons. The first part is the positive number format, the second is the negative number format, and the third part is the zero number format.

The `positions` parameter is an array of three integers (a `TripleInt` value), which specifies the starting position in `outString` of each of three formatting specifications:

- `positions[fPositive]`. The index in `outString` of the first byte of the formatting specification for positive number values.
- `positions[fNegative]`. The index in `outString` of the first byte of the formatting specification for negative number values.
- `positions[fZero]`. The index in `outString` of the first byte of the formatting specification for zero number values.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NumberFormatting.h`

GetIndString

Loads a string from a string list (`'STR#'`) resource into memory, given the resource ID of the string list and the index of the individual string. (Deprecated in Mac OS X v10.4. Use `CFBundleCopyLocalizedString` instead.)

```
void GetIndString (
   Str255 theString,
   short strListID,
   short index
);
```

Parameters

`theString`
On output, the Pascal string result; specifically, a copy of the string from a string list that has the resource ID provided in the `strListID` parameter. If the resource that you specify cannot be read or the index that you specify is out of range for the string list, `GetIndString` sets `theString` to an empty string.

`strListID`
The resource ID of the `'STR#'` resource that contains the string list.

`index`
The index of the string in the list. This is a value from 1 to the number of strings in the list that is referenced by the `strListID` parameter.

Discussion
If necessary, `GetIndString` reads the string list from the resource file by calling the Resource Manager function `GetResource`. `GetIndString` accesses the string specified by the `index` parameter and copies it into `theString`.

Special Considerations

`GetIndString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

GetString

Loads a string from a string (`'STR'`) resource into memory. (Deprecated in Mac OS X v10.4. Use `CFBundleCopyLocalizedString` instead.)

```
StringHandle GetString (
   short stringID
);
```

Parameters

`stringID`
The resource ID of the string (`'STR '`) resource containing the string.

Return Value
A handle to a string with the specified resource ID. If necessary, `GetString` reads the handle form the resource file. If `GetString` cannot read the resource, it returns `NULL`.

Discussion
`GetString` calls the `GetResource` function of the Resource Manager to access the string. This means that if the specified resource is already in memory, `GetString` simply returns its handle.

Like the `NewString` (page 2051) function, `GetString` returns a handle whose size is based upon the actual length of the string.

If your application uses a large number of strings, it is more efficient to store them in a string list (`'STR#'`) resource than as individual resources in the resource file. You then use the `GetIndString` (page 2044) function to access each string in the list.

Special Considerations

`GetString` does not create a copy of the string.

`GetString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

IdenticalString

Compares two Pascal strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
short IdenticalString (
   ConstStr255Param aStr,
   ConstStr255Param bStr,
   Handle itl2Handle
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

itl2Handle

A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information.

The `itl2Handle` parameter is used to specify a string-manipulation resource. If the value of this parameter is `NULL`, `IdenticalString` makes use of the resource for the current script. The string-manipulation resource includes tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value
Returns 0 if the two strings are equal; 1 if they are not equal. It compares the two strings without regard for secondary sorting order, the meaning of which depends on the language of the strings. For example, for the English language, using only primary differences means that `IdenticalString` ignores diacritical marks and does not distinguish between lowercase and uppercase. For example, if the two strings are `'Rose'` and `'rosé'`, `IdenticalString` considers them equal and returns 0.

Discussion
`IdenticalString` uses only primary differences in its comparison.

Special Considerations

`IdenticalString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`StringCompare.h`

IdenticalText

Compares two text strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
short IdenticalText (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   Handle itl2Handle
);
```

Parameters

aPtr

A pointer to the first character of the first text string.

bPtr

A pointer to the first character of the second text string.

aLen

The length, in bytes, of the first text string.

bLen

The length, in bytes, of the second text string.

itl2Handle

A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information.

The `itl2Handle` parameter is used to specify a string-manipulation resource. If the value of this parameter is `NULL`, `IdenticalText` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value

0 if the two text strings are equal; 1 if they are not equal. It compares the strings without regard for secondary sorting order, which means that it ignores diacritical marks and does not distinguish between lowercase and uppercase. For example, if the two text strings are `'Rose'` and `'rosé'`, `IdenticalText` considers them equal and returns 0.

Discussion

`IdenticalText` uses only primary sorting order in its comparison.

Special Considerations

`IdenticalText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

InvokeIndexToStringUPP

Call an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
Boolean InvokeIndexToStringUPP (
   short item,
   ScriptCode *itemsScript,
   StringPtr *itemsStringPtr,
   void *yourDataPtr,
   IndexToStringUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeIndexToStringUPP`, as the system calls your index-to-string callback function for you. See the callback `IndexToStringProcPtr` (page 2071) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

LanguageOrder

Determines the order in which strings in two different languages should be sorted. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short LanguageOrder (
   LangCode language1,
   LangCode language2
);
```

Parameters

language1
The language code of the first language.

language2
The language code of the second language.

Return Value
A value that indicates the sorting order: –1 if strings in the first language should be sorted before sorting text in the second language, 1 if strings in the first language should be sorted after sorting strings in the second language, or 0 if the sorting order does not matter (that is, if the languages are the same).

Discussion
`LanguageOrder` takes a pair of language codes and determines in which order strings from the first language should be sorted relative to strings from the second language.

"Implicit Language Codes" (page 2082) are listed in the Constants section. The implicit language codes `scriptCurLang` and `scriptDefLang` are not valid for `LanguageOrder` because the script system being used is not specified as a parameter to this function.

Special Considerations

`LanguageOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

LowercaseText

Converts any uppercase characters in a text string into their lowercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringLowercase` instead.)

```
void LowercaseText (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

`textPtr`

A pointer to the text string to be converted.

`len`

The number of bytes in the text string. The text string can be up to 32 KB in length.

`script`

The script code for the script system whose resources are used to determine the results of converting characters.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion
`LowercaseText` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts any uppercase characters in the text into lowercase.

If `LowercaseText` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`LowercaseText` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

Munger

Searches text for a specified string pattern and replaces it with another string.

```
long Munger (
   Handle h,
   long offset,
   const void *ptr1,
   long len1,
   const void *ptr2,
   long len2
);
```

Parameters

h

A handle to the text string that is being manipulated.

offset

The byte offset in the destination string at which `Munger` begins its operation.

ptr1

A pointer to the first character in the string for which `Munger` is searching.

len1

The number of bytes in the string for which `Munger` is searching.

ptr2

A pointer to the first character in the substitution string.

len2

The number of bytes in the substitution string.

Return Value

A negative value if `Munger` cannot find the designated string.

Discussion

`Munger` manipulates bytes in a string to which you specify a handle in the `h` parameter. The manipulation begins at a byte offset, specified in `offset`, in the string. `Munger` searches for the string specified by `ptr1` and `len1`; when it finds an instance of that string, it replaces it with the substitution string, which is specified by `ptr2` and `len2`.

`Munger` operates on a byte-by-byte basis, which can produce inappropriate results for 2-byte script systems. The `ReplaceText` (page 2056) function works properly for all languages. You are encouraged to use `ReplaceText` instead of `Munger` whenever possible.

`Munger` takes special action if either of the specified pointer values is `NULL` or if either of the length values is `0`.

- If `ptr1` is `NULL`, `Munger` replaces characters without searching. It replaces `len1` characters starting at the `offset` location with the substitution string.
- If `ptr1` is `NULL` and `len1` is negative, `Munger` replaces all of the characters from the `offset` location to the end of the string with the substitution string.
- If `len1` is 0, `Munger` inserts the substitution string without replacing anything. `Munger` inserts the string at the `offset` location and returns the offset of the first byte past where the insertion occurred.
- If `ptr2` is `NULL`, `Munger` searches but does not replace. In this case, `Munger` returns the offset at which the string was found.
- If `len2` is 0 and `ptr2` is not `NULL`, `Munger` searches and deletes. In this case, `Munger` returns the offset at which it deleted.

- If the portion of the string from the `offset` location to its end matches the beginning of the string that `Munger` is searching for, `Munger` replaces that portion with the substitution string.

Be careful not to specify an offset with a value that is greater than the length of the destination string. Unpredictable results may occur.

`Munger` calls the `GetHandleSize` and `SetHandleSize` functions to access or modify the length of the string it is manipulating.

Special Considerations

`Munger` may move memory; your application should not call this function at interrupt time.

The destination string must be in a relocatable block that was allocated by the Memory Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextUtils.h`

NewIndexToStringUPP

Creates a new universal procedure pointer (UPP) to an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
IndexToStringUPP NewIndexToStringUPP (
   IndexToStringProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your index-to-string callback.

Return Value
On return, a UPP to the index-to-string callback.

Discussion
See the callback `IndexToStringProcPtr` (page 2071) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

NewString

Allocates memory in the heap for a string, copies its contents, and produces a handle for the heap version of the string. (Deprecated in Mac OS X v10.4. Use `CFStringCreateCopy` instead.)

```
StringHandle NewString (
   ConstStr255Param theString
);
```

Parameters

theString

A Pascal string that you want copied onto the heap.

Return Value

A handle to the newly allocated string. If the string cannot be allocated, `NewString` returns `NULL`. The size of the allocated string is based on the actual length of `theString`, which may not be 255 bytes.

Discussion

Before using Pascal string functions that can change the length of the string, it is a good idea to maximize the size of the string object on the heap. You can call either the `SetString` (page 2057) function or the Memory Manager function `SetHandleSize` to modify the string's size.

Special Considerations

`NewString` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

NumToString

Converts a long integer value into a Pascal string. (Deprecated in Mac OS X v10.4. Use `CFStringCreateWithFormat` instead.)

```
void NumToString (
   long theNum,
   Str255 theString
);
```

Parameters

theNum

A long integer value. If the value of the number in the parameter `theNum` is negative, the string begins with a minus sign; otherwise, the sign is omitted.

theString

On output, contains the Pascal string representation of the number. Leading zeros are suppressed, except that a value of 0 produces the string "0". `NumToString` does not include thousand separators or decimal points in its formatted output.

Discussion

`NumToString` creates a string representation of `theNum` as a base-10 value and returns the result in `theString`.

Unless patched by a script system with different rules, this function assumes that you are using standard numeric token processing, meaning that the Roman script system number processing rules are used.

For functions that make use of the token-processing information that is found in the tokens (`'itl4'`) resource of script systems for converting numbers, see the sections "Using Number Format Specification Strings for International Number Formatting" and "Converting Between Strings and Floating-Point Numbers".

Special Considerations

`NumToString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NumberFormatting.h`

p2cstr

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
char * p2cstr (
   StringPtr aStr
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

P2CStr

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
Ptr P2CStr (
    StringPtr pString
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

p2cstrcpy

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void p2cstrcpy (
   char *dst,
   ConstStr255Param src
);
```

Parameters

dst

On output, the C string.

src

The Pascal string you want to convert.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

RelString

Compares two Pascal strings using the string comparison rules of the Macintosh file system and returns a value that indicates the sorting order of the first string relative to the second string. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short RelString (
   ConstStr255Param str1,
   ConstStr255Param str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters

str1

One of the Pascal strings to be compared.

str2

The other Pascal string to be compared.

caseSensitive

A flag that indicates how to handle case-sensitive information during the comparison. If the value of `caseSens` is `TRUE`, uppercase characters are distinguished from the corresponding lowercase characters. If it is `FALSE`, case information is ignored.

diacSensitive

A flag that indicates how to handle information about diacritical marks during the string comparison. If the value of `diacSensitive` is `TRUE`, characters with diacritical marks are distinguished from the corresponding characters without diacritical marks during the comparison. If it is `FALSE`, diacritical marks are ignored.

Return Value

Returns –1 if the first string is less than the second string, 0 if the two strings are equal, and 1 if the first string is greater than the second string. It compares the two strings in the same manner as does the `EqualString` function, by simply looking at the ASCII values of their characters. However, `RelString` provides more information about the two strings—it indicates their relationship to each other, rather than determining if they are exactly equal.

Discussion

This function does not make use of any script or language information; it assumes the original Macintosh character set only.

Special Considerations

The `RelString` function is not localizable and does not work properly with non-Roman script systems.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

relstring

Compares two strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

Not recommended

```
short relstring (
   const char *str1,
   const char *str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters

str1

The string to be compared to `str2`.

str2

The string to be compared to `str1`.

caseSensitive

A flag that indicates how to handle case-sensitive information during the comparison.

diacSensitive

A flag that indicates how to handle information about diacritical marks during the string comparison.

Return Value
Returns –1 if the first string is less than the second string, 0 if the two strings are equal, and 1 if the first string is greater than the second string.

Discussion
This function is not recommended. Instead, see the function `RelString` (page 2054).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

ReplaceText

Searches text on a character-by-character basis, replacing all instances of a string in that text with another string. (Deprecated in Mac OS X v10.4. Use `CFStringReplace` instead.)

```
short ReplaceText (
    Handle baseText,
    Handle substitutionText,
    Str15 key
);
```

Parameters

baseText
A handle to the string in which `ReplaceText` is to substitute text.

substitutionText
A handle to the string that `ReplaceText` uses as substitute text.

key
A Pascal string of less than 16 bytes that `ReplaceText` searches for.

Return Value
An integer value; if positive, it indicates the number of substitutions performed; if negative, it indicates an error. The constant `noErr` is returned if there was no error and no substitutions were performed.

Discussion
`ReplaceText` searches the text specified by the `baseText` parameter for instances of the string in the `key` parameter and replaces each instance with the text specified by the `substitutionText` parameter. `ReplaceText` searches on a character-by-character basis (as opposed to byte-by-byte), so it works properly for all script systems, including 2-byte script systems. It recognizes 2-byte characters in script systems that contain them and advances the search appropriately after encountering a 2-byte character.

Special Considerations

`ReplaceText` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
StringCompare.h

ScriptOrder

Determines the order in which strings in two different scripts should be sorted. (Deprecated in Mac OS X v10.4. Use CFStringCompare or UCCompareText (page 2151) instead.)

```
short ScriptOrder (
   ScriptCode script1,
   ScriptCode script2
);
```

Parameters

script1
The script code of the first script.

script2
The script code of the second script.

Return Value
A value that indicates the sorting order: –1 if strings in the first script should be sorted before strings in the second script are sorted, 1 if strings in the first script should be sorted after strings in the second script are sorted, or 0 if the sorting order does not matter (that is, if the scripts are the same).

Discussion
Text of the system script is always first in a sorted list, regardless of the result returned by this function. When determining the order in which text from two different script systems should be sorted, the system script always sorts first, and scripts that are not enabled and installed always sort last. Invalid script or language codes always sort after valid ones.

Special Considerations

ScriptOrder may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
StringCompare.h

SetString

Changes the contents of a string referenced by a string handle, replacing the previous contents by copying the specified string. (Deprecated in Mac OS X v10.4. Use CFStringCreateWithPascalString and CFStringReplaceAll.)

```
void SetString (
   StringHandle theString,
   ConstStr255Param strNew
);
```

Parameters

theString

A Pascal string.

strNew

A handle to the string in memory whose contents you are replacing. If the new string (`theString`) is larger than the string originally referenced by `strNew`, `SetString` automatically resizes the handle and copies in the contents of the specified string.

Special Considerations

`SetString` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

StringOrder

Compares two Pascal strings, taking into account the script system and language for each of the strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short StringOrder (
   ConstStr255Param aStr,
   ConstStr255Param bStr,
   ScriptCode aScript,
   ScriptCode bScript,
   LangCode aLang,
   LangCode bLang
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

aScript

The script code for the second string.

bScript

The script code for the first string.

aLang

The language code for the first string.

bLang

The language code for the second string.

Return Value
–1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string. The ordering of script and language codes, which is based on information in the script-sorting resource, is considered in determining the relationship of the two strings.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates whether the first string is less than, equal to, or greater than the second string.

"Implicit Language Codes" (page 2082) are listed in the Constants section. Most applications specify the language code `scriptCurLang` for both the `aLang` and `bLang` values.

`StringOrder` first calls `ScriptOrder` (page 2057); if the result of `ScriptOrder` is not 0 (that is, if the strings use different scripts), `StringOrder` returns the same result.

`StringOrder` next calls `LanguageOrder` (page 2048); if the result of `LanguageOrder` is not 0 (that is, if the strings use different languages), `StringOrder` returns the same result.

At this point, `StringOrder` has two strings that are in the same script and language, so it compares them by using the sorting rules for that script and language, applying both the primary and secondary sorting orders. If that script is not installed and enabled, it uses the sorting rules specified by the system script or the font script, depending on the state of the international resources selection flag.

The `StringOrder` function is primarily used to insert Pascal strings in a sorted list; for sorting, rather than using this function, it may be faster to sort first by script and language by using the `ScriptOrder` and `LanguageOrder` functions, and then to call the `CompareString` (page 2035) function, to sort strings within a script or language group.

Special Considerations

`StringOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

StringToExtended

Converts a string representation of a number into a floating-point number, using a `NumFormatStringRec` structure to specify how the input number string is formatted. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterCreateStringWithNumber` instead.)

```
FormatStatus StringToExtended (
   ConstStr255Param source,
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   extended80 *x
);
```

Parameters

source

A Pascal string that contains the string representation of a number.

myCanonical

A pointer to the internal representation of the formatting information for numbers, as produced by the `StringToFormatRec` function.

partsTable

A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

x

On output, contains a pointer to the 80-bit SANE representation of the floating-point number.

Return Value

A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `StringToExtended` to a type `FormatResultType` before working with it. `StringToExtended` returns an 80-bit, not a 96-bit, representation. See the description of the `FormatStatus` data type.

Discussion

`StringToExtended` uses the internal representation of number formatting information that was created by a prior call to `StringToFormatRec` to parse the input number string. It uses the number parts table to determine the components of the number string that is being converted. `StringToExtended` parses the string and then converts the string to a simple form, stripping nondigits and replacing the decimal point before converting it into a floating-point number. If the input string does not match any of the patterns, then `StringToExtended` parses the string as well as it can and returns a confidence level result that indicates the parsing difficulties.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StringToFormatRec

Creates a number format specification string structure from a number format specification string that you supply in a Pascal string. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterSetFormat` instead.)

```
FormatStatus StringToFormatRec (
   ConstStr255Param inString,
   const NumberParts *partsTable,
   NumFormatString *outString
);
```

Parameters

inString

A Pascal string that contains the number formatting specification.

The `inString` parameter contains a number format specification string that specifies how numbers appear. This string contains up to three specifications, separated by semicolons. The positive number format is specified first, the negative number format is second, and the zero number format is last. If the string contains only one part, that is the format of all three types of numbers. If the string contains two parts, the first part is the format for positive and zero number values, and the second part is the format for negative numbers.

partsTable

A pointer to a structure, usually obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString

On output, a pointer to a `NumFormatStringRec` structure that contains the values that form the internal representation of the format specification. The format of the data in this structure is private.

Return Value

A value that denotes the confidence level for the conversion that was performed. The low byte of the value is of type `FormatResultType`. Be sure to cast the result of `StringToFormatRec` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion

`StringToFormatRec` converts a number format specification string into the internal representation contained in a number format string structure. It uses information in the current script's tokens resource to determine the components of the number. `StringToFormatRec` checks the validity both of the input format string and of the number parts table (since this table can be programmed by the application). `StringToFormatRec` ignores spurious characters.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Special Considerations

`StringToFormatRec` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StringToNum

Converts the Pascal string representation of a base-10 number into a long integer value. (Deprecated in Mac OS X v10.4. Use `CFStringGetIntValue` instead.)

```
void StringToNum (
   ConstStr255Param theString,
   long *theNum
);
```

Parameters

theString

A Pascal string representation of a base-10 number. The numeric string can be padded with leading zeros or with a sign.

theNum

On output, contains a pointer to the numeric value.

Discussion

Unless patched by a script system with different rules, this function assumes that you are using standard numeric token processing, meaning that the Roman script system number processing rules are used.

For functions that make use of the token-processing information that is found in the tokens (`'itl4'`) resource of script systems for converting numbers, see the sections "Using Number Format Specification Strings for International Number Formatting" and "Converting Between Strings and Floating-Point Numbers".

The 32-bit result is negated if the string begins with a minus sign. Integer overflow occurs if the magnitude is greater than or equal to 2 raised to the 31st power. `StringToNum` performs the negation using the two's complement method: the state of each bit is reversed and then 1 is added to the result. For example, here are possible results produced by `StringToNum`:

- The value of `theString` is "-23". `StringToNum` returns the value -23 in `theNum`.
- The value of `theString` is "-0". `StringToNum` returns the value 0 in `theNum`.
- The value of `theString` is "055". `StringToNum` returns the value 55 in `theNum`.
- The value of `theString` is "2147483648" (magnitude is 2^31). `StringToNum` returns the value –2147483648 in `theNum`.
- The value of `theString` is "–2147483648". `StringToNum` returns the value –2147483648 in `theNum`.
- The value of `theString` is "4294967295" (magnitude is 2^32–1). `StringToNum` returns the value -1 in `theNum`.
- The value of `theString` is "–4294967295". `StringToNum` returns the value 1 in `theNum`.

`StringToNum` does not check whether the characters in the string are between 0 and 9; instead, it takes advantage of the fact that the ASCII values for these characters are $30 through $39, and masks the last four bits for use as a digit. For example, `StringToNum` converts 2: to the number 30 since the character code for the colon (:) is $3A. Because `StringToNum` operates this way, spaces are treated as zeros (the character code for a space is $20), and other characters do get converted into numbers. For example, the character codes for 'C', 'A', and 'T' are $43, $41, and $54 respectively. Hence, the strings 'CAT', '+CAT', and '-CAT' would produce the results 314, 314, and -314.

One consequence of this conversion method is that `StringToNum` does not ignore thousand separators (the "," character in the United States), which can lead to improper conversions. It is a good idea to ensure that all characters in `theString` are valid digits before you call `StringToNum`.

Special Considerations

`StringToNum` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StripDiacritics

Strips any diacritical marks from a text string. (Deprecated in Mac OS X v10.4. Use `CFStringTransform` instead.)

```
void StripDiacritics (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

`textPtr`

A pointer to the text string to be stripped.

`len`

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

`script`

The script code for the script system whose rules are used for determining which character results from stripping a diacritical mark.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`StripDiacritics` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It strips any diacritical marks from the text.

If `StripDiacritics` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`StripDiacritics` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

TextOrder

Compares two text strings, taking into account the script and language for each of the strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` (page 2151) instead.)

```
short TextOrder (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   ScriptCode aScript,
   ScriptCode bScript,
   LangCode aLang,
   LangCode bLang
);
```

Parameters

aPtr
A pointer to the first character of the first text string.

bPtr
A pointer to the first character of the second text string.

aLen
The length, in bytes, of the first text string.

bLen
The length, in bytes, of the second text string.

aScript
The script code for the first text string.

bScript
The script code for the second text string.

aLang
The language code for the first text string.

bLang
The language code for the second text string.

Return Value

Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string. The ordering of script and language codes, which is based on information in the script-sorting resource, is considered in determining the relationship of the two strings.

Discussion

This function takes both primary and secondary sorting orders into consideration and returns a value that indicates whether the first string is less than, equal to, or greater than the second string.

"Implicit Language Codes" (page 2082) are listed in the Constants section. Most applications specify the language code `scriptCurLang` for both the `aLang` and `bLang` values.

`TextOrder` first calls `ScriptOrder` (page 2057); if the result of `ScriptOrder` is not 0 (that is, if the strings use different scripts), `TextOrder` returns the same result.

`TextOrder` next calls `LanguageOrder` (page 2048); if the result of `LanguageOrder` is not 0 (that is, if the strings use different languages), `TextOrder` returns the same result.

At this point, `TextOrder` has two strings that are in the same script and language, so it compares them by using the sorting rules for that script and language, applying both the primary and secondary sorting orders. If that script is not installed and enabled, it uses the sorting rules specified by the system script or the font script, depending on the state of the international resources selection flag.

The `TextOrder` function is primarily used to insert text strings in a sorted list; for sorting, rather than using this function, it may be faster to sort first by script and language by using the `ScriptOrder` and `LanguageOrder` functions, and then to call the `CompareText` (page 2036) function, to sort strings within a script or language group.

Special Considerations

`TextOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

TypeSelectClear

Clears the key list and resets the type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectFlushSelectorData` instead.)

Not recommended.

```
void TypeSelectClear (
   TypeSelectRecord *tsr
);
```

Parameters

tsr

A pointer to the type-select record you want to clear.

Discussion
The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

TypeSelectCompare

Compares a text buffer to the keystroke buffer. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectCompare` instead.)

Not recommended.

```
short TypeSelectCompare (
   const TypeSelectRecord *tsr,
   ScriptCode testStringScript,
   StringPtr testStringPtr
);
```

Parameters

tsr

A type select record that contains the keystroke buffer.

testStringScript

The script code of the test string.

testStringPtr

A pointer to the text you want to compare to the keystroke buffer.

Return Value

A numerical value that represents the ordering of the characters in the keystroke buffer with respect to the test string buffer. The value -1 is returned if characters in the keystroke buffer sort before those in `testStringPtr`; 0 if characters in the keystroke buffer are the same as those in `testStringPtr`, and 1 if the characters in the keystroke buffer sort after those in `testStringPtr`.

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

TypeSelectFindItem

Finds the closest match between a specified list of characters and the keystrokes stored in the type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectFindItem` instead.)

Not recommended.

```
short TypeSelectFindItem (
   const TypeSelectRecord *tsr,
   short listSize,
   TSCode selectMode,
   IndexToStringUPP getStringProc,
   void *yourDataPtr
);
```

Parameters

tsr

A pointer to the type select record that contains the keystrokes you want to compare.

listSize

The size of the list to search through.

selectMode

The select mode. See `Type Select Modes` (page 2083)for a list of the constants you can supply.

getStringProc

A pointer to your index-to-string callback function. See `IndexToStringProcPtr` (page 2071) for more information.

yourDataPtr

A pointer to your data structure. This is passed to your index-to-string callback, and can be `NULL`, depending on how you implement your callback function.

Return Value

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

TypeSelectNewKey

Creates a new type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectCreateSelector` instead.)

Not recommended.

```
Boolean TypeSelectNewKey (
   const EventRecord *theEvent,
   TypeSelectRecord *tsr
);
```

Parameters

theEvent

A pointer to an event record.

tsr

A pointer to a type select record.

Return Value

Returns `true` if the function executed successfully; `false` otherwise.

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

UppercaseStripDiacritics

Converts any lowercase characters in a text string into their uppercase equivalents and strips any diacritical marks from the text. (Deprecated in Mac OS X v10.4. Use `CFStringTransform` instead.)

```
void UppercaseStripDiacritics (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be converted.

len

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

script

The script code of the script system whose resources are used to determine the results of converting characters.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`UppercaseStripDiacritics` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts lowercase characters in the text into their uppercase equivalents and also strips diacritical marks from the text string. This function combines the effects of the `UppercaseText` (page 2069) and `StripDiacritics` (page 2063) functions.

If `UppercaseStripDiacritics` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`UppercaseStripDiacritics` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

UppercaseText

Converts any lowercase characters in a text string into their uppercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

```
void UppercaseText (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be converted.

len

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

script

The script code of the script system whose case conversion rules are used for determining uppercase character equivalents.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the specified `script`. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`UppercaseText` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts any lowercase characters in the text into uppercase.

If `UppercaseText` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`UppercaseText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

UpperString

Converts any lowercase letters in a Pascal string to their uppercase equivalents, using the Macintosh file system rules. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

```
void UpperString (
   Str255 theString,
   Boolean diacSensitive
);
```

Parameters

theString

On input, this is the Pascal string to be converted. On output, this contains the string resulting from the conversion. `UpperString` traverses the characters in `theString` and converts any lowercase characters with character codes in the range 0x00 through 0xD8 into their uppercase equivalents. `UpperString` places the converted characters in `theString`.

diacSensitive

A flag that indicates whether the case conversion is to strip diacritical marks. If the value of this parameter is `TRUE`, diacritical marks are considered in the conversion; if it is `FALSE`, any diacritical marks are stripped.

Discussion

Only a subset of the Roman character set (character codes with values through $D8) are converted. Use this function to emulate the behavior of the Macintosh file system.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextUtils.h`

upperstring

Converts any lowercase letters in a Pascal string to their uppercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

Not recommended

```
void upperstring (
   char *theString,
   Boolean diacSensitive
);
```

Parameters

`theString`

On input, this is the Pascal string to be converted. On output, this contains the string resulting from the conversion.

`diacSensitive`

A flag that indicates whether the case conversion is to strip diacritical marks. If the value of this parameter is `TRUE`, diacritical marks are considered in the conversion; if it is `FALSE`, any diacritical marks are stripped.

Discussion
You should use the function `CFStringUppercase` instead of this one.

Carbon Porting Notes

Use `UpperString` instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

Callbacks

IndexToStringProcPtr

Defines a pointer to your index-to-string callback function that retrieves the string associated with an index value.

Not recommended.

```
typedef Boolean (*IndexToStringProcPtr)
(
    short item,
    ScriptCode * itemsScript,
    StringPtr * itemsStringPtr,
    void * yourDataPtr
);
```

If you name your function `MyIndexToStringProc`, you would declare it like this:

```
Boolean MyIndexToStringProcPtr (
    short item,
    ScriptCode * itemsScript,
    StringPtr * itemsStringPtr,
    void * yourDataPtr
);
```

Parameters

item
The index value for which the `TypeSelect` function requests a string.

itemsScript
The script code of the string specified by `itemsStringPtr`.

itemsStringPtr
On return, points to the string that matches the index specify by the `item` parameter.

yourDataPtr
A pointer to your data structure. This is passed to your index-to-string callback, and can be `NULL`, depending on how you implement your callback function.

Return Value
Returns `true` if a string matching that index value was found; `false` otherwise.

Discussion
The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Availability
Not recommended. Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

Data Types

BreakTable

Contains information used to determine the boundaries of a word.

```
struct BreakTable {
    char charTypes[256];
    short tripleLength;
    short triples[1];
};
typedef struct BreakTable BreakTable;
typedef BreakTable * BreakTablePtr;
```

Discussion
You can supply a `BreakTable` as a parameter to the function `FindWordBreaks` (page 2041).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

FormatClass

Defines a data type used to access entries in a triple integer array.

```
typedef SInt8 FormatClass;
```

Discussion
Each of the three `FVector` entries in a triple integer array is accessed by one of the values of the `FormatClass` type. See `FVector` (page 2073) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

FormatStatus

Defines a data type used to denote the confidence level for a conversion.

```
typedef short FormatStatus;
```

Discussion
A `FormatStatus` value is returned by the functions `ExtendedToString` (page 2039), `StringToExtended` (page 2059), `FormatRecToString` (page 2043), and `StringToFormatRec` (page 2060).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

FVector

Contains position and length information for one portion of a formatted numeric string.

```
struct FVector {
    short start;
    short length;
};
typedef struct FVector FVector;
typedef FVector TripleInt[3];
```

Fields

`start`

The starting byte position in the string of the specification information.

`length`

The number of bytes used in the string for the specification information.

Discussion

The `FVector` data structure is used in the `TripleInt` (page 2078) array.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NumberFormatting.h`

IndexToStringUPP

Defines a universal procedure pointer to an index-to-string callback.

```
typedef IndexToStringProcPtr IndexToStringUPP;
```

Discussion

For more information, see the description of the `IndexToStringProcPtr` (page 2071) callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

NBreakTable

Contains information used by the `FindWordBreaks` function to determine word boundaries.

```
struct NBreakTable {
    SInt8 flags1;
    SInt8 flags2;
    short version;
    short classTableOff;
    short auxCTableOff;
    short backwdTableOff;
    short forwdTableOff;
    short doBackup;
    short length;
    char charTypes[256];
    short tables[1];
};
typedef struct NBreakTable NBreakTable;
typedef NBreakTable * NBreakTablePtr;
```

Fields

`flags1`
: The high-order byte of the break table format flags. If the high-order bit of this byte is set to 1, this break table is in the format used by `FindWordBreaks`.

`flags2`
: The low-order byte of the break table format flags. If the value in this byte is 0, the break table belongs to a 1-byte script system; in this case `FindWordBreaks` does not check for 2-byte characters.

`version`
: The version of this break table.

`classTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the class table.

`auxCTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the auxiliary class table.

`backwdTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the backward-processing table.

`forwdTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the forward-processing table.

`doBackup`
: The minimum byte offset into the buffer for doing backward processing. If the selected character for `FindWordBreaks` has a byte offset less than `doBackup`, `FindWordBreaks` skips backward processing altogether and starts from the beginning of the buffer.

`length`
: The length in bytes of the entire break table, including the individuals tables.

`charTypes`
: The class table.

`tables`
: The data of the auxiliary class table, backward table, and forward table.

Discussion

The tables have this format and content:

- The class table is an array of 256 signed bytes. Offsets into the table represent byte values; if the entry at a given offset in the table is positive, it means that a byte whose value equals that offset is a single-byte character, and the entry at that offset is the class number for the character. If the entry is negative, it means that the byte is the first byte of a 2-byte character code, and the auxiliary class table must be used to determine the character class. Odd negative numbers are handled differently from even negative numbers.
- The auxiliary class table assigns character classes to 2-byte characters. It is used when the class table determines that a byte value represents the first byte of a 2-byte character.
  - The auxiliary class table handles odd negative values from the class table as follows. If the first word of the auxiliary class table is equal to or greater than zero, it represents the default class number for 2-byte character codes—the class assigned to every odd negative value from the class table. If the first word is less than zero, it is the negative of the offset from the beginning of the auxiliary class table to a first-byte class table (a table of 2-byte character classes that can be determined from just the first byte). The value from the class table is negated, 1 is subtracted from it to obtain an even offset, and the value at that offset into the first-byte class table is the class to be assigned.
  - The auxiliary class table handles even negative values from the class table as follows. The auxiliary class table begins with a variable-length word array. The words that follow the first word are offsets to row tables. Row tables have the same format as the class table, but are used to map the second byte of a 2-byte character code to a class number. If the entry in the class table for a given byte is an even negative number, `FindWordBreaks` negates this value to obtain the offset from the beginning of the auxiliary class table to the appropriate word, which in turn contains an offset to the appropriate row table. That row table is then used to map the second byte of the character to a class number.
- The backward-processing table is a state table used by `FindWordBreaks` for backward searching. Using the backward-processing table, `FindWordBreaks` starts at a specified character, moving backward as necessary until it encounters a word boundary.
- The forward-processing table is a state table used by `FindWordBreaks` for forward searching. Using the forward-processing table, `FindWordBreaks` starts at one word boundary and moves forward until it encounters another word boundary.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

NumFormatString

Contains data that represents the internal number formatting specification.

```
struct NumFormatString {
    UInt8 fLength;
    UInt8 fVersion;
    char data[254];
};
typedef struct NumFormatString NumFormatString;
typedef NumFormatString NumFormatStringRec;
```

Fields

`fLength`
The number of bytes in the data actually used for this number formatting specification.

`fVersion`
The version number of the number formatting specification.

`data`
The data that comprises the number formatting specification.

Discussion

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

NumFormatStringRec

Defines an internal numeric representation that is independent of region, language, and other multicultural consideration.

```
typedef NumFormatString NumFormatStringRec;
```

Discussion
To allow for all of the international variations in numeric presentation styles, you need to include in your function calls a number parts table from a tokens (`'itl4'`) resource. You can usually use the number parts table in the standard tokens resource that is supplied with the system. You also need to define the format of input and output numeric strings, including which characters (if any) to use as thousand separators, whether to indicate negative values with a minus sign or by enclosing the number in parentheses, and how to display zero values.

To make it possible to map a number that was formatted for one specification into another format, the Mac OS defines an internal numeric representation that is independent of region, language, and other multicultural considerations: the `NumFormatStringRec` structure. This structure is created from a number format specification string that defines the appearance of numeric strings.

Four of the numeric string functions use the number formatting specification, defined by the `NumFormatStringRec` data type: `StringToFormatRec` (page 2060), `FormatRecToString` (page 2043), `StringToExtended` (page 2059), and `ExtendedToString` (page 2039). The number format specification structure contains the data that represents the internal number formatting specification information. This data is stored in a private format.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

ScriptRunStatus

Contains script-specific information for a script run.

```
struct ScriptRunStatus {
    SInt8 script;
    SInt8 runVariant;
};
typedef struct ScriptRunStatus ScriptRunStatus;
```

Fields

`script`

The script code of the subscript run. Zero indicates the Roman script system.

`runVariant`

Script-specific information about the run, in the same format as that returned by the `CharacterType` function. This information includes the type of subscript—for example, Kanji, Katakana, or Hiragana for a Japanese script system.

Discussion

The `FindScriptRun` (page 2040) function returns the script run status structure, defined by the `ScriptRunStatus` data type, when it completes its processing, which is to find a run of subscript text in a string.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

TripleInt

Defines a data type used to return the position and length information for three different portions of a formatted numeric string.

```
typedef FVector TripleInt[3];
```

Discussion

The `FormatRecToString` (page 2043) function uses the triple-integer array, defined by the `TripleInt` data type, to return the starting position and length in a string of three different portions of a formatted numeric string: the positive value string, the negative value string, and the zero value string. Each element of the triple integer array is an `FVector` structure. Each of the three `FVector` entries in the triple integer array is accessed by one of the values of the `FormatClass` type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NumberFormatting.h`

TypeSelectRecord

Contains a buffer of keystrokes, the script code associated with the keystrokes, and timer information.

```
struct TypeSelectRecord {
    unsigned long tsrLastKeyTime;
    ScriptCode tsrScript;
    Str63 tsrKeyStrokes;
};
typedef struct TypeSelectRecord TypeSelectRecord;
```

Fields

`tsrLastKeyTime`
A value that indicates timeout information.

`tsrScript`
A script code.

`tsrKeyStrokes`
The keystroke buffer.

Discussion

The `TypeSelectRecord` data structure is passed as a parameter to the functions `TypeSelectNewKey` (page 2067), `TypeSelectFindItem` (page 2066), `TypeSelectCompare` (page 2066), and `TypeSelectClear` (page 2065).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TypeSelect.h`

Constants

Format Result Types

Specify values that can be returned in the low byte of a format status (`FormatStatus`) value.

```
enum {
    fFormatOK = 0,
    fBestGuess = 1,
    fOutOfSynch = 2,
    fSpuriousChars = 3,
    fMissingDelimiter = 4,
    fExtraDecimal = 5,
    fMissingLiteral = 6,
    fExtraExp = 7,
    fFormatOverflow = 8,
    fFormStrIsNAN = 9,
    fBadPartsTable = 10,
    fExtraPercent = 11,
    fExtraSeparator = 12,
    fEmptyFormatString = 13
};
typedef SInt8 FormatResultType;
```

Constants

`fFormatOK`
Specifies format is okay.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fBestGuess`
Specifies the format is the best guess.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fOutOfSynch`
Specifies the format is out of sync.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fSpuriousChars`
Specifies the format contains spurious characters.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fMissingDelimiter`
Specifies a missing delimiter.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraDecimal`
Specifies the format contains an extra decimal sign.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fMissingLiteral`
Specifies the format is missing a literal.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraExp`
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fFormatOverflow`
Specifies a format overflow.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fFormStrIsNAN`
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fBadPartsTable`
Specifies the parts table is bad.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraPercent`
Specifies the format contains an extra percent sign.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraSeparator`
Specifies an extra separator.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fEmptyFormatString`
Specifies the format string is empty.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

Discussion
A format result type is returned in the low byte of a format status (`FormatStatus`) value. A `FormatStatus` (page 2073) value is returned by the functions `ExtendedToString` (page 2039), `StringToExtended` (page 2059), `FormatRecToString` (page 2043), and `StringToFormatRec` (page 2060). A format status value denotes the confidence level for a conversion.

TripleInt Index Values

Specify an index for a `TripleInt` array.

```
enum {
    fPositive = 0,
    fNegative = 1,
    fZero = 2
};
```

Constants

`fPositive`

Specifies the positive value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

`fNegative`

Specifies the negative value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

`fZero`

Specifies the zero value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

Discussion

See `TripleInt` (page 2078) for more information.

NumFormatString Version

Specifies the first version of the `NumFormatString` data structure.

```
enum {
    fVNumber = 0
};
```

Discussion

See `NumFormatString` (page 2076) for more information.

Implicit Language Codes

Specify implicit language codes.

```
enum {
    systemCurLang = -2,
    systemDefLang = -3,
    currentCurLang = -4,
    currentDefLang = -5,
    scriptCurLang = -6,
    scriptDefLang = -7
};
```

Constants

`systemCurLang`
Specifies the current language for system script (from `'itlb'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`systemDefLang`
Specifies the default language for system script (from `'itlm'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`currentCurLang`
Specifies the current language for current script (from `'itlb'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`currentDefLang`
Specifies the default language for current script (from `'itlm'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`scriptCurLang`
Specifies the current language for specified script (from `'itlb'`)
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`scriptDefLang`
Specifies the default language for specified script (from `'itlm'`)
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

Discussion
The functions `LanguageOrder` (page 2048), `StringOrder` (page 2058), and `TextOrder` (page 2064) accept as parameters implicit language codes listed here, as well as explicit language codes.

Type Select Modes

Contains type-select code information.

```
typedef SInt16 TSCode;
enum {
    tsPreviousSelectMode = -1,
    tsNormalSelectMode = 0,
    tsNextSelectMode = 1
};
```

Constants

`tsPreviousSelectMode`
Specifies previous-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

`tsNormalSelectMode`
Specifies normal-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

`tsNextSelectMode`
Specifies next-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

Discussion
This structure is passed as a parameter to the function `TypeSelectFindItem` (page 2066).

Obsolete Language Code Values

Specify language code values that are no longer used.

```
enum {
    iuSystemCurLang = systemCurLang,
    iuSystemDefLang = systemDefLang,
    iuCurrentCurLang = currentCurLang,
    iuCurrentDefLang = currentDefLang,
    iuScriptCurLang = scriptCurLang,
    iuScriptDefLang = scriptDefLang
};
```

Thread Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Threads.h

Overview

You can use the Thread Manager to provide cooperatively scheduled threads, or multiple points of execution, in an application. You can think of the Thread Manager as an enhancement to the classic Mac OS Process Manager, which governs how applications work together in the Mac OS cooperative multitasking environment.

Important: Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Consider using the Thread Manager for applications with more than one thread if these threads can execute only in the cooperative multitasking environment of the classic Mac OS Process Manager.

Alternatively, you should consider using the Multiprocessing Services to implement separate paths of execution for tasks that are reentrant and can therefore can be preemptively scheduled.

Using Thread Manager routines, you can create threads and thread pools and set them up to run; turn scheduling on and off; work with stacks; create dialog boxes that yield control to other threads; pass information between threads; install custom scheduling and context-switching functions; and use threads to make asynchronous I/O calls.

The Thread Manager provides only cooperative threading for PowerPC applications. Applications can use the Multiprocessing Services API to create preemptively scheduled tasks.

Note that several Thread Manager functions that did not require you to pass universal procedure pointers (UPPs) for callbacks now require them in Carbon. See the Carbon Porting Notes for more information.

Functions by Task

Creating and Disposing of Threads

`DisposeThread` (page 2091)
Deletes a thread when it finishes executing.

NewThread (page 2104)
Creates a new thread or allocates one from the existing pool of threads.

Creating and Getting Information About Thread Pools

CreateThreadPool (page 2088)
Creates a pool of threads for your application.

GetDefaultThreadStackSize (page 2095)
Determines the default stack size required by a thread.

GetFreeThreadCount (page 2095) Deprecated in Mac OS X v10.3
Determines how many threads are available to be allocated in a thread pool. (Deprecated. There is no replacement.)

GetSpecificFreeThreadCount (page 2096) Deprecated in Mac OS X v10.3
Determines how many threads with a stack size equal to or greater than the specified size are available to be allocated in a thread pool. (Deprecated. There is no replacement.)

Getting Information About Specific Threads

GetCurrentThread (page 2094)
Obtains the thread ID of the currently executing thread.

GetThreadState (page 2098)
Obtains the state of a thread.

ThreadCurrentStackSpace (page 2117)
Determines the amount of stack space that is available for any thread in your application.

Getting Information and Scheduling Threads During Interrupts

GetThreadCurrentTaskRef (page 2097)
Obtains a thread task reference.

GetThreadStateGivenTaskRef (page 2099)
Obtains the state of a thread when your application is not necessarily the current process—for example, during execution of an interrupt function.

SetThreadReadyGivenTaskRef (page 2110)
Changes the state of a thread from stopped to ready when your application is not the current process.

Installing Custom Scheduling, Switching, Terminating, and Debugging Functions

SetDebuggerNotificationProcs (page 2108)
Installs functions that notify the debugger when a thread is created, disposed of, or scheduled.

SetThreadScheduler (page 2110)
Installs a custom scheduling function (custom scheduler).

SetThreadSwitcher (page 2114)
Installs a custom context-switching function for any thread.

SetThreadTerminator (page 2115)
Installs a custom thread-termination function for a thread.

Preventing Scheduling

SetThreadStateEndCritical (page 2113)
Changes the state of the current thread and exits that thread's critical section at the same time.

ThreadBeginCritical (page 2116)
Indicates that the thread is entering a critical code section.

ThreadEndCritical (page 2118)
Indicates that the thread is leaving a critical code section.

Scheduling Threads

SetThreadState (page 2112)
Changes the state of any thread.

YieldToAnyThread (page 2118)
Relinquishes the current thread's control.

YieldToThread (page 2119)
Relinquishes the current thread's control to a particular thread.

Miscellaneous

DisposeDebuggerDisposeThreadUPP (page 2090)

DisposeDebuggerNewThreadUPP (page 2090)

DisposeDebuggerThreadSchedulerUPP (page 2091)

DisposeThreadEntryUPP (page 2092)

DisposeThreadSchedulerUPP (page 2093)

DisposeThreadSwitchUPP (page 2093)

DisposeThreadTerminationUPP (page 2094)

InvokeDebuggerDisposeThreadUPP (page 2100)

InvokeDebuggerNewThreadUPP (page 2100)

Functions

CreateThreadPool

Creates a pool of threads for your application.

```
OSErr CreateThreadPool (
   ThreadStyle threadStyle,
   SInt16 numToCreate,
   Size stackSize
);
```

Parameters

threadStyle

The type of thread to create for this set of threads in the pool. Cooperative is the only type that you can specify. Historically, the Thread Manger supported two types of threads, preemptive and cooperative. However, due to severe limitations on their use, the Thread Manager no longer supports preemptive threads.

numToCreate

The number of threads to create for the pool.

stackSize

The stack size for this set of threads in the pool. This stack must be large enough to handle saved thread context, normal application stack usage, interrupt handling functions, and CPU exceptions. Specify a stack size of 0 to request the Thread Manager's default stack size for the specified type of thread.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The `CreateThreadPool` function creates the specified number of threads with the specified stack requirements. It places the threads that it creates into a pool for use by your application.

When you call `CreateThreadPool`, if the Thread Manager is unable to create all the threads that you specify, it does not create any at all and returns the `memFullErr` result code.

The threads in the pool are indistinguishable except by stack size. That is, you cannot refer to them individually. When you want to use a thread to execute some code in your application, you allocate a thread of a specific size from the pool using the `NewThread` function. The `NewThread` function assigns a thread ID to the thread and specifies the function that is the entry point to the thread.

Note that it is not strictly necessary to create a pool of threads before allocating a thread. If you wish, you can use the `NewThread` function to create and allocate a thread in one step. The advantage of using `CreateThreadPool` is that you can allocate memory for threads early in your application's execution before memory is used or fragmented.

Before making any calls to `CreateThreadPool`, be certain that you first have called the Memory Manager function `MaxApplZone` to extend the application heap to its limit. You must call `MaxApplZone` from the main application thread before any other threads in your application run.

To allocate a thread from the pool created with `CreateThreadPool`, use the `NewThread` (page 2104) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

DisposeDebuggerDisposeThreadUPP

```
void DisposeDebuggerDisposeThreadUPP (
   DebuggerDisposeThreadUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DisposeDebuggerNewThreadUPP

```
void DisposeDebuggerNewThreadUPP (
   DebuggerNewThreadUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DisposeDebuggerThreadSchedulerUPP

```
void DisposeDebuggerThreadSchedulerUPP (
   DebuggerThreadSchedulerUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DisposeThread

Deletes a thread when it finishes executing.

```
OSErr DisposeThread (
   ThreadID threadToDump,
   void *threadResult,
   Boolean recycleThread
);
```

Parameters

threadToDump

The thread ID of the thread to delete.

threadResult

A pointer to the thread's result. The `DisposeThread` function places this result to an address which you originally specify with the `threadResult` parameter of the `NewThread` function when you create or allocate the thread. Pass a value of `NULL` if you are not interested in obtaining a function result.

recycleThread

A Boolean value that specifies whether to return the thread to the allocation pool or to remove it entirely. Specify `False` to dispose of the thread entirely and `True` to return it to the thread pool.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

When a thread finishes executing, the Thread Manager automatically calls `DisposeThread` to delete it. Therefore, the only reason for you to explicitly call `DisposeThread` is to recycle a terminating thread. To do so, set the `recycleThread` parameter to `True`. The Thread Manager clears out the thread's internal data structure, resets it, and puts the thread in the thread pool where it can be used again as necessary.

The `DisposeThread` function sets the `threadResult` parameter to the thread's function result. You allocate the storage for the thread result when you create or allocate a thread with the `NewThread` function.

You cannot explicitly dispose of the main application thread. If you attempt to do so, `DisposeThread` returns the `threadProtocolErr` result code.

When your application terminates, the Thread Manager calls `DisposeThread` to terminate any active threads. It terminates stopped and ready threads first but in no special order. It terminates the currently running thread last. This thread should always be the main application thread.

To install a callback function to do special cleanup when a thread terminates, use the `SetThreadTerminator` (page 2115) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

DisposeThreadEntryUPP

```
void DisposeThreadEntryUPP (
   ThreadEntryUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

DisposeThreadSchedulerUPP

```
void DisposeThreadSchedulerUPP (
   ThreadSchedulerUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DisposeThreadSwitchUPP

```
void DisposeThreadSwitchUPP (
   ThreadSwitchUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DisposeThreadTerminationUPP

```
void DisposeThreadTerminationUPP (
   ThreadTerminationUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

GetCurrentThread

Obtains the thread ID of the currently executing thread.

```
OSErr GetCurrentThread (
    ThreadID * currentThreadID
);
```

Parameters

currentThreadID

On return, a pointer to the thread ID of the current thread.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

You can use the thread ID obtained by `GetCurrentThread` in functions such as `GetThreadState` and `SetThreadState` to get and set the state of a thread.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

GetDefaultThreadStackSize

Determines the default stack size required by a thread.

```
OSErr GetDefaultThreadStackSize (
   ThreadStyle threadStyle,
   Size *stackSize
);
```

Parameters

threadStyle

The type of thread to get information about. Cooperative is the only type that you can specify. Historically, the Thread Manger supported two types of threads, preemptive and cooperative, but the Thread Manager no longer supports preemptive threads.

stackSize

On return, a pointer to the default stack size (in bytes). When you create a thread pool or an individual thread, this is the stack size that the Thread Manager allocates when you specify the default size.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

Keep in mind that the default stack size is not an absolute value that you must use but is a rough estimate.

To determine how much stack space is available for a particular thread, use the `ThreadCurrentStackSpace` (page 2117) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

GetFreeThreadCount

Determines how many threads are available to be allocated in a thread pool. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
OSErr GetFreeThreadCount (
   ThreadStyle threadStyle,
   SInt16 *freeCount
);
```

Parameters

threadStyle

The type of thread to get information about. Cooperative is the only type that you can specify. Historically, the Thread Manger supported two types of threads, preemptive and cooperative, but the Thread Manager no longer supports preemptive threads.

freeCount
On return, a pointer to the number of threads available to be allocated.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The number of threads in the pool varies throughout execution of your application. Calls to `CreateThreadPool` add threads to the pool and calls to the function `NewThread` (page 2104) , when an existing thread is allocated, reduce the number of threads. You also add threads to the pool when you dispose of a thread with the `DisposeThread` (page 2091) function and specify that the thread be recycled.

Use the `GetSpecificFreeThreadCount` (page 2096) function to determine how many threads of a particular stack size are available.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Threads.h`

GetSpecificFreeThreadCount

Determines how many threads with a stack size equal to or greater than the specified size are available to be allocated in a thread pool. (Deprecated in Mac OS X v10.3. There is no replacement.)

```
OSErr GetSpecificFreeThreadCount (
   ThreadStyle threadStyle,
   Size stackSize,
   SInt16 *freeCount
);
```

Parameters

threadStyle
The type of thread to get information about. Cooperative is the only type that you can specify. Historically, the Thread Manger supported two types of threads, preemptive and cooperative, but the Thread Manager no longer supports preemptive threads.

stackSize
The stack size of the threads to get information about.

freeCount
On return, a pointer to the number of threads of the specified stack size available to be allocated.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The `GetSpecificFreeThreadCount` function determines how many threads with a stack size equal to or greater than the specified size are available to be allocated. Use this function instead of `GetFreeThreadCount` (page 2095) when you are interested not simply in the total number of available threads but when you want to know the number of available threads of a specified stack size as well.

The number of threads in the pool varies throughout execution of your application. Calls to the function `CreateThreadPool` (page 2088) add threads to the pool and calls to the function `NewThread` (page 2104) , when an existing thread is allocated, reduce the number of threads. You also add threads to the pool when you dispose of a thread with the `DisposeThread` (page 2091) function and specify that the thread be recycled.

To determine how many threads of any stack size are available, use the `GetFreeThreadCount` function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Threads.h`

GetThreadCurrentTaskRef

Obtains a thread task reference.

```
OSErr GetThreadCurrentTaskRef (
   ThreadTaskRef *threadTRef
);
```

Parameters

threadTRef
On return, a pointer to a thread task reference.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The thread task reference is somewhat of a misnomer because it identifies your application context, not a particular thread. Identifying your application context is necessary in situations where you aren't guaranteed that your application is the current context—such as during the execution of an interrupt function. In such cases, you need both the thread ID to identify the thread and the thread task reference to identify the application context.

After you obtain the thread task reference, you can use it in the `GetThreadStateGivenTaskRef` (page 2099) and `SetThreadReadyGivenTaskRef` (page 2110) functions to get and set information about specific threads in your application at times when you are not guaranteed that your application is the current context.

To get information about a thread when your application is not the current process, use the `GetThreadStateGivenTaskRef` function.

To change the state of a thread from stopped to ready when your application is not the current process, use the `SetThreadReadyGivenTaskRef` function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

GetThreadState

Obtains the state of a thread.

```
OSErr GetThreadState (
   ThreadID threadToGet,
   ThreadState *threadState
);
```

Parameters

threadToGet
The thread ID of the thread about which you want information.

threadState
On return, a pointer to the state of the thread specified by `threadToGet`.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
A thread can be in one of three states: ready to execute (`kReadyThreadState`), stopped (`kStoppedThreadState`), or executing (`kRunningThreadState`).

To change the state of a specified thread, use `SetThreadState` (page 2112).

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

GetThreadStateGivenTaskRef

Obtains the state of a thread when your application is not necessarily the current process—for example, during execution of an interrupt function.

```
OSErr GetThreadStateGivenTaskRef (
   ThreadTaskRef threadTRef,
   ThreadID threadToGet,
   ThreadState *threadState
);
```

Parameters

threadTRef

The thread task reference of the application containing the thread whose state you want to determine.

threadToGet

The thread ID of the thread whose state you want to determine.

threadState

A pointer to a thread state variable in which the function places the state of the specified thread.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

You can use `GetThreadStateGivenTaskRef` at times when you aren't guaranteed that your application is the current context, such as during execution of an interrupt function. In such cases you must identify the thread task reference (the application context) as well as the thread ID.

To determine the thread task reference (application context) for your application, use the `GetThreadCurrentTaskRef` (page 2097) function.

To change the state of a thread from stopped to ready when your application is not the current process, use the `SetThreadReadyGivenTaskRef` (page 2110) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeDebuggerDisposeThreadUPP

```
void InvokeDebuggerDisposeThreadUPP (
   ThreadID threadDeleted,
   DebuggerDisposeThreadUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeDebuggerNewThreadUPP

```
void InvokeDebuggerNewThreadUPP (
   ThreadID threadCreated,
   DebuggerNewThreadUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeDebuggerThreadSchedulerUPP

```
ThreadID InvokeDebuggerThreadSchedulerUPP (
   SchedulerInfoRecPtr schedulerInfo,
   DebuggerThreadSchedulerUPP userUPP
);
```

Parameters

schedulerInfo

userUPP

Return Value

See the description of the `ThreadID` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeThreadEntryUPP

```
voidPtr InvokeThreadEntryUPP (
   void *threadParam,
   ThreadEntryUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeThreadSchedulerUPP

```
ThreadID InvokeThreadSchedulerUPP (
   SchedulerInfoRecPtr schedulerInfo,
   ThreadSchedulerUPP userUPP
);
```

Parameters

schedulerInfo

userUPP

Return Value

See the description of the `ThreadID` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeThreadSwitchUPP

```
void InvokeThreadSwitchUPP (
   ThreadID threadBeingSwitched,
   void *switchProcParam,
   ThreadSwitchUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

InvokeThreadTerminationUPP

```
void InvokeThreadTerminationUPP (
   ThreadID threadTerminated,
   void *terminationProcParam,
   ThreadTerminationUPP userUPP
);
```

Parameters

userUPP

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

NewDebuggerDisposeThreadUPP

```
DebuggerDisposeThreadUPP NewDebuggerDisposeThreadUPP (
   DebuggerDisposeThreadProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `DebuggerDisposeThreadUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewDebuggerNewThreadUPP

```
DebuggerNewThreadUPP NewDebuggerNewThreadUPP (
   DebuggerNewThreadProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `DebuggerNewThreadUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewDebuggerThreadSchedulerUPP

```
DebuggerThreadSchedulerUPP NewDebuggerThreadSchedulerUPP (
   DebuggerThreadSchedulerProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `DebuggerThreadSchedulerUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewThread

Creates a new thread or allocates one from the existing pool of threads.

Modified

```
OSErr NewThread (
   ThreadStyle threadStyle,
   ThreadEntryTPP threadEntry,
   void *threadParam,
   Size stackSize,
   ThreadOptions options,
   void **threadResult,
   ThreadID *threadMade
);
```

Parameters

threadStyle

The type of thread to create. Cooperative is the only type that you can specify. Historically, the Thread Manger supported two types of threads, preemptive and cooperative, but the Thread Manager no longer supports preemptive threads.

threadEntry

A pointer to the thread entry function.

threadParam

A pointer to a value that the Thread Manager passes as a parameter to the thread entry function. Specify `NULL` if you are passing no information.

stackSize

The stack size (in bytes) to allocate for this thread. This stack must be large enough to handle saved thread context, normal application stack usage, interrupt handling functions, and CPU exceptions. Specify a stack size of 0 (zero) to request the Thread Manager's default stack size.

options

Options that define characteristics of the new thread. See the `Thread Option Constants` (page 2132) data type for details on the options. You sum the options together to create a single `options` parameter.

threadResult

On return, a pointer to the address of a location to hold the function result provided by the `Thread Option Constants` (page 2132) function when the thread terminates. Specify `NULL` for this parameter if you are not interested in the function result.

threadMade

On return, a pointer to the thread ID of the newly created or allocated thread. If there is an error, `threadMade` points to a value of `kNoThreadID`.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

The `NewThread` function obtains a thread ID that you can use in other Thread Manager functions to identify the thread. If you want to allocate a thread from the pool of threads, specify the `kUsePremadeThread` option of the `options` parameter. Otherwise, `NewThread` creates a new thread.

When you request a thread from the existing pool, the Thread Manager allocates one that best fits your specified stack size. If you specify the `kExactMatchThread` option of the `options` parameter, the Thread Manager allocates a thread whose stack exactly matches your stack-size requirement or, if it can't allocate one because no such thread exists, it returns the `threadTooManyReqsErr` result code.

Before making any calls to `NewThread`, be certain that you first have called the Memory Manager function `MaxApplZone` to extend the application heap to its limit. You must call `MaxApplZone` from the main application thread before any other threads in your application run.

When you call the `NewThread` function, you pass, as the `threadEntry` parameter, a pointer to the name of the entry function to the thread. When the newly created thread runs initially, it begins by executing this function.

You can use the `threadParam` parameter to pass thread-specific information to a newly created or allocated thread. In the data structure pointed to by this parameter, you could place something like A5 information or the address of a window to update. You could also use this parameter to specify a place for a thread's local storage.

Be sure to create the storage for the `threadResult` parameter in a place that is guaranteed to be available when the thread terminates—for example, in an application global variable or in a local variable of the application's main function (the main thread, by definition, cannot be disposed of so it is always available). Do not create the storage in a local variable of a subfunction that completes before the thread terminates or the storage will become invalid.

For Carbon applications, the pointer to your thread entry function must be a universal procedure pointer (UPP).

To dispose of a thread, use the DisposeThread function.

See the description of the `Thread Option Constants` (page 2132) data type for details on the characteristics you can specify in the `options` parameter.

For more information about the thread entry function, see the `ThreadEntryProcPtr` (page 2122) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Carbon Porting Notes

For Carbon applications, you must create and pass a universal procedure pointer (UPP) to specify the new thread callback. Use the `NewThreadEntryUPP` (page 2106) and `DisposeThreadEntryUPP` (page 2092) functions to create and remove the UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewThreadEntryUPP

```
ThreadEntryUPP NewThreadEntryUPP (
   ThreadEntryProcPtr userRoutine
);
```

Parameters

`userRoutine`

Return Value

See the description of the `ThreadEntryUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewThreadSchedulerUPP

```
ThreadSchedulerUPP NewThreadSchedulerUPP (
   ThreadSchedulerProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `ThreadSchedulerUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

NewThreadSwitchUPP

```
ThreadSwitchUPP NewThreadSwitchUPP (
   ThreadSwitchProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `ThreadSwitchUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

NewThreadTerminationUPP

```
ThreadTerminationUPP NewThreadTerminationUPP (
   ThreadTerminationProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `ThreadTerminationUPP` data type.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

SetDebuggerNotificationProcs

Installs functions that notify the debugger when a thread is created, disposed of, or scheduled.

Modified

```
OSErr SetDebuggerNotificationProcs (
   DebuggerNewThreadTPP notifyNewThread,
   DebuggerDisposeThreadTPP notifyDisposeThread,
   DebuggerThreadSchedulerTPP notifyThreadScheduler
);
```

Parameters

notifyNewThread

A pointer to the callback function that notifies the debugger when a thread is created.

notifyDisposeThread

A pointer to the callback function that notifies the debugger when a thread is disposed of. This function is called whether you manually dispose of a thread with the `DisposeThread` function or if a thread disposes of itself automatically when it returns from its highest level of code.

notifyThreadScheduler

A pointer to the callback function that notifies the debugger when a thread is scheduled.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
You generally use this function only during development of an application.

The `SetDebuggerNotificationProcs` function installs three separate callback functions that return the thread ID of a newly created thread, the thread ID of a newly disposed of thread, and the thread ID of a newly scheduled thread.

The `SetDebuggerNotificationProcs` function always installs all three of the debugging functions. You cannot set only one or two of these functions, nor can you chain them together. These restrictions ensure that the function that calls `SetDebuggerNotificationProcs` owns all three of the debugging functions. If you want to prevent one or two of these debugging functions from being called, you can do so by setting them to `NULL`.

To guarantee that the debugger is getting an accurate view of scheduling, the Thread Manager doesn't call the scheduling-notification callback function until both the generic Thread Manager scheduler and any custom thread scheduler have decided on a thread to schedule.

For Carbon applications, the pointers you pass to specify the callbacks must be universal procedure pointers (UPPs).

To create or allocate a new thread, use the `NewThread` (page 2104) function.

To dispose of a thread, use the `DisposeThread` function.

To schedule a thread, you can use a yield function such as `YieldToAnyThread` (page 2118) or `YieldToThread` (page 2119) or a function to change the state of a thread, such as `SetThreadState` (page 2112).

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Carbon Porting Notes

For Carbon applications, you must create and pass a universal procedure pointer (UPP) to specify the notification callbacks. You must use the designated UPP creation and disposal functions. For example, for the new thread notifier, you call the `NewDebuggerNewThreadUPP` (page 2104) and `DisposeDebuggerNewThreadUPP` (page 2090) functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

SetThreadReadyGivenTaskRef

Changes the state of a thread from stopped to ready when your application is not the current process.

```
OSErr SetThreadReadyGivenTaskRef (
   ThreadTaskRef threadTRef,
   ThreadID threadToSet
);
```

Parameters

threadTRef

The thread task reference of the application containing the thread whose state you want to change.

threadToSet

The thread ID of the thread whose state you want to change.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

When you mark a thread as ready to run with this function, the Thread Manager does not put it immediately into the scheduling queue but does so the next time it reschedules threads.

You can use `SetThreadStateGivenTaskRef` at times when you aren't guaranteed that your application is the current context, such as during execution of an interrupt function. In such cases you must identify the thread task reference (the application context) as well as the thread ID.

You obtain the thread task reference for your application with the `GetThreadCurrentTaskRef` (page 2097) function.

The `SetThreadReadyGivenTaskRef` function allows you to do one thing only—change a thread from stopped to ready to execute. You cannot change the state of an executing thread to ready or stopped, nor can you change the state of a ready thread to executing or stopped with this call.

To determine the state of a thread when your application is not the current process, use the `GetThreadStateGivenTaskRef` (page 2099) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

SetThreadScheduler

Installs a custom scheduling function (custom scheduler).

Modified

```
OSErr SetThreadScheduler (
   ThreadSchedulerTPP threadScheduler
);
```

Parameters

threadScheduler

A pointer to a custom scheduler. Specify `NULL` if you want to remove an installed custom scheduler and use the default Thread Manager scheduling mechanism.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

The `SetThreadScheduler` function installs a custom scheduler that runs in conjunction with the default Thread Manager scheduling mechanism. The Thread Manager uses a scheduler information structure to pass the custom scheduler the ID of the current thread and the ID of the thread that the Thread Manager has scheduled to run next.

A custom scheduler should return to the Thread Manager the ID of the thread that it determines to schedule. If it does not determine a particular thread to schedule, it should return the constant `kNoThreadID` and the Thread Manager default scheduling mechanism schedules the next thread.

If you already have a custom scheduler installed when you call `SetThreadScheduler`, it replaces the old one with a new one. If you want to remove your custom scheduler and return to using the default Thread Manager scheduling mechanism, call `SetThreadScheduler` and specify a value of `NULL` for the parameter.

The `SetThreadScheduler` function automatically disables scheduling to avoid any reentrancy problems with the custom scheduling function. Therefore, in your custom scheduling function, you should make no yield calls or other calls that would cause scheduling to occur.

For Carbon applications, the pointer to your thread scheduler function must be a universal procedure pointer (UPP).

For more information on the custom scheduling function, see the `ThreadSchedulerProcPtr` (page 2123) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Carbon Porting Notes

For Carbon applications, you must create and pass a universal procedure pointer (UPP) to specify the thread scheduler callback. Use the `NewThreadSchedulerUPP` (page 2107) and `DisposeThreadSchedulerUPP` (page 2093) functions to create and remove the UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

SetThreadState

Changes the state of any thread.

```
OSErr SetThreadState (
   ThreadID threadToSet,
   ThreadState newState,
   ThreadID suggestedThread
);
```

Parameters

threadToSet

The thread ID of the thread whose state is to be changed.

newState

The new state for the thread. You can specify ready to execute (`kReadyThreadState`), stopped (`kStoppedThreadState`), or executing (`kRunningThreadState`).

suggestedThread

The thread ID of the next thread to run. You specify this thread if you are changing the state of the currently executing thread to stopped or ready to run. Pass `kNoThreadID` if you do not want to specify a particular thread to run next. In this case, the Thread Manager schedules the next available thread to run.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

The effect of `SetThreadState` depends on whether the thread you specify for changing is the currently executing thread or another thread. If you specify the current thread and thus change the state to stopped or ready, `SetThreadState` invokes the Thread Manager scheduling mechanism. The current thread relinquishes control (it is put in the state you specify, stopped or ready) and the Thread Manager schedules the thread that you specify with the `suggestedThread` parameter. If this thread is unavailable for running, or if you passed `kNoThreadID`, the Thread Manager schedules the next available thread.

If you change the state of the current thread to ready, the Thread Manager suspends it awaiting of the CPU. When it is rescheduled, `SetThreadState` regains control and returns to the function that called it.

If you have installed a custom scheduler, the Thread Manager passes it the thread ID of the suspended thread.

If you specify a thread other than the currently executing thread, no rescheduling occurs. If you change the state from ready to stopped, the thread is removed from the scheduling queue. The Thread Manager does not schedule this thread for execution again until you change its state to ready. On the other hand, if you change the state from stopped to ready, you have in effect put the thread in the scheduling queue, and the Thread Manager gives it CPU time as soon as it reaches the top of the scheduling queue.

Threads must yield in the CPU addressing mode (24-bit or 32-bit) in which the application was launched.

To obtain the state of any thread, use the `GetThreadState` (page 2098) function.

To relinquish control to the next available thread, use the `YieldToAnyThread` (page 2118) function. To relinquish control to a specific thread, use the `YieldToThread` (page 2119) function.

To set the state of the current thread before it exits a critical section of code, use the `SetThreadStateEndCritical` (page 2113) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

SetThreadStateEndCritical

Changes the state of the current thread and exits that thread's critical section at the same time.

```
OSErr SetThreadStateEndCritical (
   ThreadID threadToSet,
   ThreadState newState,
   ThreadID suggestedThread
);
```

Parameters

threadToSet

The thread ID of the thread whose state is to be changed.

newState

The new state for the thread. You can specify ready to execute (`kReadyThreadState`), stopped (`kStoppedThreadState`) or executing (`kRunningThreadState`).

suggestedThread

The thread ID of the next thread to run. You specify this thread if you are changing the state of the currently executing thread to stopped or ready to run. Pass `kNoThreadID` if you do not want to specify a particular thread to run next. In this case, the Thread Manager schedules the next available thread to run.

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

The `SetThreadStateEndCritical` function does in one step the same thing that `ThreadEndCritical` and `SetThreadState` functions do in two steps.

Historically, the primary purpose of the `SetThreadStateEndCritical` function was to close the scheduling window at the end of a critical section. A preemptive thread that was waiting while the critical section of code was executing could begin executing before you changed the state of the current thread to stopped with the `SetThreadState` function. Obviously, because the Thread Manager no longer supports preemptive threads, this function is no longer necessary to close the scheduling window, but you can still use it to change the state of a thread and exit a critical section in one step instead of two.

When you change the state of the currently executing thread, the Thread Manager schedules the thread you specify with the `suggestedThread` parameter. If this thread is unavailable or if you pass `kNoThreadID`, the Thread Manager schedules the next available thread.

To mark a section of code as critical, use the `ThreadBeginCritical` (page 2116) and the `ThreadEndCritical` (page 2118) functions.

To change the state of any thread, use the `SetThreadState` (page 2112) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

SetThreadSwitcher

Installs a custom context-switching function for any thread.

Modified

```
OSErr SetThreadSwitcher (
   ThreadID thread,
   ThreadSwitchTPP threadSwitcher,
   void *switchProcParam,
   Boolean inOrOut
);
```

Parameters

thread

The thread ID of the thread to associate with a context-switching function.

threadSwitcher

A pointer to the context-switching function.

switchProcParam

A pointer to a thread-specific parameter that you pass to the context-switching function.

inOrOut

A Boolean value that indicates whether the Thread Manager calls the context-switching function when the specified thread switches in (`True`) or when it is switched out by another thread (`False`).

Return Value

A result code. See "Thread Manager Result Codes" (page 2134).

Discussion

The custom switching function allows you to save context information in addition to the default context information that the Thread Manager automatically saves when it switches contexts. The default context information consists of the CPU registers, the FPU registers (if any), and the location of the thread's context.

You must actually define two context-switching functions, one for leaving a thread and another for entering a thread. When leaving a thread, you call the outer context-switching function to save additional context information. When reentering a thread, you call the inner context-switching function to restore the extra information that was saved on exit. Use the `inOrOut` parameter of the `SetThreadSwitcher` function to specify which type of context-switching function is being installed.

You can pass a different `switchProcParam` parameter to each thread, which allows you to write a single, application-wide custom switching function and then pass any thread-specific information when the Thread Manager calls the switching function for that thread.

The `SetThreadSwitcher` function automatically disables scheduling to avoid any reentrancy problems with the custom switching function. Therefore, in the custom switching function, you should make no yield calls or other calls that would cause scheduling to occur.

For Carbon applications, the pointer to your thread switcher function must be a universal procedure pointer (UPP).

For more information on the custom context-switching function, see the `ThreadSwitchProcPtr` (page 2124) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Carbon Porting Notes

For Carbon applications, you must create and pass a universal procedure pointer (UPP) to specify the thread switcher callback. Use the `NewThreadSwitchUPP` (page 2107) and `DisposeThreadSwitchUPP` (page 2093) functions to create and remove the UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

SetThreadTerminator

Installs a custom thread-termination function for a thread.

Modified

```
OSErr SetThreadTerminator (
   ThreadID thread,
   ThreadTerminationTPP threadTerminator,
   void *terminationProcParam
);
```

Parameters

thread

The thread ID of the thread to associate with the thread-termination function.

threadTerminator
A pointer to the thread-termination function.

terminationProcParam
A pointer to a thread-specific parameter that you pass to the thread-termination function.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The Thread Manager calls the custom termination function whenever the specified thread completes execution of its code or when you manually dispose of the thread with the `DisposeThread` (page 2091) function.

You can pass a different `terminationProcParam` parameter to each thread, which allows you to write a single, application-wide custom thread-termination function and then pass any thread-specific information when the Thread Manager calls the termination function for that thread.

For Carbon applications, the pointer to your thread terminator function must be a universal procedure pointer (UPP).

For more information on the custom thread-termination function, see the `ThreadTerminationProcPtr` (page 2125) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Carbon Porting Notes

For Carbon applications, you must create and pass a universal procedure pointer (UPP) to specify the thread terminator callback. Use the `NewThreadTerminationUPP` (page 2108) and `DisposeThreadTerminationUPP` (page 2094) functions to create and remove the UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

ThreadBeginCritical

Indicates that the thread is entering a critical code section.

```
OSErr ThreadBeginCritical (
   void
);
```

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The `ThreadBeginCritical` function disables scheduling by marking the beginning of a section of critical code. That is, no other threads in the current application can run—even if the current thread yields control—until the current thread exits the critical section (by calling the `ThreadEndCritical` function). Disabling scheduling allows the currently executing function to look at or change shared or global data safely. You can nest critical sections within a thread.

To mark the end of a critical code section and turn scheduling back on, use the `ThreadEndCritical` (page 2118) function. If you also need to set the state of the current thread before scheduling is turned back on, use the `SetThreadStateEndCritical` (page 2113) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

ThreadCurrentStackSpace

Determines the amount of stack space that is available for any thread in your application.

```
OSErr ThreadCurrentStackSpace (
   ThreadID thread,
   ByteCount *freeStack
);
```

Parameters

thread
The thread ID of the thread about which you want information.

freeStack
On return, a pointer to the amount of stack space (in bytes) that is available to the specified thread.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
This function is primarily useful during debugging since you determine the maximum amount of stack space you need for any particular thread before you ship your application. However, if your application calls a recursive function that could call itself many times, you might want to use `ThreadCurrentStackSpace` to keep track of the stack space and take appropriate action if it becomes too low.

To determine the default size that the Thread Manager assigns to threads use the `GetDefaultThreadStackSize` (page 2095) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

ThreadEndCritical

Indicates that the thread is leaving a critical code section.

```
OSErr ThreadEndCritical (
   void
);
```

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
After a call to the Thread, all scheduling operations are now available to the application.

Use the `ThreadBeginCritical` (page 2116) function to mark the beginning of a critical code section and turn scheduling off.

If you need to set the state of the current thread before scheduling is turned back on, use the `SetThreadStateEndCritical` (page 2113) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

YieldToAnyThread

Relinquishes the current thread's control.

```
OSErr YieldToAnyThread (
   void
);
```

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The `YieldToAnyThread` function invokes the Thread Manager's scheduling mechanism. The current thread relinquishes control and the Thread Manager schedules the next available thread.

The current thread is suspended in the ready state and awaits rescheduling when the CPU is available. When the suspended thread is scheduled again, `YieldToAnyThread` regains control and returns to the function that called it.

If you have installed a custom scheduler, the Thread Manager passes it the thread ID of the suspended thread.

In each thread you must make one or more strategically placed calls to relinquish control to another thread. You can either make this yield call or another yield call such as `YieldToThread`; or you can make a call such as `SetThreadState` to explicitly change the state of the thread.

Threads must yield in the CPU addressing mode (24-bit or 32-bit) in which the application was launched.

To relinquish control to a specific thread, use the `YieldToThread` (page 2119) function.

To change the state of a specified thread, use the `SetThreadState` (page 2112) function.

Special Considerations

Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Threads.h`

YieldToThread

Relinquishes the current thread's control to a particular thread.

```
OSErr YieldToThread (
   ThreadID suggestedThread
);
```

Parameters

`suggestedThread`
The ID of the thread to yield control to.

Return Value
A result code. See "Thread Manager Result Codes" (page 2134).

Discussion
The `YieldToThread` function invokes the Thread Manager's scheduling mechanism. The current thread relinquishes control and passes the thread ID of a thread for the Thread Manager to schedule. The Thread Manager schedules this thread if it is available. Otherwise, the Thread Manager schedules the next available thread.

The current thread is suspended in the ready state and awaits rescheduling when the CPU is available. When the suspended thread is scheduled again, `YieldToThread` regains control and returns to the function that called it.

If you have installed a custom scheduler, the Thread Manager passes it the thread ID of the suspended thread.

In each thread you must make one or more strategically placed calls to relinquish control to another thread. You can either make this yield call or another yield call such as `YieldToAnyThread`; or you can make a call such as `SetThreadState` to explicitly change the state of the thread.

Threads must yield in the CPU addressing mode (24-bit or 32-bit) in which the application was launched.

To relinquish control without naming a specific thread, use the `YieldToAnyThread` (page 2118) function.

To change the state of a specified thread, use the `SetThreadState` (page 2112) function.

Special Considerations
Active development with the Thread Manager is not recommended. The API is intended only for developers who are porting their applications to Mac OS X and whose code relies on the cooperative threading model. If you are writing a new Carbon application, you should use POSIX threads or the Multiprocessing Services API instead. See *Threading Programming Guide* for more information.

Availability
Available in Mac OS X v10.0 and later.

Callbacks

DebuggerDisposeThreadProcPtr

Defines a pointer to a dispose thread debugging callback function. A dispose thread debugging callback function is a debugging function that the Thread Manager calls whenever it disposes of a thread.

```
typedef void (*DebuggerDisposeThreadProcPtr)
(
    ThreadID threadDeleted
);
```

If you name your function `MyDebuggerDisposeThreadProc`, you would declare it like this:

```
void MyDebuggerDisposeThreadProcPtr (
    ThreadID threadDeleted
);
```

Parameters

threadDeleted

The thread ID of the thread being disposed of.

Return Value

Discussion

The `MyDebuggerDisposeThreadCallback` function is one of three debugging functions that you can install with the `SetDebuggerNotificationProcs` (page 2108) function. The Thread Manager calls `MyDebuggerDisposeThreadCallback` whenever an application disposes of a thread. The thread manager calls this debugging function whether you manually call `DisposeThread` (page 2091) to dispose of a thread or if a thread finishes executing its code and the Thread Manager automatically disposes of it.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DebuggerNewThreadProcPtr

Defines a pointer to a new thread debugging callback function. A new thread debugging callback function is a debugging function that the Thread Manager calls whenever it creates a new thread.

```
typedef void (*DebuggerNewThreadProcPtr)
(
    ThreadID threadCreated
);
```

If you name your function `MyDebuggerNewThreadProc`, you would declare it like this:

```
void MyDebuggerNewThreadProcPtr (
    ThreadID threadCreated
);
```

Parameters

threadCreated

The thread ID of the thread being created.

Return Value

Discussion

The `MyDebuggerNewThreadCallback` function is one of three debugging functions that you can install with the `SetDebuggerNotificationProcs` (page 2108) function. The Thread Manager calls `MyDebuggerNewThreadCallback` whenever an application creates or allocates a new thread with the `NewThread` (page 2104) function. The Thread Manager does not call `MyDebuggerNewThreadCallback` when an application creates a thread pool with the `CreateThreadPool` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

DebuggerThreadSchedulerProcPtr

Defines a pointer to a thread scheduler debugging callback function. A thread scheduler debugging callback function is a debugging function that the Thread Manager calls whenever a thread is scheduled.

```
typedef ThreadID (*DebuggerThreadSchedulerProcPtr)
(
    SchedulerInfoRecPtr schedulerInfo
);
```

If you name your function `MyDebuggerThreadSchedulerProc`, you would declare it like this:

```
ThreadID MyDebuggerThreadSchedulerProcPtr
(
    SchedulerInfoRecPtr schedulerInfo
);
```

Parameters

schedulerInfo

A pointer to a scheduler information structure that the `SetDebuggerNotificationProcs` function passes to the `MyDebuggerThreadSchedulerCallback` function. Among other information, the scheduler information structure contains the ID of the current thread and the ID of the thread that the Thread Manager has scheduled to run next.

Return Value

See the description of the `ThreadID` data type.

Discussion

The `MyDebuggerThreadSchedulerCallback` function is one of three debugging functions that you can install with the `SetDebuggerNotificationProcs` (page 2108) function. The Thread Manager calls `MyDebuggerThreadSchedulerCallback` whenever an application schedules a new thread to run. The `MyDebuggerThreadSchedulerCallback` function gets the last look at the thread being scheduled—that is, the Thread Manager calls this function after the Thread Manager default scheduling mechanism and a custom scheduler, if you have installed one, decide on the next thread to schedule.

If you wish, you can use this debugging callback function to schedule a different thread than that chosen by the Thread Manager and any custom scheduling function. The `MyDebuggerThreadSchedulerCallback` returns the thread ID of the next thread to schedule. The `MyDebuggerThreadSchedulerCallback` can specify `kNoThreadID` for the thread ID if you do not want to change the decision of the Thread Manager default scheduler or a custom scheduler.

To schedule a thread, use functions such as `YieldToAnyThread` (page 2118) , `YieldToThread` (page 2119) , and `SetThreadState` (page 2112).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

ThreadEntryProcPtr

Defines a pointer to a thread entry callback function. Your thread entry callback function provides an entry point to a thread that you create in your application.

```
typedef voidPtr (*ThreadEntryProcPtr)
(
    void * threadParam
);
```

If you name your function `MyThreadEntryProc`, you would declare it like this:

```
voidPtr MyThreadEntryProcPtr (
    void * threadParam
);
```

Parameters

threadParam

A pointer to a `void` data structure passed to this function by the `NewThread` function.

Return Value

Discussion

When you create or allocate a new thread with the `NewThread` function, you pass the name of this entry function. You also pass a parameter that the Thread Manager passes on to the `MyThreadEntryCallback` function. You can use this parameter to pass thread-specific information to the newly created or allocated thread. For example, you could pass something like A5 information or the address of a window to update. Or you could use this parameter to specify local storage for a thread that other threads could access.

When the code in a thread finishes executing, the Thread Manager automatically calls the `DisposeThread` (page 2091) function to dispose of the thread. The `MyThreadEntryCallback` function passes its function result to `DisposeThread`. The `DisposeThread` function passes this result back to the `NewThread` function that called `MyThreadEntryCallback` to begin with.

This mechanism allows you to spawn a thread that does some work and then continue with your original thread. When the spawned thread is finished doing its work—for example a calculation—it returns the result to the original thread.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

ThreadSchedulerProcPtr

Defines a pointer to a thread scheduler callback function. Your thread scheduler callback function supplements the Thread Manager default scheduling mechanism.

```
typedef ThreadID (*ThreadSchedulerProcPtr)
(
    SchedulerInfoRecPtr schedulerInfo
);
```

If you name your function `MyThreadSchedulerProc`, you would declare it like this:

```
ThreadID MyThreadSchedulerProcPtr (
    SchedulerInfoRecPtr schedulerInfo
);
```

Parameters

schedulerInfo

A pointer to the scheduler information structure that the Thread Manager uses to pass information to `MyThreadSchedulerCallback`.

Return Value

See the description of the `ThreadID` data type.

Discussion

The `MyThreadSchedulerCallback` function does not supplant the Thread Manager scheduling mechanism but rather works in conjunction with it.

Whenever scheduling occurs, the Thread Manager passes a scheduler information structure to `MyThreadSchedulerCallback`. Among other information, the scheduler information structure contains the thread ID of the current thread and the thread ID of the thread that the application has scheduled to run next.

The `MyThreadSchedulerCallback` function returns to the Thread Manager the thread ID of the thread that it has chosen to schedule and the Thread Manager does the actual scheduling. If `MyThreadSchedulerCallback` decides not to schedule a thread, it returns the constant `kNoThreadID` and the Thread Manager default scheduling mechanism schedules the next thread.

When the `SetThreadScheduler` function installs the custom scheduler, it automatically disables scheduling to avoid any reentrancy problems. Therefore, in the custom scheduler, you should make no yield calls or other calls that would cause scheduling to occur.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

ThreadSwitchProcPtr

Defines a pointer to a thread switch callback function. Your thread switch callback function adds to the thread context information that the Thread Manager saves and restores.

```
typedef void (*ThreadSwitchProcPtr) (
    ThreadID threadBeingSwitched,
    void * switchProcParam
);
```

If you name your function `MyThreadSwitchProc`, you would declare it like this:

```
void MyThreadSwitchProcPtr (
    ThreadID threadBeingSwitched,
    void * switchProcParam
);
```

Parameters

threadBeingSwitched

The thread ID of the thread whose context is being switched.

switchProcParam

A pointer to a parameter that the `SetThreadSwitcher` function passes to `MyThreadSwitchCallback`.

Return Value

Discussion

The custom switching function allows you to save and restore context information in addition to the default context information that the Thread Manager automatically saves and restores when it switches contexts. You must actually define two context-switching functions, one for leaving a thread and another for entering a thread. When leaving a thread, you call the outer context-switching function to save additional context information. When reentering a thread, you call the inner context-switching function to restore the extra information that was saved on exit.

The default context information consists of the CPU registers, the FPU registers (if any), and the location of the thread's context.

When the `SetThreadSwitcher` function installs the custom switching function, it automatically disables scheduling to avoid any reentrancy problems. Therefore, in the custom switching function, you should make no yield calls or other calls that would cause scheduling to occur.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Threads.h`

ThreadTerminationProcPtr

Defines a pointer to a thread termination callback function. Your thread termination callback function does additional cleanup when the code in a thread finishes executing.

```
typedef void (*ThreadTerminationProcPtr)
(
    ThreadID threadTerminated,
    void * terminationProcParam
);
```

If you name your function `MyThreadTerminationProc`, you would declare it like this:

```
void MyThreadTerminationProcPtr (
    ThreadID threadTerminated,
    void * terminationProcParam
);
```

Parameters

threadTerminated

The thread ID of the thread being disposed of.

terminationProcParam

A pointer to a `void` data structure that the `SetThreadTerminator` function passes to `MyThreadTerminationCallback`.

Return Value

Discussion
You use the `SetThreadTerminator` function to install the `MyThreadTerminationCallback` custom termination function. The custom termination function allows you to do additional cleanup when the code in a thread finishes executing or when you call the `DisposeThread` (page 2091) function to manually dispose of a thread.

Availability
Available in Mac OS X v10.0 and later.

SchedulerInfoRec

```
struct SchedulerInfoRec {
    UInt32 InfoRecSize;
    ThreadID CurrentThreadID;
    ThreadID SuggestedThreadID;
    ThreadID InterruptedCoopThreadID;
};
typedef struct SchedulerInfoRec SchedulerInfoRec;
typedef SchedulerInfoRec * SchedulerInfoRecPtr;
```

Fields

`InfoRecSize`
The size of the structure.

`CurrentThreadID`
The thread ID of the current thread.

`SuggestedThreadID`
The thread ID of the thread that the application has suggested to run.

`InterruptedCoopThreadID`
Historically, the thread ID of a preempted cooperative thread if a cooperative thread has been interrupted and has not yet resumed execution. Because it no longer supports preemptive threads, the Thread Manager always passes the constant `kNoThreadID` to indicate that there is no thread that has been interrupted.

Discussion

You can, if you wish, use the `SetThreadScheduler` (page 2110) function to install a custom scheduling function to work in conjunction with the default Thread Manager scheduling mechanism. The Thread Manager uses the scheduler information structure to pass information to the custom scheduling function that allows it to decide which thread, if any, to schedule next.

Availability

Declared In
`Threads.h`

ThreadTaskRef

Represents a thread task reference.

```
typedef void* ThreadTaskRef;
```

Discussion
In certain cases, such as during execution of an interrupt function, your application is not guaranteed to be the current process. Since threads are defined within an application context, it follows that in cases such as these, you cannot get or set information about any particular threads in your application unless you have a way of identifying the application context. The thread task reference gives you a way of doing this.

You can obtain the thread task reference by calling `GetThreadCurrentTaskRef` (page 2097) at a time when you know your application is the current context. Later, during execution of an interrupt function, you can use the thread task reference to identify your application. For example, you can pass the thread task reference to functions such as `GetThreadStateGivenTaskRef` (page 2099) and `SetThreadReadyGivenTaskRef` (page 2110) in an interrupt function to get and set information about the state of particular threads in your application.

Availability
Available in Mac OS X v10.0 and later.

Constants

Thread ID Constants

The `ThreadID` data type defines the thread ID.

```
typedef UInt32 ThreadID;
enum {
    kNoThreadID = 0,
    kCurrentThreadID = 1,
    kApplicationThreadID = 2
};
```

Constants

`kNoThreadID`
Indicates no thread; for example, you can use a function such as `SetThreadState` (page 2112) to put the current thread in the stopped state and pass `kNoThreadID` to indicate that you don't care which thread runs next.

Available in Mac OS X v10.0 and later.

Declared in `Threads.h`.

`kCurrentThreadID`
Identifies the currently executing thread.

Available in Mac OS X v10.0 and later.

Declared in `Threads.h`.

`kApplicationThreadID`
Identifies the main application thread this is the cooperative thread that the Thread Manager creates at launch time. You cannot dispose of this thread. All applications—even those that are not aware of the Thread Manager—have one main application thread. The Thread Manager assumes that the main application thread is responsible for event gathering when an operating-system event occurs, the Thread Manager schedules the main application thread as the next thread to execute.

Available in Mac OS X v10.0 and later.

Declared in `Threads.h`.

Discussion
The Thread Manager assigns a thread ID to each thread that you create or allocate with the `NewThread` (page 2104) function. The thread ID uniquely identifies a thread within an application context. You can use the thread ID in functions that schedule execution of a particular thread, dispose of a thread, and get and set information about a thread; for example, you pass the thread ID to functions such as `YieldToThread` (page 2119) , `DisposeThread` (page 2091) , and `GetThreadState` (page 2098) .

In addition to the specific thread IDs that the `NewThread` function returns, you can use the three Thread Manager constants described here.

Thread Option Constants

```
typedef UInt32 ThreadOptions;
enum {
    kNewSuspend = (1 << 0),
    kUsePremadeThread = (1 << 1),
    kCreateIfNeeded = (1 << 2),
    kFPUNotNeeded = (1 << 3),
    kExactMatchThread = (1 << 4)
};
```

Constants

`kNewSuspend`
Begin a new thread in the stopped state.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kUsePremadeThread`
Use a thread from the existing supply.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kCreateIfNeeded`
Create a new thread if one with the proper style and stack size requirements does not exist.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kFPUNotNeeded`
Do not save the FPU context. This saves time when switching contexts. Note, however, that for PowerPC threads, the Thread Manager always saves the FPU registers regardless of how you set this option. Because the PowerPC microprocessor uses the FPU registers for optimizations, they could contain necessary information.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kExactMatchThread`
Allocate a thread from the pool only if it exactly matches the stack-size request. Without this option, a thread is allocated that best fits the request—that is, a thread whose stack is greater than or equal to the requested size.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

Discussion
When you create or allocate a new thread with the `NewThread` (page 2104) function, you can specify thread options that define certain characteristics of the thread, using the values described here. To specify more than one option, you sum them together and pass them as a single parameter to the `NewThread` function.

The `ThreadOptions` data type defines the thread options.

Thread State Constants

```
typedef UInt16 ThreadState;
enum {
    kReadyThreadState = 0,
    kStoppedThreadState = 1,
    kRunningThreadState = 2
};
```

Constants
`kReadyThreadState`
The thread is ready to run.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kStoppedThreadState`
The thread is stopped and not ready to run.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kRunningThreadState`
The thread is running.
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

Discussion
The Thread Manager functions which get and set information about the state of a thread, such as `GetThreadState` (page 2098) and `SetThreadState` (page 2112) , use these values.

Thread Style Constants

```
typedef UInt32 ThreadStyle;
enum {
    kCooperativeThread = 1L << 0,
    kPreemptiveThread = 1L << 1
};
```

Constants
`kCooperativeThread`
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

`kPreemptiveThread`
Available in Mac OS X v10.0 and later.
Declared in `Threads.h`.

Discussion
Historically, the Thread Manager defined two types of threads to run in an application context: cooperative and preemptive, but now it supports only cooperative threads.

Although the Thread Manager only supports a single type of thread, many Thread Manager functions (for historical reasons) require you to use the thread type to specify the type of the thread.

The `ThreadStyle` data type specifies the type of a thread.

Because there is only one type of thread (cooperative) the thread type accepts a single value, `kCooperativeThread`.

Result Codes

The most common result codes returned by Thread Manager are listed below.

Result Code	Value	Description
`threadTooManyReqsErr`	-617	Available in Mac OS X v10.0 and later.
`threadNotFoundErr`	-618	Available in Mac OS X v10.0 and later.
`threadProtocolErr`	-619	Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Thread Manager selectors defined in the Gestalt Manager. For more information see Inside Mac OS X: Gestalt Manager Reference.

Time Manager Reference

Framework: CoreServices/CoreServices.h

Declared in Timer.h

Overview

The Time Manager allows applications and other software to schedule routines for execution at a later time. By suitably defining the routine that is to be executed later, you can use the Time Manager to accomplish a wide range of time-related activities. For example, because a routine can reschedule itself for later execution, the Time Manager allows your application to perform periodic or repeated actions. You can use the Time Manager to schedule routines for execution after a specified delay; set up tasks that run periodically; compute the time a routine takes to run; and coordinate and synchronize actions in the Macintosh computer.

The Time Manager provides a hardware-independent method of performing these time-related tasks. In general, you should use the Time Manager instead of timing loops, which can vary in duration because they depend on clock speed and interrupt-handling speed.

Carbon supports the Time Manager. However, the interface for callbacks will change because the current task record is accessible only from 68K code.

Functions by Task

Installing and Removing Tasks

`InstallTimeTask` (page 2137) Deprecated in Mac OS X v10.4
: Installs a task structure into the Time Manager task queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`InstallXTimeTask` (page 2138) Deprecated in Mac OS X v10.4
: Installs a task, taking advantage of the drift-free, fixed-frequency timing services of the extended Time Manager. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`RemoveTimeTask` (page 2143) Deprecated in Mac OS X v10.4
: Removes a task from the Time Manager queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Activating Tasks

`PrimeTimeTask` (page 2142) Deprecated in Mac OS X v10.4
Activates a task in the Time Manager queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Measuring Time

`Microseconds` (page 2141)
Determines the number of microseconds that have elapsed since system startup time.

Working With Your Time Manager Callback Function

`NewTimerUPP` (page 2141)
Creates a new universal procedure pointer (UPP) to your Time Manager task callback. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`InvokeTimerUPP` (page 2140)
Invokes your Time Manager task callback function. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`DisposeTimerUPP` (page 2137)
Disposes of the universal procedure pointer (UPP) to your Time Manager task callback function. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Obsolete Functions

`InsTime` (page 2139) Deprecated in Mac OS X v10.4
Installs a task record into the Time Manager task queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`InsXTime` (page 2139) Deprecated in Mac OS X v10.4
Installs an extended task record into the Time Manager task queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`PrimeTime` (page 2142) Deprecated in Mac OS X v10.4
Activates a task in the Time Manager queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

`RmvTime` (page 2144) Deprecated in Mac OS X v10.4
Remove a task from the Time Manager queue. (Deprecated. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Functions

DisposeTimerUPP

Disposes of the universal procedure pointer (UPP) to your Time Manager task callback function. (**Deprecated.** Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
void DisposeTimerUPP (
   TimerUPP userUPP
);
```

Parameters

userUPP

A UPP to your callback function.

Discussion

See the callback `TimerProcPtr` (page 2145) for more information.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Timer.h`

InstallTimeTask

Installs a task structure into the Time Manager task queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
OSErr InstallTimeTask (
   QElemPtr tmTaskPtr
);
```

Parameters

tmTaskPtr

A pointer to an original task structure to be installed in the queue.

Return Value

A result code. See "Time Manager Result Codes" (page 2147).

Discussion

The `InstallTimeTask` function adds the Time Manager task structure specified by the `tmTaskPtr` parameter to the Time Manager queue. Your application should fill in the `tmAddr` field of the task structure and should set the `tmCount` field to 0. The `tmTaskPtr` parameter must point to an original Time Manager task structure.

With the revised and extended Time Managers, you can set the `tmAddr` field to `NULL` if you do not want a task to execute when the delay passed to the `PrimeTime` function expires. Also, the revised Time Manager resets the high-order bit of the `qType` field to 0 when you call the `InsTime` function.

The `InstallTimeTask` function, which returns a value of type `OSErr`, takes the place of `InsTime`.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0.2 and later when running Mac OS 9.1 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`Timer.h`

InstallXTimeTask

Installs a task, taking advantage of the drift-free, fixed-frequency timing services of the extended Time Manager. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
OSErr InstallXTimeTask (
   QElemPtr tmTaskPtr
);
```

Parameters

`tmTaskPtr`

A pointer to an extended task structure to be installed in the queue.

Return Value

A result code. See "Time Manager Result Codes" (page 2147).

Discussion

The `InstallXTimeTask` function adds the Time Manager task structure specified by `tmTaskPtr` to the Time Manager queue. Use `InstallXTimeTask` only if you wish to use the drift-free, fixed-frequency timing services of the extended Time Manager; use `InstallTimeTask` in all other cases. The `tmTaskPtr` parameter must point to an extended Time Manager task structure. Your application must fill in the `tmAddr` field of that task. You should set the `tmWakeUp` and `tmReserved` fields to 0 the first time you call `InsXTime`.

With the extended Time Manager, you can set `tmAddr` to `NULL` if you do not want a task to execute when the delay passed to `PrimeTime` expires. Also, `InsXTime` resets the high-order bit of the `qType` field to 0.

The `InstallXTimeTask` function, which returns a value of type `OSErr`, takes the place of InsXTime.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0.2 and later when running Mac OS 9.1 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`Timer.h`

InsTime

Installs a task record into the Time Manager task queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Not Recommended

```
void InsTime (
   QElemPtr tmTaskPtr
);
```

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`Timer.h`

InsXTime

Installs an extended task record into the Time Manager task queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Not Recommended

```
void InsXTime (
   QElemPtr tmTaskPtr
);
```

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Timer.h`

InvokeTimerUPP

Invokes your Time Manager task callback function. (**Deprecated.** Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
void InvokeTimerUPP (
   TMTaskPtr tmTaskPtr,
   TimerUPP userUPP
);
```

Parameters

tmTaskPtr
A pointer to a structure of type `TMTask` containing the information about the task.

userUPP
A UPP to your callback function.

Discussion
See the callback `TimerProcPtr` (page 2145) for more information.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Timer.h`

Microseconds

Determines the number of microseconds that have elapsed since system startup time.

```
void Microseconds (
   UnsignedWide *microTickCount
);
```

Parameters

microTickCount

The number of microseconds elapsed since system startup.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X 10.0 and later.

Declared In

`Timer.h`

NewTimerUPP

Creates a new universal procedure pointer (UPP) to your Time Manager task callback. (**Deprecated.** Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
TimerUPP NewTimerUPP (
   TimerProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your Time Manager event callback function. For information on how to create a Time Manager event callback see `TimerProcPtr` (page 2145)

Return Value

A UPP to your callback function. See the description of the `TimerUPP` data type.

Discussion

See the callback `TimerProcPtr` (page 2145) for more information.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Timer.h`

PrimeTime

Activates a task in the Time Manager queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Not Recommended

```
void PrimeTime (
   QElemPtr tmTaskPtr,
   long count
);
```

Discussion
This function is deprecated. You should use the function `PrimeTimeTask` (page 2142) instead.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Timer.h`

PrimeTimeTask

Activates a task in the Time Manager queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
OSErr PrimeTimeTask (
   QElemPtr tmTaskPtr,
   long count
);
```

Parameters

tmTaskPtr
A pointer to a task structure already installed in the queue.

count
The desired delay before execution of the task.

Return Value
A result code. See "Time Manager Result Codes" (page 2147).

Discussion
The `PrimeTimeTask` function schedules the task specified by the `tmAddr` field of the structure pointed to by the *tmTaskPtr* parameter for execution after the delay specified by the *count* parameter has elapsed.

If the *count* parameter is a positive value, it is interpreted as milliseconds. If *count* is a negative value, it is interpreted in negated microseconds. Microsecond delays are allowable only in the revised and extended Time Managers.

The task record specified by the *tmTaskPtr* parameter must already be installed in the queue (by a previous call to the functions `InstallTimeTask` (page 2137) or `InstallXTimeTask` (page 2138)) before your application calls the `PrimeTimeTask` function. The `PrimeTimeTask` function returns immediately, and the specified task is executed after the specified delay has elapsed. If you call the `PrimeTimeTask` function with a time delay of 0, the task runs as soon as interrupts are enabled.

In the revised and extended Time Managers, the `PrimeTimeTask` function sets the high-order bit of the `qType` field to 1. In addition, any value of the *count* parameter that exceeds the maximum millisecond delay is reduced to the maximum. If you stop an unexpired task (by calling the function `RemoveTimeTask` (page 2143)) and then reinstall it (by calling the `InstallXTimeTask` function), you can continue the previous delay by calling the `PrimeTimeTask` function with the *count* parameter set to 0.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability

Available in CarbonLib 1.0.2 and later when running Mac OS 9.1 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`Timer.h`

RemoveTimeTask

Removes a task from the Time Manager queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

```
OSErr RemoveTimeTask (
   QElemPtr tmTaskPtr
);
```

Parameters

tmTaskPtr

A pointer to a task structure to be removed from the queue.

Return Value

A result code. See "Time Manager Result Codes" (page 2147).

Discussion

The `RemoveTimeTask` function removes the Time Manager task structure specified by the *tmTaskPtr* parameter from the Time Manager queue. In both the revised and extended Time Managers, if the specified task record is active (that is, if it has been activated but the specified time has not yet elapsed), the `tmCount` field of the task structure returns the amount of time remaining. To provide the greatest accuracy, the unused

time is reported as negated microseconds if that value is small enough to fit into the `tmCount` field (even if the delay was originally specified in milliseconds); otherwise, the unused time is reported in positive milliseconds. If the time has already expired, the `tmCount` field contains 0.

In the revised and extended Time Managers, the `RemoveTimeTask` function sets the high-order bit of the `qType` field to 0.

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability
Available in CarbonLib 1.0.2 and later when running Mac OS 9.1 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Timer.h`

RmvTime

Remove a task from the Time Manager queue. (Deprecated in Mac OS X v10.4. Use Carbon Event Loop timers or Cocoa NSTImers instead.)

Not Recommended

```
void RmvTime (
   QElemPtr tmTaskPtr
);
```

Special Considerations

Carbon Event timers and Cocoa NSTimers provide a simpler and more efficient way to handle timed or periodic tasks. For more information about using Carbon Event timers, see the timers section in *Carbon Event Manager Programming Guide*. For information about NSTimers, see *Timer Programming Topics for Cocoa*. Both Carbon event timers and NSTimers are built on top of the lower-level Core Foundation CFRunLoop timers. For CFRunLoop information, see *Run Loops*.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Timer.h`

Callbacks

TimerProcPtr

Defines a pointer to your application-defined Time Manager task that is executed after a specified delay.

```
typedef void (*TimerProcPtr) (
    TMTaskPtr tmTaskPtr
);
```

If you name your function `MyTimerProc`, you would declare it like this:

```
void MyTimerProc (
    TMTaskPtr tmTaskPtr
);
```

Parameters

tmTaskPtr

A pointer to a structure of type `TMTask` containing the information about the task.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Timer.h`

Data Types

TimerUPP

Defines a data type for the `TimerProcPtr` callback function.

```
typedef TimerProcPtr TimerUPP;
```

Discussion

For more information, see the description of the `TimerProcPtr` (page 2145) callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Timer.h`

TMTask

Contains information for a Time Manager task.

```
struct TMTask {
    QElemPtr qLink;
    short qType;
    TimerUPP tmAddr;
    long tmCount;
    long tmWakeUp;
    long tmReserved;
};
typedef struct TMTask TMTask;
typedef TMTask * TMTaskPtr;
```

Fields

`qLink`

A pointer to the next element in the Time Manager queue. This field is used internally by the Time Manager.

`qType`

The type of queue. The Time Manager automatically sets this field to the appropriate value. The high-order bit of this field is a flag that indicates whether the task is active.

`tmAddr`

A pointer to the function that is to execute after the delay specified in a call to `PrimeTime`.

`tmCount`

Reserved in the original Time Manager. In the revised or extended Time Manager, the amount of time remaining until the task's scheduled execution time. This field is valid only after you call `RmvTime` with a task that has not yet executed.

`tmWakeUp`

In the extended Time Manager, the time when the task specified in the `tmAddr` field was last executed. This field is used internally by the Time Manager. You should set it to 0 when you first install a task structure.

`tmReserved`

Reserved.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Timer.h`

Constants

Active Task Constant

Defines a constant for an active task.

```
enum {
    kTMTaskActive = (1L << 15)
};
```

Constants

`kTMTaskActive`

The high bit of the `qType` field in the `TMTask` structure is set if the task is active.

Available in Mac OS X v10.0 and later.

Declared in `Timer.h`.

Result Codes

The most common result codes returned by Time Manager is `noErr`, which has a value of 0.

Gestalt Constants

You can check for version and feature availability information by using the Time Manager Version selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Unicode Utilities Reference

Framework: CoreServices/CoreServices.h
Declared in UnicodeUtilities.h

Overview

Unicode Utilities allow applications and text service components (such as input methods) to perform various operations on Unicode text; for example, Unicode key translation. Resources defined for use with Unicode Utilities permit control of Unicode-related text behavior, such as the specification of Unicode keyboard layouts.

Carbon fully supports the Unicode Utilities.

Functions by Task

Inputting Unicode Text

`UCKeyTranslate` (page 2162)
Converts a combination of a virtual key code, a modifier key state, and a dead-key state into a string of one or more Unicode characters.

Comparing Unicode Strings

`UCCreateCollator` (page 2155)
Creates an object encapsulating locale and collation information, for the purpose of performing Unicode string comparison.

`UCCompareText` (page 2151)
Uses locale-specific collation information to compare Unicode strings.

`UCGetCollationKey` (page 2160)
Uses locale-specific collation information to generate a collation key for a Unicode string.

`UCCompareCollationKeys` (page 2150)
Uses collation keys to compare Unicode strings.

`UCDisposeCollator` (page 2158)
Disposes a collator object.

`UCCompareTextDefault` (page 2153)
Uses the default system locale to compare Unicode strings.

`UCCompareTextNoLocale` (page 2154)
Uses a fixed, locale-insensitive order to compare Unicode strings.

Identifying Unicode Text Boundaries

`UCCreateTextBreakLocator` (page 2156)
Creates an object encapsulating locale and text-break information, for the purpose of finding boundaries in Unicode text.

`UCFindTextBreak` (page 2159)
Uses locale-specific text-break information to find boundaries in Unicode text.

`UCDisposeTextBreakLocator` (page 2158)
Disposes a text-break locator object.

Functions

UCCompareCollationKeys

Uses collation keys to compare Unicode strings.

```
OSStatus UCCompareCollationKeys (
   const UCCollationValue *key1Ptr,
   ItemCount key1Length,
   const UCCollationValue *key2Ptr,
   ItemCount key2Length,
   Boolean *equivalent,
   SInt32 *order
);
```

Parameters

key1Ptr
A pointer to the collation key (a `UCCollationValue` array) for the first string to compare. You can obtain a collation key with the function `UCGetCollationKey` (page 2160). The collation key supplied in `key1Ptr` for the first string must be generated with the same collator object as that used to generate the collation key supplied in `key2Ptr` for the second string.

key1Length
An `ItemCount` value specifying the actual length of the collation key supplied in the `key1Ptr` parameter. You can obtain this value from the function `UCGetCollationKey` (page 2160) when you obtain the new collation key.

key2Ptr
A pointer to the collation key (a `UCCollationValue` array) for the second string to compare. You can obtain a collation key with the function `UCGetCollationKey` (page 2160). The collation key supplied in `key2Ptr` for the second string must be generated with the same collator object as that used to generate the collation key supplied in `key1Ptr` for the first string.

key2Length
An `ItemCount` value specifying the actual length of the collation key supplied in the `key2Ptr` parameter. You can obtain this value from the function `UCGetCollationKey` (page 2160) when you obtain the new collation key.

equivalent

A pointer to a `Boolean` value or pass `NULL`. On return, `UCCompareCollationKeys` produces a value of `true` if the strings represented by the collation keys are equivalent for the options you have specified in the collator object. If you wish simply to sort a list of strings in order, using your specified options, you can pass `NULL` for the `equivalent` parameter and only use the `order` parameter's result. In this case, all available comparison criteria are used to put the strings in a deterministic order, even if they are considered "equivalent" for the options you have specified. Note that you can set either the `equivalent` or the `order` parameters to `NULL`, but not both.

order

A pointer to a signed, 32-bit integer value, or pass `NULL`. If you wish simply to test the strings represented by the collation keys for equivalence, using your specified options (which can be much faster than determining ordering), you can pass `NULL` for the `order` parameter and only use the `equivalent` parameter's result. (Note that either the `equivalent` or the `order` parameters may be `NULL`, but not both.

Return Value
A result code. This function can return `paramErr`, for example, if `key1Ptr` or `key2Ptr` are `NULL`.

Discussion
If you wish to compare the same strings several times, as when sorting a list of strings, it may be most efficient for you to derive a collation key for each string and then compare the collation keys. A collation key is a transformation of the string that depends on the collator object (that is, it depends on the locale, the collation variant if any, and the collation options).

Collation keys that are generated using the same collator object—but for different strings—can quickly be compared with each other, without further reference to the collator object or collation tables. The disadvantage is that the collation keys may be rather large. After you use the function `UCGetCollationKey` (page 2160) to create a collation key from a given string and collator object, you can call the `UCCompareCollationKeys` function to compare two collation keys that were generated with the same collator object.

If you are comparing different strings, it may be more efficient for you to call the function `UCCompareText` (page 2151) multiple times using the same collator object.

Note that collation keys should be used only in a runtime context. They should not be stored in a persistent state (such as to disk) because the format of a collation key could change in the future.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeUtilities.h`

UCCompareText

Uses locale-specific collation information to compare Unicode strings.

```
OSStatus UCCompareText (
   CollatorRef collatorRef,
   const UniChar *text1Ptr,
   UniCharCount text1Length,
   const UniChar *text2Ptr,
   UniCharCount text2Length,
   Boolean *equivalent,
   SInt32 *order
);
```

Parameters

collatorRef

A valid reference to a collator object; `NULL` is not allowed. You can use the function `UCCreateCollator` (page 2155) to obtain a collator reference.

text1Ptr

A pointer to the first Unicode string (a `UniChar` array) to compare.

text1Length

The total count of Unicode characters in the first string being compared.

text2Ptr

A pointer to the second Unicode string to compare.

text2Length

The total count of Unicode characters in the second string being compared.

equivalent

A pointer to a `Boolean` value or `NULL`. On return, `UCCompareText` produces a value of `true` if the strings are equivalent for the options you have specified in the collator object. If you wish simply to sort a list of strings in order, using your specified options, you can pass `NULL` for the `equivalent` parameter and only use the `order` parameter's result. In this case, all available comparison criteria are used to put the strings in a deterministic order, even if they are considered "equivalent" for the options you have specified. Note that you can set either the `equivalent` or the `order` parameters to `NULL`, but not both.

order

A pointer to a signed, 32-bit integer value, or pass `NULL`. If you wish simply to test strings for equivalence, using your specified options (which can be much faster than determining ordering), you can pass `NULL` for the `order` parameter and only use the `equivalent` parameter's result. (Note that either the `equivalent` or the `order` parameters may be `NULL`, but not both.

Return Value

A result code. The function can return `paramErr` (for example, if `collatorRef`, `text1Ptr`, or `text2Ptr` are `NULL`.

Discussion

You can use the `UCCompareText` function to perform various types of string comparison for a given set of locale and collation specifications. You can

- simply test whether two strings are equivalent
- determine the relative ordering of two strings
- check whether a given string is equivalent to any string in an ordered list

You can also call the `UCCompareText` function multiple times to compare different strings using the same collator object. If you wish to compare the same strings several times, as when sorting a list of strings, it may be more efficient for you to derive a collation key for each string and then compare the collation keys. For more on comparison using collation keys, see the functions `UCGetCollationKey` (page 2160) and `UCCompareCollationKeys` (page 2150).

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeUtilities.h`

UCCompareTextDefault

Uses the default system locale to compare Unicode strings.

```
OSStatus UCCompareTextDefault (
   UCCollateOptions options,
   const UniChar *text1Ptr,
   UniCharCount text1Length,
   const UniChar *text2Ptr,
   UniCharCount text2Length,
   Boolean *equivalent,
   SInt32 *order
);
```

Parameters

options
A `UCCollateOptions` value specifying any collation options for the string comparison.

text1Ptr
A pointer to the first Unicode string (a `UniChar` array) to compare.

text1Length
The total count of Unicode characters in the first string being compared.

text2Ptr
A pointer to the second Unicode string to compare.

text2Length
The total count of Unicode characters in the second string being compared.

equivalent
A pointer to a `Boolean` value or pass `NULL`. On return, `UCCompareTextDefault` produces a value of `true` if the strings are equivalent for the options you have specified. If you wish simply to sort a list of strings in order, using your specified options, you can pass `NULL` for the `equivalent` parameter and only use the `order` parameter's result. In this case, all available comparison criteria are used to put the strings in a deterministic order, even if they are considered "equivalent" for the options you have specified. Note that you can set either the `equivalent` or the `order` parameters to `NULL`, but not both.

order

A pointer to a signed, 32-bit integer value, or pass `NULL`. If you wish simply to test the strings for equivalence, using your specified options (which can be much faster than determining ordering), you can pass `NULL` for the `order` parameter and only use the `equivalent` parameter's result. (Note that either the `equivalent` or the `order` parameters may be `NULL`, but not both.

Return Value
A result code.

Discussion
You can call the `UCCompareTextDefault` function when you want to use a simple collation function that requires minimum setup. This function uses the system default collation order (that is, the collation order for a `LocaleRef` of `NULL` and a variant of 0), and it does not require a collator object or collation keys.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeUtilities.h`

UCCompareTextNoLocale

Uses a fixed, locale-insensitive order to compare Unicode strings.

```
OSStatus UCCompareTextNoLocale (
   UCCollateOptions options,
   const UniChar *text1Ptr,
   UniCharCount text1Length,
   const UniChar *text2Ptr,
   UniCharCount text2Length,
   Boolean *equivalent,
   SInt32 *order
);
```

Parameters

options

A `UCCollateOptions` value specifying the fixed ordering scheme to use for the string comparison. This value must be nonzero. Bits 24-31 of `UCCollateOptionsValue` specify which fixed ordering scheme to use. Currently there is only scheme—`kUCCollateTypeHFSExtended`. See "Fixed Ordering Scheme" (page 2177) for additional details.

text1Ptr

A pointer to the first Unicode string (a `UniChar` array) to compare.

text1Length

The total count of Unicode characters in the first string being compared.

text2Ptr

A pointer to the second Unicode string to compare.

text2Length

The total count of Unicode characters in the second string being compared.

equivalent

A pointer to a `Boolean` value or pass `NULL`. On return, `UCCompareTextNoLocale` produces a value of `true` if the strings are equivalent for the ordering scheme you have specified. If you wish simply to sort a list of strings in order, using the specified ordering scheme, you can pass `NULL` for the `equivalent` parameter and only use the `order` parameter's result. In this case, all available comparison criteria are used to put the strings in a deterministic order, even if they are considered "equivalent" for the specified ordering scheme. Note that you can set either the `equivalent` or the `order` parameters to `NULL`, but not both.

order

A pointer to a signed, 32-bit integer value, or pass `NULL`. If you wish simply to test the strings for equivalence, using the specified ordering scheme (which can be much faster than determining ordering), you can pass `NULL` for the `order` parameter and only use the `equivalent` parameter's result. (Note that either the `equivalent` or the `order` parameters may be `NULL`, but not both.

Return Value
A result code. This function can return `paramErr` if you pass an invalid value for one of the parameters. For example, if you pass `0` for the `options` paramter, the function returns `paramErr`.

Discussion
You can call the `UCCompareTextNoLocale` function when you want to perform a fixed, locale-insensitive comparison that is guaranteed not to change from one system release to the next. This type of comparison could be used for sorting a Unicode key string in a database, for example. The `UCCompareTextNoLocale` function can provide comparison according to various fixed ordering schemes (only one is supported for Mac OS 8.6 and 9.0). This type of comparison is not usually used for a user-visible ordering, so the ordering schemes need not match any user's expectation of a sensible collation order.

The `UCCompareTextNoLocale` function does not require a collator object or collation keys. Another advantage of `UCCompareTextNoLocale` on Mac OS 9 is that it is exported from the `UnicodeUtilitiesCoreLib` library, which does not depend on other libraries (the other comparison functions exported from `UnicodeUtilitiesLib`, which depends on `LocalesLib` and `TextCommon`).

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeUtilities.h`

UCCreateCollator

Creates an object encapsulating locale and collation information, for the purpose of performing Unicode string comparison.

```
OSStatus UCCreateCollator (
   LocaleRef locale,
   LocaleOperationVariant opVariant,
   UCCollateOptions options,
   CollatorRef *collatorRef
);
```

Parameters

locale

A valid `LocaleRef` representing a specific locale, or pass `NULL` to request the default system locale. You can supply the value `kUnicodeCollationClass` in the `opClass` parameter of the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales` to obtain the locales available for collation on the current system.

opVariant

A `LocaleOperationVariant` value identifying a collation variant within the locale specified in the `locale` parameter. You can also pass 0 to request the default collation variant for any locale. To obtain the varieties of locale-specific collation that are currently available, you can supply the value `kUnicodeCollationClass` in the `opClass` parameter of the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales`.

options

A `UCCollateOptions` value specifying any collation options that you want to use for the string comparison.

collatorRef

A pointer to a value of type `CollatorRef`. On return, the `CollatorRef` value contains a valid reference to a new collator object.

Return Value

A result code. The function can return memory errors and `paramErr`, for example, if the `collatorRef` parameter is `NULL`. It can also return resource errors in Mac OS 9 and CarbonLib.

Discussion

To perform Unicode string comparison, you must supply locale and collation specifications to a collation function such as `UCCompareText` (page 2151). You provide this information by means of a collator object, created via the `UCCreateCollator` function. When finished with the collator object, you dispose of it using the function `UCDisposeCollator` (page 2158).

Special Considerations

The collator object is allocated in the current heap. This function can move memory.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.

Available in Mac OS X 10.0 and later.

Declared In

`UnicodeUtilities.h`

UCCreateTextBreakLocator

Creates an object encapsulating locale and text-break information, for the purpose of finding boundaries in Unicode text.

```
OSStatus UCCreateTextBreakLocator (
   LocaleRef locale,
   LocaleOperationVariant opVariant,
   UCTextBreakType breakTypes,
   TextBreakLocatorRef *breakRef
);
```

Parameters

locale

A valid `LocaleRef` representing a specific locale, or pass `NULL` to request the default system locale. You can supply the value `kUnicodeTextBreakClass` in the `opClass` parameter of the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales` to obtain the locales available for finding text boundaries on the current system.

opVariant

A `LocaleOperationVariant` value identifying a text-break operation variant within the locale specified in the `locale` parameter. You can also pass 0 to request the default text-break variant for any locale. To obtain the varieties of locale-specific text-break variants that are currently available, you can supply the value `kUnicodeTextBreakClass` in the `opClass` parameter of the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales`.

breakTypes

A `UCTextBreakType` value specifying each type of text boundary that the text-break locator should support. You do not need to create a text-break locator solely for the `BreakChar` type; it is locale-independent and automatically supported by the function `UCFindTextBreak` (page 2159). If `BreakChar` is the only type for which you call the `UCCreateTextBreakLocator` function, on return the `breakRef` parameter returns a `NULL` value (with no error).

breakRef

A pointer to a value of type `TextBreakLocatorRef`. On return, the `TextBreakLocatorRef` value contains a valid reference to a new text-break locator object.

Return Value

A result code. The function can return memory errors and `paramErr` (for example, if the `breakRef` parameter is `NULL` or if invalid bits are set in the `breakTypes` parameter). It can also return resource errors in Mac OS 9 and CarbonLib.

Discussion

To find boundaries in Unicode text, you must supply locale and text-break specifications to the function `UCFindTextBreak` (page 2159). You provide this information by means of a text-break locator object, created via the `UCCreateTextBreakLocator` function. When finished with the text-break locator object, you should dispose of it using the function `UCDisposeTextBreakLocator` (page 2158).

The `UCCreateTextBreakLocator` function creates a text-break locator object for a specified locale, a specified text-break variant within that locale, and a specified set of break types. The different types of breaks or boundaries in a line of Unicode text can include

- Boundaries of characters (treating surrogate pairs as a single character).
- Boundaries of character clusters. A cluster is a group of characters that should be treated as single text element for editing operations such as cursor movement. Typically this includes groups such as a base character followed by a sequence of combining characters, for example, a Hangul syllable represented as a sequence of conjoining jamo characters or an Indic consonant cluster.
- Boundaries of words. This can be used to determine what to highlight as the result of a double-click.
- Potential line break locations.

Special Considerations

This function can move memory.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.

Declared In

`UnicodeUtilities.h`

UCDisposeCollator

Disposes a collator object.

```
OSStatus UCDisposeCollator (
   CollatorRef *collatorRef
);
```

Parameters

`collatorRef`

A reference to a valid collator object. The `UCDisposeCollator` function sets `*collatorRef` to `NULL`.

Return Value

A result code.

Discussion

To perform Unicode string comparison, you must supply locale and collation specifications to a collation function such as `UCCompareText` (page 2151). You provide this information by means of a collator object, created via the function `UCCreateCollator` (page 2155). When finished with the collator object, you should dispose of it using the function `UCDisposeCollator`.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In

`UnicodeUtilities.h`

UCDisposeTextBreakLocator

Disposes a text-break locator object.

```
OSStatus UCDisposeTextBreakLocator (
   TextBreakLocatorRef *breakRef
);
```

Parameters

`breakRef`

A reference to a valid text-break locator object. The `UCDisposeTextBreakLocator` function sets `*breakRef` to `NULL`.

Return Value

A result code. This function can return `paramErr`, for example, if the `breakRef` parameter is `NULL`.

Discussion
To find boundaries in Unicode text, you must supply locale and text-break specifications to the function `UCFindTextBreak` (page 2159). You provide this information by means of a text-break locator object, created via the function `UCCreateTextBreakLocator` (page 2156). When finished with the text-break locator object, you should dispose of it using the function `UCDisposeTextBreakLocator`.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.

Declared In
`UnicodeUtilities.h`

UCFindTextBreak

Uses locale-specific text-break information to find boundaries in Unicode text.

```
OSStatus UCFindTextBreak (
   TextBreakLocatorRef breakRef,
   UCTextBreakType breakType,
   UCTextBreakOptions options,
   const UniChar *textPtr,
   UniCharCount textLength,
   UniCharArrayOffset startOffset,
   UniCharArrayOffset *breakOffset
);
```

Parameters

breakRef
A valid reference to a text-break locator object. If the type of boundary specified by the `breakType` parameter is `BreakChar`, you can pass `NULL`. You use the function `UCCreateTextBreakLocator` (page 2156) to obtain a text-break locator object reference. If non-`NULL`, the text-break locator object must support the type of boundary specified in the `breakType` parameter.

breakType
A value of type `UCTextBreakType`, with exactly one bit set to specify a single type of boundary to be located. Since support for finding character boundaries is locale-independent and built into the `UCFindTextBreak` function, if you specify `BreakChar` as the type of boundary, then the `breakRef` parameter is ignored and may be `NULL`.

options
A `UCTextBreakOptions` value to specify the operation of the `UCFindTextBreak` function. You can use text-break locator options to control some location-independent aspects of a text-boundary search. Note that if you do not specify any `UCTextBreakOptions` values, `UCFindTextBreak` searches forward, but assumes that the `startOffset` value refers to the character preceding the offset rather than the one at the offset. This can result in `UCFindTextBreak` returning an offset that is equal to the start offset.

textPtr
A pointer to the initial character of the Unicode string to search.

textLength
The total count of Unicode characters in the string to search.

startOffset

A UniCharArrayOffset value specifying the offset from which UCFindTextBreak is to begin searching for the next text boundary of the type specified in the breakType parameter. If startOffset == 0 then kUCTextBreakLeadingEdgeMask must be set in the options parameter; if startOffset == textLength then kUCTextBreakLeadingEdgeMask must not be set.

breakOffset

A pointer to a UniCharArrayOffset value. On return, the value pointed to by the breakOffset parameter is set to the offset of the text boundary located by UCFindTextBreak. In normal usage (when exactly one of kUCTextBreakLeadingEdgeMask and kUCTextBreakGoBackwardsMask are set), the result returned in breakOffset is not equal to that supplied in the startOffset parameter unless an error occurs (and the function result is other than noErr). However, when kUCTextBreakLeadingEdgeMask and kUCTextBreakGoBackwardsMask are both set or both clear, the result produced in breakOffset can be equal to the value of startOffset.

Return Value
A result code. The text-break locator referenced by the breakRef parameter must support the type of boundary specified in the breakType parameter; otherwise, the function returns kUCTextBreakLocatorMissingType.

Discussion
The UCFindTextBreak function starts from a specified offset in a text buffer, and then proceeds forward or backward (as requested) until it finds the next text boundary of a particular locale-specific type, using a given set of options. The different types of breaks or boundaries in a line of Unicode text can include

- Boundaries of characters (treating surrogate pairs as a single character).
- Boundaries of character clusters. A cluster is a group of characters that should be treated as single text element for editing operations such as cursor movement. Typically this includes groups such as a base character followed by a sequence of combining characters, for example, a Hangul syllable represented as a sequence of conjoining jamo characters or an Indic consonant cluster.
- Boundaries of words. This can be used to determine what to highlight as the result of a double-click.
- Potential line break locations.

Finding boundaries of characters is a locale-independent operation, and support for it is built directly into the UCFindTextBreak function. If that is the only type of text boundary that you wish to locate, it is not necessary to call UCCreateTextBreakLocator and create a text-break locator object.

When finished with the text-break locator object, dispose it using the function UCDisposeTextBreakLocator (page 2158).

Availability
Available in CarbonLib 1.0 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.

Declared In
UnicodeUtilities.h

UCGetCollationKey

Uses locale-specific collation information to generate a collation key for a Unicode string.

```
OSStatus UCGetCollationKey (
   CollatorRef collatorRef,
   const UniChar *textPtr,
   UniCharCount textLength,
   ItemCount maxKeySize,
   ItemCount *actualKeySize,
   UCCollationValue collationKey[]
);
```

Parameters

collatorRef

A valid reference to a collator object; `NULL` is not allowed. You can use the function `UCCreateCollator` (page 2155) to obtain a collator reference.

textPtr

A pointer to the Unicode string (a `UniChar` array) for which to generate a collation key.

textLength

The total count of Unicode characters in the string referenced by the `textPtr` parameter.

maxKeySize

An `ItemCount` value specifying the length of the `UCCollationValue` array passed in the `collationKey` parameter. This dimension should typically be at least `5*textLength`, as the byte length of a collation key is typically more than 16 times the number of Unicode characters in the string.

actualKeySize

On return, the actual length of the `UCCollationValue` array returned in the `collationKey` parameter.

collationKey

An array of `UCCollationValue` values. On return, the array contains the new collation key. The collation key consists of a sequence of primary weights for all of the collation text elements in the string, followed by a separator and a sequence of secondary weights for all of the text elements in the string, and so on for several levels of significance. The separator is usually 0; however, 1 is used as the separator at the boundary between levels that are significant and levels that are insignificant for the options you supply in the collator object.

Return Value

A result code. The function can return `paramErr`, for example, if the parameters `collatorRef`, `textPtr`, `actualKeySize`, or `collationKey` are `NULL`. It can also return memory errors. If `maxKeySize` is too small for the collation key, the function returns `kUCOutputBufferTooSmall`.

Discussion

If you want to compare the same strings several times, as when sorting a list of strings, it may be most efficient for you to derive a collation key for each string and then compare the collation keys. A collation key is a transformation of the string that depends on the collator object (that is, it depends on the locale, the collation variant if any, and the collation options).

Collation keys that are generated using the same collator object—but for different strings—can quickly be compared with each other, without further reference to the collator object or collation tables. The disadvantage is that the collation keys may be rather large. After you use the `UCGetCollationKey` function to create a collation key from a given string and collator object, you can call the function `UCCompareCollationKeys` (page 2150) to compare two collation keys that were generated with the same collator object.

If you are comparing different strings, it may be more efficient for you to call the function `UCCompareText` (page 2151) multiple times using the same collator object.

Note that collation keys should be used only in a runtime context. They should not be stored in a persistent state (such as to disk) because the format of a collation key could change in the future.

Special Considerations

This function can move memory.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.6 or later.
Available in Mac OS X 10.0 and later.

Declared In

`UnicodeUtilities.h`

UCKeyTranslate

Converts a combination of a virtual key code, a modifier key state, and a dead-key state into a string of one or more Unicode characters.

```
OSStatus UCKeyTranslate (
   const UCKeyboardLayout *keyLayoutPtr,
   UInt16 virtualKeyCode,
   UInt16 keyAction,
   UInt32 modifierKeyState,
   UInt32 keyboardType,
   OptionBits keyTranslateOptions,
   UInt32 *deadKeyState,
   UniCharCount maxStringLength,
   UniCharCount *actualStringLength,
   UniChar unicodeString[]
);
```

Parameters

keyLayoutPtr

A pointer to the first element in a resource of type `'uchr'`. Pass a pointer to the `'uchr'` resource that you wish the `UCKeyTranslate` function to use when converting the virtual key code to a Unicode character. The resource handle associated with this pointer need not be locked, since the `UCKeyTranslate` function does not move memory.

virtualKeyCode

An unsigned 16-bit integer. Pass a value specifying the virtual key code that is to be translated. For ADB keyboards, virtual key codes are in the range from 0 to 127.

keyAction

An unsigned 16-bit integer. Pass a value specifying the current key action. See "Key Actions" (page 2178) for descriptions of possible values.

modifierKeyState

An unsigned 32-bit integer. Pass a bit mask indicating the current state of various modifier keys. You can obtain this value from the modifiers field of the event record as follows:

```
modifierKeyState = ((EventRecord.modifiers) >> 8) & 0xFF;
```

keyboardType

An unsigned 32-bit integer. Pass a value specifying the physical keyboard type (that is, the keyboard shape shown by Key Caps). You can call the function `LMGetKbdType` for this value.

keyTranslateOptions

A bit mask of options for controlling the `UCKeyTranslate` function. See "Key Translation Options Flag" (page 2181) and "Key Translation Options Mask" (page 2182) for descriptions of possible values.

deadKeyState

A pointer to an unsigned 32-bit value, initialized to zero. The `UCKeyTranslate` function uses this value to store private information about the current dead key state.

maxStringLength

A value of type `UniCharCount`. Pass the number of 16-bit Unicode characters that are contained in the buffer passed in the `unicodeString` parameter. This may be a value of up to 255, although it would be rare to get more than 4 characters.

actualStringLength

A pointer to a value of type `UniCharCount`. On return this value contains the actual number of Unicode characters placed into the buffer passed in the `unicodeString` parameter.

unicodeString

An array of values of type `UniChar`. Pass a pointer to the buffer whose sized is specified in the `maxStringLength` parameter. On return, the buffer contains a string of Unicode characters resulting from the virtual key code being handled. The number of characters in this string is less than or equal to the value specified in the `maxStringLength` parameter.

Return Value

A result code. If you pass `NULL` in the `keyLayoutPtr` parameter, `UCKeyTranslate` returns `paramErr`. The `UCKeyTranslate` function also returns `paramErr` for an invalid `'uchr'` resource format or for invalid `virtualKeyCode` or `keyAction` values, as well as for `NULL` pointers to output values.The result `kUCOutputBufferTooSmall` (-25340) is returned for an output string length greater than `maxStringLength`.

Discussion

The `UCKeyTranslate` function uses the data in a Unicode keyboard-layout (`'uchr'`) resource to map a combination of virtual key code and modifier key state to a sequence of up to 255 Unicode characters. This mapping process depends on, and may update, a dead key state; the `UCKeyTranslate` function and the `'uchr'` resource support multiple dead keys. The mapping may also depend on the specific type of key action and the type of physical keyboard being used. The `UCKeyTranslate` function supports non-ADB keyboards, an extensible set of modifier keys, and other possible extensions.

In most cases, your application does not need to call the `UCKeyTranslate` function, since the Text Services Manager automatically calls it on your behalf to handle input from a Unicode keyboard layout. However, there may be some circumstances in which your application should call `UCKeyTranslate`. For example, your application may need to determine what character(s) would have been generated for the virtual key code in the current key-down event if a different modifier-and-key combination had been used.

The basic process by which `UCKeyTranslate` uses the `'uchr'` resource to translate virtual key codes into Unicode characters is detailed in the following steps:

1. The bit pattern specifying the modifier key state is mapped by the `UCKeyModifiersToTableNum` structure to a table number.

2. The table number maps to an offset within a `UCKeyToCharTableIndex` structure that refers to the actual key-code-to-character tables.

3. The key-code-to-character tables map the virtual key code to `UCKeyOutput` values, for which there are two possibilities:

- If bits 15 and 14 of the `UCKeyOutput` value are 01, the `UCKeyOutput` value is an index into the offsets contained in a `UCKeyStateRecordsIndex` structure. If this occurs, the mapping process for the virtual key code continues on to the next step
- Otherwise, the `UCKeyOutput` value produces one or more Unicode characters, either directly or via reference to a `UCKeySequenceDataIndex` structure. This ends the mapping process for a given virtual key code.

4. The offsets in a `UCKeyStateRecordsIndex` structure refer to `UCKeyStateRecord` dead-key state records.

5. The dead-key state records map from the current dead-key state to one or more Unicode characters to be output or the following dead-key state (if any). The mapping process for a given virtual key code may end with the dead-key state record or, if there is no dead-key state record entry for the key code, with a default state terminator, as specified in the resource's `UCKeyStateTerminators` table.

`UnicodeUtilities.h`

Data Types

CollatorRef

Refers to an opaque object that encapsulates locale and collation information for the purpose of performing Unicode string comparison.

```
typedef struct OpaqueCollatorRef * CollatorRef;
```

Discussion
You can obtain a `CollatorRef` value from the function `UCCreateCollator` (page 2155).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

TextBreakLocatorRef

Refers to an opaque object that encapsulates locale and text-break information for the purpose of finding boundaries in Unicode text.

```
typedef struct OpaqueTextBreakLocatorRef * TextBreakLocatorRef;
```

Discussion
You can obtain a `TextBreakLocatorRef` value from the function `UCCreateTextBreakLocator` (page 2156).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCCollationValue

Specifies a Unicode collation key.

```
typedef UInt32 UCCollationValue;
```

Discussion
Collation keys consist of an array of `UCCollationValue` values. The collation key consists of a sequence of primary weights for all of the collation text elements in the string, followed by a separator and a sequence of secondary weights for all of the text elements in the string, and so on for several levels of significance. The separator is usually 0; however, 1 is used as the separator at the boundary between levels that are significant and levels that are insignificant for the options you supply in the collator object. You can obtain a collation key with the function `UCGetCollationKey` (page 2160).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyboardLayout

Provides header data for a `'uchr'` resource.

```
struct UCKeyboardLayout {
    UInt16 keyLayoutHeaderFormat;
    UInt16 keyLayoutDataVersion;
    ByteOffset keyLayoutFeatureInfoOffset;
    ItemCount keyboardTypeCount;
    UCKeyboardTypeHeader keyboardTypeList[1];
};
typedef struct UCKeyboardLayout UCKeyboardLayout;
```

Fields

`keyLayoutHeaderFormat`
An unsigned 16-bit integer identifying the format of the structure. Set to `kUCLayoutHeaderFormat`.

`keyLayoutDataVersion`
An unsigned 16-bit integer identifying the version of the data in the resource, in binary code decimal format. For example, 0x0100 would equal version 1.0.

`keyLayoutFeatureInfoOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeyLayoutFeatureInfo` (page 2168), if such is used in the resource. May be 0 if no `UCKeyLayoutFeatureInfo` table is included in the resource.

`keyboardTypeCount`
: An unsigned 32-bit integer specifying the number of `UCKeyboardTypeHeader` structures in the `keyboardTypeList[]` field's array.

`keyboardTypeList`
: A variable-length array containing structures of type `UCKeyboardTypeHeader`. Each `UCKeyboardTypeHeader` entry specifies a range of physical keyboard types and contains offsets to each of the key mapping sections to be used for that range of keyboard types.

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyboardLayout` type is used in the `'uchr'` resource header. It specifies version and format information, offsets to the various subtables, and an array of `UCKeyboardTypeHeader` entries.

You should use low-ASCII (0 - 0x7F) only for the KCHR/uchr resource names and you should use Unicode in the Info.plist file when you specify strings for the user-interface (UI).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyboardTypeHeader

Specifies a range of physical keyboard types in a `'uchr'` resource.

```
struct UCKeyboardTypeHeader {
    UInt32 keyboardTypeFirst;
    UInt32 keyboardTypeLast;
    ByteOffset keyModifiersToTableNumOffset;
    ByteOffset keyToCharTableIndexOffset;
    ByteOffset keyStateRecordsIndexOffset;
    ByteOffset keyStateTerminatorsOffset;
    ByteOffset keySequenceDataIndexOffset;
};
typedef struct UCKeyboardTypeHeader UCKeyboardTypeHeader;
```

Fields
`keyboardTypeFirst`
: An unsigned 32-bit integer specifying the first keyboard type in this entry. For the initial entry (that is, the default entry) in an array of `UCKeyboardTypeHeader` structures, you should set this value to 0. The initial `UCKeyboardTypeHeader` entry is used if the keyboard type passed to the function `UCKeyTranslate` (page 2162) does not match any other entry, that is, if it is not within the range of values specified by `keyboardTypeFirst` and `keyboardTypeLast` for any entry.

`keyboardTypeLast`
: An unsigned 32-bit integer specifying the last keyboard type in this entry. For the initial entry (that is, the default entry) in an array of `UCKeyboardTypeHeader` structures, you should set this value to 0.

`keyModifiersToTableNumOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeyModifiersToTableNum` (page 2169). The `'uchr'` resource requires a `UCKeyModifiersToTableNum` structure, therefore this field must contain a non-zero value.

`keyToCharTableIndexOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeyToCharTableIndex` (page 2176). The `'uchr'` resource requires a `UCKeyToCharTableIndex` structure, therefore this field must contain a non-zero value.

`keyStateRecordsIndexOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeyStateRecordsIndex` (page 2174), if such is used in the resource. This value may be 0 if no dead-key state records are included in the resource.

`keyStateTerminatorsOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeyStateTerminators` (page 2175), if such is used in the resource. This value may be 0 if no dead-key state terminators are included in the resource.

`keySequenceDataIndexOffset`
: An unsigned 32-bit integer providing an offset to a structure of type `UCKeySequenceDataIndex` (page 2170), if such is used in the resource. This value may be 0 if no character key sequences are included in the resource.

Discussion
The `UCKeyboardTypeHeader` type is used in a structure of type `UCKeyboardLayout` (page 2165) to specify a range of physical keyboard types and contains offsets to each of the key mapping sections to be used for that range of keyboard types. Typically, you use an array of `UCKeyboardTypeHeader` structures, of which the first entry in the array is the default and will be used if the keyboard type does not fall within the range for any other entry. See `UCKeyboardLayout` (page 2165) for a further discussion of the context for use of the `UCKeyboardTypeHeader` type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyCharSeq

Specifies the output of a dead-key state in a `'uchr'` resource.

```
typedef UInt16 UCKeyCharSeq;
```

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyCharSeq` type is a 16-bit value used in the third key mapping section of the `'uchr'` resource to specify the output of a dead-key state.

Specifically, the dead-key state record—a structure of type `UCKeyStateRecord` (page 2173) —uses a `UCKeyCharSeq` value to contain the character output that results from the resolution of a given dead-key state. You can use a `UCKeyCharSeq` value in a dead-key state record to represent either an index to a Unicode character sequence or a single Unicode character. The `UCKeyCharSeq` type is similar to the type `UCKeyOutput` (page 2169) , but does not itself support indices into dead-key state records.

The interpretation of `UCKeyCharSeq` depends on bits 15 and 14.

If they are 10 (that is, for values in the range of 0x8000–0xBFFF), then bits 0–13 are an index into the `charSequenceOffsets[` field of a structure of type `UCKeySequenceDataIndex` (page 2170) , which contains offsets to a separate resource-wide list of Unicode character sequences. If a `UCKeySequenceDataIndex` structure is not present in the resource or the index is beyond the end of the list, then the entire value (that is, bits 0–15) is a single Unicode character to emit. Otherwise (for values in the range of 0x0000–0x7FFF and 0xC000–0xFFFD), bits 0–15 are a single Unicode character, with the exception that a value of 0xFFFE–0xFFFF means no character output (these are invalid Unicode codes).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyLayoutFeatureInfo

Specifies the longest possible output string to be produced by the current `'uchr'` resource.

```
struct UCKeyLayoutFeatureInfo {
    UInt16 keyLayoutFeatureInfoFormat;
    UInt16 reserved;
    UniCharCount maxOutputStringLength;
};
typedef struct UCKeyLayoutFeatureInfo UCKeyLayoutFeatureInfo;
```

Fields

`keyLayoutFeatureInfoFormat`
: An unsigned 16-bit integer identifying the format of the `UCKeyLayoutFeatureInfo` structure. Set to `kUCKeyLayoutFeatureInfoFormat`.

`reserved`
: Reserved. Set to 0.

`maxOutputStringLength`
: An unsigned 32-bit integer specifying the longest possible output string of Unicode characters to be produced by this `'uchr'` resource.

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyLayoutFeatureInfo` type is used in the header section of the `'uchr'` resource.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyModifiersToTableNum

Maps a modifier key combination to a particular key-code-to-character table number in a 'uchr' resource.

```
struct UCKeyModifiersToTableNum {
    UInt16 keyModifiersToTableNumFormat;
    UInt16 defaultTableNum;
    ItemCount modifiersCount;
    UInt8 tableNum[1];
};
typedef struct UCKeyModifiersToTableNum UCKeyModifiersToTableNum;
```

Fields

keyModifiersToTableNumFormat
: An unsigned 16-bit integer identifying the format of the UCKeyModifiersToTableNum structure. Set to kUCKeyModifiersToTableNumFormat.

defaultTableNum
: An unsigned 16-bit integer identifying the table number to use for modifier combinations that are outside of the range included in the tableNum field.

modifiersCount
: An unsigned 32-bit integer specifying the range of modifier bit combinations for which there are entries in the tableNum[] field.

tableNum
: An array of unsigned 8-bit integers that map modifier bit combinations to table numbers. These values are indexes into the keyToCharTableOffsets array in a UCKeyToCharTableIndex (page 2176)structure; these, in turn, are offsets to the actual key-code-to character tables, which follow the UCKeyToCharTableIndex structure in the 'uchr' resource.

Discussion

The Unicode keyboard-layout ('uchr') resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The 'uchr' format consists of a header information section and five key mapping data sections. The UCKeyModifiersToTableNum type is used in the first key mapping section of the 'uchr' resource. It maps a modifier key combination to a particular key-code-to-character table number.

Availability

Available in Mac OS X v10.0 and later.

Declared In

UnicodeUtilities.h

UCKeyOutput

Specifies values in key-code-to-character tables in a 'uchr' resource.

```
typedef UInt16 UCKeyOutput;
```

Discussion

The Unicode keyboard-layout ('uchr') resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The 'uchr' format consists of a header information section and five key mapping data sections. The UCKeyOutput type is a 16-bit value used in the second key mapping section of a 'uchr' resource to specify values in key-code-to-character tables.

You use a `UCKeyOutput` value in a key-code-to-character table to represent one of the following: an index to a dead-key state record, an index to a Unicode character sequence, or a single Unicode character.

The interpretation of a `UCKeyOutput` value depends on bits 15 and 14.

If they are 01 (that is, for values in the range of 0x4000-0x7FFF), then bits 0-13 are an index into the `keyStateRecordOffsets` field of a structure of type `UCKeyStateRecordsIndex` (page 2174) , which contains offsets to a separate resource-wide list of dead-key state records.

If they are 10 (that is, for values in the range of 0x8000-0xBFFF), then bits 0-13 are an index into the `charSequenceOffsets` field of a structure of type `UCKeySequenceDataIndex` (page 2170) , which contains offsets to a separate resource-wide list of Unicode character sequences. If a `UCKeySequenceDataIndex` structure is not present in the resource or the index is beyond the end of the list, then the entire value (that is, bits 0-15) is a single Unicode character to emit.

Otherwise (for values in the range of 0x0000-0x3FFF and 0xC000-0xFFFD), bits 0-15 are a single Unicode character, with the exception that a value of 0xFFFE-0xFFFF means no character output (these are invalid Unicode codes).

Most single Unicode characters that are likely to be generated by direct keyboard input are in the range 0x0000-0x33FF or 0xE000-0xFFFD, and so are covered by the single-character cases above. Characters outside this range can still be generated by direct keyboard input, in which case they must be represented as 1-character sequences. The fifth key mapping section of the `'uchr'` resource, introduced by the `UCKeySequenceDataIndex` type, provides for this option.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeySequenceDataIndex

Contains offsets to a list of character sequences for a `'uchr'` resource.

```
struct UCKeySequenceDataIndex {
    UInt16 keySequenceDataIndexFormat;
    UInt16 charSequenceCount;
    UInt16 charSequenceOffsets[1];
};
typedef struct UCKeySequenceDataIndex UCKeySequenceDataIndex;
```

Fields

`keySequenceDataIndexFormat`
An unsigned 16-bit integer identifying the format of the `UCKeySequenceDataIndex` structure. Set to `kUCKeySequenceDataIndexFormat`.

`charSequenceCount`
An unsigned 16-bit integer specifying the number of Unicode character sequences that follow the end of the `UCKeySequenceDataIndex` structure.

`charSequenceOffsets`
: An array of offsets from the beginning of the `UCKeySequenceDataIndex` structure to the Unicode character sequences that follow it. Because a given offset indicates both the beginning of a new character sequence and the end of the sequence that precedes it, the length of each sequence is determined by the difference between the offset to that sequence and the value of the next offset in the array. The array contains one more entry than the number of character sequences; the final entry is the offset to the end of the final character sequence.

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeySequenceDataIndex` type is used in the fifth key mapping section of the `'uchr'` resource.

The `UCKeySequenceDataIndex` structure contains offsets to a list of character sequences for the `'uchr'` resource. This permits a single keypress to generate a sequence of characters, or to generate a single character outside the range that can be represented directly by values of type `UCKeyOutput` (page 2169) or `UCKeyCharSeq` (page 2167).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyStateEntryRange

Maps from a dead-key state to either the resultant Unicode character(s) or the new dead key state produced when the current state is terminated by a given character key for a `'uchr'` resource.

```
struct UCKeyStateEntryRange {
    UInt16 curStateStart;
    UInt8 curStateRange;
    UInt8 deltaMultiplier;
    UCKeyCharSeq charData;
    UInt16 nextState;
};
typedef struct UCKeyStateEntryRange UCKeyStateEntryRange;
```

Fields

`curStateStart`
: An unsigned 16-bit integer specifying the beginning of a given dead-key state range.

`curStateRange`
: An unsigned 8-bit integer specifying the number of entries in a given dead-key state range.

`deltaMultiplier`
: An unsigned 8-bit integer.

`charData`
: A value of type `UCKeyCharSeq`. This base character value is used to determine the actual Unicode character(s) produced when a given dead-key state terminates.

`nextState`
: An unsigned 16-bit integer. This base dead-key state value is used to determine the following dead-key state, if any.

Discussion
The `UCKeyStateEntryRange` type is used in the `stateEntryData[]` field of a structure of type `UCKeyStateRecord` (page 2173). You should use the `UCKeyStateEntryRange` format for complex (multiple) dead-key states.

For each virtual key code, an entry in its dead-key state record maps from the current dead-key state to the Unicode character(s) produced or to the next dead-key state, as follows.

If the current dead-key state is within a valid dead-key state range for the given input character—that is, if its value is greater than or equal to `curStateStart` and less than or equal to `curStateStart + curStateRange`—then

- If the base `charData` value for the given dead-key state range is in the range of valid Unicode characters, a character is produced and the dead-key state may be terminated.

and/or

- If the base `nextState` value is not 0, a new dead-key state is produced.

In the first case, the output character is determined as follows: The base `charData` value is incremented by the resulting product of (the difference between the current state and the start of that state's range) and (a multiplier). That is:

```
charData += (curState - curStateStart) * deltaMultiplier
```

Similarly, in the second case, the resulting dead-key state, which is the new `curState` value, is determined as follows: The base `nextState` value is incremented by the resulting product of (the difference between the current state and the start of that state's range) and (a multiplier). That is:

```
nextState += (curState - curStateStart) * deltaMultiplier
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyStateEntryTerminal

Maps from a dead-key state to the Unicode character(s) produced when that state is terminated by a given character key for a `'uchr'` resource.

```
struct UCKeyStateEntryTerminal {
    UInt16 curState;
    UCKeyCharSeq charData;
};
typedef struct UCKeyStateEntryTerminal UCKeyStateEntryTerminal;
```

Fields
`curState`
An unsigned 16-bit integer specifying the current dead-key state.

`charData`

A value of type `UCKeyCharSeq` specifying the Unicode character(s) produced when a given character key is pressed.

Discussion

The `UCKeyStateEntryTerminal` type is used in the `stateEntryData[]` field of a structure of type `UCKeyStateRecord` (page 2173). You should use the `UCKeyStateEntryTerminal` format for simple dead-key states that are terminated by a single keystroke, as in the U.S. keyboard layout. Each entry maps from the current dead-key state to the Unicode character(s) produced when a given character key is pressed that terminates the dead-key state.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`UnicodeUtilities.h`

UCKeyStateRecord

Determines dead-key state transitions in a `'uchr'` resource.

```
struct UCKeyStateRecord {
    UCKeyCharSeq stateZeroCharData;
    UInt16 stateZeroNextState;
    UInt16 stateEntryCount;
    UInt16 stateEntryFormat;
    UInt32 stateEntryData[1];
};
typedef struct UCKeyStateRecord UCKeyStateRecord;
```

Fields

`stateZeroCharData`

A value of type `UCKeyCharSeq` specifying the Unicode character(s) produced from a given key code while no dead-key state is in effect.

`stateZeroNextState`

An unsigned 16-bit integer specifying the dead-key state produced from a given key code when no previous dead-key state is in effect. If the `UCKeyStateRecord` structure does not initiate a dead-key state (but only provides terminators for other dead-key states), this will be 0. A non-zero value specifies the resulting new dead-key state and refers to the current state entry within the `stateEntryData[]` field for the following dead-key state record that is applied.

`stateEntryCount`

An unsigned 16-bit integer specifying the number of elements in the `stateEntryData` field's array for a given dead-key state record.

`stateEntryFormat`

An unsigned 16-bit integer specifying the format of the data in the `stateEntryData` field's array. This should be 0 if the `stateEntryCount` field is set to 0. Currently available values are `kUCKeyStateEntryTerminalFormat` and `kUCKeyStateEntryRangeFormat`; see "Key State Entry Formats" (page 2181) for descriptions of these values.

`stateEntryData`

An array of dead-key state entries, whose size depends on their format, but which will always be a multiple of 4 bytes. Each entry maps from the current dead-key state to the Unicode character(s) that result when a given character key is pressed or to the next dead-key state, if any. The format of the entry is specified by the `stateEntryFormat` field to be either that of type `UCKeyStateEntryTerminal` (page 2172) or `UCKeyStateEntryRange` (page 2171).

Discussion

The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyStateRecord` type is used in the third key mapping section of the `'uchr'` resource to determine dead-key state transitions. The `UCKeyStateRecord` structure permits complex dead-key state processing, such as a series of transitions from one dead-key state directly into another, in which each transition can emit a sequence of one or more Unicode characters.

Any modifier key combination which initiates a dead-key state or which is a valid terminator of a dead-key state refers to one of these records via the `UCKeyOutput` (page 2169) values in key-code-to-character tables. A `UCKeyOutput` value may index the offsets contained in a `UCKeyStateRecordsIndex` (page 2174) structure, which in turn refers to the actual dead-key state records.

Each `UCKeyStateRecord` structure maps from the current dead-key state to the character data to be output or the following dead-key state (if any), as follows:

- If the current dead-key state is zero (that is, there are no dead keys in effect) the value in `stateZeroCharData` is output and the state is set to the value in `stateZeroNextState` (this can be used to initiate a dead-key state).
- If the current dead-key state is non-zero and there is an entry for the state in `stateEntryData`, then the corresponding value in `stateEntryData.charData` is output. The next state is then set to either a `kUCKeyStateEntryTerminalFormat` or a `kUCKeyStateEntryRangeFormat` value; in either case, if the next dead-key state is 0, this implements a valid dead-key state terminator.
- If the current dead-key state is non-zero, and there is no entry for the state in `stateEntryData`, the default state terminator is output from the `'uchr'` resource's `UCKeyStateTerminators` (page 2175) table for the current state (or nothing may be output, if there is no `UCKeyStateTerminators` table or it has no entry for the current state). Then the value in `stateZeroCharData` is output, and the state is set to the value in `stateZeroNextState`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`UnicodeUtilities.h`

UCKeyStateRecordsIndex

Provides a count of, and offsets to, dead-key state records in a `'uchr'` resource.

```
struct UCKeyStateRecordsIndex {
    UInt16 keyStateRecordsIndexFormat;
    UInt16 keyStateRecordCount;
    ByteOffset keyStateRecordOffsets[1];
};
typedef struct UCKeyStateRecordsIndex UCKeyStateRecordsIndex;
```

Fields

`keyStateRecordsIndexFormat`

An unsigned 16-bit integer identifying the format of the `UCKeyStateRecordsIndex` structure. Set to `kUCKeyStateRecordsIndexFormat`.

`keyStateRecordCount`

An unsigned 16-bit integer specifying the number of dead-key state records that are included in the resource.

`keyStateRecordOffsets`

An array of offsets from the beginning of the resource to each of the `UCKeyStateRecord` values that follow this structure in the `'uchr'` resource.

Discussion

The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyStateRecordsIndex` type is used in the third key mapping section of the `'uchr'` resource.

The `UCKeyStateRecordsIndex` structure is an index to dead-key state records of type `UCKeyStateRecord` (page 2173). Any keycode-modifier combination which initiates a dead-key state or which is a valid terminator of a dead-key state refers to one of these records, via the `UCKeyStateRecordsIndex` structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`UnicodeUtilities.h`

UCKeyStateTerminators

Lists the default terminators for each dead-key state handled by a `'uchr'` resource.

```
struct UCKeyStateTerminators {
    UInt16 keyStateTerminatorsFormat;
    UInt16 keyStateTerminatorCount;
    UCKeyCharSeq keyStateTerminators[1];
};
typedef struct UCKeyStateTerminators UCKeyStateTerminators;
```

Fields

`keyStateTerminatorsFormat`

An unsigned 16-bit integer identifying the format of the `UCKeyStateTerminators` structure. Set to `kUCKeyStateTerminatorsFormat`.

`keyStateTerminatorCount`

An unsigned 16-bit integer specifying the number of default dead-key state terminators contained in the `keyStateTerminators[]` array.

`keyStateTerminators`
: An array of default dead-key state terminators, described as values of type `UCKeyCharSeq` (page 2167); the value `keyStateTerminators[0]` is the terminator for state 1, and so on.

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyStateTerminators` type is used in the fourth key mapping section of the `'uchr '` resource.

The `UCKeyStateTerminators` structure contains the list of default terminators (characters or sequences) for each dead-key state that is handled by a `'uchr'` resource. When a dead-key state is in effect but a modifier-and-key combination is typed which has no special handling for that state, the default terminator for the state is output before the modifier-and-key combination is processed. If this table is not present or does not extend far enough to have a terminator for the state, nothing is output when the state terminates.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

UCKeyToCharTableIndex

Provides a count of, and offsets to, key-code-to-character tables in a `'uchr'` resource.

```
struct UCKeyToCharTableIndex {
    UInt16 keyToCharTableIndexFormat;
    UInt16 keyToCharTableSize;
    ItemCount keyToCharTableCount;
    ByteOffset keyToCharTableOffsets[1];
};
typedef struct UCKeyToCharTableIndex UCKeyToCharTableIndex;
```

Fields
`keyToCharTableIndexFormat`
: An unsigned 16-bit integer identifying the format of the `UCKeyToCharTableIndex` structure. Set to `kUCKeyToCharTableIndexFormat`.

`keyToCharTableSize`
: An unsigned 16-bit integer specifying the number of virtual key codes supported by this resource; for ADB keyboards this is 128 (with virtual key codes ranging from 0 to 127).

`keyToCharTableCount`
: An unsigned 32-bit integer specifying the number of key-code-to-character tables, typically 6 to 12.

`keyToCharTableOffsets`
: An array of offsets from the beginning of the `'uchr'` resource to each of the `UCKeyOutput` key-code-to-character tables in the `keyToCharData[]` array that follows this structure in the resource.

Discussion
The Unicode keyboard-layout (`'uchr'`) resource contains the data necessary to map virtual key codes to Unicode character codes for a given keyboard layout. The `'uchr'` format consists of a header information section and five key mapping data sections. The `UCKeyToCharTableIndex` type is used in the second key mapping section of the `'uchr'` resource. The `UCKeyToCharTableIndex` structure precedes the list of key-code-to-character tables, each of which maps a key code to a 16-bit value of type `UCKeyOutput` (page 2169).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`UnicodeUtilities.h`

Constants

Fixed Ordering Scheme

Specifies to use the fixed ordering scheme.

```
enum {
    kUCCollateTypeHFSExtended = 1
};
```

Constants
`kUCCollateTypeHFSExtended`
The `kUCCollateTypeHFSExtended` ordering scheme sorts maximally decomposed Unicode according to the rules used by the HFS Extended volume format for its catalog. When this order is used, other collation options are ignored; this order is always case-insensitive (for decomposed characters) and ignores the Unicode characters 200C-200F, 202A-202E, 206A-206F, FEFF.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
`UCCollateOptions` is a 32-bit value. Bits 0-23 are described in "String Comparison Options" (page 2183). The field consisting of bits 24-31 is used for values that specify which fixed ordering scheme to use with the function `UCCompareTextNoLocale` (page 2154). Currently only one such scheme is provided.

Constants are provided for setting and testing the `UCCollateOptions` field that specifies the ordering scheme. These values are described in "Fixed Ordering Masks 1" (page 2177) and "Fixed Ordering Masks 2" (page 2178).

Fixed Ordering Masks 1

Set and test the `UCCollateOptions` field that specifies a fixed ordering scheme.

```
enum {
    kUCCollateTypeSourceMask = 0x000000FF,
    kUCCollateTypeShiftBits = 24
};
```

Constants
`kUCCollateTypeSourceMask`
You can use this mask, in conjunction with the `kUCCollateTypeShiftBits` constant, to obtain a value identifying a fixed ordering scheme.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateTypeShiftBits`

You can use this value, along with one of the constants described in "Fixed Ordering Scheme" (page 2177), to specify a fixed ordering scheme. You can also use this value, in conjunction with the `kUCCollateTypeSourceMask` constant, to obtain a value identifying a fixed ordering scheme.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
You can use these constants to set or obtain a value that specifies a fixed ordering scheme. For a description of the available types of fixed ordering schemes, see "Fixed Ordering Scheme" (page 2177).

For example, to specify `kUCCollateTypeHFSExtended` in the `options` parameter of the function `UCCompareTextNoLocale` (page 2154) , the `kUCCollateTypeHFSExtended` value must be shifted by `kUCCollateTypeShiftBits` :

```
options = kUCCollateTypeHFSExtended kUCCollateTypeShiftBits;
```

You would obtain the ordering scheme value from the `options` parameter as follows:

```
fixedOrderType = ((options > > kUCCollateTypeShiftBits) &
kUCCollateTypeSourceMask);
```

See also "Fixed Ordering Masks 2" (page 2178).

Fixed Ordering Masks 2

Test the `UCCollateOptions` field that specifies a fixed ordering scheme.

```
enum {
    kUCCollateTypeMask = kUCCollateTypeSourceMask << kUCCollateTypeShiftBits
};
```

Constants
`kUCCollateTypeMask`

You can use this mask to directly test bits 24-31 of a `UCCollateOptions` value.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
See also "Fixed Ordering Scheme" (page 2177).

See also "Fixed Ordering Masks 1" (page 2177).

Key Actions

Indicate the current key action.

```
enum {
    kUCKeyActionDown = 0,
    kUCKeyActionUp = 1,
    kUCKeyActionAutoKey = 2,
    kUCKeyActionDisplay = 3
};
```

Constants

`kUCKeyActionDown`
The user is pressing the key.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeUtilities.h`.

`kUCKeyActionUp`
The user is releasing the key.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeUtilities.h`.

`kUCKeyActionAutoKey`
The user has the key in an "auto-key" pressed state that is, the user is holding down the key for an extended period of time and is thereby generating multiple key strokes from the single key.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeUtilities.h`.

`kUCKeyActionDisplay`
The user is requesting information for key display, as in the Key Caps application.
Available in Mac OS X v10.0 and later.
Declared in `UnicodeUtilities.h`.

Discussion

You can supply the following constants for the `keyAction` parameter of the function `UCKeyTranslate` (page 2162) to indicate the current key action.

Key Format Codes

Indicate a structure format used in a `'uchr'` resource.

```
enum {
    kUCKeyLayoutHeaderFormat = 0x1002,
    kUCKeyLayoutFeatureInfoFormat = 0x2001,
    kUCKeyModifiersToTableNumFormat = 0x3001,
    kUCKeyToCharTableIndexFormat = 0x4001,
    kUCKeyStateRecordsIndexFormat = 0x5001,
    kUCKeyStateTerminatorsFormat = 0x6001,
    kUCKeySequenceDataIndexFormat = 0x7001
};
```

Constants

`kUCKeyLayoutHeaderFormat`
The format of a structure of type `UCKeyboardLayout` (page 2165).
Available in Mac OS X v10.0 and later.
Declared in `UnicodeUtilities.h`.

`kUCKeyLayoutFeatureInfoFormat`
The format of a structure of type `UCKeyLayoutFeatureInfo` (page 2168).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyModifiersToTableNumFormat`
The format of a structure of type `UCKeyModifiersToTableNum` (page 2169).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyToCharTableIndexFormat`
The format of a structure of type `UCKeyToCharTableIndex` (page 2176).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyStateRecordsIndexFormat`
The format of a structure of type `UCKeyStateRecordsIndex` (page 2174).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyStateTerminatorsFormat`
The format of a structure of type `UCKeyStateTerminators` (page 2175).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeySequenceDataIndexFormat`
The format of a structure of type `UCKeySequenceDataIndex` (page 2170).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
These constants are those currently defined to be used within the various structures in a `'uchr'` resource to indicate each structure's format.

Key Output Index Masks

Test the bits in `UCKeyOutput` values.

```
enum {
    kUCKeyOutputStateIndexMask = 0x4000,
    kUCKeyOutputSequenceIndexMask = 0x8000,
    kUCKeyOutputTestForIndexMask = 0xC000,
    kUCKeyOutputGetIndexMask = 0x3FFF
};
```

Constants
`kUCKeyOutputStateIndexMask`
If the bit specified by this mask is set, the `UCKeyStateRecordsIndex` (page 2174) `UCKeyOutput` value contains an index into a structure of type `UCKeyStateRecordsIndex` (page 2174).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyOutputSequenceIndexMask`
If the bit specified by this mask is set, the `UCKeyOutput` value contains an index into a structure of type `UCKeySequenceDataIndex` (page 2170).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyOutputTestForIndexMask`
You can use this mask to test the bits (14–15) in the `UCKeyOutput` value that determine whether the value contains an index to any other structure. If both bits specified by this mask are clear, the `UCKeyOutput` value does not contain an index to any other structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyOutputGetIndexMask`
You can use this mask to test the bits (0–13) in a `UCKeyOutput` value that provide the actual index to another structure.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
You can use these masks to test the bits in `UCKeyOutput` values.

Key State Entry Formats

Indicate the format for dead-key state records.

```
enum {
    kUCKeyStateEntryTerminalFormat = 0x0001,
    kUCKeyStateEntryRangeFormat = 0x0002
};
```

Constants
`kUCKeyStateEntryTerminalFormat`
Specifies that the entry format is that of a structure of type `UCKeyStateEntryTerminal` (page 2172). Use this format for simple (single) dead-key states, as in the U.S. keyboard layout.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCKeyStateEntryRangeFormat`
Specifies that the entry format is that of a structure of type `UCKeyStateEntryRange` (page 2171). Use this format for complex (multiple) dead-key states, as in the hex input and Hangul input keyboard layouts.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
These constants are used in `UCKeyStateRecord` structures to indicate the format for dead-key state records.

Key Translation Options Flag

Indicates the dead-key processing state.

```
enum {
    kUCKeyTranslateNoDeadKeysBit = 0
};
```

Constants

`kUCKeyTranslateNoDeadKeysBit`

The bit number of the bit that turns off dead-key processing. This prevents setting any new dead-key states, but allows completion of any dead-key states currently in effect.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion

Theis constant is the currently defined bit assignment for the `keyTranslateOptions` parameter of the function `UCKeyTranslate` (page 2162).

Key Translation Options Mask

Specifies the mask for the bit that controls dead-key processing state.

```
enum {
    kUCKeyTranslateNoDeadKeysMask = 1L << kUCKeyTranslateNoDeadKeysBit
};
```

Constants

`kUCKeyTranslateNoDeadKeysMask`

The mask for the bit that turns off dead-key processing. This prevents setting any new dead-key states, but allows completion of any dead-key states currently in effect.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion

This constant is the currently defined mask for the `keyTranslateOptions` parameter of the function `UCKeyTranslate` (page 2162).

Operation Class

Identifies collation as a class of Unicode utility operations.

```
enum {
    kUnicodeCollationClass = 'ucol'
};
```

Constants

`kUnicodeCollationClass`

Identifies collation as a class of operations.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion

The locales and collation variants available for collation operations can be determined by calling the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales` with the `opClass` parameter set to the `kUnicodeCollationClass` constant.

Standard Options Mask

Specifies standard options for Unicode string comparison.

```
enum {
    kUCCollateStandardOptions = kUCCollateComposeInsensitiveMask
| kUCCollateWidthInsensitiveMask
};
```

Constants

`kUCCollateStandardOptions`

If the `kUCCollateComposeInsensitiveMask` and `kUCCollateWidthInsensitiveMask` bits are set, then (1) precomposed and decomposed representations of the same text element will be treated as equivalent, and (2) fullwidth and halfwidth compatibility forms will be treated as equivalent to the corresponding non-compatibility characters.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion

For descriptions of other collation options, see "String Comparison Options" (page 2183).

String Comparison Options

Specifies options for Unicode string comparison.

```
typedef UInt32 UCCollateOptions;
enum {
    kUCCollateComposeInsensitiveMask = 1L << 1,
    kUCCollateWidthInsensitiveMask = 1L << 2,
    kUCCollateCaseInsensitiveMask = 1L << 3,
    kUCCollateDiacritInsensitiveMask = 1L << 4,
    kUCCollatePunctuationSignificantMask = 1L << 15,
    kUCCollateDigitsOverrideMask = 1L << 16,
    kUCCollateDigitsAsNumberMask = 1L << 17
};
```

Constants

`kUCCollateComposeInsensitiveMask`

If the corresponding bit is set, then precomposed and decomposed representations of the same text element are treated as equivalent. This option is among those set by the `kUCCollateStandardOptions` constant, as described in "Standard Options Mask" (page 2183).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateWidthInsensitiveMask`

If the corresponding bit is set, then fullwidth and halfwidth compatibility forms are treated as equivalent to the corresponding non-compatibility characters. This option is among those set by the `kUCCollateStandardOptions` constant, as described in "Standard Options Mask" (page 2183).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateCaseInsensitiveMask`
If the corresponding bit is set, then uppercase and titlecase characters are treated as equivalent to the corresponding lowercase characters.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateDiacritInsensitiveMask`
If the corresponding bit is set, then characters with diacritics are treated as equivalent to the corresponding characters without diacritics.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollatePunctuationSignificantMask`
If the corresponding bit is set, then punctuation and symbols are treated as significant instead of ignorable. This will produce results closer to the behavior of the older non-Unicode Mac OS collation functions. This option is available with Mac OS 9 and later.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateDigitsOverrideMask`
If the corresponding bit is set, then the number-handling behavior is specified by the remaining number-handling option bits, instead of by the collation information for the locale. If the bit is clear, the locale controls how numbers are handled and the remaining number-handling option bits are ignored. This option is available with Mac OS 9 and later.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCCollateDigitsAsNumberMask`
If the corresponding bit is set (and if the bit corresponding to `kUCCollateDigitsOverrideMask` is also set), then numeric substrings up to six digits long are collated by their numeric value—that is, they are treated as a single text element whose primary weight depends on the numeric value of the digit string. This primary weight will be greater than the weight of any valid Unicode character, but less than the primary weight of any unassigned Unicode character. For example, this will result in "Chapter 9" sorting before "Chapter 10." Currently, these digit strings can include digits with numeric value 0-9 in any script (excluding the ideographic characters for 1-9). If the bit is clear, digits are treated like other characters for sorting. Numeric substrings longer than 6 digits are always treated as normal characters. This option is available with Mac OS 9 and later.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion
For a description of the `UCCollateOptions` values, see "Standard Options Mask" (page 2183).

Text Break Options

Specifies options for locating boundaries in Unicode text.

```
typedef UInt32 UCTextBreakOptions;
enum {
    kUCTextBreakLeadingEdgeMask = 1L << 0,
    kUCTextBreakGoBackwardsMask = 1L << 1,
    kUCTextBreakIterateMask = 1L << 2
};
```

Constants

`kUCTextBreakLeadingEdgeMask`

If the corresponding bit is set, then the starting offset for the `UCFindTextBreak` function is assumed to be in the word containing the character following the offset; this is the normal case when searching forward. If the corresponding bit is clear, then the starting offset for `UCFindTextBreak` is assumed to be in the word containing the character preceding the offset; this is the normal case when searching backward.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCTextBreakGoBackwardsMask`

If the corresponding bit is set, then `UCFindTextBreak` searches backward from the value provided in its `startOffset` parameter to find the next text break. If the corresponding bit is clear, then `UCFindTextBreak` searches forward from the `startOffset` value to find the next text break.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCTextBreakIterateMask`

The corresponding bit may be set to indicate to the `UCFindTextBreak` function that the specified starting offset is a known break of the type specified in the `breakType` parameter. This permits `UCFindTextBreak` to optimize its search for the subsequent break of the same type. When iterating through all the breaks of a particular type in a particular buffer, this bit should be set for all calls except the first (since the initial `startOffset` value may not be a known break of the specified type).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Text Break Types

Specifies kinds of text boundaries.

```
typedef UInt32 UCTextBreakType;
enum {
    kUCTextBreakCharMask = 1L << 0,
    kUCTextBreakClusterMask = 1L << 2,
    kUCTextBreakWordMask = 1L << 4,
    kUCTextBreakLineMask = 1L << 6
};
```

Constants

`kUCTextBreakCharMask`

If the bit specified by this mask is set, boundaries of characters may be located (with surrogate pairs treated as a single character).

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCTextBreakClusterMask`
: If the bit specified by this mask is set, boundaries of character clusters may be located. A cluster is a group of characters that should be treated as single text element for editing operations such as cursor movement. Typically this includes groups such as a base character followed by a sequence of combining characters, for example, a Hangul syllable represented as a sequence of conjoining jamo characters or an Indic consonant cluster.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCTextBreakWordMask`
: If the bit specified by this mask is set, boundaries of words may be located. This can be used to determine what to highlight as the result of a double-click.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

`kUCTextBreakLineMask`
: If the bit specified by this mask is set, potential line breaks may be located.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Text Boundary Operation Class

Identifies the class of Unicode utility operations that find text boundaries.

```
enum {
    kUnicodeTextBreakClass = 'ubrk'
};
```

Constants

`kUnicodeTextBreakClass`
: Identifies the class of Unicode utility operations that find text boundaries.

Available in Mac OS X v10.0 and later.

Declared in `UnicodeUtilities.h`.

Discussion

The locales and text-break variants available for finding boundaries in Unicode text can be determined by calling the Locales Utilities functions `LocaleOperationCountLocales` and `LocaleOperationGetLocales` with the `opClass` parameter set to the `kUnicodeTextBreakClass` constant.

Other References

Backup Core Reference

Framework: CoreServices/CoreServices.h

Declared in BackupCore.h

Overview

Backup Core is a C language API that supplies a low-level interface to file and folder settings used by Backup. Introduced in Mac OS X v10.5, Backup is a built-in, user-configurable backup solution that protects user data from accidental loss.

The Backup Core API includes a function you can use to exclude from Backup temporary or otherwise unimportant folders and files your application creates. In addition, you can use this function to allow your users to make backup decisions from within the context of your application.

Functions

CSBackupIsItemExcluded

Returns a Boolean value indicating whether an item is currently excluded from the backup.

```
Boolean CSBackupIsItemExcluded (
    CFURLRef item,
    Boolean * excludeByPath
);
```

Parameters

item

The URL of the item.

excludeByPath

If `true`, the item's backup exclusion status applies to its location; if `false`, the item's backup exclusion status applies to itself, regardless of its location. See `CSBackupSetItemExcluded` (page 2190) for more information. Can be `NULL`.

Return Value

`true` if the item or any of its ancestors are currently excluded from backup, `false` otherwise.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`BackupCore.h`

CSBackupSetItemExcluded

Includes or excludes an item from the backup.

```
OSStatus CSBackupSetItemExcluded (
    CFURLRef item,
    Boolean exclude,
    Boolean excludeByPath
);
```

Parameters

item

The URL of the file or folder to be included or excluded from the backup.

exclude

Pass `true` to exclude this item from backup (Backup will not back up this item). Pass `false` to stop excluding this item (Backup will back up this item if the user so chooses).

excludeByPath

Pass `true` to indicate that this item is excluded because of its location (its absolute path). Pass `false` to indicate that this item is excluded regardless of its location (and regardless of whether the user moves the item).

Return Value

A result code. Returns `noErr` if the item was successfully included or excluded from the backup.

Discussion

Backup skips files and folders marked for exclusion. If a folder is marked for exclusion, the folder and all its contents are excluded from the backup process. You can exclude specific paths that do not exist yet, but that you plan to create later, by passing the planned URL in `item` and passing `true` in `excludeByPath`. Note that if you pass `false` in `excludeByPath`, the URL must already exist.

Your application can allow users to change the backup exclusion status of any file or folder to which it has write access. To change the backup exclusion status of a path, your application must be running with administrator privileges.

Availability

Available in Mac OS X v10.5 and later.

`BackupCore.h`

Low Memory Accessors Reference

Framework: CoreServices/CoreServices.h

Declared in LowMem.h

Overview

Note: This document was previously titled *Carbon Specification for Low Memory Accessors*.

Low-memory accessors are functions you can use to obtain or update information stored in low-memory variables. In general, don't think of the values returned by low-memory accessors as residing in low memory—think of them as global information for a process, possibly associated with a specific manager or service, that is set or returned by Mac OS X. These functions allow you to access useful system information (such as the location of the mouse) stored as global variables in so-called "low memory."

The practice of accessing low memory directly was questionable in earlier versions of Mac OS, and certainly is not suggested now. In some cases, better, safer functions exist in other interfaces for obtaining the same information. To facilitate the porting of legacy applications, Carbon supports many of the low-memory accessors. However, you should always avoid using low-memory accessors if there are direct calls to obtain the same information.

Functions

LMGetApFontID

(Deprecated in Mac OS X v10.4. Use `GetAppFont` instead.)

```
SInt16 LMGetApFontID (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`LowMem.h`

LMGetBootDrive

```
SInt16 LMGetBootDrive (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMGetBufPtr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetBufPtr (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetBufTgDate

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetBufTgDate (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetBufTgFBkNum

(Deprecated in Mac OS X v10.5.)

```
SInt16 LMGetBufTgFBkNum (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetBufTgFFlg

(Deprecated in Mac OS X v10.5.)

```
SInt16 LMGetBufTgFFlg (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetBufTgFNum

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetBufTgFNum (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCPUFlag

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UInt8 LMGetCPUFlag (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCurApName

(Deprecated in Mac OS X v10.5.)

```
StringPtr LMGetCurApName (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCurApRefNum

(Deprecated in Mac OS X v10.5.)

```
FSIORefNum LMGetCurApRefNum (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCurPageOption

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
SInt16 LMGetCurPageOption (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCurPitch

(Deprecated in Mac OS X v10.5.)

```
SInt16 LMGetCurPitch (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetCurStackBase

(Deprecated in Mac OS X v10.4. Use the Thread Manager function `ThreadCurrentStackSpace` (page 2117) or the POSIX threads function `pthread_get_stackaddr_np` instead.)

```
Ptr LMGetCurStackBase (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetDefltStack

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetDefltStack (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetDiskFormatingHFSDefaults

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetDiskFormatingHFSDefaults (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetFinderName

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
StringPtr LMGetFinderName (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetGZMoveHnd

(Deprecated in Mac OS X v10.5.)

```
Handle LMGetGZMoveHnd (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetGZRootHnd

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Handle LMGetGZRootHnd (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetHeapEnd

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetHeapEnd (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetHighHeapMark

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetHighHeapMark (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetIntlSpec

```
Ptr LMGetIntlSpec (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LowMem.h`

LMGetJStash

(Deprecated in Mac OS X v10.5.)

```
UniversalProcPtr LMGetJStash (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetLvl2DT

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UniversalProcPtr LMGetLvl2DT (
   short vectorNumber
);
```

Parameters

vectorNumber

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetMemTop

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetMemTop (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetMinStack

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetMinStack (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetMinusOne

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
SInt32 LMGetMinusOne (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetOneOne

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetOneOne (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetPrintErr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
SInt16 LMGetPrintErr (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetResErr

```
SInt16 LMGetResErr (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LowMem.h`

LMGetResLoad

```
UInt8 LMGetResLoad (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LowMem.h`

LMGetRndSeed

(Deprecated in Mac OS X v10.5.)

```
SInt32 LMGetRndSeed (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetScrDmpEnb

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UInt8 LMGetScrDmpEnb (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
LowMem.h

LMGetSdVolume

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UInt8 LMGetSdVolume (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetSEvtEnb

Returns a value that specifies the system event enabled bit. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
UInt8 LMGetSEvtEnb (
   void
);
```

Discussion
`LMGetSEvtEnb` returns a signed 16-bit integer that describes the low-memory system event enabled bit, a byte that, if set to 0, causes `SystemEvent` to always return `false`.

The value obtained by `LMGetSEvtEnb` is also accessible in the system global variable `SEvtEnb`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetSoundBase

(Deprecated in Mac OS X v10.5.)

```
Ptr LMGetSoundBase (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetSoundLevel

(Deprecated in Mac OS X v10.5.)

```
UInt8 LMGetSoundLevel (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetSoundPtr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetSoundPtr (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetStackLowPoint

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
Ptr LMGetStackLowPoint (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetSysFontFam

(Deprecated in Mac OS X v10.4. Use `GetSysFont` instead.)

```
SInt16 LMGetSysFontFam (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMGetSysFontSize

(Deprecated in Mac OS X v10.4. Use `GetDefFontSize` instead.)

```
SInt16 LMGetSysFontSize (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`LowMem.h`

LMGetSysMap

```
SInt16 LMGetSysMap (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMGetSysResName

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
StringPtr LMGetSysResName (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetTmpResLoad

```
UInt8 LMGetTmpResLoad (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMGetToExtFS

(Deprecated in Mac OS X v10.5.)

```
UniversalProcPtr LMGetToExtFS (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMGetToolScratch

(Deprecated in Mac OS X v10.4. Use process global data instead.)

```
Ptr LMGetToolScratch (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetApFontID

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetApFontID (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
LowMem.h

LMSetBootDrive

```
void LMSetBootDrive (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetBufPtr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetBufPtr (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetBufTgDate

(Deprecated in Mac OS X v10.5.)

```
void LMSetBufTgDate (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetBufTgFBkNum

(Deprecated in Mac OS X v10.5.)

```
void LMSetBufTgFBkNum (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetBufTgFFlg

(Deprecated in Mac OS X v10.5.)

```
void LMSetBufTgFFlg (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetBufTgFNum

(Deprecated in Mac OS X v10.5.)

```
void LMSetBufTgFNum (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCPUFlag

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetCPUFlag (
   UInt8 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCurApName

(Deprecated in Mac OS X v10.5.)

```
void LMSetCurApName (
   ConstStr31Param curApNameValue
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCurApRefNum

(Deprecated in Mac OS X v10.5.)

```
void LMSetCurApRefNum (
   FSIORefNum value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCurPageOption

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetCurPageOption (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCurPitch

(Deprecated in Mac OS X v10.5.)

```
void LMSetCurPitch (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetCurStackBase

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetCurStackBase (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetDefltStack

(Deprecated in Mac OS X v10.5.)

```
void LMSetDefltStack (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetDiskFormatingHFSDefaults

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetDiskFormatingHFSDefaults (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetFinderName

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetFinderName (
   ConstStr15Param finderNameValue
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetGZMoveHnd

(Deprecated in Mac OS X v10.5.)

```
void LMSetGZMoveHnd (
   Handle value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetGZRootHnd

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetGZRootHnd (
   Handle value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetHeapEnd

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetHeapEnd (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetHighHeapMark

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetHighHeapMark (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetIntlSpec

```
void LMSetIntlSpec (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetJStash

(Deprecated in Mac OS X v10.5.)

```
void LMSetJStash (
   UniversalProcPtr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetLvl2DT

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetLvl2DT (
   UniversalProcPtr Lvl2DTValue,
   short vectorNumber
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetMemTop

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetMemTop (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetMinStack

(Deprecated in Mac OS X v10.5.)

```
void LMSetMinStack (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetMinusOne

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetMinusOne (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetOneOne

(Deprecated in Mac OS X v10.5.)

```
void LMSetOneOne (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetPrintErr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetPrintErr (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`LowMem.h`

LMSetResErr

```
void LMSetResErr (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`LowMem.h`

LMSetResLoad

```
void LMSetResLoad (
   UInt8 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetRndSeed

(Deprecated in Mac OS X v10.5.)

```
void LMSetRndSeed (
   SInt32 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetScrDmpEnb

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetScrDmpEnb (
   UInt8 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetSdVolume

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSdVolume (
   UInt8 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetSEvtEnb

Sets the low-memory system event enabled bit. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSEvtEnb (
   UInt8 value
);
```

Parameters

value

An unsigned 8-bit integer that describes the value of the system event enabled bit.

Discussion

`LMSetSEvtEnb` specifies an unsigned 8-bit integer that sets the low-memory system event enabled bit, a byte that, if set to 0, causes the `SystemEvent` to always return `false`.

The value set by `LMSetSEvtEnb` is also accessible in the system global variable `SEvtEnb`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`LowMem.h`

LMSetSoundBase

(Deprecated in Mac OS X v10.5.)

```
void LMSetSoundBase (
   Ptr value
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`LowMem.h`

LMSetSoundLevel

(Deprecated in Mac OS X v10.5.)

```
void LMSetSoundLevel (
   UInt8 value
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetSoundPtr

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSoundPtr (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetStackLowPoint

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetStackLowPoint (
   Ptr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetSysFontFam

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSysFontFam (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
LowMem.h

LMSetSysFontSize

```
void LMSetSysFontSize (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetSysMap

```
void LMSetSysMap (
   SInt16 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetSysResName

(Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
void LMSetSysResName (
   ConstStr15Param sysResNameValue
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetTmpResLoad

```
void LMSetTmpResLoad (
   UInt8 value
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
LowMem.h

LMSetToExtFS

(Deprecated in Mac OS X v10.5.)

```
void LMSetToExtFS (
   UniversalProcPtr value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
LowMem.h

LMSetToolScratch

(Deprecated in Mac OS X v10.4. Use process global data instead.)

```
void LMSetToolScratch (
   const void *toolScratchValue
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
LowMem.h

Core Endian Reference

Framework: CoreServices/CoreServices.h
Declared in Endian.h

Overview

Core Endian Reference provides routines for converting data between big endian and little endian format. These routines are useful for developers who write code that must compile for multiple architectures, including:

- Macintosh developers who want to produce a universal binary.
- QuickTime developers who want their code to run in Windows as well as in Mac OS X.

Both QuickTime and Macintosh developers can use this API to handle reading or writing data to a file or network packet.

Macintosh developers can use this API to create and install callbacks that are invoked by Mac OS X automatically when your application:

- reads and writes custom resource data
- sends or receives custom Apple events
- reads and writes custom pasteboard data

The functions in this API are designed to do nothing when the target runtime is already in the desired format.

For more information see:

- Universal Binary Programming Guidelines
- QuickTime API Reference

Functions by Task

Working With Flippers

`CoreEndianInstallFlipper` (page 2226)
Installs a flipper callback for the specified data type.

`CoreEndianGetFlipper` (page 2225)
Obtains the flipper callback that is installed for the specified data type.

`CoreEndianFlipData` (page 2224)
Calls the flipper callback associated with the specified data type.

Changing the Endian Format

`Endian16_Swap` (page 2227)
Changes the endian format of an unsigned 16-bit integer.

`Endian32_Swap` (page 2227)
Changes the endian format of an unsigned 32-bit integer.

`Endian64_Swap` (page 2227)
Changes the endian format of an unsigned 64-bit integer.

Converting from Big-Endian to Native Format

`EndianS16_BtoN` (page 2228)
Converts a signed 16-bit big-endian value to the equivalent value in the computer's native format.

`EndianS32_BtoN` (page 2231)
Converts a signed 32-bit big-endian value to the equivalent value in the computer's native format.

`EndianS64_BtoN` (page 2233)
Converts a signed 64-bit big-endian value to the equivalent value in the computer's native format.

`EndianU16_BtoN` (page 2236)
Converts an unsigned 16-bit big-endian value to the equivalent value in the computer's native format.

`EndianU32_BtoN` (page 2238)
Converts an unsigned 32-bit big-endian value to the equivalent value in the computer's native format.

`EndianU64_BtoN` (page 2240)
Converts an unsigned 64-bit big-endian value to the equivalent value in the computer's native format.

Converting from Native Format to Big-Endian Format

`EndianS16_NtoB` (page 2229)
Converts a signed 16-bit value in the computer's native format to the equivalent big-endian value.

`EndianS32_NtoB` (page 2232)
Converts a signed 32-bit value in the computer's native format to the equivalent big-endian value.

`EndianS64_NtoB` (page 2234)
Converts a signed 64-bit value in the computer's native format to the equivalent big-endian value.

`EndianU16_NtoB` (page 2237)
Converts an unsigned 16-bit value in the computer's native format to the equivalent big-endian value.

`EndianU32_NtoB` (page 2239)
Converts an unsigned 32-bit value in the computer's native format to the equivalent big-endian value.

`EndianU64_NtoB` (page 2242)
Converts an unsigned 64-bit value in the computer's native format to the equivalent big-endian value.

Converting from Little-Endian Format to Native Format

`EndianS16_LtoN` (page 2229)
Converts a signed 16-bit little-endian value to the equivalent value in the computer's native format.

`EndianS32_LtoN` (page 2232)
Converts a signed 32-bit little-endian value to the equivalent value in the computer's native format.

`EndianS64_LtoN` (page 2234)
Converts a signed 64-bit little-endian value to the equivalent value in the computer's native format.

`EndianU16_LtoN` (page 2236)
Converts an unsigned 16-bit little-endian value to the equivalent value in the computer's native format.

`EndianU32_LtoN` (page 2239)
Converts an unsigned 32-bit little-endian value to the equivalent value in the computer's native format.

`EndianU64_LtoN` (page 2241)
Converts an unsigned 64-bit little-endian value to the equivalent value in the computer's native format.

Converting from Native Format to Little-Endian Format

`EndianS16_NtoL` (page 2230)
Converts a signed 16-bit value in the computer's native format to the equivalent little-endian value.

`EndianS32_NtoL` (page 2232)
Converts a signed 32-bit value in the computer's native format to the equivalent little-endian value.

`EndianS64_NtoL` (page 2235)
Converts a signed 64-bit value in the computer's native format to the equivalent little-endian value.

`EndianU16_NtoL` (page 2237)
Converts an unsigned 16-bit value in the computer's native format to the equivalent little-endian value.

`EndianU32_NtoL` (page 2240)
Converts an unsigned 32-bit value in the computer's native format to the equivalent little-endian value.

`EndianU64_NtoL` (page 2242)
Converts an unsigned 64-bit value in the computer's native format to the equivalent little-endian value.

Converting from Big-Endian to Little-Endian Format

`EndianS16_BtoL` (page 2228)
Converts a signed 16-bit big-endian value to the equivalent little-endian value.

`EndianS32_BtoL` (page 2230)
Converts a signed 32-bit big-endian value to the equivalent little-endian value.

`EndianS64_BtoL` (page 2233)
Converts a signed 64-bit big-endian value to the equivalent little-endian value.

`EndianU16_BtoL` (page 2235)
Converts an unsigned 16-bit big-endian value to the equivalent little-endian value.

`EndianU32_BtoL` (page 2238)
Converts an unsigned 32-bit big-endian value to the equivalent little-endian value.

`EndianU64_BtoL` (page 2240)
Converts an unsigned 64-bit big-endian value to the equivalent little-endian value.

Converting From Little-Endian to Big-Endian Format

`EndianS16_LtoB` (page 2229)
Converts a signed 16-bit little-endian value to the equivalent big-endian value.

`EndianS32_LtoB` (page 2231)
Converts a signed 32-bit little-endian value to the equivalent big-endian value.

`EndianS64_LtoB` (page 2234)
Converts a signed 64-bit little-endian value to the equivalent big-endian value.

`EndianU16_LtoB` (page 2236)
Converts an unsigned 16-bit little-endian value to the equivalent big-endian value.

`EndianU32_LtoB` (page 2238)
Converts an unsigned 32-bit little-endian value to the equivalent big-endian value.

`EndianU64_LtoB` (page 2241)
Converts an unsigned 64-bit little-endian value to the equivalent big-endian value.

Functions

CoreEndianFlipData

Calls the flipper callback associated with the specified data type.

```
OSStatus CoreEndianFlipData (
   OSType dataDomain,
   OSType dataType,
   SInt16 id,
   void *data,
   ByteCount dataLen,
   Boolean currentlyNative
);
```

Parameters

dataDomain
An `OSType` value that specifies the domain of the flipper callback you want to invoke. Pass `kCoreEndianResourceManagerDomain` (page 2248) if your callback applies to resource data. Pass `kCoreEndianAppleEventManagerDomain` (page 2248) if your callback applies to Apple event data. See "Domain Types" (page 2247) for more information.

dataType

An `OSType` value that specifies the type of data that needs to be byte-swapped. This is the four character code of the resource type or Apple event. This never needs to be byte-swapped even though GDB and Xcode display the resource in byte-swapped order.

id

The resource ID of the data type. The Resource Manager byte-swaps this for you so you can compare the resource ID against constants in your code. If the data is not a resource, pass `0`.

data

A pointer to the first byte of the data to be byte swapped.

dataLen

The length of the data (in bytes) to be byte swapped.

currentlyNative

A Boolean value that indicates the direction to byte swap. Pass `true` when the data specified by the `data` parameter uses the byte ordering of the currently executing code. On a PowerPC system, `true` specifies that the data is in big-endian format. On an x86 system, `true` specifies that the data is in little-endian format.

Return Value

A result code. Returns `noErr` if the data is byte swapped and `handlerNotFound` if the data is not byte swapped. Note that data is only byte swapped if it needs to be byte swapped.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`Endian.h`

CoreEndianGetFlipper

Obtains the flipper callback that is installed for the specified data type.

```
OSStatus CoreEndianGetFlipper (
   OSType dataDomain,
   OSType dataType,
   CoreEndianFlipProc *proc,
   void **refcon
);
```

Parameters

dataDomain

An `OSType` value that specifies the domain of the flipper callback you want to obtain. Pass `kCoreEndianResourceManagerDomain` (page 2248) to obtain a callback that applies to resource data. Pass `kCoreEndianAppleEventManagerDomain` (page 2248) to obtain a callback that applies to Apple event data. See "Domain Types" (page 2247) for more information.

dataType

An `OSType` value that specifies the type of data associated with the flipper callback you want to obtain. This is the four character code of the resource type or Apple event. This never needs to be byte-swapped even though GDB and Xcode display the resource in byte-swapped order.

proc

On output, points to the flipper callback that is installed for the data type specified by the `dataType` parameter.

refCon
On output, points to a 32-bit value that references callback-specific data.

Return Value
A result code. Returns `noErr` if the flipper callback is found.

Discussion
You can call the function `CoreEndianGetFlipper` to determine whether a flipper for a given data type is available.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Endian.h`

CoreEndianInstallFlipper

Installs a flipper callback for the specified data type.

```
OSStatus CoreEndianInstallFlipper (
   OSType dataDomain,
   OSType dataType,
   CoreEndianFlipProc proc,
   void *refcon
);
```

Parameters

dataDomain
An `OSType` value that specifies the domain to which the flipper callback applies. Pass `kCoreEndianResourceManagerDomain` (page 2248) if your callback applies to resource data. Pass `kCoreEndianAppleEventManagerDomain` (page 2248) if your callback applies to Apple event data. See "Domain Types" (page 2247) for more information.

dataType
An `OSType` value that specifies the type of data for which you want your flipper callback installed. This is the four character code of the resource type or Apple event.

proc
A pointer to your flipper callback. The flipper callback is installed into a per-process table that is searched before the system table.

refCon
A 32-bit value containing or referring to data needed by the callback.

Return Value
A result code. Returns `noErr` if your flipper callback is installed.

Discussion
You should install the callback by calling the function `CoreEndianInstallFlipper` when your application calls its initialization routine or when you open your resource file.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Endian.h`

Endian16_Swap

Changes the endian format of an unsigned 16-bit integer.

```
UInt16 Endian16_Swap (
    UInt16    value
);
```

Parameters

value

An unsigned 16-bit integer input.

Return Value

The unsigned 16-bit integer result.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 5 and later for Windows.

Declared In

`Endian.h`

Endian32_Swap

Changes the endian format of an unsigned 32-bit integer.

```
UInt32 Endian32_Swap (
    UInt32    value
);
```

Parameters

value

An unsigned 32-bit integer input.

Return Value

The unsigned 32-bit integer result.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 5 and later for Windows.

Declared In

`Endian.h`

Endian64_Swap

Changes the endian format of an unsigned 64-bit integer.

```
static UInt64 Endian64_Swap (
   UInt64 value
);
```

Parameters

value

An unsigned 64-bit integer input.

Return Value
The unsigned 64-bit integer result.

Availability
Available in Mac OS X v10.0 and later.
Available in QuickTime 5 and later for Windows.

Declared In
`Endian.h`

EndianS16_BtoL

Converts a signed 16-bit big-endian value to the equivalent little-endian value.

```

Callbacks

CoreEndianFlipProc

Defines a pointer to a callback function that byte-swaps your custom data.

```
typedef CALLBACK_API (OSStatus, CoreEndianFlipProc)
   (OSType dataDomain,
   OSType dataType,
   short id,
   void *dataPtr,
   UInt32 dataSize,
   Boolean currentlyNative,
   void *refcon
);
```

You would declare your flipper callback function as follows if your were to name it `MyCoreEndianFlipProc`:

```
OSStatus MyCoreEndianFlipProc (
   OSType dataDomain,
   OSType dataType,
   short id,
   void *dataPtr,
   UInt32 dataSize,
   Boolean currentlyNative,
   void *refcon
);
```

Parameters

dataDomain

An `OSType` value that specifies the domain to which the flipper callback applies. The value `kCoreEndianResourceManagerDomain` signifies the domain is resource data. The value `kCoreEndianAppleEventManagerDomain` signifies the domain is Apple event data. See "Domain Types" (page 2247) for more information on the values that can be passed to your callback.

dataType

The type of data to be byte swapped by the callback. This is the four character code of the resource type or Apple event.

id

The resource id of the data type. The value `0` signifies the data is not a resource.

dataPtr

On input, points to the data to be flipped. On output, points to the byte-swapped data.

dataSize

The size of the data pointed to the by the `dataPtr` parameter.

currentlyNative

A Boolean value that indicates the direction to byte swap. The value `true` specifies the data pointed to by the `dataPtr` parameter uses the byte ordering of the currently executing code. On a PowerPC system, `true` specifies that the data is in big-endian format. On an x86 system, `true` specifies that the data is in little-endian format.

refcon

A 32-bit value that contains or refers to data needed by the callback.

Return Value
A result code that indicates whether the byte swapping is successful. Your callback should return `noErr` if the resource is byte swapped without error, `handlerNotFound` if you chose not to byte swap the data, and the appropriate result code to indicate an error condition if the data is bad. The result code you return is propagated through the appropriate manager (Resource Manager (`ResError`) or Apple Event Manager) to the caller.

Discussion
You should write each flipper callback so it traverses the data structure that contains the data and performs the following tasks:

- Byte swaps all Resource Manager counts and lengths so that array indexes are associated with the appropriate value
- Byte swaps all integers and longs so that when you read them into variables of a compatible type the values can be operated on correctly (such as numerical, offset, and shift operations)

A flipper callback must be bidirectional because it can be called by the Resource Manager or Apple Event Manager when you read data as well as when you write data. The system ensures that your flipper callback is invoked at the appropriate times.

Your flipper callback is not invoked on a microprocessor that uses big-endian byte ordering. It is called with `currentlyNative` set to `false` when data is read (or received) and `true` when the data is set to be written (or sent).

Availability
Available in Mac OS X 10.3 and later.

Declared In
`Endian.h`

Data Types

BigEndianLong

Protects a big-endian long value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianLong {
long bigEndianValue;
};
typedef struct BigEndianLong  BigEndianLong;
// Big-endian host
typedef long  BigEndianLong;
```

Fields
`bigEndianValue`
A long value.

Availability
Available in Mac OS X v10.0 and later.
Available in QuickTime 4 and later for Windows.

Declared In
`Endian.h`

BigEndianUnsignedLong

Protects a big-endian unsigned long value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianUnsignedLong {
 unsigned long    bigEndianValue;
 };
typedef struct BigEndianUnsignedLong BigEndianUnsignedLong;
// Big-endian host
typedef unsigned long  BigEndianUnsignedLong;
```

Fields
`bigEndianValue`
An unsigned long value.

Availability
Available in Mac OS X v10.0 and later.
Available in QuickTime 4 and later for Windows.

Declared In
`Endian.h`

BigEndianShort

Protects a big-endian short value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianShort {
 short    bigEndianValue;
};
typedef struct BigEndianShort  BigEndianShort;
// Big-endian host
typedef short BigEndianShort;
```

Fields
`bigEndianValue`
A short value.

Availability
Available in Mac OS X v10.0 and later.
Available in QuickTime 4 and later for Windows.

Declared In
`Endian.h`

BigEndianUnsignedShort

Protects a big-endian unsigned short value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianUnsignedShort {
 unsigned short    bigEndianValue;
};
typedef struct BigEndianUnsignedShort  BigEndianUnsignedShort;
// Big-endian host
typedef unsigned short BigEndianUnsignedShort;
```

Fields

`bigEndianValue`

An unsigned short value.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 4 and later for Windows.

Declared In

`Endian.h`

BigEndianFixed

Protects a big-endian Fixed value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianFixed {
Fixed    bigEndianValue;
};
typedef struct BigEndianFixed  BigEndianFixed;
// Big-endian host
typedef Fixed BigEndianFixed;
```

Fields

`bigEndianValue`

A fixed value.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 4 and later for Windows.

Declared In

`Endian.h`

BigEndianUnsignedFixed

Protects a big-endian unsigned Fixed value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianUnsignedFixed {
UnsignedFixed    bigEndianValue;
};
typedef struct BigEndianUnsignedFixed  BigEndianUnsignedFixed;
// Big-endian host
typedef UnsignedFixed BigEndianUnsignedFixed;
```

Fields

`bigEndianValue`

An unsigned fixed value.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 4 and later for Windows.

Declared In

`Endian.h`

BigEndianOSType

Protects a big-endian OSType value from being changed by little-endian code.

```
// Little-endian host
struct BigEndianOSType {
OSType    bigEndianValue;
};
typedef struct BigEndianOStype  BigEndianOStype;
// Big-endian host
typedef OSType BigEndianOSType;
```

Fields

`bigEndianValue`

An OSType value.

Availability

Available in Mac OS X v10.0 and later.

Available in QuickTime 4 and later for Windows.

Constants

Domain Types

Specify the domain to which a flipper callback should be applied.

```
enum {
    kCoreEndianResourceManagerDomain = 'rsrc',
    kCoreEndianAppleEventManagerDomain = 'aevt'
};
```

Constants

`kCoreEndianResourceManagerDomain`

Specifies that the domain is limited to the resources for a specific application.

Available in Mac OS X v10.4 and later.

Declared in `Endian.h`.

`kCoreEndianAppleEventManagerDomain`

Specifies that the domain is limited to Apple events.

Available in Mac OS X v10.4 and later.

Declared in `Endian.h`.

Discussion

The data types have specific meanings within their domain, although some data types can be registered with the same callback in several domains.

Availability

Available in Mac OS X 10.3 and later.

Error Handler Reference

Framework: CoreServices/CoreServices.h

Declared in MacErrors.h
MacTypes.h

Overview

In Mac OS 9, Error Handler provides a system service that displays system alerts seen during startup, and assumes control when certain low-level errors occur. For detailed information, see the chapter "System Error Handler" in *Inside Macintosh: Operating System Utilities*. A PDF version of this chapter is available at http://developer.apple.com/documentation/mac/pdf/Operating_System_Utilities/pdf.html.

Note: In Mac OS X, Error Handler is no longer used for this purpose—for more information, see `SysError` (page 2249).

The header `MacErrors.h` defines result codes that are used by many Carbon functions to indicate their return status. Developers can also define custom result codes for their own applications, using the range 1000 through 9999 inclusive (Apple reserves all values outside of this range for internal use.) For more information, see Technical Q&A OV02 at http://developer.apple.com/qa/ov/ov02.html.

Functions

SysError

In Mac OS 9, displays a low-level system alert or dialog. The appearance and semantics of the alert or dialog can vary, depending on the error code passed in.

Not recommended

```
void SysError (
   short errorCode
);
```

Parameters

errorCode

A value or code that indicates a specific condition.

Discussion

A Carbon application running in Mac OS 9 can use this function to simulate a low-level system error. To exit in a more graceful manner when a serious error occurs, your application should call `ExitToShell` instead.

In Mac OS X, this function:

1. Prints a message containing the value of `errorCode` in the console log. Does not display a system alert or dialog.
2. If the variable `USERBREAK` is defined in the process environment, raises a `SIGINT` signal. Otherwise, returns control to the caller.

If a signal is raised and the caller does not handle the signal, the calling process is automatically terminated.

Availability
Not recommended in Carbon. Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later. Available in Mac OS X 10.0 and later.

Declared In
`MacErrors.h`

Data Types

OSErr

A numeric code used in Carbon to indicate the return status of a function.

```
typedef SInt16 OSErr;
```

Discussion
The system software sometimes uses error codes to inform an application that a requested service is not possible. Many functions return a result code of type `OSErr` that indicates whether the function completed successfully, and if not, what the reason for failure was.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IOMacOSTypes.h`

OSStatus

A numeric code used in Carbon to indicate the return status of a function.

```
typedef SInt32 OSStatus;
```

Discussion
The system software sometimes uses error codes to inform an application that a requested service is not possible. Many functions return a result code of type `OSStatus` that indicates whether the function completed successfully, and if not, what the reason for failure was.

If you want to use `OSStatus` to define error codes for your application, Apple recommends that you use values in the range 1000 through 9999 inclusive. Values outside of this range are reserved by Apple for internal use.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSTypes.h`

Finder Interface Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	Finder.h FinderRegistry.h

Overview

The Finder is an application that works with the system software to keep track of files and manage the user's desktop display. This document describes the programming interface your application should use to interact with the Finder. For example, you can use this interface to:

- Set up the resources the Finder needs to display and start up your application
- Set up the resources the Finder uses to display information about other files related to your application
- Examine or change Finder-related information stored in a volume's catalog file
- Support stationery pads

Data Types

CustomBadgeResource

```
struct CustomBadgeResource {
    SInt16 version;
    SInt16 customBadgeResourceID;
    OSType customBadgeType;
    OSType customBadgeCreator;
    OSType windowBadgeType;
    OSType windowBadgeCreator;
    OSType overrideType;
    OSType overrideCreator;
};
typedef struct CustomBadgeResource CustomBadgeResource;
typedef CustomBadgeResource * CustomBadgeResourcePtr;
```

Fields

`version`

`customBadgeResourceID`

`customBadgeType`

`customBadgeCreator`

`windowBadgeType`

`windowBadgeCreator`

`overrideType`

`overrideCreator`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

ExtendedFolderInfo

Defines an extended directory information structure. The `ExtendedFolderInfo` structure is preferred over the `DXInfo` structure.

```
struct ExtendedFolderInfo {
    Point scrollPosition;
    SInt32 reserved1;
    UInt16 extendedFinderFlags;
    SInt16 reserved2;
    SInt32 putAwayFolderID;
};
typedef struct ExtendedFolderInfo ExtendedFolderInfo;
```

Fields

`scrollPosition`

Scroll position within the Finder window. The Finder does not necessarily save this position immediately upon user action.

`reserved1`
Reserved (set to 0).

`extendedFinderFlags`
Extended Finder flags. See "Extended Finder Flags " (page 2262).

`reserved2`
Reserved (set to 0).

`putAwayFolderID`
If the user moves the folder onto the desktop, the directory ID of the folder from which the user moves it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

FolderInfo

Defines a directory information structure. The `FolderInfo` structure is preferred over the `DInfo` structure.

```
struct FolderInfo {
    Rect windowBounds;
    UInt16 finderFlags;
    Point location;
    UInt16 reservedField;
};
typedef struct FolderInfo FolderInfo;
```

Fields
`windowBounds`
The rectangle for the window that the Finder displays when the user opens the folder.

`finderFlags`
Finder flags. See "Finder Flags" (page 2261).

`location`
Location of the folder in the parent window.

`reservedField`
Reserved. Set to 0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

DInfo

Defines a directory information structure.

```
struct DInfo {
    Rect frRect;
    UInt16 frFlags;
    Point frLocation;
    SInt16 frView;
};
typedef struct DInfo DInfo;
```

Fields

`frRect`

The rectangle for the window that the Finder displays when the user opens the folder.

`frFlags`

Reserved.

`frLocation`

Location of the folder in the parent window.

`frView`

The manner in which folders are displayed; this is set by the user with commands from the View menu of the Finder.

Discussion

The Finder manipulates the fields in the directory information record. Your application shouldn't have to check or set any of these fields directly

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Finder.h`

DXInfo

Defines an extended directory information structure.

```
struct DXInfo {
    Point frScroll;
    SInt32 frOpenChain;
    SInt8 frScript;
    SInt8 frXFlags;
    SInt16 frComment;
    SInt32 frPutAway;
};
typedef struct DXInfo DXInfo;
```

Fields

`frScroll`

Scroll position within the Finder window. The Finder does not necessarily save this position immediately upon user action.

`frOpenChain`

Chain of directory IDs for open folders. The Finder numbers directory IDs. The Finder does not necessarily save this information immediately upon user action.

`frScript`
: Extended flags. If the high-bit is set, the script system for displaying the folder's name. Ordinarily, the Finder (and the Standard File Package) displays the names of all desktop objects in the current system script, which depends on the region-specific configuration of the system. The high bit of the byte in the fdScript field is set by default to 0, which causes the Finder to display the folder's name in the current system script. If the high bit is set to 1, the Finder (and the Standard File Package) displays the filename and directory name in the script whose code is recorded in the remaining 7 bits. However, as of system software version 7.1, the Window Manager and Dialog Manager do not support multiple simultaneous scripts, so the system script is always used for displaying filenames and directory names in dialog boxes, window titles, and other user interface elements used by the Finder. Therefore, until the system software's script capability is fully implemented, you should treat this field as reserved.

`frXFlags`
: Extended flags. See "Extended Finder Flags " (page 2262).

`frComment`
: Reserved (set to 0). If the high-bit is clear, an ID number for the comment that is displayed in the information window when the user selects a folder and chooses the Get Info command from the File menu. The numbers that identify comments are assigned by the Finder.

`frPutAway`
: If the user moves the folder onto the desktop, the directory ID of the folder from which the user moves it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

ExtendedFileInfo

Defines an extended file information structure. The `ExtendedFileInfo` structure is preferred over the `FXInfo` structure.

```
struct ExtendedFileInfo {
    SInt16 reserved1[4];
    UInt16 extendedFinderFlags;
    SInt16 reserved2;
    SInt32 putAwayFolderID;
};
typedef struct ExtendedFileInfo ExtendedFileInfo;
```

Fields

`reserved1`
: Reserved (set to 0).

`extendedFinderFlags`
: Extended flags. See "Extended Finder Flags " (page 2262).

`reserved2`
: Reserved (set to 0).

`putAwayFolderID`
: If the user moves the file onto the desktop, the directory ID of the folder from which the user moves the file.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

FileInfo

Defines a file information structure. The `FileInfo` structure is preferred over the `FInfo` structure.

```
struct FileInfo {
    OSType fileType;
    OSType fileCreator;
    UInt16 finderFlags;
    Point location;
    UInt16 reservedField;
};
typedef struct FileInfo FileInfo;
```

Fields

`fileType`
File type.

`fileCreator`
The signature of the application that created the file.

`finderFlags`
Finder flags. See "Finder Flags" (page 2261).

`location`
The location--specified in coordinates local to the window--of the file's icon within its window.

`reservedField`
The window in which the file's icon appears; this information is meaningful only to the Finder.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

FInfo

Defines a file information structure.

```
struct FInfo {
    OSType fdType;
    OSType fdCreator;
    UInt16 fdFlags;
    Point fdLocation;
    SInt16 fdFldr;
};
typedef struct FInfo FInfo;
```

Fields

`fdType`
File type.

`fdCreator`
The signature of the application that created the file.

`fdFlags`
Finder flags. See "Finder Flags" (page 2261).

`fdLocation`
The location--specified in coordinates local to the window--of the file's icon within its window.

`fdFldr`
The window in which the file's icon appears; this information is meaningful only to the Finder.

Discussion

You typically set a file's type and creator when you create the file. The Finder manipulates the other fields in the file information record, which is a data structure of type `FInfo`. After you have created a file, you can use the File Manager function `FSpGetFInfo` to return the file information record, then change the `fdType` and `fdCreator` fields by using the File Manager function `FSpSetFInfo`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Finder.h`

FXInfo

Defines an extended file information structure.

```
struct FXInfo {
    SInt16 fdIconID;
    SInt16 fdReserved[3];
    SInt8 fdScript;
    SInt8 fdXFlags;
    SInt16 fdComment;
    SInt32 fdPutAway;
};
typedef struct FXInfo FXInfo;
```

Fields

`fdIconID`
An ID number for the file's icon; the numbers that identify icons are assigned by the Finder.

`fdReserved`
Reserved.

`fdScript`
: Extended flags. Script code if high-bit is set.

`fdXFlags`
: Extended flags.

`fdComment`
: Reserved (set to 0). If the high-bit is clear, an ID number for the comment that is displayed in the information window when the user selects a file and chooses the Get Info command from the File menu. The numbers that identify comments are assigned by the Finder.

`fdPutAway`
: If the user moves the file onto the desktop, the directory ID of the folder from which the user moves the file.

Discussion
The Finder manipulates the fields in the extended file information records ; your application shouldn't have to check or set any of these fields directly.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

RoutingResourceEntry

```
struct RoutingResourceEntry {
    OSType creator;
    OSType fileType;
    OSType targetFolder;
    OSType destinationFolder;
    OSType reservedField;
};
typedef struct RoutingResourceEntry RoutingResourceEntry;
typedef RoutingResourceEntry * RoutingResourcePtr;
```

Fields
`creator`
`fileType`
`targetFolder`
`destinationFolder`
`reservedField`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Finder.h`

Constants

Finder Flags

Specify flags used by the Finder.

```
enum {
    kIsOnDesk = 0x0001,
    kColor = 0x000E,
    kIsShared = 0x0040,
    kHasNoINITs = 0x0080,
    kHasBeenInited = 0x0100,
    kHasCustomIcon = 0x0400,
    kIsStationery = 0x0800,
    kNameLocked = 0x1000,
    kHasBundle = 0x2000,
    kIsInvisible = 0x4000,
    kIsAlias = 0x8000
};
```

Constants

`kIsOnDesk`

Unused and reserved in System 7; set to 0.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kColor`

Three bits of color coding.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kIsShared`

The file is an application that can be executed by multiple users simultaneously. Defined only for applications; otherwise, set to 0.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kHasNoINITs`

The file contains no 'INIT' resources; set to 0. Reserved for directories; set to 0.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kHasBeenInited`

The Finder has recorded information from the file's bundle resource into the desktop database and given the file or folder a position on the desktop.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kHasCustomIcon`

The file or directory contains a customized icon.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kIsStationery`
For a file, this bit indicates that the file is a stationery pad. For directories, this bit is reserved--in which case, set to 0.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kNameLocked`
The file or directory can't be renamed from the Finder, and the icon cannot be changed.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kHasBundle`
For a file, this bit indicates that the file contains a bundle resource. For a directory, this bit indicates that the directory is a file package. Note that not all file packages have this bit set; many file packages are identified by other means, such as a recognized package extension in the name. The proper way to determine if an item is a package is through Launch Services.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kIsInvisible`
The file or directory is invisible from the Finder and from the Navigation Services dialogs.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kIsAlias`
For a file, this bit indicates that the file is an alias file. For directories, this bit is reserved--in which case, set to 0.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

Extended Finder Flags

Define flags used by the extended file and folder information structures.

```
enum {
    kExtendedFlagsAreInvalid = 0x8000,
    kExtendedFlagHasCustomBadge = 0x0100,
    kExtendedFlagHasRoutingInfo = 0x0004
};
```

Constants

`kExtendedFlagsAreInvalid`
If set the other extended flags are ignored.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kExtendedFlagHasCustomBadge`
Set if the file or folder has a badge resource.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

`kExtendedFlagHasRoutingInfo`

Set if the file contains routing info resource.

Available in Mac OS X v10.0 and later.

Declared in `Finder.h`.

Finder Error Codes

```
enum {
    errFinderIsBusy = -15260,
    errFinderWindowNotOpen = -15261,
    errFinderCannotPutAway = -15262,
    errFinderWindowMustBeIconView = -15263,
    errFinderWindowMustBeListView = -15264,

};
```

fOnDesk

Obsolete. Use the constants described in "Finder Flags."

```
enum {
    fOnDesk = kIsOnDesk,
    fHasBundle = kHasBundle,
    fInvisible = kIsInvisible
};
```

formAlias

```
enum {
    formAlias = typeAlias,
    formCreator = pFileCreator
};
```

fTrash

Obsolete.

```
enum {
    fTrash = -3,
    fDesktop = -2,
    fDisk = 0
};
```

Clipping File Creator and Types

```
enum {
    kClippingCreator = 'drag',
    kClippingPictureType = 'clpp',
    kClippingTextType = 'clpt',
    kClippingSoundType = 'clps',
    kClippingUnknownType = 'clpu'
};
```

kContainerFolderAliasType

```
enum {
    kContainerFolderAliasType = 'fdrp',

    keyAENoAutoRouting = 'rout',
    keyLocalPositionList = 'mvpl',
    keyGlobalPositionList = 'mvpg',
    keyRedirectedDocumentList = 'fpdl'
};
```

Constants

`keyIconAndMask`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`key32BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`key8BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`key4BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`key8BitMask`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keySmallIconAndMask`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keySmall8BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keySmall4BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keySmall32BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keySmall8BitMask`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyMini1BitMask`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyMini4BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyMini8BitIcon`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyAEUsing`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyAEReplacing`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyAENoAutoRouting`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyLocalPositionList`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyGlobalPositionList`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

`keyRedirectedDocumentList`
Available in Mac OS X v10.0 and later.
Declared in `FinderRegistry.h`.

};
```

Result Codes

The most common result codes returned by Finder Interface are listed below.

Result Code	Value	Description
errOffsetInvalid	-1800	Available in Mac OS X v10.0 and later.
errOffsetIsOutsideOfView	-1801	Available in Mac OS X v10.0 and later.
errTopOfDocument	-1810	Available in Mac OS X v10.0 and later.
errTopOfBody	-1811	Available in Mac OS X v10.0 and later.
errEndOfDocument	-1812	Available in Mac OS X v10.0 and later.
errEndOfBody	-1813	Available in Mac OS X v10.0 and later.
desktopDamagedErr	-1305	The desktop database has become corrupted Available in Mac OS X v10.0 and later.

MDImporter Reference

Framework:	CoreServices/CoreServices.h
Declared in	MDImporter.h
Companion guides	Spotlight Overview Spotlight Importer Programming Guide Plug-ins

Overview

An MDImporter is responsible for returning the metadata contained with a file. The Spotlight server is notified when a file is changed and loads the appropriate importer to extract the metadata. An importer is implemented as a CFPlugin.

Callbacks

ImporterImportData

Defines a pointer to an importer import callback that imports importers.

```
typedef Boolean (* ImporterImportData)
(
void *thisInterface,
CFMutableDictionaryRef attributes,
CFStringRef contentTypeUTI,
CFStringRef pathToFile
)
```

If you name your function `GetMetadataForFile`, you would declare it like this:

```
Boolean GetMetadataForFile
(
void *thisInterface,
CFMutableDictionaryRef attributes,
CFStringRef contentTypeUTI,
CFStringRef pathToFile
)
```

Parameters

thisInterface

The CFPlugin object that is called. This value is passed to the callback function.

attributes

A mutable dictionary that you should populate with the metadata key/value pairs. This dictionary is created and passed to the callback function.

contentTypeUTI

The content type of the file as a uniform type identifier. This value is passed to the callback function.

pathToFile

The full path to the file. This value is passed to the callback function.

Return Value

Your callback function should return `true` if the metadata was successfully returned, `false` if the metadata was not returned.

Constants

kMDImporterTypeID

Type ID of an importer plug-in.

```
#define kMDImporterTypeID
CFUUIDGetConstantUUIDWithBytes(kCFAllocatorDefault,0x8B,0x08,0xC4,0xBF,0x41,0x5
B,0x11,0xD8,0xB3,0xF9,0x00,0x03,0x93,0x67,0x26,0xFC);
```

Constants

`kMDImporterTypeID`

Only importers with this type ID are loaded.

Available in Mac OS X v10.4 and later.

Declared in `MDImporter.h`.

Discussion

The string representation of this UUID is `8B08C4BF-415B-11D8-B3F9-0003936726FC`.

kMDImporterInterfaceID

Interface required by a importer plug-in.

```
#define kMDImporterInterfaceID
CFUUIDGetConstantUUIDWithBytes(kCFAllocatorDefault,0x6E,0xBC,0x27,0xC4,0x89,0x9
C,0x11,0xD8,0x84,0xAE,0x00,0x03,0x93,0x67,0x26,0xFC);
```

Constants

`kMDImporterInterfaceID`

Importers must implement an interface corresponding to this UUID.

Available in Mac OS X v10.4 and later.

Declared in `MDImporter.h`.

Discussion

The string representation of this UUID is `6EBC27C4-899C-11D8-84A3-0003936726FC`.

MDSchema Reference

Framework:	CoreServices/CoreServices.h
Declared in	MDSchema.h
Companion guide	Spotlight Overview

Overview

The MDSchema functions provide information about the metadata returned for an item including the type of metadata provided for a file type, the localized display name for a metadata attribute key, and the schema for a metadata attribute key.

Functions

MDSchemaCopyAllAttributes

Returns an array containing all the metadata attributes defined in the schema.

```
CFArrayRef MDSchemaCopyAllAttributes (
   void
);
```

Availability
Available in Mac OS X version 10.4 or later.

Declared In
`MDSchema.h`

MDSchemaCopyAttributesForContentType

Returns a dictionary containing the metadata attributes for the specified UTI type.

```
MD_BEGIN_C_DECLS CFDictionaryRef MDSchemaCopyAttributesForContentType (
   CFStringRef contentTypeUTI
);
```

Parameters
utiType
The UTI type.

Return Value
A dictionary containing `kMDAttributeDisplayValues` and `kMDAttributeAllValues` keys. Returns `NULL` if the UTI type is unknown.

Discussion
This function returns the metadata attributes for the specified UTI type only.

Availability
Available in Mac OS X version 10.4 or later.

Declared In
`MDSchema.h`

MDSchemaCopyDisplayDescriptionForAttribute

Returns the localized description of a metadata attribute key.

```
CFStringRef MDSchemaCopyDisplayDescriptionForAttribute (
   CFStringRef name
);
```

Parameters

name
The name of the metadata attribute key.

Return Value
The localized description of the metadata attribute, or `NULL` if no localized description is available.

Availability
Available in Mac OS X version 10.4 or later.

Declared In
`MDSchema.h`

MDSchemaCopyDisplayNameForAttribute

Returns the localized display name of a metadata attribute key.

```
CFStringRef MDSchemaCopyDisplayNameForAttribute (
   CFStringRef name
);
```

Parameters

name
The name of the metadata attribute key.

Return Value
The localized display name of the metadata attribute, or `NULL` if no localized display name is available.

Availability
Available in Mac OS X version 10.4 or later.

Declared In
`MDSchema.h`

MDSchemaCopyMetaAttributesForAttribute

Returns a dictionary describing the values for the specified metadata attribute key.

```
CFDictionaryRef MDSchemaCopyMetaAttributesForAttribute (
   CFStringRef name
);
```

Parameters

name

The name of the metadata attribute key.

Return Value

A dictionary describing the schema of the metadata attribute key.

Availability

Available in Mac OS X version 10.4 or later.

Declared In

`MDSchema.h`

Constants

Available Metadata Attribute Keys

Specify the available metadata attribute keys for a content type.

```
const CFStringRef     kMDAttributeDisplayValues;
const CFStringRef     kMDAttributeAllValues;
```

Constants

`kMDAttributeDisplayValues`

An array of strings containing the available display metadata attribute keys, or `NULL` if the type is not known by the system.

Available in Mac OS X v10.4 and later.

Declared in `MDSchema.h`.

`kMDAttributeAllValues`

An array of strings containing available the metadata attribute keys, or `NULL` if the type is not known by the system.

Available in Mac OS X v10.4 and later.

Declared in `MDSchema.h`.

Discussion

These keys are in the dictionary returned by the function `MDSchemaCopyAttributesForContentType`.

Availability

Available in Mac OS X version 10.4 and later.

Metadata Attribute Schema Description Keys

Specify the schema of a metadata attribute key.

```
const CFStringRef kMDAttributeName;
const CFStringRef kMDAttributeType;
const CFStringRef kMDAttributeMultiValued;
```

Constants

`kMDAttributeName`

A string containing the name of the metadata attribute key.

Available in Mac OS X v10.4 and later.

Declared in `MDSchema.h`.

`kMDAttributeType`

A CFNumberRef or CFTypeId describing the type of data returned as the value of the metadata attribute key.

Available in Mac OS X v10.4 and later.

Declared in `MDSchema.h`.

`kMDAttributeMultiValued`

A boolean that indicates if the metadata attribute value is multi-valued. If this is `TRUE`, the metadata attribute value is an array of the types specified in `kMDAttributeType`.

Available in Mac OS X v10.4 and later.

Declared in `MDSchema.h`.

Discussion

These keys are in the dictionary returned by the function `MDSchemaCopyMetaAttributesForAttribute`.

Availability

Available in Mac OS X version 10.4 and later.

Open Transport Reference

Framework:	CoreServices/CoreServices.h
Declared in	OpenTransport.h OpenTransportProviders.h OpenTransportProtocol.h

Overview

Open Transport is the Mac OS 8 and 9 API for accessing TCP/IP networks, such as the Internet, at the transport level. For Mac OS X, Apple provides Open Transport as a compatibility library to ease migration of legacy applications. As such, Mac OS X does not support the entire Open Transport API.

In new Mac OS X applications you should not use Open Transport but should instead use BSD Sockets or, when possible, higher-level Core Services and Core Foundation APIs such as CFNetwork, CFURL, CFSocket, and CFStream. You can also use Cocoa networking classes such as NSURL, NSURLHandle, and NSNetService.

In Mac OS X, Open Transport provides limited support for endpoints and port access, and no support for the XTI or UNIX STREAMS interfaces. If you want your application to run in Mac OS 8 and 9 and in Mac OS X, use Open Transport for your Mac OS 8 and 9 version and Apple's newer APIs for your Mac OS X version.

For more information about Open Transport, see:

http://developer.apple.com/macos/opentransport/

Mac OS X supports only these Open Transport providers:

- TCP, UDP, and Raw IP Endpoints
- TCP/IP Services Providers and TCP/IP Mapper Providers (for the Domain Name Resolver protocol)
- DDP endpoints, AppleTalk Services Providers, and AppleTalk Mappers (for the Name Binding Protocol)
- OT/PPP endpoints

Mac OS X does not support ADSP, ATP, ASP, PAP, or serial endpoints.

You may have to revise your code if it uses Open Transport in one of the following ways:

- Your application uses a function that directly gains access to a network port. Ports are read-only in Mac OS X. Code that communicates directly with network interfaces must use the IOKit API.
- Your application uses the transaction-based endpoint feature of Open Transport. This feature is not supported in Mac OS X. Removal of this capability should affect only users of AppleTalk protocols such as ASP.

- Your application uses Open Transport's XTI interfaces or UNIX STREAMS interfaces. Mac OS X will not support these interfaces. You can obtain similar functionality using supported high-level functions.
- In Mac OS X, one cannot assume that Open Transport deferred tasks and notifiers procedures run at deferred task level. They may be preempted by the main event loop or another Mac OS X thread. You should always use atomic operations to access data shared between deferred tasks and notifiers and main system tasks.

Mac OS X does not support functions for:

- accessing Open Transport hash lists
- accessing the Open Transport port name or icon
- directly manipulating CFM or ASLM libraries

Client context parameters have been added to a number of OT functions. (An OT client is an application or a shared library.) Each client of Open Transport now has its own client context so that OT can track resources it allocates on behalf of the client. OT resources are objects like endpoints, timer tasks, and blocks of memory. To find out more about Open Transport resources management, see *"Understanding Open Transport Asset Tracking"* at:

http://developer.apple.com/technotes/tn/tn1173.html

Mac OS X introduces a new type, `OTClientContextPtr`, that represents the OT client context. This new type is passed as an extra parameter to functions that allocate OT resources. Before Mac OS X, the OT client context was determined by the Open Transport static libraries that you linked to your application. Now the OT client context is determined explicitly. The same Carbon binary can run on Mac OS 8/9 and Mac OS X, and you do not have to link your application to the static libraries.

You can use `InitOpenTransportinContext` to replace `InitOpenTransport`. It functions identically except that it also takes a client context pointer and a flags parameter to indicate whether you are initializing OT for an application or a shared library. When your application or shared library is done using Open Transport you should call `CloseOpenTransportInContext` to dispose of the Open Transport resources allocated for the client.

The following functions now take a client context:

- `CloseOpenTransportInContext` (page 2301)
- `OTAllocInContext` (page 2308)
- `OTAllocMemInContext` (page 2309)
- `OTAsyncOpenAppleTalkServicesInContext` (page 2310)
- `OTAsyncOpenEndpointInContext` (page 2310)
- `OTAsyncOpenInternetServicesInContext` (page 2311)
- `OTAsyncOpenMapperInContext` (page 2312)
- `OTCreateDeferredTaskInContext` (page 2329)
- `OTCreateTimerTaskInContext` (page 2330)
- `OTOpenAppleTalkServicesInContext` (page 2372)
- `OTOpenEndpointInContext` (page 2373)

- OTOpenInternetServicesInContext (page 2374)
- OTOpenMapperInContext (page 2374)

As a convenience, applications may pass a null pointer to these routines and Open Transport will use the context that was passed to InitOpenTransport. However, shared libraries must always pass a valid OTClientContextPtr.

If you want to keep your application source code compatible with pre-Mac OS X systems, you may define the C preprocessor constant OTCARBONAPPLICATION to 1 to use the old routine names without the "InContext" suffix.

Mac OS X applications must pass UPPs instead of procedure pointers for Open Transport callback routines. You can use these new functions to create UPPs:

OTNotifyUPP replaces OTNotifyProcPtr

OTProcessUPP replaces OTNotifyProcPtr

OTListSearchUPP replaces OTListSearchProcPtr

You can use these functions to allocate and free UPPs:

- NewOTNotifyUPP (page 2305)
- DisposeOTNotifyUPP (page 2302)
- NewOTProcessUPP (page 2306)
- DisposeOTProcessUPP (page 2303)
- NewOTListSearchUPP (page 2305)
- DisposeOTListSearchUPP (page 2302)

These functions have been modified to take an OTNotifyUPP UPP instead of a procedure pointer:

- OTAsyncOpenAppleTalkServicesInContext (page 2310)
- OTAsyncOpenInternetServicesInContext (page 2311)
- OTInstallNotifier (page 2361)
- OTAsyncOpenEndpointInContext (page 2310)
- OTAsyncOpenMapperInContext (page 2312)

These functions have been modified to take an OTProcessUPP UPP instead of a procedure pointer:

- OTCreateTimerTaskInContext (page 2330)
- OTCreateDeferredTaskInContext (page 2329)

These functions have been modified to take an OTListSearchUPP UPP instead of a procedure pointer:

- OTFindLink (page 2339)
- OTFindAndRemoveLink (page 2338)

Functions by Task

Initializing and Closing Open Transport

`CloseOpenTransportInContext` (page 2301) Deprecated in Mac OS X v10.4
Unregisters your application or code resource connection to Open Transport.

`InitOpenTransportInContext` (page 2303) Deprecated in Mac OS X v10.4
Initializes the parts of Open Transport for use by the application or code resource.

Creating, Cloning, and Disposing of a Configuration Structure

`OTCloneConfiguration` (page 2322) Deprecated in Mac OS X v10.4
Copies an `OTConfiguration` structure.

`OTCreateConfiguration` (page 2328) Deprecated in Mac OS X v10.4
Creates a structure defining a provider's configuration.

`OTDestroyConfiguration` (page 2333) Deprecated in Mac OS X v10.4
Deletes an `OTConfiguration` structure.

Opening and Closing Providers

`OTCloseProvider` (page 2323) Deprecated in Mac OS X v10.4
Closes a provider of any type—endpoint, mapper, or service provider.

Controlling a Provider's Modes of Operation

`OTAckSends` (page 2307) Deprecated in Mac OS X v10.4
Specifies that a provider make an internal copy of data being sent and that it notify you when it has finished sending data.

`OTCancelSynchronousCalls` (page 2321) Deprecated in Mac OS X v10.4
Cancels any currently executing synchronous function for a specified provider.

`OTDontAckSends` (page 2335) Deprecated in Mac OS X v10.4
Specifies that a provider copy data before sending it.

`OTIsAckingSends` (page 2363) Deprecated in Mac OS X v10.4
Determines whether a provider is acknowledging sends.

`OTIsSynchronous` (page 2364) Deprecated in Mac OS X v10.4
Returns a provider's current mode of execution.

`OTSetAsynchronous` (page 2390) Deprecated in Mac OS X v10.4
Sets a provider's mode of execution to asynchronous.

`OTSetBlocking` (page 2391) Deprecated in Mac OS X v10.4
Allows a provider to wait or block until it is able to send or receive data.

`OTSetNonBlocking` (page 2396) Deprecated in Mac OS X v10.4
Disallows a provider from waiting if it cannot currently complete a function that sends or receives data.

`OTSetSynchronous` (page 2397) Deprecated in Mac OS X v10.4
Sets a provider's mode of execution to synchronous.

Using Notifier Functions with Providers

`OTEnterNotifier` (page 2336) Deprecated in Mac OS X v10.4
Limits the notifications that can be sent to your notifier.

`OTInstallNotifier` (page 2361) Deprecated in Mac OS X v10.4
Installs a notifier function.

`OTLeaveNotifier` (page 2364) Deprecated in Mac OS X v10.4
Allows Open Transport to resume sending primary and completion events.

`OTRemoveNotifier` (page 2386) Deprecated in Mac OS X v10.4
Removes a provider's notifier function.

`OTUseSyncIdleEvents` (page 2406) Deprecated in Mac OS X v10.4
Allows synchronous idle events to be sent to your notifier.

Sending Module-Specific Commands to Providers

`OTIoctl` (page 2362) Deprecated in Mac OS X v10.4
Sends a module-specific command to an Open Transport protocol module.

Creating Endpoints

`OTAsyncOpenEndpointInContext` (page 2310) Deprecated in Mac OS X v10.4
Opens an endpoint and installs a notifier callback function for the endpoint.

`OTOpenEndpointInContext` (page 2373) Deprecated in Mac OS X v10.4
Opens an endpoint that operates synchronously.

Binding and Unbinding Endpoints

`OTBind` (page 2319) Deprecated in Mac OS X v10.4
Assigns an address to an endpoint.

`OTUnbind` (page 2405) Deprecated in Mac OS X v10.4
Dissociates an endpoint from its address or cancels an asynchronous call to the `OTBind` function.

Obtaining Information About an Endpoint

`OTGetEndpointInfo` (page 2344) Deprecated in Mac OS X v10.4
Obtains information about an endpoint that has been opened.

`OTGetEndpointState` (page 2345) Deprecated in Mac OS X v10.4
Obtains the current state of an endpoint.

`OTGetProtAddress` (page 2348) Deprecated in Mac OS X v10.4
Obtains the address to which an endpoint is bound and, if the endpoint is currently connected, obtains the address of its peer.

`OTLook` (page 2367) Deprecated in Mac OS X v10.4
Determines the current asynchronous event pending for an endpoint.

`OTResolveAddress` (page 2387) Deprecated in Mac OS X v10.4
Returns the protocol address that corresponds to the name of an endpoint.

Allocating Structures for Endpoints

`OTFree` (page 2341) Deprecated in Mac OS X v10.4
Frees memory allocated using the OTAlloc function.

Determining if Bytes Are Available for Endpoints

`OTCountDataBytes` (page 2327) Deprecated in Mac OS X v10.4
Returns the amount of data currently available to be read.

Functions for Connectionless Transactionless Endpoints

`OTRcvUData` (page 2381) Deprecated in Mac OS X v10.4
Reads data sent by a client using a connectionless transactionless protocol.

`OTRcvUDErr` (page 2382) Deprecated in Mac OS X v10.4
Clears an error condition indicated by a `T_UDERR` event and returns the reason for the error.

`OTSndUData` (page 2400) Deprecated in Mac OS X v10.4
Sends data using a connectionless transactionless endpoint.

Establishing Connection for Endpoints

`OTAccept` (page 2306) Deprecated in Mac OS X v10.4
Accepts an incoming connection request.

`OTConnect` (page 2326) Deprecated in Mac OS X v10.4
Requests a connection to a remote peer.

`OTListen` (page 2366) Deprecated in Mac OS X v10.4
Listens for an incoming connection request.

`OTRcvConnect` (page 2379) Deprecated in Mac OS X v10.4
Reads the status of an outstanding or completed asynchronous call to the`OTConnect` function.

Functions for Connection-Oriented Transactionless Endpoints

`OTRcv` (page 2377) Deprecated in Mac OS X v10.4
Reads data sent using a connection-oriented transactionless protocol.

`OTSnd` (page 2397) Deprecated in Mac OS X v10.4
Sends data to a remote peer.

Tearing Down an Endpoint Connection

`OTRcvDisconnect` (page 2379) Deprecated in Mac OS X v10.4
Identifies the cause of a connection break or of a connection rejection, acknowledges and clears the corresponding disconnection event.

`OTRcvOrderlyDisconnect` (page 2380) Deprecated in Mac OS X v10.4
Acknowledges a request for an orderly disconnect.

`OTSndDisconnect` (page 2399) Deprecated in Mac OS X v10.4
Tears down an open connection (abortive disconnect) or rejects an incoming connection request.

`OTSndOrderlyDisconnect` (page 2399) Deprecated in Mac OS X v10.4
Initiates or completes an orderly disconnection.

Checking Synchronous Calls

`OTCanMakeSyncCall` (page 2322) Deprecated in Mac OS X v10.4
Checks whether you can call a synchronous function.

Working With Timer Tasks

`OTCancelTimerTask` (page 2321) Deprecated in Mac OS X v10.4
Cancels a task that was already scheduled for execution.

`OTCreateTimerTaskInContext` (page 2330) Deprecated in Mac OS X v10.4
Creates a task to be scheduled.

`OTDestroyTimerTask` (page 2334) Deprecated in Mac OS X v10.4
Disposes of a timer task.

`OTScheduleTimerTask` (page 2389) Deprecated in Mac OS X v10.4
Schedules a timer task to be executed at the specified time.

Working With Deferred Tasks

`OTCreateDeferredTaskInContext` (page 2329) Deprecated in Mac OS X v10.4
Creates a reference to a task that can be scheduled to run at deferred task time.

`OTDestroyDeferredTask` (page 2334) Deprecated in Mac OS X v10.4
Destroys a deferred task created with the `OTCreateDeferredTask` function.

`OTScheduleDeferredTask` (page 2388) Deprecated in Mac OS X v10.4
Schedules a task for execution at deferred task time.

Creating Mappers

`OTAsyncOpenMapperInContext` (page 2312) Deprecated in Mac OS X v10.4
Creates an asynchronous mapper and installs a notifier function for the mapper provider.

`OTOpenMapperInContext` (page 2374) Deprecated in Mac OS X v10.4
Creates a synchronous mapper provider and returns a mapper reference.

Registering and Deleting Names with Mappers

`OTDeleteName` (page 2331) Deprecated in Mac OS X v10.4
Removes a previously registered entity name.

`OTDeleteNameByID` (page 2332) Deprecated in Mac OS X v10.4
Removes a previously registered name as specified by its name ID.

`OTRegisterName` (page 2384) Deprecated in Mac OS X v10.4
Registers an entity name on the network.

Looking Up Names for Mappers

`OTLookupName` (page 2368) Deprecated in Mac OS X v10.4
Finds and returns all addresses that correspond to a particular name or name pattern, or confirms that a name is registered.

Determining and Changing Option Values

`OTOptionManagement` (page 2375) Deprecated in Mac OS X v10.4
Determines an endpoint's current or default option values or changes these values.

Finding Options

`OTFindOption` (page 2339) Deprecated in Mac OS X v10.4
Finds a specific option in an options buffer.

`OTNextOption` (page 2371) Deprecated in Mac OS X v10.4
Locates the next `TOption` structure in a buffer.

Getting Information About Ports

`OTFindPort` (page 2340) Deprecated in Mac OS X v10.4
Obtains information about a port that corresponds to a given port name.

`OTFindPortByRef` (page 2341) Deprecated in Mac OS X v10.4
Obtains information about a port that corresponds to its given port reference.

`OTGetBusTypeFromPortRef` (page 2343) Deprecated in Mac OS X v10.4
Extracts the value of the bus type from a port reference.

`OTGetDeviceTypeFromPortRef` (page 2343) Deprecated in Mac OS X v10.4
Extracts the value of the hardware device type from a port reference.

`OTGetIndexedPort` (page 2346) Deprecated in Mac OS X v10.4
Iterates through the ports available on your computer.

`OTGetSlotFromPortRef` (page 2349) Deprecated in Mac OS X v10.4
Extracts slot information from a port reference.

Registering New Ports

`OTCreatePortRef` (page 2329) Deprecated in Mac OS X v10.4
Creates a port reference that describes a port's hardware characteristics.

Registering as a Client

`OTRegisterAsClientInContext` (page 2383) Deprecated in Mac OS X v10.4
Registers your application as a client of Open Transport and gives Open Transport a notifier function it can use to send you events.

`OTUnregisterAsClientInContext` (page 2405) Deprecated in Mac OS X v10.4
Removes your application as a client of Open Transport.

Allocating and Freeing Memory

`OTAllocMemInContext` (page 2309) Deprecated in Mac OS X v10.4
Allocates memory using an explicit client context.

`OTFreeMem` (page 2342) Deprecated in Mac OS X v10.4
Frees memory allocated with the `OTAllocMem` function.

Memory Manipulation Utility Functions

`OTMemcmp` (page 2369) Deprecated in Mac OS X v10.4
Compares the contents of two memory locations.

`OTMemcpy` (page 2370) Deprecated in Mac OS X v10.4
Copies data from one memory location to another; the source and destination locations must not overlap.

`OTMemmove` (page 2370) Deprecated in Mac OS X v10.4
Copies data from one memory location to another; the source and destination locations may overlap.

`OTMemset` (page 2370) Deprecated in Mac OS X v10.4
Sets the specified memory range to a specific value.

`OTMemzero` (page 2371) Deprecated in Mac OS X v10.4
Initializes the specified memory range to 0.

Idling and Delaying Processing

`OTDelay` (page 2331) Deprecated in Mac OS X v10.4
Delays processing for a specified number of seconds. This function is only provided for compatibility with the UNIX `sleep` function.

`OTIdle` (page 2350) Deprecated in Mac OS X v10.4
Idles your computer.

String Manipulation Utility Functions

`OTStrCat` (page 2401) Deprecated in Mac OS X v10.4
Concatenates two C strings.

`OTStrCopy` (page 2402) Deprecated in Mac OS X v10.4
Copies a C string.

`OTStrEqual` (page 2402) Deprecated in Mac OS X v10.4
Determines whether two C strings are the same.

`OTStrLength` (page 2402) Deprecated in Mac OS X v10.4
Returns the length of a C string.

Timestamp Utility Functions

`OTElapsedMicroseconds` (page 2335) Deprecated in Mac OS X v10.4
Calculates the time elapsed in microseconds since a specified time.

`OTElapsedMilliseconds` (page 2335) Deprecated in Mac OS X v10.4
Calculates the time elapsed in milliseconds since a specified time.

`OTGetClockTimeInSecs` (page 2343) Deprecated in Mac OS X v10.4
Returns the number of seconds that have elapsed since system boot time.

`OTGetTimeStamp` (page 2350) Deprecated in Mac OS X v10.4
Obtains the current timestamp.

`OTSubtractTimeStamps` (page 2403) Deprecated in Mac OS X v10.4
Subtracts one timestamp value from another.

`OTTimeStampInMicroseconds` (page 2404) Deprecated in Mac OS X v10.4
Calculates the time elapsed in microseconds since since a specified time.

`OTTimeStampInMilliseconds` (page 2404) Deprecated in Mac OS X v10.4
Calculates the time elapsed in milliseconds since since a specified time.

OTLIFO List Utility Functions

`OTLIFODequeue` (page 2365) Deprecated in Mac OS X v10.4
Removes the first link in a LIFO list and returns a pointer to it.

`OTLIFOEnqueue` (page 2365) Deprecated in Mac OS X v10.4
Places a link at the front of a LIFO list.

`OTLIFOStealList` (page 2366) Deprecated in Mac OS X v10.4
Removes all links in a LIFO list and returns a pointer to the first link in the list.

`OTReverseList` (page 2387) Deprecated in Mac OS X v10.4
Reverses the order in which entries are linked in a list.

OTFIFO List Utility Functions

`OTAddFirst` (page 2308) Deprecated in Mac OS X v10.4
Places a link at the front of a FIFO list.

`OTAddLast` (page 2308) Deprecated in Mac OS X v10.4
Adds a link to the end of a FIFO list.

`OTFindAndRemoveLink` (page 2338) Deprecated in Mac OS X v10.4
Finds a link in a FIFO list and removes it.

`OTFindLink` (page 2339) Deprecated in Mac OS X v10.4
Finds a link in a FIFO list and returns a pointer to it.

`OTGetFirst` (page 2345) Deprecated in Mac OS X v10.4
Returns a pointer to the first element in a FIFO list.

`OTGetIndexedLink` (page 2346) Deprecated in Mac OS X v10.4
Returns a pointer to the link at a specified position in a FIFO list.

`OTGetLast` (page 2347) Deprecated in Mac OS X v10.4
Returns the last element in a FIFO list.

`OTIsInList` (page 2363) Deprecated in Mac OS X v10.4
Determines whether the specified link is in the specified list.

`OTRemoveFirst` (page 2385) Deprecated in Mac OS X v10.4
Removes the first link in a FIFO list.

`OTRemoveLast` (page 2385) Deprecated in Mac OS X v10.4
Removes the last link in a FIFO list.

`OTRemoveLink` (page 2386) Deprecated in Mac OS X v10.4
Removes the last link in a FIFO list.

Adding and Removing List Elements

`OTDequeue` (page 2333) Deprecated in Mac OS X v10.4
Removes an element from a list.

`OTEnqueue` (page 2336) Deprecated in Mac OS X v10.4
Adds an element to a list.

Atomic Operations

`OTAtomicAdd16` (page 2316) Deprecated in Mac OS X v10.4
Atomically adds a 16-bit value to a memory location.

`OTAtomicAdd32` (page 2316) Deprecated in Mac OS X v10.4
Atomically adds a 32-bit value to a memory location.

`OTAtomicAdd8` (page 2317) Deprecated in Mac OS X v10.4
Atomically adds an 8-bit value to a memory location.

`OTAtomicClearBit` (page 2317) Deprecated in Mac OS X v10.4
Clears a bit in a byte.

`OTAtomicSetBit` (page 2318) Deprecated in Mac OS X v10.4
Sets a specified bit in a byte.

`OTAtomicTestBit` (page 2318) Deprecated in Mac OS X v10.4
Tests a bit in a byte and returns its current state.

`OTCompareAndSwap16` (page 2324) Deprecated in Mac OS X v10.4
Atomically compares two 16-bit values and changes one of these values if they are the same.

`OTCompareAndSwap32` (page 2324) Deprecated in Mac OS X v10.4
Atomically compares two 32-bit values and changes one of these values if they are the same.

`OTCompareAndSwap8` (page 2325) Deprecated in Mac OS X v10.4
Atomically compares two 8-bit values and changes one of these values if they are the same.

`OTCompareAndSwapPtr` (page 2325) Deprecated in Mac OS X v10.4
Atomically compares the value of a pointer at a memory location and atomically swaps it with a second pointer value if the compare is successful.

Handling No-Copy Receives

`OTBufferDataSize` (page 2320) Deprecated in Mac OS X v10.4
Obtains the size of the no-copy receive buffer.

`OTReadBuffer` (page 2383) Deprecated in Mac OS X v10.4
Copies data out of a no-copy receive buffer.

`OTReleaseBuffer` (page 2384) Deprecated in Mac OS X v10.4
Returns the no-copy receive buffer to the system.

Resolving Internet Addresses

`OTInetAddressToName` (page 2350) Deprecated in Mac OS X v10.4
Determines the canonical domain name of the host associated with an internet address.

`OTInetStringToAddress` (page 2355) Deprecated in Mac OS X v10.4
Resolves a domain name to its equivalent internet addresses.

Opening a TCP/IP Service Provider

`OTAsyncOpenInternetServicesInContext` (page 2311) Deprecated in Mac OS X v10.4
Opens the TCP/IP service provider and returns an Internet services reference.

`OTOpenInternetServicesInContext` (page 2374) Deprecated in Mac OS X v10.4
Opens the TCP/IP service provider and returns an internet services reference.

Getting Information About an Internet Host

`OTInetMailExchange` (page 2353) Deprecated in Mac OS X v10.4
Returns mail-exchange-host names and preference information for a domain name you specify.

`OTInetSysInfo` (page 2356) Deprecated in Mac OS X v10.4
Returns details about a host's processor and operating system.

Retrieving DNS Query Information

`OTInetQuery` (page 2354) Deprecated in Mac OS X v10.4
Executes a generic DNS query.

Internet Address Utilities

`OTInetGetInterfaceInfo` (page 2351) Deprecated in Mac OS X v10.4
Returns internet address information about the local host.

`OTInetHostToString` (page 2352) Deprecated in Mac OS X v10.4
Converts an an address in InetHost format into a character string in dotted-decimal notation.

`OTInetStringToHost` (page 2356) Deprecated in Mac OS X v10.4
Converts an IP address string from dotted-decimal notation or hexadecimal notation to an `InetHost` data type.

`OTInitDNSAddress` (page 2358) Deprecated in Mac OS X v10.4
Fills in a DNSAddress structure with the data you provide.

`OTInitInetAddress` (page 2359) Deprecated in Mac OS X v10.4
Fills in an InetAddress structure with the data you provide.

Single Link Multi-Homing

`OTInetGetSecondaryAddresses` (page 2352) Deprecated in Mac OS X v10.4
Returns the active secondary IP addresses.

AppleTalk Utility Functions

`OTCompareDDPAddresses` (page 2325) Deprecated in Mac OS X v10.4
Compares two DDP address structures.

`OTExtractNBPName` (page 2337) Deprecated in Mac OS X v10.4
Extracts the name part of an NBP name from an NBP entity structure.

`OTExtractNBPType` (page 2337) Deprecated in Mac OS X v10.4
Extracts the type part of an NBP name from an NBP entity structure.

`OTExtractNBPZone` (page 2338) Deprecated in Mac OS X v10.4
Extracts the zone part of an NBP name from an NBP entity structure.

`OTGetNBPEntityLengthAsAddress` (page 2348) Deprecated in Mac OS X v10.4
Obtains the size of an NBP entity structure.

`OTInitDDPAddress` (page 2357) Deprecated in Mac OS X v10.4
Initializes a DDP address structure.

`OTInitDDPNBPAddress` (page 2358) Deprecated in Mac OS X v10.4
Initializes a combined DDP-NBP address structure.

`OTInitNBPAddress` (page 2360) Deprecated in Mac OS X v10.4
Initializes an NBP address structure.

`OTInitNBPEntity` (page 2360) Deprecated in Mac OS X v10.4
Initializes an NBP entity structure.

`OTSetAddressFromNBPEntity` (page 2389) Deprecated in Mac OS X v10.4
Stores an NBP entity structure as an NBP address string.

`OTSetAddressFromNBPString` (page 2390) Deprecated in Mac OS X v10.4
Copies an NBP name string into an NBP address buffer.

`OTSetNBPEntityFromAddress` (page 2394) Deprecated in Mac OS X v10.4
Parses and stores an NBP address into an NBP entity.

`OTSetNBPName` (page 2394) Deprecated in Mac OS X v10.4
Stores the name part of an NBP name into an NBP entity structure.

`OTSetNBPType` (page 2395) Deprecated in Mac OS X v10.4
Stores the type part of an NBP name in an NBP entity structure.

`OTSetNBPZone` (page 2396) Deprecated in Mac OS X v10.4
Stores the zone part of an NBP name in an NBP entity structure.

Opening an AppleTalk Service Provider

`OTAsyncOpenAppleTalkServicesInContext` (page 2310) Deprecated in Mac OS X v10.4
Opens an asynchronous AppleTalk service provider in context.

`OTOpenAppleTalkServicesInContext` (page 2372) Deprecated in Mac OS X v10.4
Opens a synchronous AppleTalk service provider.

Obtaining Information About Zones

`OTATalkGetLocalZones` (page 2314) Deprecated in Mac OS X v10.4
Obtains a list of the zones available on your network.

`OTATalkGetMyZone` (page 2314) Deprecated in Mac OS X v10.4
Obtains the AppleTalk zone name of the node on which your application is running.

`OTATalkGetZoneList` (page 2315) Deprecated in Mac OS X v10.4
Obtains a list of all the zones available on the AppleTalk internet.

Obtaining Information About Your AppleTalk Environment

`OTATalkGetInfo` (page 2313) Deprecated in Mac OS X v10.4
Obtains information about the AppleTalk environment for a given node.

Miscellaneous Functions

`DisposeOTListSearchUPP` (page 2302) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a list search callback.

`DisposeOTNotifyUPP` (page 2302) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a notification callback.

`DisposeOTProcessUPP` (page 2303) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a process callback.

`InvokeOTListSearchUPP` (page 2304) Deprecated in Mac OS X v10.4
Calls a list search callback.

`InvokeOTNotifyUPP` (page 2304) Deprecated in Mac OS X v10.4
Calls a notification callback.

`InvokeOTProcessUPP` (page 2305) Deprecated in Mac OS X v10.4
Calls a process callback.

`NewOTListSearchUPP` (page 2305) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a list search callback.

`NewOTNotifyUPP` (page 2305) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a notification callback.

`NewOTProcessUPP` (page 2306) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a process callback.

`OTAllocInContext` (page 2308) Deprecated in Mac OS X v10.4
Allocates a data structure of a specified type.

`OTClearBit` (page 2322) Deprecated in Mac OS X v10.4
Clears a bit atomically.

`OTIsBlocking` (page 2363) Deprecated in Mac OS X v10.4
Returns a boolean indicating whether a provider is blocking.

`OTSetBit` (page 2391) Deprecated in Mac OS X v10.4
Sets a bit atomically.

`OTSetBusTypeInPortRef` (page 2392) Deprecated in Mac OS X v10.4
Sets bus type for a port reference.

`OTSetDeviceTypeInPortRef` (page 2393) Deprecated in Mac OS X v10.4
Sets device type for a port reference.

`OTSetFirstClearBit` (page 2393) Deprecated in Mac OS X v10.4
Atomcially sets the first clear bit in a specified bit map.

`OTTestBit` (page 2403) Deprecated in Mac OS X v10.4
Atomically tests a bit in a specified bit map.

Functions

CloseOpenTransportInContext

Unregisters your application or code resource connection to Open Transport. (Deprecated in Mac OS X v10.4.)

```
void CloseOpenTransportInContext (
   OTClientContextPtr clientContext
);
```

Parameters

clientContext

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Carbon Porting Notes

The `CloseOpenTransportinContext` function acts like the pre-Carbon `CloseOpenTransport` function except that it takes an additional parameter, an `OTClientContextPtr`, which can be `NULL` for applications. Other types of clients must provide a valid client context pointer.

Declared In

`OpenTransport.h`

DisposeOTListSearchUPP

Disposes of a universal procedure pointer (UPP) to a list search callback. (Deprecated in Mac OS X v10.4.)

```
void DisposeOTListSearchUPP (
   OTListSearchUPP userUPP
);
```

Parameters

userUPP

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`OpenTransport.h`

DisposeOTNotifyUPP

Disposes of a universal procedure pointer (UPP) to a notification callback. (Deprecated in Mac OS X v10.4.)

```
void DisposeOTNotifyUPP (
   OTNotifyUPP userUPP
);
```

Parameters

userUPP

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

DisposeOTProcessUPP

Disposes of a universal procedure pointer (UPP) to a process callback. (Deprecated in Mac OS X v10.4.)

```
void DisposeOTProcessUPP (
   OTProcessUPP userUPP
);
```

Parameters

userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

InitOpenTransportInContext

Initializes the parts of Open Transport for use by the application or code resource. (Deprecated in Mac OS X v10.4.)

```
OSStatus InitOpenTransportInContext (
   OTInitializationFlags flags,
   OTClientContextPtr *outClientContext
);
```

Parameters

flags
Tells Open Transport whether your code is an application or a plug-in.

outClientContext
Returns the client context pointer.

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
In Carbon, the `InitOpenTransportInContext` function acts like the pre-Carbon InitOpenTransport function, except that it takes parameters that specify initialization context explicitly.

Use the flags parameter to tell Open Transport whether your code is an application or some other target (for example, a plug-in that runs in an application context but is not the application itself). The second parameter returns the client context pointer, which you must pass to other asset-creation routines. For more information, see Understanding Open Transport Asset Tracking at http://developer.apple.com/technotes/tn/tn1173.html.

Availability
Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

InvokeOTListSearchUPP

Calls a list search callback. (Deprecated in Mac OS X v10.4.)

```
Boolean InvokeOTListSearchUPP (
   const void *ref,
   OTLink *linkToCheck,
   OTListSearchUPP userUPP
);
```

Parameters
ref
linkToCheck
userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

InvokeOTNotifyUPP

Calls a notification callback. (Deprecated in Mac OS X v10.4.)

```
void InvokeOTNotifyUPP (
   void *contextPtr,
   OTEventCode code,
   OTResult result,
   void *cookie,
   OTNotifyUPP userUPP
);
```

Parameters
contextPtr
code
result
cookie
userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

InvokeOTProcessUPP

Calls a process callback. (Deprecated in Mac OS X v10.4.)

```
void InvokeOTProcessUPP (
   void *arg,
   OTProcessUPP userUPP
);
```

Parameters

arg

userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

NewOTListSearchUPP

Creates a new universal procedure pointer (UPP) to a list search callback. (Deprecated in Mac OS X v10.4.)

```
OTListSearchUPP NewOTListSearchUPP (
   OTListSearchProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `OTListSearchUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

NewOTNotifyUPP

Creates a new universal procedure pointer (UPP) to a notification callback. (Deprecated in Mac OS X v10.4.)

```
OTNotifyUPP NewOTNotifyUPP (
   OTNotifyProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `OTNotifyUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

NewOTProcessUPP

Creates a new universal procedure pointer (UPP) to a process callback. (Deprecated in Mac OS X v10.4.)

```
OTProcessUPP NewOTProcessUPP (
   OTProcessProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `OTProcessUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`OpenTransport.h`

OTAccept

Accepts an incoming connection request. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAccept (
   EndpointRef listener,
   EndpointRef worker,
   TCall *call
);
```

Parameters

listener

worker

call

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTAckSends

Specifies that a provider make an internal copy of data being sent and that it notify you when it has finished sending data. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAckSends (
   ProviderRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
By default, providers make an internal copy of data before sending it and they do not acknowledge sends. If you use the `OTAckSends` function to specify that the provider acknowledge sends and you call a function that sends data, the provider does not copy the data before sending it. Instead, it reads data directly from your buffer while sending. For this reason, you must not change the contents of your buffer until the provider is no longer using it. The provider lets you know that it has finished using the buffer by calling your notifier function and passing `T_MEMORYRELEASED` event code for the `code` parameter, a pointer to the buffer that was sent in the `cookie` parameter, and the size of the buffer in the `result` parameter.

If you have not installed a notifier function for the provider, this function returns the `kOTAccessErr` result.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTAddFirst

Places a link at the front of a FIFO list. (Deprecated in Mac OS X v10.4.)

```
void OTAddFirst (
   OTList *list,
   OTLink *link
);
```

Parameters

list

link

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTAddLast

Adds a link to the end of a FIFO list. (Deprecated in Mac OS X v10.4.)

```
void OTAddLast (
   OTList *list,
   OTLink *link
);
```

Parameters

list

link

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTAllocInContext

Allocates a data structure of a specified type. (Deprecated in Mac OS X v10.4.)

```
void * OTAllocInContext (
   EndpointRef ref,
   OTStructType structType,
   UInt32 fields,
   OSStatus *err,
   OTClientContextPtr clientContext
);
```

Parameters

ref

structType

fields

err

clientContext

Discussion

In general, Apple recommends that you avoid the OTAllocInContext call because using it extensively causes your program to allocate and deallocate many memory blocks, with each extra memory allocation costing time.

Under Carbon, OTAllocInContext takes a client context pointer. Applications may pass NULL after calling InitOpenTransport(kInitOTForApplicationMask, ...). Non-applications must always pass a valid client context.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTAllocMemInContext

Allocates memory using an explicit client context. (Deprecated in Mac OS X v10.4.)

```
void * OTAllocMemInContext (
   OTByteCount size,
   OTClientContextPtr clientContext
);
```

Parameters

size

clientContext

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTAsyncOpenAppleTalkServicesInContext

Opens an asynchronous AppleTalk service provider in context. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAsyncOpenAppleTalkServicesInContext (
   OTConfigurationRef cfig,
   OTOpenFlags flags,
   OTNotifyUPP proc,
   void *contextPtr,
   OTClientContextPtr clientContext
);
```

Parameters

cfig

flags

proc

contextPtr

clientContext

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTAsyncOpenEndpointInContext

Opens an endpoint and installs a notifier callback function for the endpoint. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAsyncOpenEndpointInContext (
   OTConfigurationRef config,
   OTOpenFlags oflag,
   TEndpointInfo *info,
   OTNotifyUPP upp,
   void *contextPtr,
   OTClientContextPtr clientContext
);
```

Parameters

config

oflag

info

upp

contextPtr

clientContext

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTAsyncOpenInternetServicesInContext

Opens the TCP/IP service provider and returns an Internet services reference. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAsyncOpenInternetServicesInContext (
   OTConfigurationRef cfig,
   OTOpenFlags oflag,
   OTNotifyUPP upp,
   void *contextPtr,
   OTClientContextPtr clientContext
);
```

Parameters

cfig

oflag

upp

contextPtr

clientContext

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTAsyncOpenMapperInContext

Creates an asynchronous mapper and installs a notifier function for the mapper provider. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTAsyncOpenMapperInContext (
   OTConfigurationRef config,
   OTOpenFlags oflag,
   OTNotifyUPP upp,
   void *contextPtr,
   OTClientContextPtr clientContext
);
```

Parameters

config

oflag

upp

contextPtr

clientContext

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTATalkGetInfo

Obtains information about the AppleTalk environment for a given node. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTATalkGetInfo (
   ATSvcRef ref,
   TNetbuf *info
);
```

Parameters
ref
info

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTATalkGetInfo` function returns the information contained in the `AppleTalkInfo` data structure that describes your current AppleTalk environment. This includes your network number and node ID, the network number and node ID of a local router, and the current network range for the extended network to which the machine is connected.

If you execute this function asynchronously, Open Transport calls your notifier with a `T_GETATALKINFOCOMPLETE` completion event to signal the function's completion and uses your notifier's `cookie` parameter for the AppleTalk information. The `cookie` parameter actually holds a pointer to a `TNetbuf` structure, which points in turn to a buffer containing the `AppleTalkInfo` structure. The maximum size of this buffer is 22 bytes.

If the machine is multihomed—that is, if multiple network numbers and node numbers are associated with the same machine—the `OTATalkGetInfo` function returns information about the node whose network number and node ID are selected in the AppleTalk control panel.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTATalkGetLocalZones

Obtains a list of the zones available on your network. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTATalkGetLocalZones (
   ATSvcRef ref,
   TNetbuf *zones
);
```

Parameters

ref

zones

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTATalkGetLocalZones` function returns a list of the zone names in your application's network if it is an extended network. These are all the zones to which your node can belong. If your application is in a nonextended network, this function returns only one zone name, the same one returned by the `OTATalkGetMyZone` function.

If you execute this function asynchronously, Open Transport calls your notifier function with a `T_GETLOCALZONESCOMPLETE` completion event to signal the function's completion and uses your notifier's `cookie` parameter for the list of zones. The `cookie` parameter actually holds a pointer to a `TNetbuf` structure, which points to a buffer containing a list of zone names, each of which is stored as a Pascal-style string. Using a Pascal-style string for the zone name is redundant since you can determine the length of the string from the `maxlen` field of the `TNetbuf` structure, but the other zone-related calls use Pascal-style strings, so this call also uses them for consistency.

Each string can be up to 32 characters in length, and if you add a length byte, each can have a maximum size of 33 bytes. As there can be a maximum of 254 zones on an extended network, the maximum size of the buffer is 8382 bytes.

Because zone names are often less than 32 characters long and AppleTalk service providers don't pad short names, 6 KB bytes is likely to be a safe value for the buffer's size, defined by the `TNetbuf->maxlen` field.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTATalkGetMyZone

Obtains the AppleTalk zone name of the node on which your application is running. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTATalkGetMyZone (
   ATSvcRef ref,
   TNetbuf *zone
);
```

Parameters

ref

zone

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTATalkGetMyZone` function gets the name of your application's AppleTalk zone. If you call this function asynchronously, Open Transport calls your application's notifier with a `T_GETMYZONECOMPLETE` completion event to signal the function's completion and uses your notifier's `cookie` parameter for the zone name. More precisely, the `cookie` parameter points to a `TNetbuf` structure that in turn points to a buffer containing the zone name, which is stored as a Pascal-style string. The string can be up to 32 characters in length, so with the addition of a length byte, the buffer can have a maximum size of 33 bytes. Using a Pascal-style string for the zone name is redundant since you can determine the length of the string from the `maxlen` field of the `TNetbuf` structure, but the other zone-related calls use Pascal-style strings, so this call also uses them for consistency.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTATalkGetZoneList

Obtains a list of all the zones available on the AppleTalk internet. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTATalkGetZoneList (
   ATSvcRef ref,
   TNetbuf *zones
);
```

Parameters

ref

zones

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The OTATalkGetZoneList function returns a list of all the zones on the AppleTalk internet to which your network belongs.

If you execute this function asynchronously, Open Transport calls your notifier function with a `T_GETZONELISTCOMPLETE` completion event to signal the function's completion and uses your notifier's `cookie` parameter for the list of zones. The `cookie` parameter actually holds a pointer to a `TNetbuf` structure,

which points to a buffer containing a list of zone names, each of which is a Pascal-style string. Using a Pascal-style string for the zone name is redundant since you can determine the length of the string from the `maxlen` field of the `TNetbuf` structure, but the other zone-related calls use Pascal-style strings, so this call also uses them for consistency.

Each string can be up to 32 characters in length, and if you add a length byte, each can have a maximum size of 33 bytes. As AppleTalk internets can have a number of extended networks, you need to allocate a buffer (using the `TNetbuf->maxlen` field) that holds as much as 64 KB of memory. To keep the buffer size as small and efficient as possible, you can set up a large buffer, test for the `kOTBufferOverflowErr` error, and then increase the size of the buffer and reissue the call if this error is returned.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTAtomicAdd16

Atomically adds a 16-bit value to a memory location. (Deprecated in Mac OS X v10.4.)

```
SInt16 OTAtomicAdd16 (
   SInt32 toAdd,
   SInt16 *dest
);
```

Parameters
toAdd
dest

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTAtomicAdd32

Atomically adds a 32-bit value to a memory location. (Deprecated in Mac OS X v10.4.)

```
SInt32 OTAtomicAdd32 (
   SInt32 toAdd,
   SInt32 *dest
);
```

Parameters

toAdd

dest

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTAtomicAdd8

Atomically adds an 8-bit value to a memory location. (Deprecated in Mac OS X v10.4.)

```
SInt8 OTAtomicAdd8 (
   SInt32 toAdd,
   SInt8 *dest
);
```

Parameters

toAdd

dest

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTAtomicClearBit

Clears a bit in a byte. (Deprecated in Mac OS X v10.4.)

```
Boolean OTAtomicClearBit (
   UInt8 *bytePtr,
   OTByteCount bitNumber
);
```

Parameters

bytePtr

bitNumber

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTAtomicSetBit

Sets a specified bit in a byte. (Deprecated in Mac OS X v10.4.)

```
Boolean OTAtomicSetBit (
   UInt8 *bytePtr,
   OTByteCount bitNumber
);
```

Parameters

bytePtr

bitNumber

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTAtomicTestBit

Tests a bit in a byte and returns its current state. (Deprecated in Mac OS X v10.4.)

```
Boolean OTAtomicTestBit (
   UInt8 *bytePtr,
   OTByteCount bitNumber
);
```

Parameters

bytePtr

bitNumber

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTBind

Assigns an address to an endpoint. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTBind (
   EndpointRef ref,
   TBind *reqAddr,
   TBind *retAddr
);
```

Parameters

ref

reqAddr

If you specify `NIL` for the `reqAddr` parameter, Open Transport chooses a protocol address for you and requests 0 as the endpoint's maximum number of concurrent outstanding connect indications.

If you want Open Transport to assign an address for you, setthe `addr.len` field of the `TBind` structure to 0.

retAddr

You can set this parameter to `nil` if you do not care to know what address the endpoint is bound to or what the negotiated value of `qlen` is.

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

You call the `OTBind` function to request an address that an endpoint be bound to. You can either use the reqAddr parameter to request that the endpoint be bound to a specific address or allow the endpoint provider to assign an address dynamically by passing nil for this parameter. Consult the documentation for the top-level protocol you are using to determine whether it is preferable to have the address assigned dynamically. The function returns the address to which the endpoint is actually bound in the retAddr parameter. This might be different from the address you requested, if you requested a specific address.

If you are binding a connection-oriented endpoint, you must use the reqAddr->qlen field to specify the number of connection requests that may be outstanding for this endpoint. The retAddr->qlen field specifies, on return, the actual number of connection requests allowed for the endpoint. This number might be smaller than the number you requested. Note that when the endpoint is actually connected, the number might be further decreased by negotiations taking place at that time.

If you call the OTBind function asynchronously and you have not installed a notifier function, the only way to determine when the function completes is to poll the endpoint using the OTGetEndpointState function. This function returns a kOTStateChangeErr until the bind completes. When the endpoint is bound, the state is either T_UNBND if the bind failed, or T_IDLE if it succeeded.

You can cancel an asynchronous bind that is still in progress by calling the OTUnbind function.

You must not bind more than one connectionless endpoint to a single address. Some connection-oriented protocols let you bind two or more endpoints to the same address. In such instances, you must use only one of the endpoints to listen for connection requests for that address. When binding the endpoint listening for a connection, you must set the reqAddr->qlen field of the OTBind function to a value greater than or equal to 1. When binding the other endpoints, you must set the reqAddr->qlen field to 0.

If you accept a connection for an endpoint that is also listening for connection requests, the address of that endpoint is deemed "busy" for the duration of the connection, and you must not bind another endpoint for listening to that same address. This requirement prevents more than one endpoint bound to the same address from accepting connection requests. If you have to bind another listening endpoint to the same address, you must first use the OTUnbind function to unbind the first endpoint or use the OTCloseProvider function to close it.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTBufferDataSize

Obtains the size of the no-copy receive buffer. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTBufferDataSize (
   OTBuffer *buffer
);
```

Parameters
buffer

Return Value
See the description of the `OTByteCount` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTCancelSynchronousCalls

Cancels any currently executing synchronous function for a specified provider. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTCancelSynchronousCalls (
   ProviderRef ref,
   OSStatus err
);
```

Parameters

ref

err

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTCancelSynchronousCalls` function cancels any currently executing synchronous function for the provider that you specify. The provider need not be in synchronous mode when you call this function.

Typically, you would call the `OTCancelSynchronousCalls` function at interrupt time by installing a Time Manager task that executes after a given amount of time has passed. You could do this to prevent a synchronous function from hanging the system.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTCancelTimerTask

Cancels a task that was already scheduled for execution. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCancelTimerTask (
   OTTimerTask timerTask
);
```

Parameters

timerTask

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTCanMakeSyncCall

Checks whether you can call a synchronous function. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCanMakeSyncCall (
   void
);
```

Parameters

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTClearBit

Clears a bit atomically. (Deprecated in Mac OS X v10.4.)

```
Boolean OTClearBit (
   UInt8 *bitMap,
   OTByteCount bitNo
);
```

Parameters
bitMap
bitNo

Discussion
OTClearBit is available to client and kernel code, but only to native architecture clients.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTCloneConfiguration

Copies an `OTConfiguration` structure. (Deprecated in Mac OS X v10.4.)

```
OTConfigurationRef OTCloneConfiguration (
   OTConfigurationRef cfig
);
```

Parameters

cfig

Return Value
See the description of the `OTConfigurationRef` data type.

Discussion
The `OTCloneConfiguration` function copies the `OTConfiguration` structure that you specify in the `cfig` parameter and returns a pointer to the copy. Because the internal format of an `OTConfiguration` structure is private, you must use the `OTCloneConfiguration` function to obtain two identical structures. For example, you can use this function when another application passes you a configuration structure that you want to reuse but for which you do not have the original configuration string. By cloning the structure, you have access to an additional copy of the configuration even without knowing its configuration string.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTCloseProvider

Closes a provider of any type—endpoint, mapper, or service provider. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTCloseProvider (
   ProviderRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTCloseProvider` function closes the provider that you specify in the `ref` parameter. Closing the provider deletes all memory reserved for it in the system heap, deletes its resources, and cancels any provider functions that are currently executing.

Open Transport does not guarantee that all outstanding functions have completed before it closes the provider. It is ultimately your responsibility to make sure that all provider functions that you care about have finished executing, before you close and delete a provider.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTCompareAndSwap16

Atomically compares two 16-bit values and changes one of these values if they are the same. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCompareAndSwap16 (
   UInt32 oldValue,
   UInt32 newValue,
   UInt16 *dest
);
```

Parameters

oldValue

newValue

dest

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTCompareAndSwap32

Atomically compares two 32-bit values and changes one of these values if they are the same. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCompareAndSwap32 (
   UInt32 oldValue,
   UInt32 newValue,
   UInt32 *dest
);
```

Parameters

oldValue

newValue

dest

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTCompareAndSwap8

Atomically compares two 8-bit values and changes one of these values if they are the same. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCompareAndSwap8 (
   UInt32 oldValue,
   UInt32 newValue,
   UInt8 *dest
);
```

Parameters

oldValue

newValue

dest

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTCompareAndSwapPtr

Atomically compares the value of a pointer at a memory location and atomically swaps it with a second pointer value if the compare is successful. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCompareAndSwapPtr (
   void *oldValue,
   void *newValue,
   void **dest
);
```

Parameters

oldValue

newValue

dest

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTCompareDDPAddresses

Compares two DDP address structures. (Deprecated in Mac OS X v10.4.)

```
Boolean OTCompareDDPAddresses (
   const DDPAddress *addr1,
   const DDPAddress *addr2
);
```

Parameters

addr1

addr2

Discussion

The `OTCompareDDPAddresses` function compares two DDP addresses for equality and returns `true` if the two addresses match. It cannot compare NBP or combined DDP-NBP addresses; using these address types always returns `false`. This function uses the zero-matches-anything AppleTalk rule when doing the matching, which means that a value of 0 in any field results in an acceptable match.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTConnect

Requests a connection to a remote peer. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTConnect (
   EndpointRef ref,
   TCall *sndCall,
   TCall *rcvCall
);
```

Parameters

ref

sndCall

rcvCall

This parameter is only meaningful for synchronous calls to the OTConnect function. See `TCall` data type.

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

If the endpoint is in synchronous mode, the OTConnect function returns after the connection is established and fills in the fields of the TCall structure (referenced by the rcvCall parameter) with the actual values associated with this connection. These might be different from the values you specified using the sndCall parameter.

If the OTConnect function returns with the kOTLookErr result, this might be either because of a pending T_LISTEN or T_DISCONNECT event. That is, either a connection request from another endpoint has interrupted execution of the function, or the remote endpoint has rejected the connection. If you don't have a notifier installed, you can call the OTLook function to identify the event that caused the kOTLookErr result. If the

event is T_LISTEN, you must accept or reject the incoming request and then continue processing the OTConnect function by calling OTRcvConnect. If the event is T_DISCONNECT, you must call the OTRcvDisconnect function to clear the error condition—that is, to deallocate memory and place the endpoint in the correct state.

If the endpoint is in asynchronous mode, the OTConnect function returns before the connection is established with a kOTNoDataErr result to indicate that the connection is in progress. When the connection is established, the endpoint provider calls your notifier, passing T_CONNECT for the code parameter. In response, you must call the OTRcvConnect function to read the connection parameters that would have been returned using the rcvCall parameter if the endpoint were in synchronous mode.

It is possible that the remote address returned in the addr field of the rcvCall parameter is not the same as the address you requested using the sndCall->addr field. This happens when the connection is accepted for a different endpoint than the one receiving the connection request.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTCountDataBytes

Returns the amount of data currently available to be read. (Deprecated in Mac OS X v10.4.)

```
OTResult OTCountDataBytes (
   EndpointRef ref,
   OTByteCount *countPtr
);
```

Parameters
ref
countPtr

Return Value
See the description of the `OTResult` data type.

Discussion
If the function returns sucessfully, the countPtr parameter points to a buffer containing the amount of data currently available to be read. This does not mean that the buffer contains all the data that was sent. That is, there might be additional data to read after you do the first read.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTCreateConfiguration

Creates a structure defining a provider's configuration. (Deprecated in Mac OS X v10.4.)

Modified

```
OTConfigurationRef OTCreateConfiguration (
   const char *path
);
```

Parameters

path

A pointer to a character string describing the provider.

Return Value

See the description of the `OTConfigurationRef` data type.

Discussion

The `OTCreateConfiguration` function creates a configuration structure that defines the software modules, hardware ports, and options that Open Transport is to use when you call a function to open a provider. This is a private structure, defined by the `OTConfiguration` data type . To create one, you use the `path` parameter to pass the `OTCreateConfiguration` function a string describing the provider service desired.

The simplest possible value of the `path` parameter is a single protocol module name of the highest-level protocol you want to use; for example, "tcp." If you do not specify a complete communications path, the Open Transport software uses default settings to construct the rest of the path. For example, if you specify "adsp" for the `path` parameter, Open Transport defaults to using the AppleTalk DataStream Protocol (ADSP) protocol module layered above the Datagram Delivery Protocol (DDP) protocol module and with LocalTalk on the default port, which is the printer port.

If you want to identify a particular port in the configuration string, you use the port name to do so (described in the section "About Port Information," beginning on page 6-5). More typically, however, you leave this value blank— for example, using a string with only "adsp" or "adsp, ddp," which configures the provider with whatever port is specified in the control panel.

To specify more than one protocol module, separate the module names with commas. You can also specify values for options by putting them in parentheses after the protocol name; for example, "adsp, ddp (Checksum=1)" specifies that ADSP is to run on top of DDP and that the checksum option is enabled.

If Open Transport cannot parse the list that you pass in the `path` parameter, the `OTCreateConfiguration` function returns `((OTConfiguration*)-1L)`. If there is insufficient memory to create an `OTConfiguration` structure, the `OTCreateConfiguration` function returns `NULL`.

The OTCreateConfiguration function returns a pointer to the configuration structure it creates. You pass this pointer as a parameter to the open-provider functions such as the OTOpenEndpoint or OTOpenMapper functions.

Availability

Modified in Carbon. Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Carbon Porting Notes

Passing inline options to `OTCreateConfiguration`-for example, `OTCreateConfiguration("tcp(NoDelay=1)")`-is not supported on Mac OS X. Instead, you should explicitly set any options using the function `OTOptionManagement`.

Declared In

`OpenTransport.h`

OTCreateDeferredTaskInContext

Creates a reference to a task that can be scheduled to run at deferred task time. (Deprecated in Mac OS X v10.4.)

```
long OTCreateDeferredTaskInContext (
   OTProcessUPP upp,
   void *arg,
   OTClientContextPtr clientContext
);
```

Parameters

upp

arg

clientContext

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTCreatePortRef

Creates a port reference that describes a port's hardware characteristics. (Deprecated in Mac OS X v10.4.)

```
OTPortRef OTCreatePortRef (
   OTBusType busType,
   OTDeviceType devType,
   OTSlotNumber slot,
   UInt16 other
);
```

Parameters

busType

The type of bus to which the hardware port is connected; for example, a NuBus or PCI bus. See "The Port Reference" for possible values for this parameter.

devType

The type of hardware device connected to the port, such as LocalTalk or Ethernet. See "The Port Reference"for possible values for this parameter.

slot
other

The port's multiport identifier—that is, a numeric value that distinguishes between ports when more than one hardware port is connected to a given slot.

Return Value
See the description of the `OTPortRef` data type.

Discussion
The `OTCreatePortRef` function creates a port reference structure, which is a 32-bit value that describes a port's hardware characteristics: its device and bus type, its physical slot number, and, where applicable, its multiport identifier.

Once you have created a port reference, you can use the `OTFindPortByRef` function to find a specific port with that particular set of characteristics.

To create a port reference, you use the `OTCreatePortRef` function. You must know all the port's hardware characteristics: its device and bus type, its slot number, and its multiport identifier (if it has one). You cannot use wildcards to fill in any element you don't know, although you can use a device type of 0 to allow matches on every kind of device type (following the zero-matches-everything rule). Possible device and bus types are described in the section "The Port Reference."

To create a port reference for a pseudodevice, use 0 as the value for the bus type, slot number, and multiport identifier, and use the constant `kOTPseudoDevice` for the device type.

Open Transport has predefined variants of the OTCreatePortRef function for the most commonly used hardware devices, such as the NuBus, PCI, and PCMCIA devices. These three variants are listed here:

```
#define OTCreateNuBusPortRef(devType, slot, other)\
OTCreatePortRef(kOTNuBus, devType, slot, other)
#define OTCreatePCIPortRef(devType, slot, other)\
OTCreatePortRef(kOTPCIBus, devType, slot, other)
#define OTCreatePCMCIAPortRef(devType, slot, other)\
OTCreatePortRef(kOTPCMCIABus, devType, slot, other)
```

Once you have identified the port structure you want, you can access the information in its port reference, by using the `OTGetDeviceTypeFromPortRef`, `OTGetBusTypeFromPortRef`, and `OTGetSlotFromPortRef` functions.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTCreateTimerTaskInContext

Creates a task to be scheduled. (Deprecated in Mac OS X v10.4.)

```
long OTCreateTimerTaskInContext (
   OTProcessUPP upp,
   void *arg,
   OTClientContextPtr clientContext
);
```

Parameters

upp

arg

clientContext

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTDelay

Delays processing for a specified number of seconds. This function is only provided for compatibility with the UNIX `sleep` function. (Deprecated in Mac OS X v10.4.)

```
void OTDelay (
   UInt32 seconds
);
```

Parameters

seconds
The number of seconds to delay.

Discussion
The `OTDelay` function delays processing for the number of seconds specified in the `seconds` parameter. While the delay is occurring, `OTDelay` continuously calls the `OTIdle` function.

You can only call the `OTDelay` function from within an application at system task time. This function is only provided for compatibility with the UNIX `sleep` function to assist with portability of UNIX code.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTDeleteName

Removes a previously registered entity name. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTDeleteName (
   MapperRef ref,
   TNetbuf *name
);
```

Parameters

ref

name

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If the name-registration protocol defined using the config parameter to the OTOpenMapper or OTAsyncOpenMapper function supports dynamic name and address registration, you can use the OTDeleteName function to delete a registered name.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTDeleteNameByID

Removes a previously registered name as specified by its name ID. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTDeleteNameByID (
   MapperRef ref,
   OTNameID nameID
);
```

Parameters

ref

nameID

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If the name-registration protocol defined using the config parameter to the OTOpenMapper or OTAsyncOpenMapper function supports dynamic name and address registration, you can use the OTDeleteNameByID function to delete a registered name.

If the mapper is in asynchronous mode, the OTDeleteNameByID function returns immediately. When the function completes execution, the mapper provider calls the notifier function, passing T_DELNAMECOMPLETE for the code parameter, and a pointer to the id parameter in the cookie parameter.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTDequeue

Removes an element from a list. (Deprecated in Mac OS X v10.4.)

```
void * OTDequeue (
   void **listHead,
   OTByteCount linkOffset
);
```

Parameters

listHead

linkOffset

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTDestroyConfiguration

Deletes an `OTConfiguration` structure. (Deprecated in Mac OS X v10.4.)

```
void OTDestroyConfiguration (
   OTConfigurationRef cfig
);
```

Parameters

cfig

Discussion
The `OTDestroyConfiguration` function deletes the `OTConfiguration` structure that you specify in the cfig parameter and releases all associated memory.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTDestroyDeferredTask

Destroys a deferred task created with the `OTCreateDeferredTask` function. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTDestroyDeferredTask (
   OTDeferredTaskRef dtCookie
);
```

Parameters

dtCookie

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

The `OTDestroyDeferredTask` function makes the `dtCookie` reference invalid and frees any resources allocated to the task when it was created. You can call this function at any time when you no longer need to schedule the deferred task object. If `dtCookie` is invalid (a value of 0), the function returns `kOTNoError` and does nothing.

If you try to destroy a deferred task that is still scheduled, the `kEAgainErr` error can occur. This is a rare situation that can only happen when you try to destroy the task from within an interrupt service routine or within another deferred task.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTDestroyTimerTask

Disposes of a timer task. (Deprecated in Mac OS X v10.4.)

```
void OTDestroyTimerTask (
   OTTimerTask timerTask
);
```

Parameters

timerTask

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProtocol.h`

OTDontAckSends

Specifies that a provider copy data before sending it. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTDontAckSends (
   ProviderRef ref
);
```

Parameters

ref

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

By default, providers do not acknowledge sends. You need to call the `OTDontAckSends` function only if you have used the `OTAckSends` function to turn on send-acknowledgment for a provider.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTElapsedMicroseconds

Calculates the time elapsed in microseconds since a specified time. (Deprecated in Mac OS X v10.4.)

```
UInt32 OTElapsedMicroseconds (
   OTTimeStamp *startTime
);
```

Parameters

startTime

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTElapsedMilliseconds

Calculates the time elapsed in milliseconds since a specified time. (Deprecated in Mac OS X v10.4.)

```
UInt32 OTElapsedMilliseconds (
   OTTimeStamp *startTime
);
```

Parameters

startTime

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

OpenTransport.h

OTEnqueue

Adds an element to a list. (Deprecated in Mac OS X v10.4.)

```
void OTEnqueue (
   void **listHead,
   void *object,
   OTByteCount linkOffset
);
```

Parameters

listHead

object

linkOffset

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

OpenTransport.h

OTEnterNotifier

Limits the notifications that can be sent to your notifier. (Deprecated in Mac OS X v10.4.)

```
Boolean OTEnterNotifier (
   ProviderRef ref
);
```

Parameters

ref

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTExtractNBPName

Extracts the name part of an NBP name from an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
void OTExtractNBPName (
   const NBPEntity *entity,
   char *name
);
```

Parameters

entity

name

A pointer to the string buffer in which to store the name portion of an NBP name string that you wish to extract from the NBP entity.

Discussion
The `OTExtractNBPName` function extracts the name part of an NBP name from the specified NBP entity structure and stores it into the string buffer specified by the `name` parameter. This function inserts a backslash (\) in front of any backslash, colon (:), or at-sign (@) it finds in an NBP name so that mapper functions can use a correctly formatted NBP name.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTExtractNBPType

Extracts the type part of an NBP name from an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
void OTExtractNBPType (
   const NBPEntity *entity,
   char *typeVal
);
```

Parameters

entity

typeVal

A pointer to the string buffer in which to store the type portion of an NBP name string that you wish to extract from the NBP entity.

Discussion
The `OTExtractNBPType` function extracts the type part of an NBP name from the specified NBP entity structure and stores it into the string buffer specified by the `type` parameter. This function inserts a backslash (\) in front of any backslash, colon (:), or at-sign (@) it finds in an NBP name so that mapper functions can use a correctly formatted NBP name.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTExtractNBPZone

Extracts the zone part of an NBP name from an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
void OTExtractNBPZone (
   const NBPEntity *entity,
   char *zone
);
```

Parameters
entity
zone
A pointer to the string buffer in which to store the type portion of an NBP name string that you wish to extract from the NBP entity.

Discussion
The `OTExtractNBPZone` function extracts the zone part of an NBP name from the specified NBP entity structure and stores it into the string buffer specified by the `zone` parameter. This function inserts a backslash (\) in front of any backslash, colon (:), or at-sign (@) it finds in an NBP name so that mapper functions can use a correctly formatted NBP name.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTFindAndRemoveLink

Finds a link in a FIFO list and removes it. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTFindAndRemoveLink (
   OTList *list,
   OTListSearchUPP proc,
   const void *ref
);
```

Parameters

list

proc

ref

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTFindLink

Finds a link in a FIFO list and returns a pointer to it. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTFindLink (
   OTList *list,
   OTListSearchUPP proc,
   const void *ref
);
```

Parameters

list

proc

ref

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTFindOption

Finds a specific option in an options buffer. (Deprecated in Mac OS X v10.4.)

```
TOption * OTFindOption (
   UInt8 *buffer,
   UInt32 buflen,
   OTXTILevel level,
   OTXTIName name
);
```

Parameters

buffer

A pointer to the buffer containing the option to be found.

buflen

The size of the buffer containing the option to be found.

level

name

Return Value

See the description of the `TOption` data type.

Discussion

Given a buffer such as might be returned by the `OTOptionManagement` function or by any endpoint function that returns a buffer containing option information, you can use the `OTFindOption` function to find a specific option in the buffer.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTFindPort

Obtains information about a port that corresponds to a given port name. (Deprecated in Mac OS X v10.4.)

```
Boolean OTFindPort (
   OTPortRecord *portRecord,
   const char *portName
);
```

Parameters

portName

A pointer to a port structure that contains information about the port you specified with the `portName` parameter.

portName

The name of the port about which you want information.

Discussion

The `OTFindPort` function returns information about a port that corresponds to a given port name. Each port in a system has a unique port name, which you can obtain through a previous call or set of calls to the `OTGetIndexedPort` function.

You must allocate the port structure; the function fills this structure with information about the port indicated by the `portName` parameter. If the function returns `false`, the contents of the structure are not significant.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTFindPortByRef

Obtains information about a port that corresponds to its given port reference. (Deprecated in Mac OS X v10.4.)

```
Boolean OTFindPortByRef (
   OTPortRecord *portRecord,
   OTPortRef ref
);
```

Parameters
portRecord
ref

Discussion
The `OTFindPortByRef` function returns information about a port identified by its port reference. A port reference is a 32-bit value that describes a port's hardware characteristics: its bus and device type, its physical slot number, and, where applicable, its multiport identifier. This identifier differentiates between multiple hardware ports on a given slot.

You must allocate the port structure; the function fills this structure with information about the port indicated by the `ref` parameter. If the function returns `false`, the contents of the structure are not significant.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTFree

Frees memory allocated using the OTAlloc function. (Deprecated in Mac OS X v10.4.)

```
OTResult OTFree (
   void *ptr,
   OTStructType structType
);
```

Parameters

ptr

A pointer to the structure to be deallocated. This is the pointer returned by the OTAlloc function.

structType

Return Value
See the description of the `OTResult` data type.

Discussion
In order to use the OTFree function, you must not have changed the memory allocated by the OTAlloc function for the structure specified by the structType parameter or for any of the buffers to which it points.

You are responsible for passing a structType parameter that exactly matches the type of structure being freed.

The OTFree function, along with the OTAlloc function, is provided mainly forcompatibility with XTI.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTFreeMem

Frees memory allocated with the `OTAllocMem` function. (Deprecated in Mac OS X v10.4.)

```
void OTFreeMem (
   void *mem
);
```

Parameters

mem

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetBusTypeFromPortRef

Extracts the value of the bus type from a port reference. (Deprecated in Mac OS X v10.4.)

```
UInt16 OTGetBusTypeFromPortRef (
   OTPortRef ref
);
```

Parameters

ref

Discussion

The `OTGetBusTypeFromPortRef` function extracts the bus type value from a port reference with unknown hardware values. You can obtain such a port reference when another application passes one to you or when you use the `OTGetIndexedPort` function to access a port structure into which another application has put its own port reference.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTGetClockTimeInSecs

Returns the number of seconds that have elapsed since system boot time. (Deprecated in Mac OS X v10.4.)

```
UInt32 OTGetClockTimeInSecs (
   void
);
```

Parameters

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTGetDeviceTypeFromPortRef

Extracts the value of the hardware device type from a port reference. (Deprecated in Mac OS X v10.4.)

```
OTDeviceType OTGetDeviceTypeFromPortRef (
   OTPortRef ref
);
```

Parameters

ref

Return Value
See the description of the `OTDeviceType` data type.

Discussion
The `OTGetDeviceTypeFromPortRef` function extracts the device type value from a port reference with unknown hardware values. You can obtain such a port reference when another application passes one to you or when you use the `OTGetIndexedPort` function to access a port structure into which another application has put its own port reference.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetEndpointInfo

Obtains information about an endpoint that has been opened. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTGetEndpointInfo (
   EndpointRef ref,
   TEndpointInfo *info
);
```

Parameters

ref

info

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The OTGetEndpointInfo function returns information about

- the maximum size of buffers used to specify an endpoint's address and option values
- the maximum size of normal and expedited data you can transfer using this endpoint or, for transaction-based endpoints, the maximum size of requests and replies
- the size of data you can transfer when initiating or tearing down a connection
- the services supported by the endpoint
- any additional characteristics of this endpoint

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetEndpointState

Obtains the current state of an endpoint. (Deprecated in Mac OS X v10.4.)

```
OTResult OTGetEndpointState (
   EndpointRef ref
);
```

Parameters

ref

Return Value
See the description of the `OTResult` data type.

Discussion
The OTGetEndpointState function returns an integer greater than or equal to 0 indicating the state of the specified endpoint. The endpoint state enumeration describes possible endpoint states and lists their decimal value.

If the function fails, it returns a negative integer specifying the error code. You must open an endpoint before you can determine its state.

You might need to know an endpoint's state in order to determine whether a function has completed or whether the endpoint is in an appropriate state for the function that you want to call next.

This function returns endpoint state information immediately, whether the endpoint is in synchronous or asynchronous mode.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetFirst

Returns a pointer to the first element in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTGetFirst (
   OTList *list
);
```

Parameters

list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetIndexedLink

Returns a pointer to the link at a specified position in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTGetIndexedLink (
   OTList *list,
   OTItemCount index
);
```

Parameters

list

index

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetIndexedPort

Iterates through the ports available on your computer. (Deprecated in Mac OS X v10.4.)

```
Boolean OTGetIndexedPort (
   OTPortRecord *portRecord,
   OTItemCount index
);
```

Parameters

portRecord

index

Discussion

The `OTGetIndexedPort` function returns information about the ports available on your local system. To iterate through all the ports on your computer, call the function repeatedly, incrementing the `index` parameter each time (starting with 0) until the function returns false. Each time the function returns true, it fills in the port structure that you provide with information about a specific port. You can use this information, for example, when specifying a provider configuration string for the `OTCreateConfiguration` function.

You must allocate the port structure; the function fills this structure with information about the port indicated by the `index` parameter. If the function returns `false`, the contents of the structure are not significant.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTGetLast

Returns the last element in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTGetLast (
   OTList *list
);
```

Parameters

list

Return Value

See the description of the `OTLink` data type.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTGetNBPEntityLengthAsAddress

Obtains the size of an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTGetNBPEntityLengthAsAddress (
   const NBPEntity *entity
);
```

Parameters

entity

Return Value

See the description of the `OTByteCount` data type.

Discussion

The `OTGetNBPEntityLengthAsAddress` function obtains the number of bytes needed to store an NBP entity structure into an NBP or combined DDP-NBP address structure.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTGetProtAddress

Obtains the address to which an endpoint is bound and, if the endpoint is currently connected, obtains the address of its peer. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTGetProtAddress (
   EndpointRef ref,
   TBind *boundAddr,
   TBind *peerAddr
);
```

Parameters

ref

boundAddr

If you are calling this function only to determine the address of the peer endpoint, you can set the boundAddr parameter to NIL.

The boundAddr->qlen field is ignored. See `EndpointRef` data type.

peerAddr

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

The OTGetProtAddress function returns the address to which an endpoint is bound in the boundAddr parameter and, if the endpoint is currently connected, the address of its peer in the peerAddr parameter. Not all endpoints support this function. A value of T_XPG4_1 in the flags field of the `TEndpointInfo` (page 2542) structure indicates that the endpoint does support this function.

You are responsible for initializing the buffers required to hold the local and peer addresses. The addr field of the `TEndpointInfo` structure specifies the maximum amount of memory needed to store the address of an endpoint. Use this value to set the size of the buffers.

The information returned by the OTGetProtAddress function is affected by the state of the endpoint specified by the ref parameter. If the endpoint is in the T_UNBND state, the boundAddr->addr.len field is set to 0. If the endpoint is not in the T_DATAXFER state, the peerAddr->addr.len field is set to 0.

If the endpoint is in asynchronous mode and a notifier is not installed, it is not possible to determine when the function completes.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetSlotFromPortRef

Extracts slot information from a port reference. (Deprecated in Mac OS X v10.4.)

```
OTSlotNumber OTGetSlotFromPortRef (
   OTPortRef ref,
   UInt16 *other
);
```

Parameters

ref

other

A pointer to a 16-bit buffer you provide into which the function places a value that distinguishes between ports when more than one hardware port is connected to a given slot. Specify `NULL` for this parameter if you do not want the function to return this information.

Return Value
See the description of the `OTSlotNumber` data type.

Discussion
The `OTGetSlotFromPortRef` function extracts slot information from a port reference with unknown hardware values. You can obtain such a port reference when another application passes one to you or when you use the `OTGetIndexedPort` function to access a port structure into which another application has put its own port reference.

Note that the slot numbers are physical; that is, they are the slot numbers returned by the Slot Manager and not the slots seen in various network configuration applications. Physical slot numbers depend on the type of card installed. For example, NuBus cards number their slots 9–13, which appear in the AppleTalk or TCP control panels as slots 1–5.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTGetTimeStamp

Obtains the current timestamp. (Deprecated in Mac OS X v10.4.)

```
void OTGetTimeStamp (
   OTTimeStamp *currentTime
);
```

Parameters

currentTime

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTIdle

Idles your computer. (Deprecated in Mac OS X v10.4.)

```
void OTIdle (
   void
);
```

Discussion
You can call the `OTIdle` function while you are waiting for asynchronous provider operations to complete. It is not necessary for the correct operation of Open Transport to call this function, but it provides compatibility for existing programs that use an idling function.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTInetAddressToName

Determines the canonical domain name of the host associated with an internet address. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetAddressToName (
   InetSvcRef ref,
   InetHost addr,
   InetDomainName name
);
```

Parameters

ref

addr

name

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If you call this function asynchronously, the TCP/IP service provider calls your notifier function with the `T_DNRADDRTONAMECOMPLETE` completion event code when the function completes. The `cookie` parameter to the notifier function contains a pointer to the `InetHost` structure you specified in the `addr` parameter. If you had more than one simultaneous outstanding call to the `OTInetAddressToName` function, you can use this information to determine which call has completed execution.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetGetInterfaceInfo

Returns internet address information about the local host. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetGetInterfaceInfo (
   InetInterfaceInfo *info,
   SInt32 val
);
```

Parameters

info

val

An index into the local host's array of configured IP interfaces. Specify 0 for information about the first interface. Specify `kDefaultInetInterface` to get information about the primary interface.

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
Because the architecture of Open Transport TCP/IP provides for multihoming, in principle a given host can receive packets simultaneously through more than one network interface. For each IP interface configured for the local host, the `OTInetGetInterfaceInfo` function provides the internet address and subnet mask, a default gateway (that is, a gateway, if any exists, that can be used to route any packet to all destinations outside the locally connected subnet), and a domain name server, if any is known. The function also returns

the version number of the `OTInetGetInterfaceInfo` function and, if available, the broadcast address for each interface. If the broadcast address is not available, you can determine it from the internet address and subnet mask.

Because multihoming has not been implemented in the initial release of Open Transport, the `OTInetGetInterfaceInfo` function never returns information for more than one interface.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetGetSecondaryAddresses

Returns the active secondary IP addresses. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetGetSecondaryAddresses (
   InetHost *addr,
   UInt32 *count,
   SInt32 val
);
```

Parameters
addr
count
val

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetHostToString

Converts an an address in InetHost format into a character string in dotted-decimal notation. (Deprecated in Mac OS X v10.4.)

```
void OTInetHostToString (
   InetHost host,
   char *str
);
```

Parameters

host

str

A pointer to a C string containing an IP address in dotteddecimal notation (for example, “12.13.14.15”). You must allocate storage for this string and provide the pointer to the function.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTInetMailExchange

Returns mail-exchange-host names and preference information for a domain name you specify. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetMailExchange (
   InetSvcRef ref,
   char *name,
   UInt16 *num,
   InetMailExchange *mx
);
```

Parameters

ref

name

A pointer to a host name, partially qualified domain name, or fully qualified domain name for which you want mail exchange information.

num

A pointer to the number of elements in the array pointed to by the `mx` parameter. When the function completes, it sets the number pointed to by the `num` parameter to the actual number of elements filled in.

mx

Return Value

A result code. See “Open Transport Result Codes” (page 2722).

Discussion

In order to deliver mail, a mail application must determine the fully qualified domain name of the host to which the mail should be sent. That host might be the final destination of the mail, a mail server, or a router. The domain name system servers maintain mail-exchange resource records that pair domain names with the hosts that can accept mail for that domain. Each domain name can be paired with any number of host

names; each record containing such a pair also contains a preference number. The mailer sends the mail to the host with the lowest preference number first and tries the others in turn until the mail is delivered or until the mailer decides that the mail is undeliverable.

The `OTInetMailExchange` function returns mail-exchange-host and preference information for the domain name you specify. You must then determine the address of the host and how best to deliver the mail. You can specify as many elements to the array of `InetMailExchange` structures as you wish.

If you call this function asynchronously, the TCP/IP service provider calls your notifier function with the `T_DNRMAILEXCHANGECOMPLETE` completion event code when the function completes. The `cookie` parameter to the notifier function contains the array pointer you specified in the `mx` parameter. If you had more than one simultaneous outstanding call to the `OTInetMailExchange` function, you can use this information to determine which call has completed execution.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetQuery

Executes a generic DNS query. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetQuery (
   InetSvcRef ref,
   char *name,
   UInt16 qClass,
   UInt16 qType,
   char *buf,
   OTByteCount buflen,
   void **argv,
   OTByteCount argvlen,
   OTFlags flags
);
```

Parameters
ref
name
qClass
qType
buf
buflen
argv
argvlen
flags

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetStringToAddress

Resolves a domain name to its equivalent internet addresses. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetStringToAddress (
   InetSvcRef ref,
   char *name,
   InetHostInfo *hinfo
);
```

Parameters

ref

name

A pointer to the domain name you want to resolve. This can be a host name, a partially qualified domain name, a fully qualified domain name, or an internet address in dotted-decimal format.

hinfo

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
Because the architecture of Open Transport TCP/IP provides for multihoming, a single host can be associated with multiple internet addresses. You can use the `OTInetStringToAddress` function to return multiple addresses for multihomed hosts.

Because multihoming has not been implemented in the initial release of Open Transport, the `OTInetStringToAddress` function never returns more than one address.

If you specify an internet address in dotted-decimal format for the `hinfo` parameter, the `OTInetStringToAddress` function places that address in the `InetHostInfo.name` field instead of a canonical domain name.

If you call the `OTInetStringToAddress` function asynchronously, the TCP/IP service provider calls your notifier function with the `T_DNRSTRINGTOADDRCOMPLETE` completion event code when the function completes. The `cookie` parameter to the notifier function contains the pointer you specified in the `hinfo` parameter. If you had more than one simultaneous outstanding call to the `OTInetStringToAddress` function, you can use this information to determine which call has completed execution.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetStringToHost

Converts an IP address string from dotted-decimal notation or hexadecimal notation to an `InetHost` data type. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetStringToHost (
   const char *str,
   InetHost *host
);
```

Parameters

str

A pointer to a character string containing an IP address in either dotted-decimal notation (for example, "12.13.14.15") or hexadecimal notation (for example, "0x0c0d0e0f").

host

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInetSysInfo

Returns details about a host's processor and operating system. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInetSysInfo (
   InetSvcRef ref,
   char *name,
   InetSysInfo *sysinfo
);
```

Parameters

ref

name

The name of the host about which you want information. This can be a host name (including the local host), a partially qualified domain name, or a fully qualified domain name.

sysinfo

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The information returned by this function is maintained by the domain name server. If you call this function asynchronously, the TCP/IP service provider calls your notifier function with the `T_DNRSYSINFOCOMPLETE` completion event code when the function completes. The `cookie` parameter to the notifier function contains a pointer to the `InetSysInfo` structure you specified in the `sysinfo` parameter. If you had more than one simultaneous outstanding call to the `OTInetSysInfo` function, you can use this information to determine which call has completed execution.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInitDDPAddress

Initializes a DDP address structure. (Deprecated in Mac OS X v10.4.)

```
void OTInitDDPAddress (
   DDPAddress *addr,
   UInt16 net,
   UInt8 node,
   UInt8 socket,
   UInt8 ddpType
);
```

Parameters

addr

net
The network number you wish to specify. Set to 0 to default to the local network.

node
The node ID you wish to specify. Set to 0 to default to the local node.

socket
The socket number you wish to specify. Set to 0 to allow Open Transport to assign a socket dynamically when you use this address to bind an endpoint.

ddpType
The DDP type you wish to specify. Set to 0 unless you are using DDP.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInitDDPNBPAddress

Initializes a combined DDP-NBP address structure. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTInitDDPNBPAddress (
   DDPNBPAddress *addr,
   const char *name,
   UInt16 net,
   UInt8 node,
   UInt8 socket,
   UInt8 ddpType
);
```

Parameters

addr

name

A pointer to the NBP string you wish to use for the NBP name.

net

The network number you wish to specify. Set to 0 to default to the local network.

node

The node ID you wish to specify. Set to 0 to default to the local node.

socket

The socket number you wish to specify. Set to 0 to allow Open Transport to assign a socket dynamically when you use this address to bind an endpoint.

ddpType

The DDP type you wish to specify. Set to 0 unless you are using DDP.

Return Value

See the description of the `OTByteCount` data type.

Discussion

The `OTInitDDPNBPAddress` function initializes a combined DDP-NBP address structure with the data provided in the parameters: NBP name, network number, node ID, socket number, and DDP type. The function returns the total size of the address structure, which is the length of the `name` parameter plus the size of a `DDPAddress` structure.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTInitDNSAddress

Fills in a DNSAddress structure with the data you provide. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTInitDNSAddress (
   DNSAddress *addr,
   char *str
);
```

Parameters

addr

str

A pointer to a domain name string. This string can be just a host name (otteam), a partially qualified domain name (for example, "otteam.ssw"), a fully qualified domain name (for example, "otteam.ssw.apple.com."), or an internet address in dotteddecimal format (for example, "17.202.99.99"), and can optionally include the port number (for example, "otteam.ssw.apple.com:25" or "17.202.99.99:25").

Return Value
See the description of the `OTByteCount` data type.

Discussion
This function fills in the `fAddressType` field of the `DNSAddress` structure with the value `AF_DNS`, fills in the `fName` field with the address string you specify, and returns the size of the resulting `DNSAddress` structure as an unsigned integer. You can use the `DNSAddress` structure to provide an address when you use a UDP or TCP endpoint. If you do so, the domain name resolver resolves the address for you automatically.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInitInetAddress

Fills in an InetAddress structure with the data you provide. (Deprecated in Mac OS X v10.4.)

```
void OTInitInetAddress (
   InetAddress *addr,
   InetPort port,
   InetHost host
);
```

Parameters

addr

port

host

Discussion
This function fills in the `fAddressType` field of the `InetAddress` structure with the value `AF_INET`. You use the InetAddress structure when providing a TCP or UDP address to the Open Transport functions `OTConnect`, `OTSndURequest`, and `OTBind`. You are not required to use the `OTInitInetAddress` function when creating an `InetAddress` structure; this function is provided for your convenience only.

Availability
Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInitNBPAddress

Initializes an NBP address structure. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTInitNBPAddress (
   NBPAddress *addr,
   const char *name
);
```

Parameters

addr

name

A pointer to the NBP string you wish to use for the NBP name.

Return Value
See the description of the `OTByteCount` data type.

Discussion
The `OTInitNBPAddress` function can be used to initialize an NBP address structure with the NBP name specified in the `name` parameter, which is assumed to already be in the correct string format. The function returns the size of the NBP address structure, which is the size of the `fAddressType` field plus the length of the string in the `name` parameter.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInitNBPEntity

Initializes an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
void OTInitNBPEntity (
   NBPEntity *entity
);
```

Parameters

entity

Discussion
The `OTInitNBPEntity` function initializes an NBP entity structure, setting the name, type and zone parts of an NBP name to empty strings.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTInstallNotifier

Installs a notifier function. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTInstallNotifier (
   ProviderRef ref,
   OTNotifyUPP proc,
   void *contextPtr
);
```

Parameters

ref

proc

For C++ applications, the `proc` parameter must point to either a C function or a static member function. See `OTNotifyUPP` data type.

contextPtr

A context pointer for your use. The provider passes this value unchanged to your notifier function when it calls the function.

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTInstallNotifier` function installs a notifier function for the provider that you specify. Changing a provider's mode of execution does not affect the notifier function. The notifier function remains installed until you remove it using the `OTRemoveNotifier` function or until you close the provider.

Before calling the `OTInstallNotifier` function, you must open the provider for which you want to install the notifier. If you open a provider asynchronously (for example, with the `OTAsyncOpenEndpoint` function), you must pass a pointer to a notifier function as a parameter to the function used to open the provider. In this case, you don't need to call the `OTInstallNotifier` function unless you want to install a different notifier function. If you do, you must call the `OTRemoveNotifier` function before calling the `OTInstallNotifier` function.

Opening a provider synchronously (for example, with the `OTOpenEndpoint` function) opens the provider but does not install a notifier function for it. If you need a notifier function for a provider opened synchronously, you must call the `OTInstallNotifier` function. This notifier would not return completion events, but would return asynchronous events advising you of the arrival of data, of changes in flow-control restrictions, and so on.

Call the `OTInstallNotifier` function only when no provider functions are executing for the provider that you specify. Otherwise, the `OTInstallNotifier` function returns the result code `kOTStateChangeErr`.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTIoctl

Sends a module-specific command to an Open Transport protocol module. (Deprecated in Mac OS X v10.4.)

```
SInt32 OTIoctl (
   ProviderRef ref,
   UInt32 cmd,
   void *data
);
```

Parameters

ref

cmd

A routine selector for the module-specific command.

data

Data to be used by the module-specific command, or a pointer to such data. The interpretation of the `data` parameter is command specific.

Discussion
The `OTIoctl` function sends a module-specific command to an Open Transport protocol module. The `OTIoctl` function runs synchronously or asynchronously, matching the provider's mode of execution.

If the `OTIoctl` function completes synchronously without error, it returns 0 or a positive integer. The positive integer's meaning is command specific. If the `OTIoctl` function fails while executing synchronously, its return value is a negative integer corresponding to an Open Transport result code.

If the `OTIoctl` function runs asynchronously, it returns immediately with a return value `kOTNoError` or another Open Transport result code. When the function completes execution, Open Transport calls the notifier function you specify, passing the event code `kStreamIoctlEvent` and a `result` parameter indicating the result of the completed `OTIoctl` function. If the value of the `result` parameter is greater than 0, the corresponding result code is defined by the command; otherwise, the value of the `result` parameter corresponds to an Open Transport result code.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTIsAckingSends

Determines whether a provider is acknowledging sends. (Deprecated in Mac OS X v10.4.)

```
Boolean OTIsAckingSends (
   ProviderRef ref
);
```

Parameters

ref

Discussion

The `OTIsAckingSends` function returns `true` if the provider acknowledges sends and `false` if it does not.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTIsBlocking

Returns a boolean indicating whether a provider is blocking. (Deprecated in Mac OS X v10.4.)

```
Boolean OTIsBlocking (
   ProviderRef ref
);
```

Parameters

ref

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTIsInList

Determines whether the specified link is in the specified list. (Deprecated in Mac OS X v10.4.)

```
Boolean OTIsInList (
   OTList *list,
   OTLink *link
);
```

Parameters

list

link

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTIsSynchronous

Returns a provider's current mode of execution. (Deprecated in Mac OS X v10.4.)

```
Boolean OTIsSynchronous (
   ProviderRef ref
);
```

Parameters

ref

Discussion

The `OTIsSynchronous` function returns `true` if a provider is in synchronous mode or returns `false` if the provider is in asynchronous mode.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTLeaveNotifier

Allows Open Transport to resume sending primary and completion events. (Deprecated in Mac OS X v10.4.)

```
void OTLeaveNotifier (
   ProviderRef ref
);
```

Parameters

ref

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTLIFODequeue

Removes the first link in a LIFO list and returns a pointer to it. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTLIFODequeue (
   OTLIFO *list
);
```

Parameters

list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTLIFOEnqueue

Places a link at the front of a LIFO list. (Deprecated in Mac OS X v10.4.)

```
void OTLIFOEnqueue (
   OTLIFO *list,
   OTLink *link
);
```

Parameters

list

link

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTLIFOStealList

Removes all links in a LIFO list and returns a pointer to the first link in the list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTLIFOStealList (
   OTLIFO *list
);
```

Parameters
list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTListen

Listens for an incoming connection request. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTListen (
   EndpointRef ref,
   TCall *call
);
```

Parameters
ref
call

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
You use the OTListen function to listen for incoming connection requests. On return, the function fills in the TCall structure referenced by the call parameter with information about the connection request. After retrieving the connection request using the OTListen function, you can reject the request using the OTSndDisconnect function, or you can accept the request using the OTAccept function.

If the endpoint is in synchronous mode and is blocking, the OTListen function returns when a connection request has arrived. If the endpoint is in asynchronous mode or is not blocking, the OTListen function returns any pending connection requests or returns the kOTNoDataErr result if there are no pending connection requests. You can also call the OTListen function from within a notifier function in response to the T_LISTEN event. In this case, the function returns a result immediately.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTLook

Determines the current asynchronous event pending for an endpoint. (Deprecated in Mac OS X v10.4.)

```
OTResult OTLook (
   EndpointRef ref
);
```

Parameters
ref

Return Value
See the description of the `OTResult` data type.

Discussion
You use the OTLook function in one of two cases. First, if the endpoint is in synchronous mode, you can call the OTLook function to poll for incoming data or connection requests. Second, certain asynchronous events might cause a synchronous function to fail with the result kOTLookErr. For example, if you call OTAccept and the endpoint gets a T_DISCONNECT event, the OTAccept function returns with kOTLookErr. In this case, you need to call the OTLook function to determine what event caused the original function to fail. Table 3-7 on page 3-26 lists the functions that might return the kOTLookErr result and the events that can cause these functions to fail.

The OTLook function returns an integer value that specifies the asynchronous event pending for the endpoint specified by the ref parameter. On error, OTLook returns a negative integer corresponding to a result code.

If there are multiple events pending, the OTLook function first looks for one ofthe following events: T_LISTEN, T_CONNECT, T_DISCONNECT, T_UDERR, or T_ORDREL. If it finds more than one of these, it returns them to you in first-in, first-out order. After processing these events, the OTLook function looks for the T_DATA, T_REQUEST, and T_REPLY events. If it finds more than one of these, it returns them to you in first-in, first-out order. You cannot use the OTLook function to poll for completion events.

Unless you are operating exclusively in synchronous mode, it is recommended that you use notifier functions to get information about pending events for an endpoint.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTLookupName

Finds and returns all addresses that correspond to a particular name or name pattern, or confirms that a name is registered. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTLookupName (
   MapperRef ref,
   TLookupRequest *req,
   TLookupReply *reply
);
```

Parameters

ref

req

reply

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
You can use the OTLookupName function to find out whether a name is registered and what address is associated with that name. You use the req parameter to supply the information needed for the search: what name should be looked up and, optionally, what node contains that information, how many matches you expect to find, and how long the search should continue before the function returns. On return, the reply parameter contains the names field that points to the buffer where the matching entries are stored and the rspcount field that specifies the number of matching entries.

For each registered name found, the OTLookupName function stores the following information in the buffer referenced by the names field of the reply parameter:

```
unsigned short addrLen; /* length of address that follows*/
unsigned short nameLen; /* length of name that follows */
unsigned char addr[]; /* address */
unsigned char name[]; /* name, padded to quad-word boundary*/
```

If you are searching for names using a name pattern and you expect that more than one name will be returned to you, you need to parse the reply buffer to extract the matching names.

If you call the OTLookupName function asynchronously, the mapper provider calls your notifier function passing one of two completion codes for the code parameter (T_LKUPNAMERESULT or T_LKUPNAMECOMPLETE) and passing the reply parameter in the cookie parameter. The mapper provider passes the T_LKUPNAMERESULT code each time it stores a name in the reply buffer, and it passes the T_LKUPNAMECOMPLETE code when it is done. When you receive this event, examine the rspcount field to determine whether there is a last name to retrieve from the reply buffer. The use of both codes is a feature that gives you a choice about how to process multiple names when searching for names matching a pattern.

- If you decide to allocate a buffer that is large enough to contain all the names returned, you can ignore the T_LKUPNAMERESULT code and call a function that parses the buffer once the OTLookupName function has completed—that is, once the provider calls your notifier function using the T_LKUPNAMECOMPLETE event.

- If you want to save memory or if you don't know how large a buffer to allocate, you can use the following method to process the names returned. Each time that the T_LKUPNAMERESULT event is passed, you must do something with the reply from the reply buffer. You can copy it somewhere, or you can delete it if it isn't a name you're interested in. Then, from inside your notifier you must set the reply->names.len field or the reply->rspcount field back to 0 (thus allowing the mapper provider to overwrite the original name). This tells the mapper provider that you are ready to receive another name. Accordingly, when the mapper provider has inserted another name into your reply buffer, it calls your notifier passing the T_LKUPNAMERESULT code, and you can process the new entry as you have processed the first entry. This method also saves you the trouble of having to parse through the buffer to extract name and address information.

The cookie parameter to the notifier contains the reply parameter.

The format of the names and protocol addresses are specific to the underlying protocol. Consult the documentation supplied for your protocol for more information.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTMemcmp

Compares the contents of two memory locations. (Deprecated in Mac OS X v10.4.)

```
Boolean OTMemcmp (
   const void *mem1,
   const void *mem2,
   OTByteCount nBytes
);
```

Parameters
mem1
mem2
nBytes

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTMemcpy

Copies data from one memory location to another; the source and destination locations must not overlap. (Deprecated in Mac OS X v10.4.)

```
void OTMemcpy (
   void *dest,
   const void *src,
   OTByteCount nBytes
);
```

Parameters

dest

src

nBytes

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTMemmove

Copies data from one memory location to another; the source and destination locations may overlap. (Deprecated in Mac OS X v10.4.)

```
void OTMemmove (
   void *dest,
   const void *src,
   OTByteCount nBytes
);
```

Parameters

dest

src

nBytes

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

OpenTransport.h

OTMemset

Sets the specified memory range to a specific value. (Deprecated in Mac OS X v10.4.)

```
void OTMemset (
   void *dest,
   OTUInt8Param toSet,
   OTByteCount nBytes
);
```

Parameters

dest

toSet

nBytes

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTMemzero

Initializes the specified memory range to 0. (Deprecated in Mac OS X v10.4.)

```
void OTMemzero (
   void *dest,
   OTByteCount nBytes
);
```

Parameters

dest

nBytes

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTNextOption

Locates the next `TOption` structure in a buffer. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTNextOption (
   UInt8 *buffer,
   UInt32 buflen,
   TOption **prevOptPtr
);
```

Parameters

buffer

A pointer to the buffer containing the option to be found.

buflen

A long specifying the size of the buffer containing the option to be found.

prevOptPtr

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

The `OTNextOption` function allows you to parse through a buffer containing `TOption` structures describing an endpoint's option values. Within the buffer, `TOption` structures are aligned to long-word boundaries. This function takes into account this padding when it calculates the beginning address of the next `TOption` structure and it returns that address in the `prevOptPtr` parameter.

The first time you call the option, set the `prevOptPtr` parameter to the beginning address of the buffer. When the function returns, the `prevOptPtr` parameter points to the next (second) option in the buffer. You can continue this process, specifying the value returned for the `prevOptPtr` parameter by the previous invocation of the function, each time you call the function to obtain the beginning address of each option in the buffer.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTOpenAppleTalkServicesInContext

Opens a synchronous AppleTalk service provider. (Deprecated in Mac OS X v10.4.)

```
ATSvcRef OTOpenAppleTalkServicesInContext (
   OTConfigurationRef cfig,
   OTOpenFlags flags,
   OSStatus *err,
   OTClientContextPtr clientContext
);
```

Parameters

cfig

flags

err

clientContext

Return Value
See the description of the `ATSvcRef` data type.

Discussion
Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTOpenEndpointInContext

Opens an endpoint that operates synchronously. (Deprecated in Mac OS X v10.4.)

```
EndpointRef OTOpenEndpointInContext (
   OTConfigurationRef config,
   OTOpenFlags oflag,
   TEndpointInfo *info,
   OSStatus *err,
   OTClientContextPtr clientContext
);
```

Parameters

config

oflag

info

err

clientContext

Return Value
See the description of the `EndpointRef` data type.

Availability
Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTOpenInternetServicesInContext

Opens the TCP/IP service provider and returns an internet services reference. (Deprecated in Mac OS X v10.4.)

```
InetSvcRef OTOpenInternetServicesInContext (
   OTConfigurationRef cfig,
   OTOpenFlags oflag,
   OSStatus *err,
   OTClientContextPtr clientContext
);
```

Parameters
cfig
oflag
err
clientContext

Return Value
See the description of the `InetSvcRef` data type.

Discussion
Applications may pass a NULL context pointer but nonapplications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTOpenMapperInContext

Creates a synchronous mapper provider and returns a mapper reference. (Deprecated in Mac OS X v10.4.)

```
MapperRef OTOpenMapperInContext (
   OTConfigurationRef config,
   OTOpenFlags oflag,
   OSStatus *err,
   OTClientContextPtr clientContext
);
```

Parameters

config

oflag

err

clientContext

Return Value
See the description of the `MapperRef` data type.

Discussion
Applications may pass a NULL pointer but non-applications must always pass a valid client context pointer.

You receive a client context pointer when you call the function `InitOpenTransportInContext` (page 2303).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTOptionManagement

Determines an endpoint's current or default option values or changes these values. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTOptionManagement (
   EndpointRef ref,
   TOptMgmt *req,
   TOptMgmt *ret
);
```

Parameters

ref

req

ret

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
To use the `OTOptionManagement` function, you must have opened an endpoint using the `OTOpenEndpoint` or `OTAsyncOpenEndpoint` functions.

You use the `OTOptionManagement` function to negotiate, retrieve, or verify an endpoint's protocol options. If the endpoint is in asynchronous mode and you have not installed a notifier function, it is not possible to determine when the function completes.

The action taken by the `OTOptionManagement` function is determined by the setting of the `req->flags` field. The following bulleted items describe the different operations that you can perform and the flag settings that you use to specify these operations.

- To negotiate values for the endpoint, you must call the `OTOptionManagement` function, specifying `T_NEGOTIATE` for the `req->flags` field. The endpoint provider evaluates the requested options, negotiates the values, and returns the resulting values in the option management structure pointed to by the `ret->opt.buf` field. The `status` field of each returned option is set to a constant that indicates the result of the negotiation. These constants are described by the "Open Transport Flags and Status Codes" (page 2702) enumeration.

  For any protocol specified, you can negotiate for the default values of all options supported by the endpoint by specifying the value `T_ALLOPT` for the `name` field of the `TOption` structure. This might be useful if you want to change current settings or if negotiations for other values have failed. The success of the negotiations depends partly on the state of the endpoint—that is, simply because these are default values does not guarantee a completely successful negotiation. When the function returns, the resulting values are returned, option by option, in the buffer pointed to by the `ret->opt.buf` field.

- To retrieve an endpoint's default option values, call the `OTOptionManagement` function, specifying `T_DEFAULT` for the `req->flags` field. You must also specify the name of the option (but not its value) in the `TOption` structure that you create for each of the options you are interested in.

  When the function returns, it passes the default values for the options back to you in the buffer pointed to by the `ret->opt.buf` field. For each option, the `status` field contains `T_NOTSUPPORT` if the protocol does not support the option, `T_READONLY` if the option is read-only, and `T_SUCCESS` in all other cases. The overall result of the request is returned in the `ret->flags` field. The meaning of this result is described by the `Open Transport Flags and Status Codes` enumeration.

  When getting an endpoint's default option values, you can specify `T_ALLOPT` for the option name. This returns all supported options for the specified level with their default values. In this case, you must set the `opt.maxlen` field to the maximum size required to hold an endpoint's option information. The `info.opt` field of the `TEndpointInfo` (page 2542) structure specifies the maximum size of a buffer used to hold option information for an endpoint.

- To retrieve an endpoint's current option values, call the `OTOptionManagement` function, specifying `T_CURRENT` for the `req->flags` field. For each option in the buffer referenced by the `req->opt.buf` field, specify the name of the option you are interested in. The function ignores any option valuesyou specify.

  When the function returns, it passes the current values for the options back to you in the buffer referenced by the `ret->opt.buf` field. For each option, the `status` field contains `T_NOTSUPPORT` if the protocol does not support the option, `T_READONLY` if the option is read-only, and `T_SUCCESS` in all other cases. The overall result of the request is returned in the `ret->flags` field. The meaning of this result is described by the "Open Transport Flags and Status Codes" (page 2702) enumeration.

  When retrieving an endpoint's current option values, you can specify `T_ALLOPT` for the option name. The function returns all supported options for the specified protocol, with their current values. In this case, you must set the `opt.maxlen` field to the maximum size required to hold an endpoint's option information. The `info.opt` field of the `TEndpointInfo` structure specifies the maximum size of a buffer used to hold option information for an endpoint.

- To check whether an endpoint provider supports certain options or option values, you must call the OTOptionManagement function, specifying T_CHECK for the req->flags field. Checking options or their values does not change the current settings of an endpoint's options.
  - To check whether an option is supported, set the `name` field of the `TOption` structure to the option name, but do not specify an option value. When the function returns, the `status` field for the corresponding `TOption` structure in the buffer pointed to by the `ret->opt.buf` field is set to `T_SUCCESS` if the option is supported, `T_NOTSUPPORT` if it is not supported or needs additional client privileges, and `T_READONLY` if it is read-only.
  - To check whether an option value is supported, set the `name` field of the `TOption` structure to the option name, and set the `value` field to the value you want to check. When the function returns, the `status` field for the corresponding `TOption` structure in the buffer pointed to by the `ret->opt.buf` field is set as it would be if you had specified the `T_NEGOTIATE` flag. The overall result of the option checks is returned in the `ret->flags` field, which contains the single worst result of the option checks. The meaning of this result is described by the `Open Transport Flags and Status Codes` enumeration.

Availability

Declared In
`OpenTransport.h`

OTRcv

Reads data sent using a connection-oriented transactionless protocol. (Deprecated in Mac OS X v10.4.)

```
OTResult OTRcv (
   EndpointRef ref,
   void *buf,
   OTByteCount nbytes,
   OTFlags *flags
);
```

Parameters

ref

buf

A pointer to a memory location where the incoming data is to be copied. You must allocate this buffer before you call the function.

nbytes

flags

Return Value
See the description of the `OTResult` data type.

Discussion
You call the `OTRcv` function to read data sent by the peer to which you are connected. If the `OTRcv` function succeeds, it returns an integer (`OTStatus`) specifying the number of bytes received. The function places the data read into the buffer referenced by the buf parameter. If the function fails, it returns a negative integer corresponding to a result code that indicates the reason for the failure. You can call this function to receive either normal or expedited data. If the data is expedited, the `T_EXPEDITED` flag is set in the flags parameter.

If `T_MORE` is set in the flags parameter when the function returns, this means that the buffer you allocated is too small to contain the data to be read and that you must call the `OTRcv` function again. If you have read x bytes with the first call, the next call to the `OTRcv` function begins to read at the (x + 1) byte. Of course, if you need it, you must copy the data in the buffer to another location before calling the function again. Each call to this function that returns with the `T_MORE` flag set means that you must call the function again to get more data. When you have read all the data, the OTRcv function returns with the `T_MORE` flag not set. If the endpoint does not support the concept of a TSDU (Transport Service Data Unit), the `T_MORE` flag is not meaningful and should be ignored. To determine whether the endpoint supports TSDUs, examine the `tsdu` field of the `TEndpointInfo` (page 2542) structure. A value of `T_INVALID` means that the endpoint does not support it.

Some protocols allow you to send zero-length data to signal the end of a logical unit. In this case, if you request more than 0 bytes when calling the OTRcv function, the function returns 0 bytes only to signal the end of a TSDU.

If the OTRcv function returns and the T_EXPEDITED bit is set in the flags parameter, this means that you are about to read expedited data. If the number of bytes of expedited data exceeds the number of bytes you specified in the reqCount parameter, both the T_EXPEDITED and the T_MORE bits are set. You must call the OTRcv function until the T_MORE flag is not set to retrieve the rest of the expedited data.

If you are calling the OTRcv function repeatedly to read normal data and a call to the function returns T_EXPEDITED in the flags parameter, the next call to the OTRcv function that returns without the T_EXPEDITED flag set returns normal data at the place it was interrupted. It is your responsibility to remember where that was and to continue processing normal data. You can determine how much normal data you read by maintaining a running total of the number of bytes returned in the OTStatus result.

If the endpoint is in asynchronous mode or is not blocking, the function returns with the kOTNoDataErr result if no data is available. If you have installed a notifier, the endpoint provider calls your notifier and passes T_DATA or T_EXDATA for the code parameter when there is data available. If you have not installed a notifier, you may poll for these events using the OTLook function. Once you receive a T_DATA or T_EXDATA event, you should continue in a loop, calling the OTRcv function until it returns with the kOTNoDataErr result.

If the endpoint is in synchronous mode and is blocking, the endpoint waits for data if none is currently available. You should avoid calling the OTRcv function this way because it might cause processing to hang if no data is available. If you are doing other operations in synchronous mode, you should put the endpoint in nonblocking mode before calling the OTRcv function.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRcvConnect

Reads the status of an outstanding or completed asynchronous call to the`OTConnect` function. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRcvConnect (
   EndpointRef ref,
   TCall *call
);
```

Parameters

ref

call

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

You call the OTRcvConnect function to determine the status of a previously issued OTConnect call. If you want to retrieve information about the connection, you must allocate buffers for the addr field and, if required, the opt and udata fields before you make the call.

If the endpoint is synchronous and blocking, the OTRcvConnect function waits for the connection to be accepted or rejected. If the connection is accepted, the function returns with a kOTNoError result. If the connection is rejected, the function returns with a kOTLookErr result. In this case, you should call the OTLook function to verify that a T_DISCONNECT event is the reason for the kOTLookErr, and then you should call the OTRcvDisconnect function to clear the event.

If the endpoint is asynchronous or nonblocking, the OTRcvConnect function returns with the kOTNoDataErr result if the connection has not yet been established.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTRcvDisconnect

Identifies the cause of a connection break or of a connection rejection, acknowledges and clears the corresponding disconnection event. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRcvDisconnect (
   EndpointRef ref,
   TDiscon *discon
);
```

Parameters

ref

discon

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
Calling the OTRcvDisconnect function clears the corresponding disconnection event and retrieves any user data sent with the disconnection.

If you do not care about data returned with the disconnection and do not needto know the reason for the disconnection nor the sequence ID, you may specify a nil pointer for the discon parameter. In this case, the provider discards any user data associated with the disconnection.

The OTRcvDisconnect function behaves in the same way for all modes of operation. If there is no disconnection request pending, the function returns with the kOTNoDisconnectErr result. If there is a disconnection request pending, the function returns either the kOTNoError or kOTBufferOverflowErr result. In the latter instance, you need to check the discon field of the `TEndpointInfo` (page 2542) structure for your endpoint and make sure that the buffer referenced by the udata.buf field is at least as big as the value specified for the discon field.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRcvOrderlyDisconnect

Acknowledges a request for an orderly disconnect. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRcvOrderlyDisconnect (
   EndpointRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The OTRcvOrderlyDisconnect function is a service that is not supported by all protocols. If it is, the servtype field of the `TEndpointInfo` (page 2542) structure has the value `T_COTS_ORD` or `T_TRANS_ORD` for the endpoint.

After using the OTRcvOrderlyDisconnect function to acknowledge receipt of a disconnection request, there will not be any more data to receive. Calls to the OTRcv function (for a transactionless connection) or to the OTRcvRequest function (for a transaction-based connection) after acknowledging a disconnection request fail with the kOTOutStateErr result. If the endpoint supports a remote orderly disconnect, you can still send data over the connection if you have not yet called the OTSndOrderlyDisconnect function.

The OTRcvOrderlyDisconnect function behaves in the same way in all modes of operation. If there is no disconnection request pending, the function returns with the kOTNoReleaseErr result. It there is a disconnection request pending, the function returns either the kOTNoError or kOTBufferOverflowErr result. In the latter instance, you need to check the discon field of the`TEndpointInfo` (page 2542) structure for your endpoint and make sure that the buffer referenced by the udata.buf field is at least as big as the value specified for the discon field.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRcvUData

Reads data sent by a client using a connectionless transactionless protocol. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRcvUData (
   EndpointRef ref,
   TUnitData *udata,
   OTFlags *flags
);
```

Parameters
ref
udata
flags

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
When the OTRcvUData function returns, it passes a pointer to a TUnitData structure containing information about the data read and a pointer to a flags variable that is set to indicate whether there is more data to be retrieved. If the buffer pointed to by the udata->udata.buf field is not large enough to hold the current data unit, the endpoint provider fills the buffer and sets the flags parameter to T_MORE to indicate that you must call the OTRcvUData function again to receive additional data. Subsequent calls to the OTRcvUData function return 0 for the length of the address and option buffers until you receive the full data unit. The last unit to be received does not have the T_MORE flag set.

If the endpoint is in asynchronous mode or is not blocking and data is not available, the OTRcvUData function fails with the kOTNoDataErr result. The endpoint provider uses the T_DATA event to notify the endpoint when data becomes available. You can use a notifier function or the OTLook function to retrieve the event. Once you get the T_DATA event, you should continue calling the OTRcvUData function until it returns the kOTNoDataErr result.

It is possible that the provider generates an erroneous T_DATA event. This is the case when the provider calls your notifier, passing T_DATA for the code parameter; but when you execute the OTRcvUData function, it returns with a kOTNoDataErr result. If this happens, you should continue normal processing and assume that the next T_DATA event is genuine.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRcvUDErr

Clears an error condition indicated by a `T_UDERR` event and returns the reason for the error. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRcvUDErr (
   EndpointRef ref,
   TUDErr *uderr
);
```

Parameters
ref
uderr

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
You use the OTRcvUDErr function if you have called the OTSndUData function and the endpoint provider has issued the T_UDERR event to indicate that the send operation did not succeed. This usually happens when the endpoint provider cannot determine immediately that you have specified a bad address or option value. For example, assume that you are using AppleTalk and you specify an NBP address. If Open Transport cannot resolve the address, it sends a T_UDERR event to your notifier function. To clear the error condition and determine the cause of the failure, you must call the OTRcvUDErr function.

If the size of the option or error data returned exceeds the size of the allocated buffers, the OTRcvUDErr function returns with the result kOTBufferOverflowErr, but the error indication is cleared anyway.

If you do not need to identify the cause of the failure, you can set the uderr pointer to nil. In this case, the OTRcvUDErr function clears the error indication without reporting any information to you. It is important, nevertheless, that you actually call the OTRcvUDErr function to clear the error condition. If you don't call this function, the endpoint remains in an invalid state for doing other send operations, and the endpoint provider is unable to deallocate memory reserved for internal buffers associated with the send operation.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTReadBuffer

Copies data out of a no-copy receive buffer. (Deprecated in Mac OS X v10.4.)

```
Boolean OTReadBuffer (
   OTBufferInfo *buffer,
   void *dest,
   OTByteCount *len
);
```

Parameters

buffer

dest

len

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransportProtocol.h

OTRegisterAsClientInContext

Registers your application as a client of Open Transport and gives Open Transport a notifier function it can use to send you events. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRegisterAsClientInContext (
   OTClientName name,
   OTNotifyUPP proc,
   OTClientContextPtr clientContext
);
```

Parameters

name

proc

clientContext

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRegisterName

Registers an entity name on the network. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTRegisterName (
   MapperRef ref,
   TRegisterRequest *req,
   TRegisterReply *reply
);
```

Parameters

ref

req

reply

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If the name-registration protocol defined using the config parameter to the OTOpenMapper or OTAsyncOpenMapper function supports dynamic name and address registration, you can use the OTRegisterName function to make a name visible on the network to other network devices.

Some protocol implementations under Open Transport allow a client to specify a name rather than an address when binding the endpoint using the OTBind function. Binding an endpoint by name causes the protocol to automatically register the name on the network if the protocol supports dynamic name registration. This is the simpler technique for registering a name and is preferred over creating a mapper provider and then using the OTRegisterName function to register the name.

The format for the requested name and address is specific to the protocol used. Please consult the documentation for the protocol you are using for format information.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTReleaseBuffer

Returns the no-copy receive buffer to the system. (Deprecated in Mac OS X v10.4.)

```
void OTReleaseBuffer (
   OTBuffer *buffer
);
```

Parameters

buffer

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransportProtocol.h

OTRemoveFirst

Removes the first link in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTRemoveFirst (
   OTList *list
);
```

Parameters

list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTRemoveLast

Removes the last link in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTRemoveLast (
   OTList *list
);
```

Parameters

list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRemoveLink

Removes the last link in a FIFO list. (Deprecated in Mac OS X v10.4.)

```
Boolean OTRemoveLink (
   OTList *list,
   OTLink *link
);
```

Parameters
list
link

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTRemoveNotifier

Removes a provider's notifier function. (Deprecated in Mac OS X v10.4.)

```
void OTRemoveNotifier (
   ProviderRef ref
);
```

Parameters
ref

Discussion
The `OTRemoveNotifier` function removes the notifier (if any) currently installed for the provider specified by the `ref` parameter.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTResolveAddress

Returns the protocol address that corresponds to the name of an endpoint. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTResolveAddress (
   EndpointRef ref,
   TBind *reqAddr,
   TBind *retAddr,
   OTTimeout timeOut
);
```

Parameters

ref

reqAddr

retAddr

timeOut

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The OTResolveAddress function returns the lowest-level address for your endpoint. Not all endpoints support this function. A value of CAN_RESOLVE_ADDR in the flags field of the TEndpointInfo (page 2542) structure indicates that the endpoint does support this function. Using this function saves you the trouble of opening and closing a mapper provider if the only reason you have for opening the mapper is to look up the address corresponding to a specific endpoint name. You would still have to open the mapper if you needed to look up a name pattern—that is, if the name included any wildcard characters.

You are responsible for initializing the buffers described by the req and ret parameters required to hold the addresses. To determine how large these buffers should be, examine the addr field of the TEndpointInfo structure, which specifies the maximum amount of memory needed to store an address for the endpoint specified by the ref parameter.

If a notifier is not installed, it is not possible to determine when the OTResolveAddress function completes.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTReverseList

Reverses the order in which entries are linked in a list. (Deprecated in Mac OS X v10.4.)

```
OTLink * OTReverseList (
   OTLink *list
);
```

Parameters

list

Return Value
See the description of the `OTLink` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTScheduleDeferredTask

Schedules a task for execution at deferred task time. (Deprecated in Mac OS X v10.4.)

```
Boolean OTScheduleDeferredTask (
   OTDeferredTaskRef dtCookie
);
```

Parameters

dtCookie

Discussion
The `OTScheduleDeferredTask` function schedules for execution at the next deferred task time the task associated with the `dtCookie` parameter, which is the reference returned by the `OTCreateDeferredTask` function.

You can call this function at any time. If you have not yet destroyed a task, you can use this function to reschedule the same task more than once.

If you makes multiple calls to the `OTScheduleDeferredTask` function before the task is executed, additional tasks are not scheduled; only one instance of each unique task can only be scheduled at a time.

This function returns `true` if it scheduled the deferred task successfully, `false` if not. If it returns `false` and the `dtCookie` parameter has a valid value (other than 0), then the task is already scheduled to run. If `dtCookie` is invalid (a value of 0), the function returns `false` and does nothing.

If you want to call Open Transport from an interrupt, you can use this function (and the `OTCreateDeferredTask` function) instead of the standard Deferred Task Manager function `DTInstall` to create a deferred task that permits you to call Open Transport function calls. This allows Open Transport to adapt to changes in the underlying operating system without affecting the client's code.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTScheduleTimerTask

Schedules a timer task to be executed at the specified time. (Deprecated in Mac OS X v10.4.)

```
Boolean OTScheduleTimerTask (
   OTTimerTask timerTask,
   OTTimeout milliSeconds
);
```

Parameters

timerTask

milliSeconds

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTSetAddressFromNBPEntity

Stores an NBP entity structure as an NBP address string. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTSetAddressFromNBPEntity (
   UInt8 *nameBuf,
   const NBPEntity *entity
);
```

Parameters

nameBuf

A pointer to the NBP address buffer in which you wish to store the NBP entity.

entity

Return Value
See the description of the `OTByteCount` data type.

Discussion
The `OTSetAddressFromNBPEntity` function stores the information in the NBP entity into the buffer specified by the `nameBuf` parameter in the format required for mapper calls—that is, if you have a backslash (\), a colon (:), or an at-sign (@) in your NBP name, this function inserts a backslash before each so that the mapper functions can handle them correctly. This function returns the number of bytes that were actually used in the buffer.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTSetAddressFromNBPString

Copies an NBP name string into an NBP address buffer. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTSetAddressFromNBPString (
   UInt8 *addrBuf,
   const char *name,
   SInt32 len
);
```

Parameters

addrBuf
A pointer to the NBP address buffer in which to store the NBP name string.

name
A pointer to the NBP name string you wish to copy into the buffer.

len
The number of characters to copy.

Return Value
See the description of the `OTByteCount` data type.

Discussion
The `OTSetAddressFromNBPString` function copies the string indicated by the `nbpName` parameter into the buffer indicated by the `addrBuf` parameter. The `len` parameter indicates the number of characters to copy. A value of -1 copies the entire `nbpName` string. The function returns the number of bytes actually copied.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTSetAsynchronous

Sets a provider's mode of execution to asynchronous. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSetAsynchronous (
   ProviderRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTSetAsynchronous` function causes all functions for the provider specified in the `ref` parameter to run asynchronously. You must install a notifier function for the provider if it needs to receive completion events. You can install a notifier function either before or after calling the `OTSetAsynchronous` function.

Changing a provider's mode of execution does not affect its notifier function, if any; the notifier function remains installed.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSetBit

Sets a bit atomically. (Deprecated in Mac OS X v10.4.)

```
Boolean OTSetBit (
   UInt8 *bitMap,
   OTByteCount bitNo
);
```

Parameters

bitMap

bitNo

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTSetBlocking

Allows a provider to wait or block until it is able to send or receive data. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSetBlocking (
   ProviderRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTSetBlocking` function causes provider functions that send or receive data to wait if current conditions prevent them from completing an operation. By default, a provider is in nonblocking mode, in which case, if a provider function were unable to complete sending or receiving data, it would return immediately with a result that would tell you why the operation was unable to complete.

If a provider is in blocking mode and you call the `OTCloseProvider` function to close the provider, Open Transport gives each Streams module up to 15 seconds to process outgoing commands. It is recommended that you call the `OTSetNonBlocking` function before you call the `OTCloseProvider` function.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSetBusTypeInPortRef

Sets bus type for a port reference. (Deprecated in Mac OS X v10.4.)

```
OTPortRef OTSetBusTypeInPortRef (
   OTPortRef ref,
   OTBusType busType
);
```

Parameters

ref

busType

Return Value
See the description of the `OTPortRef` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Carbon Porting Notes

OT ports are read only in Carbon. In Mac OS X, code that communicates directly with network interfaces must use the IOKit API.

Declared In
`OpenTransport.h`

OTSetDeviceTypeInPortRef

Sets device type for a port reference. (Deprecated in Mac OS X v10.4.)

```
OTPortRef OTSetDeviceTypeInPortRef (
   OTPortRef ref,
   OTDeviceType devType
);
```

Parameters

ref

devType

Return Value
See the description of the `OTPortRef` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Carbon Porting Notes

OT ports are read only in Carbon. In Mac OS X, code that communicates directly with network interfaces must use the IOKit API.

Declared In
`OpenTransport.h`

OTSetFirstClearBit

Atomcially sets the first clear bit in a specified bit map. (Deprecated in Mac OS X v10.4.)

```
OTResult OTSetFirstClearBit (
   UInt8 *bitMap,
   OTByteCount startBit,
   OTByteCount numBits
);
```

Parameters

bitMap

startBit

numBits

Return Value
See the description of the `OTResult` data type.

Discussion
Sets the first clear bit in `bitMap` , starting with `startBit` and giving up after `numBits`. Returns the bit number that was set, or a `kOTNotFoundErr` error if there was no clear bit available

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProtocol.h`

OTSetNBPEntityFromAddress

Parses and stores an NBP address into an NBP entity. (Deprecated in Mac OS X v10.4.)

```
Boolean OTSetNBPEntityFromAddress (
   NBPEntity *entity,
   const UInt8 *addrBuf,
   OTByteCount len
);
```

Parameters

entity

addrBuf

A pointer to the address buffer in which to store the NBP name string.

len

Discussion
The `OTSetNBPEntityFromAddress` function parses an NBP address or a combined DDP-NBP address into the NBP name's constituent parts (name, type, and zone) and stores the result in an NBP entity. The function ignores the DDP address part of a combined DDP-NBP address. From the NBP entity, each of the constituent parts of the name can be later retrieved or changed.

This function returns `true` if it worked successfully; it returns `false` if it had to truncate any data—that is, if the address had data that was too long in one of the fields, each of which only holds 32 characters of data. When this occurs, Open Transport still stores the data, but in a truncated form.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransportProviders.h`

OTSetNBPName

Stores the name part of an NBP name into an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
Boolean OTSetNBPName (
   NBPEntity *entity,
   const char *name
);
```

Parameters

entity

name

A pointer to the name portion of an NBP name string that you wish to store.

Discussion

The `OTSetNBPName` function stores the NBP name specified by the `name` parameter into the NBP entity structure indicated by the `nbpEntity` parameter, deleting any previous name stored there. This function returns `false` if the `name` parameter is longer than the maximum allowed for a name part of an NBP name (32 characters).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTSetNBPType

Stores the type part of an NBP name in an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
Boolean OTSetNBPType (
   NBPEntity *entity,
   const char *typeVal
);
```

Parameters

entity

typeVal

A pointer to the type portion of an NBP name string that you wish to store.

Discussion

The `OTSetNBPType` function stores the NBP type specified by the `type` parameter into the NBP entity structure indicated by the `nbpEntity` parameter, deleting any previous type stored there. The type supplied must not have any escape characters stored in it, although you do not receive any error message if you do use such characters. This function returns `false` if the `type` parameter is longer than the maximum allowed for type part of an NBP name (32 characters).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTSetNBPZone

Stores the zone part of an NBP name in an NBP entity structure. (Deprecated in Mac OS X v10.4.)

```
Boolean OTSetNBPZone (
   NBPEntity *entity,
   const char *zone
);
```

Parameters

entity

zone

A pointer to the zone portion of an NBP name string that you wish to store.

Discussion

The `OTSetNBPZone` function stores the NBP zone specified by the `zone` parameter into the NBP entity structure indicated by the `nbpEntity` parameter, deleting any previous zone stored there. The zone supplied must not have any of the NBP escape characters stored in it, although you do not receive any error message if you do use such characters. This function returns `false` if the zone parameter is longer than the maximum allowed for zone part of an NBP name (32 characters).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProviders.h`

OTSetNonBlocking

Disallows a provider from waiting if it cannot currently complete a function that sends or receives data. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSetNonBlocking (
   ProviderRef ref
);
```

Parameters

ref

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Discussion

The `OTSetNonBlocking` function causes provider functions to return a result code immediately, instead of waiting for a function that sends or receives data to complete. When you open a provider, its mode of operation is set to nonblocking by default.

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSetSynchronous

Sets a provider's mode of execution to synchronous. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSetSynchronous (
   ProviderRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
The `OTSetSynchronous` function causes all provider functions to run synchronously when using the provider that you specify.

Changing a provider's mode of execution does not affect its notifier function, if any is installed for this provider; the notifier function remains installed.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSnd

Sends data to a remote peer. (Deprecated in Mac OS X v10.4.)

```
OTResult OTSnd (
   EndpointRef ref,
   void *buf,
   OTByteCount nbytes,
   OTFlags flags
);
```

Parameters

ref

buf

A pointer to the data being sent. If you are sending data that is not stored contiguously, this is a pointer to an OTData structure that describes the first data fragment.

nbytes
flags

Return Value
See the description of the `OTResult` data type.

Discussion
You use the OTSnd function to send data to a remote peer. Before you use this function, you must establish a connection with the peer.

If the OTSnd function succeeds, it returns an integer (OSStatus) specifying the number of bytes that were actually sent. If it fails, it returns a negative integer corresponding to a result code that indicates the reason for the failure.

You specify the data to be sent by passing a pointer to the data (buf) and byspecifying the size of the data (nbytes). The maximum size of the data you can send is specified by the `tsdu` field of the `TEndpointInfo` (page 2542) structure for the endpoint.

Some protocols use expedited data for control or attention messages. To determine whether the endpoint supports this service, examine the `etsdu` field of the `TEndpointInfo` structure. A positive integer for the `etsdu` field indicates the maximum size in bytes of expedited data that you can send. To send expedited data, you must set the T_EXPEDITED bit of the flags parameter.

If you want to break up the data sent into smaller logical units, you can set the T_MORE bit of the flags parameter to indicate that you are using additional calls to the OTSnd function to send more data that belongs to the same logical unit. To indicate that the last data unit is being sent, you must specify 0 for nbytes and turn off the T_MORE flag. This is the only circumstance under which it is permitted to send a zero-length data unit. If the endpoint does not support the sending of zero-length data, the OTSnd function fails with the kOTBadDataErr result.

If the endpoint is in blocking mode, the OTSnd function returns after it actually sends the data. If flow-control restrictions prevent its sending the data, it retries the operation until it is able to send it. If the endpoint is in nonblocking mode, the OTSnd function returns with the kOTFlowErr result if flow-control restrictions prevent the data from being sent. When the endpoint provider is able to send the data, it returns a T_GODATA event to let you know that it is possible to send data.

The following table shows how the endpoint's mode of execution and blocking status affects the behavior of the OTSnd function.

Table 44-1

	Blocking	Nonblocking
Synchronous	The function returns when the provider lifts flow-control restrictions The kOTFlowErr result is never returned.	The function returns immediately. The kOTFlowErr result might be returned.
Asynchronous	The function returns immediately. The kOTFlowErr result is never returned.	The function returns immediately. The kOTFlowErr result might be returned.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
OpenTransport.h

OTSndDisconnect

Tears down an open connection (abortive disconnect) or rejects an incoming connection request. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSndDisconnect (
   EndpointRef ref,
   TCall *call
);
```

Parameters

ref

call

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
There are two functions that you can use to tear down a connection: OTSndDisconnect for an abortive disconnect, or OTSndOrderlyDisconnect for an orderly disconnect. It is recommended that you use the OTSndOrderlyDisconnect function for tearing down a connection whenever possible and that you use the OTSndDisconnect function only for rejecting incoming connection requests.

If the endpoint is in asynchronous mode, the OTSndDisconnect function returns immediately with a result of kOTNoError to indicate that the disconnection process has begun and that your notifier function will be called when the process completes.

When the connection has been broken, the provider issues a T_DISCONNECTCOMPLETE event. If you have installed a notifier function, Open Transport calls your notifier and passes this event in the code parameter. The cookie parameter contains the call parameter. If you have not installed a notifier function, you cannot determine when this function completes.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
OpenTransport.h

OTSndOrderlyDisconnect

Initiates or completes an orderly disconnection. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSndOrderlyDisconnect (
   EndpointRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
You call the `OTSndOrderlyDisconnect` function to initiate an orderly release of a connection and to indicate to the peer endpoint that you have no more data to send. After calling this function, you must not send any more data over the connection. However, you can still continue to receive data if the peer endpoint has not yet called the `OTSndOrderlyDisconnect` function.

This function is a service that is not supported by all protocols. If it is supported, the servtype field of the `TEndpointInfo` (page 2542) structure has the value `T_COTS_ORD` or `T_TRANS_ORD`.

The `OTSndOrderlyDisconnect` function behaves exactly the same in all modes of operation.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSndUData

Sends data using a connectionless transactionless endpoint. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTSndUData (
   EndpointRef ref,
   TUnitData *udata
);
```

Parameters

ref

udata

A pointer to a TUnitData structure that specifies thedata to be sent and its destination.

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If the endpoint is in synchronous, blocking mode, the OTSndUData function returns immediately. If flow-control restrictions prevent its sending the data, it retries the operation until it is able to send it. If the endpoint is in nonblocking mode, the OTSndUData function returns a kOTFlowErr result if flow-control restrictions prevent the data from being sent. When the endpoint provider is able to send the data, it calls your notifier function, passing T_GODATA for the code parameter. You can then call the OTSndUData function from your notifier to send the data. You can also retrieve this event by polling the endpoint using the OTLook function.

Some endpoint providers are not able to detect immediately whether you specified incorrect address or option information. In such cases, the provider calls your notifier function when it detects the error, passing the T_UDERR for the code parameter to advise you that an error has occurred. You can determine the cause of this event by calling the OTRcvUDErr function and examining the value of the uderr->error parameter. It is important that you call the OTRcvUDErr function even if you are not interested in examining the cause of the error. Failing to do this leaves the endpoint in an invalid state for doing other sends and makes the endpoint provider unable to deallocate memory reserved for internal buffers associated with the send.

The next table shows how the endpoint's mode of execution and blocking status affects the behavior of the OTSndUData function.

Table 44-2

	Blocking	Nonblocking
Synchronous	The function returns when the provider lifts flow-control restrictions The kOTFlowErr result is never returned.	The function returns immediately. the kOTFlowErr result might be returned
Asynchronous	The function returns immediately. The kOTFlowErr result is never returned.	the function returns immediately. the kOTFlowErr result might be returned.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTStrCat

Concatenates two C strings. (Deprecated in Mac OS X v10.4.)

```
void OTStrCat (
   char *dest,
   const char *src
);
```

Parameters
dest
src

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTStrCopy

Copies a C string. (Deprecated in Mac OS X v10.4.)

```
void OTStrCopy (
   char *dest,
   const char *src
);
```

Parameters

dest

src

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTStrEqual

Determines whether two C strings are the same. (Deprecated in Mac OS X v10.4.)

```
Boolean OTStrEqual (
   const char *src1,
   const char *src2
);
```

Parameters

src1

src2

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTStrLength

Returns the length of a C string. (Deprecated in Mac OS X v10.4.)

```
OTByteCount OTStrLength (
   const char *str
);
```

Parameters

str

Return Value
See the description of the `OTByteCount` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTSubtractTimeStamps

Subtracts one timestamp value from another. (Deprecated in Mac OS X v10.4.)

```
OTTimeStamp * OTSubtractTimeStamps (
   OTTimeStamp *result,
   OTTimeStamp *startTime,
   OTTimeStamp *endEnd
);
```

Parameters

result
startTime
endEnd

Return Value
See the description of the `OTTimeStamp` data type.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTTestBit

Atomically tests a bit in a specified bit map. (Deprecated in Mac OS X v10.4.)

```
Boolean OTTestBit (
   UInt8 *bitMap,
   OTByteCount bitNo
);
```

Parameters

bitMap

bitNo

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransportProtocol.h`

OTTimeStampInMicroseconds

Calculates the time elapsed in microseconds since since a specified time. (Deprecated in Mac OS X v10.4.)

```
UInt32 OTTimeStampInMicroseconds (
   OTTimeStamp *delta
);
```

Parameters

delta

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`OpenTransport.h`

OTTimeStampInMilliseconds

Calculates the time elapsed in milliseconds since since a specified time. (Deprecated in Mac OS X v10.4.)

```
UInt32 OTTimeStampInMilliseconds (
   OTTimeStamp *delta
);
```

Parameters

delta

Availability

Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTUnbind

Dissociates an endpoint from its address or cancels an asynchronous call to the `OTBind` function. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTUnbind (
   EndpointRef ref
);
```

Parameters

ref

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Discussion
If you call the `OTUnbind` function asynchronously and you have not installed a notifier function, the only way to determine that the endpoint has been unbound is to use the OTGetEndpointState function to poll the state of the endpoint. The function returns the kOTStateChangeErr result when the OTUnbind function returns. If the function succeeds, the state of the endpoint is T_UNBND. If it fails, its state is T_IDLE.

After you unbind an endpoint, you can no longer use it to send or receive information. You can use the OTCloseProvider function to deallocate memory reserved for the endpoint, or you can use the OTBind function to associate it with another address and then resume transferring data or establishing a connection.

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTUnregisterAsClientInContext

Removes your application as a client of Open Transport. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTUnregisterAsClientInContext (
   OTClientContextPtr clientContext
);
```

Parameters

clientContext

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

OTUseSyncIdleEvents

Allows synchronous idle events to be sent to your notifier. (Deprecated in Mac OS X v10.4.)

```
OSStatus OTUseSyncIdleEvents (
   ProviderRef ref,
   Boolean useEvents
);
```

Parameters

ref

useEvents

Return Value
A result code. See "Open Transport Result Codes" (page 2722).

Availability
Available in CarbonLib 1.0 and later when OpenTransport 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`OpenTransport.h`

Callbacks by Task

Notifier Callbacks

`OTNotifyProcPtr` (page 2419)

System, Timer, and Deferred Task Callbacks

`OTProcessProcPtr` (page 2420)

Linked List Callbacks

Miscellaneous Callbacks

Callbacks

admin_t

```
typedef OTInt32 (*admin_t) ();
```

If you name your function `MyAdmin_tCallback`, you would declare it like this:

```
OTInt32 MyAdmin_tCallback ();
```

Parameters

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

bufcallp_t

```
typedef void (*bufcallp_t) (
    SInt32 size
);
```

If you name your function `MyBufcallp_tCallback`, you would declare it like this:

```
void MyBufcallp_tCallback (
    SInt32 size
);
```

Parameters

size

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

bufcall_t

```
typedef void (*bufcall_t) (
    SInt32 size
);
```

If you name your function `MyBufcall_tCallback`, you would declare it like this:

```
void MyBufcall_tCallback (
    SInt32 size
);
```

Parameters

size

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

closeOld_t

```
typedef OTInt32 (*closeOld_t) (
    queue *q
);
```

If you name your function `MyCloseOld_tCallback`, you would declare it like this:

```
OTInt32 MyCloseOld_tCallback (
    queue *q
);
```

Parameters

q

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

closep_t

```
typedef OTInt32 (*closep_t) (
    queue *q,
    OTInt32 foo,
    cred_t *cred
);
```

If you name your function `MyClosep_tCallback`, you would declare it like this:

```
OTInt32 MyClosep_tCallback (
    queue *q,
    OTInt32 foo,
    cred_t *cred
);
```

Parameters

q

foo

cred

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

esbbcallProc

```
typedef void (*esbbcallProc) (
    SInt32 arg
);
```

If you name your function `MyEsbbcallCallback`, you would declare it like this:

```
void MyEsbbcallCallback (
    SInt32 arg
);
```

Parameters

arg

Carbon Porting Notes

This function is not needed in Carbon because the STREAMS subsystem is not available on Mac OS X.

FreeFuncType

```
typedef void (*FreeFuncType) (
    char *arg
);
```

If you name your function `MyFreeFuncTypeCallback`, you would declare it like this:

```
void MyFreeFuncTypeCallback (
    char *arg
);
```

Parameters

arg

Carbon Porting Notes

This function is not needed in Carbon because the STREAMS subsystem is not available on Mac OS X.

old_closep_t

```
typedef OTInt32 (*old_closep_t) (
    queue *q
);
```

If you name your function `MyOld_closep_tCallback`, you would declare it like this:

```
OTInt32 MyOld_closep_tCallback (
    queue *q
);
```

Parameters

q

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

old_openp_t

```
typedef OTInt32 (*old_openp_t) (
    queue *q,
    dev_t dev,
    OTInt32 foo,
    OTInt32 bar
);
```

If you name your function `MyOld_openp_tCallback`, you would declare it like this:

```
OTInt32 MyOld_openp_tCallback (
```

```
    queue *q,
    dev_t dev,
    OTInt32 foo,
    OTInt32 bar
);
```

Parameters

q

dev

foo

bar

Return Value
See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

openOld_t

```
typedef OTInt32 (*openOld_t) (
    queue *q,
    dev_t dev,
    OTInt32 foo,
    OTInt32 bar
);
```

If you name your function `MyOpenOld_tCallback`, you would declare it like this:

```
OTInt32 MyOpenOld_tCallback (
    queue *q,
    dev_t dev,
    OTInt32 foo,
    OTInt32 bar
);
```

Parameters

q

dev

foo

bar

Return Value
See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

openp_t

```
typedef OTInt32 (*openp_t) (
    queue *q,
    dev_t *dev,
    OTInt32 foo,
    OTInt32 bar,
    cred_t *cred
);
```

If you name your function `MyOpenp_tCallback`, you would declare it like this:

```
OTInt32 MyOpenp_tCallback (
    queue *q,
    dev_t *dev,
    OTInt32 foo,
    OTInt32 bar,
    cred_t *cred
);
```

Parameters

q
dev
foo
bar
cred

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

OTAllocMemProcPtr

```
typedef void (*OTAllocMemProcPtr) (
    OTByteCount size
);
```

If you name your function `MyOTAllocMemProc`, you would declare it like this:

```
void MyOTAllocMemProc (
    OTByteCount size
);
```

Parameters

size

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

OTCanConfigureProcPtr

```
typedef Boolean (*OTCanConfigureProcPtr)
(
    OTConfigurationRef cfig,
    UInt32 pass
);
```

If you name your function `MyOTCanConfigureProc`, you would declare it like this:

```
Boolean MyOTCanConfigureProc (
    OTConfigurationRef cfig,
    UInt32 pass
);
```

Parameters

cfig

pass

Carbon Porting Notes

Carbon does not support access to Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTCFConfigureProcPtr

```
typedef OSStatus (*OTCFConfigureProcPtr)
(
    TOTConfiguratorRef cfigor,
    OTConfigurationRef cfig
);
```

If you name your function `MyOTCFConfigureProc`, you would declare it like this:

```
OSStatus MyOTCFConfigureProc (
    TOTConfiguratorRef cfigor,
    OTConfigurationRef cfig
);
```

Parameters

cfigor

cfig

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Carbon Porting Notes

Carbon does not support access to Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTCFCreateStreamProcPtr

```
typedef OSStatus (*OTCFCreateStreamProcPtr)
(
    TOTConfiguratorRef cfigor,
    OTConfigurationRef cfig,
    OTOpenFlags oFlags,
    OTNotifyUPP proc,
    void *contextPtr
);
```

If you name your function `MyOTCFCreateStreamProc`, you would declare it like this:

```
OSStatus MyOTCFCreateStreamProc (
    TOTConfiguratorRef cfigor,
    OTConfigurationRef cfig,
    OTOpenFlags oFlags,
    OTNotifyUPP proc,
    void *contextPtr
);
```

Parameters

cfigor

cfig

oFlags

proc

contextPtr

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Carbon Porting Notes

Carbon does not support access to Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTCFHandleSystemEventProcPtr

```
typedef void (*OTCFHandleSystemEventProcPtr)
(
    TOTConfiguratorRef cfigor,
    OTEventCode code,
    OTResult result,
    void *cookie
);
```

If you name your function `MyOTCFHandleSystemEventProc`, you would declare it like this:

```
void MyOTCFHandleSystemEventProc (
    TOTConfiguratorRef cfigor,
    OTEventCode code,
    OTResult result,
    void *cookie
);
```

Parameters

cfigor

code

result

cookie

Carbon Porting Notes

Carbon does not support access to Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTCreateConfiguratorProcPtr

```
typedef OSStatus (*OTCreateConfiguratorProcPtr)
(
    TOTConfiguratorRef *cfigor
);
```

If you name your function `MyOTCreateConfiguratorProc`, you would declare it like this:

```
OSStatus MyOTCreateConfiguratorProc (
    TOTConfiguratorRef *cfigor
);
```

Parameters

cfigor

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Carbon Porting Notes

Carbon does not support access to Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTGateProcPtr

```
typedef Boolean (*OTGateProcPtr) (
    OTLink *thisLink
);
```

If you name your function `MyOTGateProc`, you would declare it like this:

```
Boolean MyOTGateProc (
    OTLink *thisLink
);
```

Parameters

thisLink

Carbon Porting Notes

Carbon does not support Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

OTGetPortIconProcPtr

```
typedef Boolean (*OTGetPortIconProcPtr)
(
    OTPortRecord *port,
    OTResourceLocator *iconLocation
);
```

If you name your function `MyOTGetPortIconProc`, you would declare it like this:

```
Boolean MyOTGetPortIconProc (
    OTPortRecord *port,
    OTResourceLocator *iconLocation
);
```

Parameters

port

iconLocation

Carbon Porting Notes

Carbon does not support access to the Open Transport port name or icon because this information is not available on Mac OS X.

OTGetPortNameProcPtr

```
typedef void (*OTGetPortNameProcPtr)
(
    OTPortRecord *port,
    OTBooleanParam includeSlot,
    OTBooleanParam includePort,
    Str255 userVisibleName
);
```

If you name your function `MyOTGetPortNameProc`, you would declare it like this:

```
void MyOTGetPortNameProc (
    OTPortRecord *port,
    OTBooleanParam includeSlot,
    OTBooleanParam includePort,
    Str255 userVisibleName
);
```

Parameters

port
includeSlot
includePort
userVisibleName

Carbon Porting Notes

Carbon does not support access to the Open Transport port name or icon because this information is not available on Mac OS X.

OTHashProcPtr

```
typedef UInt32 (*OTHashProcPtr) (
    OTLink *linkToHash
);
```

If you name your function `MyOTHashProc`, you would declare it like this:

```
UInt32 MyOTHashProc (
    OTLink *linkToHash
);
```

Parameters

linkToHash

Carbon Porting Notes

Carbon does not support Open Transport hash lists because Apple has not identified a developer need for them.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

OTHashSearchProcPtr

```
typedef Boolean (*OTHashSearchProcPtr)
(
    const void *ref,
    OTLink *linkToCheck
);
```

If you name your function `MyOTHashSearchProc`, you would declare it like this:

```
Boolean MyOTHashSearchProc (
    const void *ref,
    OTLink *linkToCheck
);
```

Parameters

ref

linkToCheck

Carbon Porting Notes

Carbon does not support Open Transport hash lists because Apple has not identified a developer need for them.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

OTListSearchProcPtr

```
typedef Boolean (*OTListSearchProcPtr)
(
    const void *ref,
    OTLink *linkToCheck
);
```

If you name your function `MyOTListSearchProc`, you would declare it like this:

```
Boolean MyOTListSearchProc (
    const void *ref,
    OTLink *linkToCheck
);
```

Parameters

ref

linkToCheck

Carbon Porting Notes

This is a function type for a user callback. Use the type `OTListSearchUPP` instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTNotifyProcPtr

```
typedef void (*OTNotifyProcPtr) (
    void *contextPtr,
    OTEventCode code,
    OTResult result,
    void *cookie
);
```

If you name your function `MyOTNotifyProc`, you would declare it like this:

```
void MyOTNotifyProc (
    void *contextPtr,
    OTEventCode code,
    OTResult result,
    void *cookie
);
```

Parameters

contextPtr

code

result

cookie

Carbon Porting Notes

This is a function type for a callback. Use the type `OTNotifyUPP` instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTProcessProcPtr

```
typedef void (*OTProcessProcPtr) (
    void *arg
);
```

If you name your function `MyOTProcessProc`, you would declare it like this:

```
void MyOTProcessProc (
    void *arg
);
```

Parameters

arg

Carbon Porting Notes

Use the `OTProcessUPP` type instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTSetupConfiguratorProcPtr

```
typedef OSStatus (*OTSetupConfiguratorProcPtr)
(
    OTCanConfigureProcPtr *canConfigure,
    OTCreateConfiguratorProcPtr *createConfigurator,
    UInt8 *configuratorType
);
```

If you name your function `MyOTSetupConfiguratorProc`, you would declare it like this:

```
OSStatus MyOTSetupConfiguratorProc (
    OTCanConfigureProcPtr *canConfigure,
    OTCreateConfiguratorProcPtr *createConfigurator,
    UInt8 *configuratorType
);
```

Parameters

canConfigure

createConfigurator

configuratorType

Return Value

A result code. See "Open Transport Result Codes" (page 2722).

Carbon Porting Notes

Carbon does not support Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTSMCompleteProcPtr

```
typedef void (*OTSMCompleteProcPtr) (
    void *contextPtr
);
```

If you name your function `MyOTSMCompleteProc`, you would declare it like this:

```
void MyOTSMCompleteProc (
    void *contextPtr
);
```

Parameters

contextPtr

Carbon Porting Notes

Carbon does not support Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

OTStateProcPtr

```
typedef void (*OTStateProcPtr) (
    OTStateMachine *sm
);
```

If you name your function `MyOTStateProc`, you would declare it like this:

```
void MyOTStateProc (
    OTStateMachine *sm
);
```

Parameters

sm

Carbon Porting Notes

Carbon does not support Open Transport configuration APIs because the Mac OS X networking stack is not based on STREAMS.

putp_t

```
typedef OTInt32 (*putp_t) (
    queue *q,
    msgb *mp
);
```

If you name your function `MyPutp_tCallback`, you would declare it like this:

```
OTInt32 MyPutp_tCallback (
    queue *q,
    msgb *mp
);
```

Parameters

q

mp

Return Value

See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

srvp_t

```
typedef OTInt32 (*srvp_t) (
    queue *q
);
```

If you name your function `MySrvp_tCallback`, you would declare it like this:

```
OTInt32 MySrvp_tCallback (
    queue *q
);
```

Parameters

q

Return Value
See the description of the `OTInt32` data type.

Carbon Porting Notes

Carbon does not support any STREAMS functionality because the STREAMS subsystem is not available on Mac OS X.

Data Types

AppleTalkInfo

Obtain informations about the current AppleTalk environment.

```
struct AppleTalkInfo {
    DDPAddress fOurAddress;
    DDPAddress fRouterAddress;
    UInt16 fCableRange[2];
    UInt16 fFlags;
};
typedef struct AppleTalkInfo AppleTalkInfo;
```

Fields

`fOurAddress`
The network number and node ID of your node.

`fRouterAddress`
The network number and node ID of the closest router on your network.

`fCableRange`
A two-element array indicating the first and last network numbers for the current extended network to which the machine is connected. For nonextended networks, this returns the name of the zone.

`fFlags`
A set of flag bits that describe the network. See `kATalkInfoIsExtended` (page 2612).

Discussion
Use the AppleTalk information structure to obtain information about the current AppleTalk environment for the node on which your application is running.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

ATSvcRef

```
typedef struct OpaqueATSvcRef * ATSvcRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

bandinfo

```
struct bandinfo {
    unsigned char bi_pri;
    char pad1;
    SInt32 bi_flag;
};
typedef struct bandinfo bandinfo;
```

Fields
`bi_pri`
`pad1`
`bi_flag`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

boolean_p

```
typedef Boolean boolean_p;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

caddr_t

```
typedef char * caddr_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`types.h`

CCMiscInfo

```
struct CCMiscInfo {
    UInt32 connectionStatus;
    UInt32 connectionTimeElapsed;
    UInt32 connectionTimeRemaining;
    UInt32 bytesTransmitted;
    UInt32 bytesReceived;
    UInt32 reserved;
};
typedef struct CCMiscInfo CCMiscInfo;
```

Fields

`connectionStatus`

`connectionTimeElapsed`

`connectionTimeRemaining`

`bytesTransmitted`

`bytesReceived`

`reserved`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

CFMLibraryInfo

```
struct CFMLibraryInfo {
    OTLink link;
    char * libName;
    StringPtr intlName;
    FSSpec * fileSpec;
    StringPtr pstring2;
    StringPtr pstring3;
};
typedef struct CFMLibraryInfo CFMLibraryInfo;
```

Fields

`link`

`libName`

`intlName`

`fileSpec`

`pstring2`

`pstring3`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

char_p

```
typedef SInt8 char_p;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

copyreq

```
struct copyreq {
    SInt32 cq_cmd;
    cred * cq_cr;
    UInt32 cq_id;
    caddr_t cq_addr;
    UInt32 cq_size;
    SInt32 cq_flag;
    mblk_t * cq_private;
    long cq_filler[4];
};
typedef struct copyreq copyreq;
```

Fields
`cq_cmd`
`cq_cr`
`cq_id`
`cq_addr`
`cq_size`
`cq_flag`
`cq_private`
`cq_filler`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

copyresp

```
struct copyresp {
    SInt32 cp_cmd;
    cred * cp_cr;
    UInt32 cp_id;
    caddr_t cp_rval;
    UInt32 cp_pad1;
    SInt32 cp_pad2;
    mblk_t * cp_private;
    long cp_filler[4];
};
typedef struct copyresp copyresp;
```

Fields

`cp_cmd`

`cp_cr`

`cp_id`

`cp_rval`

`cp_pad1`

`cp_pad2`

`cp_private`

`cp_filler`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

cred

```
struct cred {
    UInt16 cr_ref;
    UInt16 cr_ngroups;
    uid_t cr_uid;
    gid_t cr_gid;
    uid_t cr_ruid;
    gid_t cr_rgid;
    uid_t cr_suid;
    gid_t cr_sgid;
    gid_t cr_groups[1];
};
typedef struct cred cred;
typedef cred cred_t;
```

Fields

`cr_ref`

`cr_ngroups`

`cr_uid`

`cr_gid`

`cr_ruid`

`cr_rgid`

`cr_suid`

`cr_sgid`

`cr_groups`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

cred_t

```
typedef cred cred_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

datab

```
struct datab {
    datab_db_f db_f;
    unsigned char * db_base;
    unsigned char * db_lim;
    unsigned char db_ref;
    unsigned char db_type;
    unsigned char db_iswhat;
    unsigned char db_filler2;
    UInt32 db_size;
    unsigned char * db_msgaddr;
    long db_filler;
};
typedef struct datab datab;
typedef datab dblk_t;
```

Fields

`db_f`

`db_base`

`db_lim`

`db_ref`

`db_type`

`db_iswhat`

`db_filler2`

`db_size`

`db_msgaddr`

`db_filler`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

datab_db_f

```
union datab_db_f {
    datab * freep;
    free_rtn * frtnp;
};
typedef union datab_db_f datab_db_f;
```

Fields

`freep`

`frtnp`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dblk_t

```
typedef datab dblk_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

DDPAddress

```
struct DDPAddress {
    OTAddressType fAddressType;
    UInt16 fNetwork;
    UInt8 fNodeID;
    UInt8 fSocket;
    UInt8 fDDPType;
    UInt8 fPad;
};
typedef struct DDPAddress DDPAddress;
```

Fields
`fAddressType`
`fNetwork`
`fNodeID`
`fSocket`
`fDDPType`
`fPad`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

DDPNBPAddress

```
struct DDPNBPAddress {
    OTAddressType fAddressType;
    UInt16 fNetwork;
    UInt8 fNodeID;
    UInt8 fSocket;
    UInt8 fDDPType;
    UInt8 fPad;
    UInt8 fNBPNameBuffer[105];
};
typedef struct DDPNBPAddress DDPNBPAddress;
```

Fields

`fAddressType`

`fNetwork`

`fNodeID`

`fSocket`

`fDDPType`

`fPad`

`fNBPNameBuffer`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

dev_t

```
typedef UInt32 dev_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`types.h`

dl_attach_req_t

```
struct dl_attach_req_t {
    UInt32 dl_primitive;
    UInt32 dl_ppa;
};
typedef struct dl_attach_req_t dl_attach_req_t;
```

Fields

`dl_primitive`

`dl_ppa`

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_bind_ack_t

```
struct dl_bind_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_sap;
    UInt32 dl_addr_length;
    UInt32 dl_addr_offset;
    UInt32 dl_max_conind;
    UInt32 dl_xidtest_flg;
};
typedef struct dl_bind_ack_t dl_bind_ack_t;
```

Fields
dl_primitive
dl_sap
dl_addr_length
dl_addr_offset
dl_max_conind
dl_xidtest_flg

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_bind_req_t

```
struct dl_bind_req_t {
    UInt32 dl_primitive;
    UInt32 dl_sap;
    UInt32 dl_max_conind;
    UInt16 dl_service_mode;
    UInt16 dl_conn_mgmt;
    UInt32 dl_xidtest_flg;
};
typedef struct dl_bind_req_t dl_bind_req_t;
```

Fields
dl_primitive
dl_sap
dl_max_conind
dl_service_mode
dl_conn_mgmt
dl_xidtest_flg

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_connect_con_t

```
struct dl_connect_con_t {
    UInt32 dl_primitive;
    UInt32 dl_resp_addr_length;
    UInt32 dl_resp_addr_offset;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
    UInt32 dl_growth;
};
typedef struct dl_connect_con_t dl_connect_con_t;
```

Fields
dl_primitive
dl_resp_addr_length
dl_resp_addr_offset
dl_qos_length
dl_qos_offset
dl_growth

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_connect_ind_t

```
struct dl_connect_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_correlation;
    UInt32 dl_called_addr_length;
    UInt32 dl_called_addr_offset;
    UInt32 dl_calling_addr_length;
    UInt32 dl_calling_addr_offset;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
    UInt32 dl_growth;
};
typedef struct dl_connect_ind_t dl_connect_ind_t;
```

Fields

`dl_primitive`

`dl_correlation`

`dl_called_addr_length`

`dl_called_addr_offset`

`dl_calling_addr_length`

`dl_calling_addr_offset`

`dl_qos_length`

`dl_qos_offset`

`dl_growth`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_connect_req_t

```
struct dl_connect_req_t {
    UInt32 dl_primitive;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
    UInt32 dl_growth;
};
typedef struct dl_connect_req_t dl_connect_req_t;
```

Fields

`dl_primitive`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_qos_length`

`dl_qos_offset`

`dl_growth`

Availability

Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_connect_res_t

```
struct dl_connect_res_t {
    UInt32 dl_primitive;
    UInt32 dl_correlation;
    UInt32 dl_resp_token;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
    UInt32 dl_growth;
};
typedef struct dl_connect_res_t dl_connect_res_t;
```

Fields
dl_primitive
dl_correlation
dl_resp_token
dl_qos_length
dl_qos_offset
dl_growth

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_data_ack_ind_t

```
struct dl_data_ack_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_src_addr_length;
    UInt32 dl_src_addr_offset;
    UInt32 dl_priority;
    UInt32 dl_service_class;
};
typedef struct dl_data_ack_ind_t dl_data_ack_ind_t;
```

Fields
dl_primitive
dl_dest_addr_length
dl_dest_addr_offset
dl_src_addr_length
dl_src_addr_offset
dl_priority
dl_service_class

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_data_ack_req_t

```
struct dl_data_ack_req_t {
    UInt32 dl_primitive;
    UInt32 dl_correlation;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_src_addr_length;
    UInt32 dl_src_addr_offset;
    UInt32 dl_priority;
    UInt32 dl_service_class;
};
typedef struct dl_data_ack_req_t dl_data_ack_req_t;
```

Fields
dl_primitive
dl_correlation
dl_dest_addr_length
dl_dest_addr_offset
dl_src_addr_length
dl_src_addr_offset
dl_priority
dl_service_class

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_data_ack_status_ind_t

```
struct dl_data_ack_status_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_correlation;
    UInt32 dl_status;
};
typedef struct dl_data_ack_status_ind_t dl_data_ack_status_ind_t;
```

Fields
dl_primitive
dl_correlation
dl_status

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_detach_req_t

```
struct dl_detach_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_detach_req_t dl_detach_req_t;
```

Fields
`dl_primitive`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_disabmulti_req_t

```
struct dl_disabmulti_req_t {
    UInt32 dl_primitive;
    UInt32 dl_addr_length;
    UInt32 dl_addr_offset;
};
typedef struct dl_disabmulti_req_t dl_disabmulti_req_t;
```

Fields
`dl_primitive`
`dl_addr_length`
`dl_addr_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_disconnect_ind_t

```
struct dl_disconnect_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_originator;
    UInt32 dl_reason;
    UInt32 dl_correlation;
};
typedef struct dl_disconnect_ind_t dl_disconnect_ind_t;
```

Fields
`dl_primitive`
`dl_originator`
`dl_reason`
`dl_correlation`

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_disconnect_req_t

```
struct dl_disconnect_req_t {
    UInt32 dl_primitive;
    UInt32 dl_reason;
    UInt32 dl_correlation;
};
typedef struct dl_disconnect_req_t dl_disconnect_req_t;
```

Fields
dl_primitive
dl_reason
dl_correlation

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_enabmulti_req_t

```
struct dl_enabmulti_req_t {
    UInt32 dl_primitive;
    UInt32 dl_addr_length;
    UInt32 dl_addr_offset;
};
typedef struct dl_enabmulti_req_t dl_enabmulti_req_t;
```

Fields
dl_primitive
dl_addr_length
dl_addr_offset

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_error_ack_t

```
struct dl_error_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_error_primitive;
    UInt32 dl_errno;
    UInt32 dl_unix_errno;
};
typedef struct dl_error_ack_t dl_error_ack_t;
```

Fields

`dl_primitive`

`dl_error_primitive`

`dl_errno`

`dl_unix_errno`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_get_statistics_ack_t

```
struct dl_get_statistics_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_stat_length;
    UInt32 dl_stat_offset;
};
typedef struct dl_get_statistics_ack_t dl_get_statistics_ack_t;
```

Fields

`dl_primitive`

`dl_stat_length`

`dl_stat_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_get_statistics_req_t

```
struct dl_get_statistics_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_get_statistics_req_t dl_get_statistics_req_t;
```

Fields

`dl_primitive`

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_info_ack_t

```
struct dl_info_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_max_sdu;
    UInt32 dl_min_sdu;
    UInt32 dl_addr_length;
    UInt32 dl_mac_type;
    UInt32 dl_reserved;
    UInt32 dl_current_state;
    SInt32 dl_sap_length;
    UInt32 dl_service_mode;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
    UInt32 dl_qos_range_length;
    UInt32 dl_qos_range_offset;
    UInt32 dl_provider_style;
    UInt32 dl_addr_offset;
    UInt32 dl_version;
    UInt32 dl_brdcst_addr_length;
    UInt32 dl_brdcst_addr_offset;
    UInt32 dl_growth;
};
typedef struct dl_info_ack_t dl_info_ack_t;
```

Fields
dl_primitive
dl_max_sdu
dl_min_sdu
dl_addr_length
dl_mac_type
dl_reserved
dl_current_state
dl_sap_length
dl_service_mode
dl_qos_length
dl_qos_offset
dl_qos_range_length
dl_qos_range_offset
dl_provider_style
dl_addr_offset
dl_version
dl_brdcst_addr_length
dl_brdcst_addr_offset
dl_growth

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_info_req_t

```
struct dl_info_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_info_req_t dl_info_req_t;
```

Fields
dl_primitive

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_ok_ack_t

```
struct dl_ok_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_correct_primitive;
};
typedef struct dl_ok_ack_t dl_ok_ack_t;
```

Fields
dl_primitive
dl_correct_primitive

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_phys_addr_ack_t

```
struct dl_phys_addr_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_addr_length;
    UInt32 dl_addr_offset;
};
typedef struct dl_phys_addr_ack_t dl_phys_addr_ack_t;
```

Fields
dl_primitive
dl_addr_length
dl_addr_offset

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_phys_addr_req_t

```
struct dl_phys_addr_req_t {
    UInt32 dl_primitive;
    UInt32 dl_addr_type;
};
typedef struct dl_phys_addr_req_t dl_phys_addr_req_t;
```

Fields
dl_primitive
dl_addr_type

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

DL_primitives

```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_priority_t

```
struct dl_priority_t {
    SInt32 dl_min;
    SInt32 dl_max;
};
typedef struct dl_priority_t dl_priority_t;
```

Fields
`dl_min`
`dl_max`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_promiscoff_req_t

```
struct dl_promiscoff_req_t {
    UInt32 dl_primitive;
    UInt32 dl_level;
};
typedef struct dl_promiscoff_req_t dl_promiscoff_req_t;
```

Fields
`dl_primitive`
`dl_level`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_promiscon_req_t

```
struct dl_promiscon_req_t {
    UInt32 dl_primitive;
    UInt32 dl_level;
};
typedef struct dl_promiscon_req_t dl_promiscon_req_t;
```

Fields

`dl_primitive`

`dl_level`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_protect_t

```
struct dl_protect_t {
    SInt32 dl_min;
    SInt32 dl_max;
};
typedef struct dl_protect_t dl_protect_t;
```

Fields

`dl_min`

`dl_max`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_qos_cl_range1_t

```
struct dl_qos_cl_range1_t {
    UInt32 dl_qos_type;

};
typedef struct dl_reply_update_req_t dl_reply_update_req_t;
```

Fields
dl_primitive
dl_correlation
dl_src_addr_length
dl_src_addr_offset

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_reply_update_status_ind_t

```
struct dl_reply_update_status_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_correlation;
    UInt32 dl_status;
};
typedef struct dl_reply_update_status_ind_t dl_reply_update_status_ind_t;
```

Fields

`dl_primitive`

`dl_correlation`

`dl_status`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_reset_con_t

```
struct dl_reset_con_t {
    UInt32 dl_primitive;
};
typedef struct dl_reset_con_t dl_reset_con_t;
```

Fields

`dl_primitive`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_reset_ind_t

```
struct dl_reset_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_originator;
    UInt32 dl_reason;
};
typedef struct dl_reset_ind_t dl_reset_ind_t;
```

Fields

`dl_primitive`

`dl_originator`

`dl_reason`

Availability

Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_reset_req_t

```
struct dl_reset_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_reset_req_t dl_reset_req_t;
```

Fields
dl_primitive

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_reset_res_t

```
struct dl_reset_res_t {
    UInt32 dl_primitive;
};
typedef struct dl_reset_res_t dl_reset_res_t;
```

Fields
dl_primitive

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_resilience_t

```
struct dl_resilience_t {
    SInt32 dl_disc_prob;
    SInt32 dl_reset_prob;
};
typedef struct dl_resilience_t dl_resilience_t;
```

Fields
dl_disc_prob
dl_reset_prob

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

dl_set_phys_addr_req_t

```
struct dl_set_phys_addr_req_t {
    UInt32 dl_primitive;
    UInt32 dl_addr_length;
    UInt32 dl_addr_offset;
};
typedef struct dl_set_phys_addr_req_t dl_set_phys_addr_req_t;
```

Fields

`dl_primitive`

`dl_addr_length`

`dl_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_subs_bind_ack_t

```
struct dl_subs_bind_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_subs_sap_offset;
    UInt32 dl_subs_sap_length;
};
typedef struct dl_subs_bind_ack_t dl_subs_bind_ack_t;
```

Fields

`dl_primitive`

`dl_subs_sap_offset`

`dl_subs_sap_length`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_subs_bind_req_t

```
struct dl_subs_bind_req_t {
    UInt32 dl_primitive;
    UInt32 dl_subs_sap_offset;

    UInt32 dl_src_addr_offset;
};
typedef struct dl_test_ind_t dl_test_ind_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_src_addr_length`

`dl_src_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_test_req_t

```
struct dl_test_req_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
};
typedef struct dl_test_req_t dl_test_req_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_test_res_t

```
struct dl_test_res_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
};
typedef struct dl_test_res_t dl_test_res_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_through_t

```
struct dl_through_t {
    SInt32 dl_target_value;
    SInt32 dl_accept_value;
};
typedef struct dl_through_t dl_through_t;
```

Fields

`dl_target_value`

`dl_accept_value`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_token_ack_t

```
struct dl_token_ack_t {
    UInt32 dl_primitive;
    UInt32 dl_token;
};
typedef struct dl_token_ack_t dl_token_ack_t;
```

Fields

`dl_primitive`

`dl_token`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_token_req_t

```
struct dl_token_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_token_req_t dl_token_req_t;
```

Fields

`dl_primitive`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_transdelay_t

```
struct dl_transdelay_t {
    SInt32 dl_target_value;
    SInt32 dl_accept_value;
};
typedef struct dl_transdelay_t dl_transdelay_t;
```

Fields

`dl_target_value`

`dl_accept_value`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_uderror_ind_t

```
struct dl_uderror_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_unix_errno;
    UInt32 dl_errno;
};
typedef struct dl_uderror_ind_t dl_uderror_ind_t;
```

Fields

`dl_primitive`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_unix_errno`

`dl_errno`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_udqos_req_t

```
struct dl_udqos_req_t {
    UInt32 dl_primitive;
    UInt32 dl_qos_length;
    UInt32 dl_qos_offset;
};
typedef struct dl_udqos_req_t dl_udqos_req_t;
```

Fields

`dl_primitive`

`dl_qos_length`

`dl_qos_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_unbind_req_t

```
struct dl_unbind_req_t {
    UInt32 dl_primitive;
};
typedef struct dl_unbind_req_t dl_unbind_req_t;
```

Fields

`dl_primitive`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_unitdata_ind_t

```
struct dl_unitdata_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_src_addr_length;
    UInt32 dl_src_addr_offset;
    UInt32 dl_group_address;
};
typedef struct dl_unitdata_ind_t dl_unitdata_ind_t;
```

Fields

`dl_primitive`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_src_addr_length`

`dl_src_addr_offset`

`dl_group_address`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_unitdata_req_t

```
struct dl_unitdata_req_t {
    UInt32 dl_primitive;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    dl_priority_t dl_priority;
};
typedef struct dl_unitdata_req_t dl_unitdata_req_t;
```

Fields

`dl_primitive`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_priority`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_xid_con_t

```
struct dl_xid_con_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_src_addr_length;
    UInt32 dl_src_addr_offset;
};
typedef struct dl_xid_con_t dl_xid_con_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_src_addr_length`

`dl_src_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_xid_ind_t

```
struct dl_xid_ind_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
    UInt32 dl_src_addr_length;
    UInt32 dl_src_addr_offset;
};
typedef struct dl_xid_ind_t dl_xid_ind_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

`dl_src_addr_length`

`dl_src_addr_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

dl_xid_req_t

```
struct dl_xid_req_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
};
typedef struct dl_xid_req_t dl_xid_req_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

dl_xid_res_t

```
struct dl_xid_res_t {
    UInt32 dl_primitive;
    UInt32 dl_flag;
    UInt32 dl_dest_addr_length;
    UInt32 dl_dest_addr_offset;
};
typedef struct dl_xid_res_t dl_xid_res_t;
```

Fields

`dl_primitive`

`dl_flag`

`dl_dest_addr_length`

`dl_dest_addr_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

DNS Address Structure

Holds host names, partially or fully-qualified domain names, or dotted-decimal format Internet addresses for use with a variety of Open Transport functions.

```
struct DNSAddress {
    OTAddressType fAddressType;
    InetDomainName fName;
};
typedef struct DNSAddress DNSAddress;
```

Fields

`fAddressType`

The address type. For a DNSAddress structure, this should be AF_DNS.

`fName`

The name to be resolved by the DNR.

Discussion

You can use the DNS (domain name system) address structure with the OTConnect function (TCP), with the OTSndUData function (UDP), or with the OTResolveAddress function (either TCP or UDP). If you do so, TCP/IP will resolve the name for you automatically. You can use the OTInitDNSAddress function to fill in a DNS address structure. The DNS address structure is defined by the DNSAddress data type.

The address you specify can be just the host name (“otteam”), a partially qualified domain name (“otteam.ssw”), a fully qualified domain name (“otteam.ssw.apple.com.”), or an internet address in dotted-decimal format (“17.202.99.99”), and can optionally include a port number (“otteam.ssw.apple.com:25” or “17.202.99.99:25”).

Because the port number is not actually part of the domain name, it is possible to have a domain name–port number combination that exceeds 255 bytes. If you wish to specify such a string, you must provide a structure based on the DNS address structure that has sufficient space to contain the full string. In any case, the domain name itself cannot exceed 255 bytes.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

DNS Query Information Structure

Returns answers to DNS queries.

```
struct DNSQueryInfo {
    UInt16 qType;
    UInt16 qClass;
    UInt32 ttl;
    InetDomainName name;
    UInt16 responseType;
    UInt16 resourceLen;
    char resourceData[4];
};
typedef struct DNSQueryInfo DNSQueryInfo;
```

Fields

`qType`

The numerical value of the DNS resource record type, such as MX and PTR, for which you wish to query.

`qClass`

The numerical value of the DNS record class, such as Inet and Hesio, for which you wish to query.

`ttl`
: An integer indicating the DNS resource record's time to live (in seconds).

`name`
: The fully qualified domain name or address for which you made the query.

`responseType`
: The type of response.

`resourceLen`
: The actual length of the resource data returned.

`resourceData`
: The resource data that is returned. This is at least 4 bytes long, and is usually longer.

Discussion
The DNS query information structure is used by the TCP/IP service provider to return answers to DNS queries made using the OTInetQuery function. The DNS query information structure is defined by the DNSQueryInfo data type. For additional information about the constant values for the DNSQueryInfo fields, see the DNS Requests for Comments (RFCs), available over the World Wide Web.

See the Internet Standard for a definitive list of values for the qType, qClass, and respnoseType fields, and for a definition of the format of the resource data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

EndpointRef

```
typedef struct OpaqueEndpointRef * EndpointRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

EnetPacketHeader

```
struct EnetPacketHeader {
    UInt8 fDestAddr[6];
    UInt8 fSourceAddr[6];
    UInt16 fProto;
};
typedef struct EnetPacketHeader EnetPacketHeader;
```

Fields

`fDestAddr`

`fSourceAddr`

`fProto`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

free_rtn

```
struct free_rtn {
    FreeFuncType free_func;
    char * free_arg;
};
typedef struct free_rtn free_rtn;
typedef free_rtn frtn_t;
```

Fields

`free_func`

`free_arg`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

frtn_t

```
typedef free_rtn frtn_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

gid_t

```
typedef UInt32 gid_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`types.h`

Internet Address Structure

Used for providing a TCP or UDP address to the `OTConnect`, `OTSndURequest`, or `OTBind` functions.

```
struct InetAddress {
    OTAddressType fAddressType;
    InetPort fPort;
    InetHost fHost;
    UInt8 fUnused[8];
};
typedef struct InetAddress InetAddress;
```

Fields

`fAddressType`
The address type. The field should be AF_INET, which identifies the structure as an InetAddress.

`fPort`
The port number.

`fHost`
The 32-bit IP address of the host.

`fUnused`
Reserved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetDHCPOption

```
struct InetDHCPOption {
    UInt8 fOptionTag;
    UInt8 fOptionLen;
    UInt8 fOptionValue;
};
typedef struct InetDHCPOption InetDHCPOption;
```

Fields
`fOptionTag`
`fOptionLen`
`fOptionValue`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetDomainName

```
typedef  InetDomainName[256];
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetHost

```
typedef UInt32 InetHost;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

Internet Host Information Sructure

Holds a set of IP addresses associated with an Internet host for use by the `OTInetStringToAddress` function.

```
struct InetHostInfo {
    InetDomainName name;
    InetHost addrs[10];
};
typedef struct InetHostInfo InetHostInfo;
```

Fields

`name`

The canonical name of the host. The canonical name is a fully qualified domain nam, never an alias.

`addrs`

Up to ten IP addresses associated with this host name. Only multihomed hosts have more than one IP address.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

Internet Interface Information Structure

Holds information about an Internet interface for use by the `OTInetGetInterfaceInfo` function.

```
struct InetInterfaceInfo {
    InetHost fAddress;
    InetHost fNetmask;
    InetHost fBroadcastAddr;
    InetHost fDefaultGatewayAddr;
    InetHost fDNSAddr;
    UInt16 fVersion;
    UInt16 fHWAddrLen;
    UInt8 * fHWAddr;
    UInt32 fIfMTU;
    UInt8 * fReservedPtrs[2];
    InetDomainName fDomainName;
    UInt32 fIPSecondaryCount;
    UInt8 fReserved[252];
};
typedef struct InetInterfaceInfo InetInterfaceInfo;
```

Fields

`fAddress`

The IP address of the interface.

`fNetmask`

The subnet mask of the local IP network.

`fBroadcastAddr`

The broadcast address for the interface.

`fDefaultGatewayAddr`

The IP address of the default router. The default is a router that can forward any packet destined outside the locally connected subnet.

`fDNSAddr`

The address of a domain name server. This value can be returned by a server or typed in by the user during configuration of the TCP/IP interface.

`fVersion`
The version of the OTInetGetInterfaceInfo function; currently equal to kInetInterfaceInfoVersion.

`fHWAddrLen`
The length (in bytes) of the hardware address. This points into the fReserved field of this structure. It can be nil if the interface has no hardware address or if it won't fit.

`fHWAddr`
A pointer to the hardware address.

`fIfMTU`
The maximum transmission unit size in bytes permitted for this interface's hardware.

`fReservedPtrs`
Reserved.

`fDomainName`
The default domain name of the host as configured in the TCP/IP control panel. This name doesn't include the host name.

`fIPSecondaryCount`
The number of IP secondary address available.

`fReserved`
Reserved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

Internet Mail Exchange Structure

Holds host names and mail preference values for use with the `OTInetMailExchange` function.

```
struct InetMailExchange {
    UInt16 preference;
    InetDomainName exchange;
};
typedef struct InetMailExchange InetMailExchange;
```

Fields
`preference`
The mail exchange preference value. The mail exchanger with the lowest preference number is the first one to which mail should be sent.

`exchange`
The fully qualified domain name of a host that can accept mail for your target host.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetPort

```
typedef UInt16 InetPort;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetSvcRef

```
typedef struct OpaqueInetSvcRef * InetSvcRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

InetSysInfo

Holds information about an Internet host for use by the `OTInetSysInfo` function.

```
struct InetSysInfo {
    char cpuType[32];
    char osType[32];
};
typedef struct InetSysInfo InetSysInfo;
```

Fields

`cpuType`
The CPU type of the specified host. This is an ASCII string maintained by the domain name server.

`osType`
The operating system running on the specified host. This is an ASCII string maintained by the domain name server.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

install_info

Fields

int_t

```
typedef  int_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

iocblk

```
struct iocblk {
    SInt32 ioc_cmd;
    cred * ioc_cr;
    UInt32 ioc_id;
    UInt32 ioc_count;
    SInt32 ioc_error;
    SInt32 ioc_rval;
    long ioc_filler[4];
};
typedef struct iocblk iocblk;
```

Fields
`ioc_cmd`
`ioc_cr`
`ioc_id`
`ioc_count`
`ioc_error`
`ioc_rval`
`ioc_filler`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

LCPEcho

```
struct LCPEcho {
    UInt32 retryCount;
    UInt32 retryPeriod;
};
typedef struct LCPEcho LCPEcho;
```

Fields

`retryCount`

`retryPeriod`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

linkblk

```
struct linkblk {
    queue_t * l_qtop;
    queue_t * l_qbot;
    SInt32 l_index;
    long l_pad[5];
};
typedef struct linkblk linkblk;
```

Fields

`l_qtop`

`l_qbot`

`l_index`

`l_pad`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

log_ctl

```
struct log_ctl {
    short mid;
    short sid;
    char level;
    char pad1;
    short flags;
    long ltime;
    long ttime;
    SInt32 seq_no;
};
typedef struct log_ctl log_ctl;
```

Fields

`mid`

`sid`

`level`

`pad1`

`flags`

`ltime`

`ttime`

`seq_no`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

major_t

```
typedef UInt16 major_t;
```

MapperRef

```
typedef struct OpaqueMapperRef * MapperRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

mblk_t

```
typedef msgb mblk_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

minor_t

```
typedef UInt16 minor_t;
```

module_info

```
struct module_info {
    unsigned short mi_idnum;
    char * mi_idname;
    long mi_minpsz;
    long mi_maxpsz;
    unsigned long mi_hiwat;
    unsigned long mi_lowat;
};
typedef struct module_info module_info;
typedef module_info * module_infoPtr;
```

Fields
mi_idnum
mi_idname
mi_minpsz
mi_maxpsz
mi_hiwat
mi_lowat

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

module_stat

```
struct module_stat {
    long ms_pcnt;
    long ms_scnt;
    long ms_ocnt;
    long ms_ccnt;
    long ms_acnt;
    char * ms_xptr;
    short ms_xsize;
};
typedef struct module_stat module_stat;
```

Fields

`ms_pcnt`

`ms_scnt`

`ms_ocnt`

`ms_ccnt`

`ms_acnt`

`ms_xptr`

`ms_xsize`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

MPS_INTR_STATE

```
typedef UInt8 MPS_INTR_STATE;
```

msgb

```
struct msgb {
    struct msgb * b_next;
    struct msgb * b_prev;
    struct msgb * b_cont;
    unsigned char * b_rptr;
    unsigned char * b_wptr;
    datab * b_datap;
    unsigned char b_band;
    unsigned char b_pad1;
    unsigned short b_flag;
};
typedef struct msgb msgb;
typedef msgb mblk_t;
```

Fields

`b_next`

`b_prev`

`b_cont`

`b_rptr`

`b_wptr`

`b_datap`

`b_band`

`b_pad1`

`b_flag`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

NBPAddress

```
struct NBPAddress {
    OTAddressType fAddressType;
    UInt8 fNBPNameBuffer[105];
};
typedef struct NBPAddress NBPAddress;
```

Fields

`fAddressType`

`fNBPNameBuffer`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

NBPEntity

```
struct NBPEntity {
    UInt8 fEntity[99];
};
typedef struct NBPEntity NBPEntity;
```

Fields
`fEntity`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

netbuf

```
struct netbuf {
     maxlen;
     len;
    char *buf;
};
```

Fields

ot_bind

Fields

ot_optmgmt

Fields

OTAddress

Defines the common structure for all Open Transport addresses.

```
struct OTAddress {
    OTAddressType fAddressType;
    UInt8 fAddress[1];
};
typedef struct OTAddress OTAddress;
```

Fields

`fAddressType`

`fAddress`

Discussion

The `OTAddress` type itself is abstract. You would not declare a structure of this type because it does not contain any address information. However, address formats defined by Open Transport protocols all use the `fAddressType` field to describe the format of the fields to follow, which do contain address information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

OTAddressType

```
typedef UInt16 OTAddressType;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

OTAutopushInfo

```
struct OTAutopushInfo {
    UInt32 sap_cmd;
    char sap_device_name[32];
    SInt32 sap_minor;
    SInt32 sap_lastminor;
    SInt32 sap_npush;
    char sap_list[8][32];
};
typedef struct OTAutopushInfo OTAutopushInfo;
```

Fields

`sap_cmd`

`sap_device_name`

`sap_minor`

`sap_lastminor`

`sap_npush`

`sap_list`

Availability

Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

OTBand

```
typedef UInt32 OTBand;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

OTBooleanParam

```
typedef Boolean OTBooleanParam;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

No-Copy Receive Buffer Structure

Receives data without copying it.

```
struct OTBuffer {
    void * fLink;
    void * fLink2;
    OTBuffer * fNext;
    UInt8 * fData;
    ByteCount fLen;
    void * fSave;
    UInt8 fBand;
    UInt8 fType;
    UInt8 fPad1;
    UInt8 fFlags;
};
typedef struct OTBuffer OTBuffer;
```

Fields

`fLink`
Reserved.

`fLink2`
Reserved.

`fNext`
A pointer to the next OTBuffer structure in the linked chain. By tracing the chain of fNext pointers, you can access all of the data associated with the message.

`fData`
: A pointer to the data portion of this OTBuffer structure.

`fLen`
: The length of data pointed to by the fData field.

`fSave`
: Reserved.

`fBand`
: The band used for the data transmission. It must be a value between 0 and 255.

`fType`
: The type of the data (normally M_DATA, M_PROTO, or M_PCPROTO).

`fPad1`
: Reserved.

`fFlags`
: The flags associated with the data (MSGMARK, MSGDELIM).

Discussion
You use the no-copy receive buffer structure when you wish to receive data without copying it with the OTRcvUData function, the OTRcvURequest function, the OTRcvUReply function, the OTRcv function, the OTRcvRequest function, and the OTRcvReply function.

If you are familiar with STREAMS mblk_t data structures, you can see that the no-copy receive buffer structure is just a slight modification of the mblk_t structure.

You can only use this buffer for data; you cannot use it for the address or options that may be associated with the incoming data. For example, in the case of an incoming TUnitData structure, you can only no-copy receive the udata portion, not the addr or opt fields.

Special Considerations

Under no circumstance write to this data structure. It is read-only. If you write to it, you can crash the system.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

Buffer Information Structure

A convenience structure for keeping track of where your application left off in an OTBuffer structure.

```
struct OTBufferInfo {
    OTBuffer * fBuffer;
    ByteCount fOffset;
    UInt8 fPad;
};
typedef struct OTBufferInfo OTBufferInfo;
```

Fields
`fBuffer`
: A pointer to the no-copy receive buffer.

`fOffset`
An offset indicating how far into the buffer you have read.

`fPad`
Reserved.

Discussion
The buffer information structure is provided for your convenience in keeping track of where you last left off in an OTBuffer structure. Because the no-copy receive buffer structure (OTBuffer) is read-only, you may need to copy the data in sections as you progress through the no-copy receive buffer. The utility function OTReadBuffer is used with this structure to easily copy the data out of an OTBuffer structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTByteCount

```
typedef ByteCount OTByteCount;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTClient

```
typedef struct OpaqueOTClient * OTClient;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTClientContextPtr

```
typedef struct OpaqueOTClientContextPtr * OTClientContextPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTClientList

Identifies the clients that denied a request to yield a port.

```
struct OTClientList {
    ItemCount fNumClients;
    UInt8 fBuffer[4];
};
typedef struct OTClientList OTClientList;
```

Fields

`fNumClients`

The number of clients in the fBuffer array, normally 1.

`fBuffer`

An array of packed Pascal strings enumerating the name of each client that rejected the request—that is, the names under which the clients registered themselves as an Open Transport clients.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

OTClientName

```
typedef UInt8 * OTClientName;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTCommand

```
typedef SInt32 OTCommand;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTConfigurationRef

```
typedef struct OTConfiguration * OTConfigurationRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTData Structure

Specifies the location and size of noncontiguous data.

```
struct OTData {
    void * fNext;
    void * fData;
    ByteCount fLen;
};
typedef struct OTData OTData;
```

Fields

`fNext`

A pointer to the OTData structure that describes the next data fragment. Specify a NULL pointer for the last data fragment.

`fData`

A pointer to the data fragment.

`fLen`

Specifies the size of the fragment in bytes.

Discussion

The OTData structure is an Apple extension used to specify the location and size of noncontiguous data. You use a pointer to this structure in place of a pointer to continguous data normally referenced in TNetbuf.buf field. You can send discontiguous data using the OTSndUData function, the OTSndURequest function, the OTSndUReply function, the OTSnd function, the OTSndRequest function, and the OTSndReply function.

Each OTData structure specifies the location of a data fragment, the size of the fragment, and the location of the OTData structure that specifies the location and size of the next data fragment. The data information structure is defined by the OTData type. For more information, see "Sending Noncontiguous Data."

Availability

Available in Mac OS X v10.0 and later.

OTError

```
typedef SInt32 OTError;
```

OTGate

```
struct OTGate {
    OTLIFO fLIFO;
    OTList fList;
    OTGateProcPtr fProc;
    SInt32 fNumQueued;
    SInt32 fInside;
};
typedef struct OTGate OTGate;
```

Fields
fLIFO
fList
fProc
fNumQueued
fInside

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

OTHashList

```
struct OTHashList {
    OTHashProcPtr fHashProc;
    ByteCount fHashTableSize;
    OTLink ** fHashBuckets;
};
typedef struct OTHashList OTHashList;
```

Fields

`fHashProc`

`fHashTableSize`

`fHashBuckets`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

OTInt32

```
typedef SInt32 OTInt32;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTISDNAddress

```
struct OTISDNAddress {
    OTAddressType fAddressType;
    UInt16 fPhoneLength;
    char fPhoneNumber[37];
};
typedef struct OTISDNAddress OTISDNAddress;
```

Fields

`fAddressType`

`fPhoneLength`

`fPhoneNumber`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

OTItemCount

```
typedef ItemCount OTItemCount;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

LIFO List Structure

Supports last-in, first-out lists in Open Transport.

```
struct OTLIFO {
    OTLink * fHead;
};
typedef struct OTLIFO OTLIFO;
```

Fields
`fHead`
A pointer to the first entry in the linked list. Set this to nil to initialize the structure before using it.

Discussion
Open Transport LIFO (last-in, first-out) lists use the LIFO list structure. You must initialize this structure by setting the structure's fHead field to NULL before using the LIFO list. Most Open Transport LIFO list operations are atomic.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTLink

Allows any data structure to be used in an Open Transport list.

```
struct OTLink {
    OTLink * fNext;
};
typedef struct OTLink OTLink;
```

Fields
`fNext`
A pointer to the next entry in the linked list.

Discussion
All of Open Transport's list utilities use the linked list structure, which may be embedded in any data structure that you want to use in an Open Transport list. A linked list structure is defined by the OTLink data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

FIFO List Structure

Supports first-in, last-out lists in Open Transport

```
struct OTList {
    OTLink * fHead;
};
typedef struct OTList OTList;
```

Fields
fHead
A pointer to the first entry in the linked list. Set this to NULL to initialize the structure before using it.

Discussion
Open Transport FIFO (first-in, first-out) lists use the FIFO list structure. You must initialize this structure by setting the structure's fHead field to NULL before using the LIFO list. The FIFO list structure is defined by the OTList data type.

None of the functions that handle a FIFO list structure are atomic.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

OTListSearchUPP

```
typedef OTListSearchProcPtr OTListSearchUPP;
```

Discussion
For more information, see the description of the OTListSearchUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

Lock Data Type

Defines a value used to ensure that Open Transport does not recursively reenter locked areas of code.

```
typedef UInt8 OTLock;
```

Discussion
The lock data type defines a value that is used by the OTClearLock function and the OTAcquireLock function to ensure that Open Transport does not recursively reenter locked areas of code. The lock data type is defined by the OTLock data type

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTNameID

```
typedef SInt32 OTNameID;
```

Availability
Available in Mac OS X v10.0 and later.

OTNotifyUPP

```
typedef OTNotifyProcPtr OTNotifyUPP;
```

Discussion
For more information, see the description of the OTNotifyUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

OTPCIInfo

```
struct OTPCIInfo {
    RegEntryID fTheID;
    void *fConfigurationInfo;
    ByteCount fConfigurationLength;
};
```

Fields

OTPortCloseStruct

Denies or accepts requests to yield a port.

```
struct OTPortCloseStruct {
    OTPortRef fPortRef;
    ProviderRef fTheProvider;
    OSStatus fDenyReason;
};
typedef struct OTPortCloseStruct OTPortCloseStruct;
```

Fields

`fPortRef`

The port requested to be closed.

`fTheProvider`

The provider that is currently using the port.

`fDenyReason`

A value that you can leave untouched to accept the yield request. To deny the request, change this value to a negative error code corresponding to the reason for your denial (normally you use the kOTUserRequestedErr error).

Discussion

When you are using a port that another client wishes to use, the other client can use the OTYieldPortRequest function (not available in Mac OS X) to ask you to yield the port. If you are registered as a client of Open Transport, you receive a kOTYieldPortRequest event, whose cookie parameter is a pointer to a port close structure. You can use this structure to deny or accept the yield request.

Currently, this callback is only used for serial ports, but it is applicable to any hardware device that cannot share a port with multiple clients. You should check the kOTCanYieldPort bit in the port structure's fInfoFlags field to see whether the port supports yielding.

If the provider is passively listening (that is, bound with a queue length (qlen) greater than 0) and you are willing to yield, you need do nothing. If, however, you are actively connected and you are willing to yield the port, you must issue a synchronous OTSndDisconnect callin order to let the port go.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

The Port Structure

Describes a port's characteristics.

```
struct OTPortRecord {
    OTPortRef fRef;
    UInt32 fPortFlags;
    UInt32 fInfoFlags;
    UInt32 fCapabilities;
    ItemCount fNumChildPorts;
    OTPortRef * fChildPorts;
    char fPortName[36];
    char fModuleName[32];
    char fSlotID[8];
    char fResourceInfo[32];
    char fReserved[164];
};
typedef struct OTPortRecord OTPortRecord;
```

Fields

`fRef`

The port reference; a 32-bit value encoding the port's device type, bus type, slot number, and multiport identifier

`fPortFlags`

Flags describing the port's status. If no bits are set, the port is currently inactive—that is, it is not in use at this time.

`fInfoFlags`

`fCapabilities`

`fNumChildPorts`

`fChildPorts`

An array of the port references for the child ports associated with this port. When you get a Port Record, this pointer typically points into the SReserved field at the end of the record.

`fPortName`

A unique name for this port. The port name is a zero-terminated string that can have a maximum length as indicated by the constant kMaxProviderNameSize.

`fModuleName`

The name of the actual STREAMS module that implements the driver for this port. Open Transport uses this name internally; applications rarely need to use this name.

`fSlotID`

An 8-byte identifier for a port's slot that contains a 7-byte character string plus a zero for termination. This identifier is typically available only for PCI cards.

`fResourceInfo`

A zero-terminated string that describes a shared library that can handle configuration information for the device. This field contains an identifier that allows Open Transport to access auxiliary information about the driver (Open Transport creates shared library IDs from this string to be able to find these extra shared libraries). This string should either be unique to the driver or should be set to a NULL string.

`fReserved`

Reserved.

Discussion

Open Transport uses a port structure to describe a port's characteristics, such as its port name, its child ports, whether it is active or disabled, whether it is private or shareable, and the kind of framing it can use.

Availability

Available in Mac OS X v10.0 and later.

Timestamp Data Type

Contains an Open Transport timestamp.

```
typedef UnsignedWide OTTimeStamp;
```

Discussion
The timestamp data type is a 64-bit value that contains an Open Transport timestamp. The timestamp has unspecified units; you must use one of the timestamp manipulation functions described in "Timestamp Utility Functions" to convert the timestamp to known quantities. The timestamp data type is defined by the OTTimeStamp data type.

struct strpeek {
    strbuf ctlbuf;
    strbuf databuf;
    long flags;
};
typedef struct strpeek strpeek;
```

Fields

`ctlbuf`

`databuf`

`flags`

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

strpfp

```
struct strpfp {
    unsigned long pass_file_cookie;
    unsigned short pass_uid;
    unsigned short pass_gid;
    sth_s * pass_sth;
};
typedef struct strpfp strpfp;
```

Fields
pass_file_cookie
pass_uid
pass_gid
pass_sth

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

strpmsg

```
struct strpmsg {
    strbuf ctlbuf;
    strbuf databuf;
    SInt32 band;
    long flags;
};
typedef struct strpmsg strpmsg;
```

Fields
ctlbuf
databuf
band
flags

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

strrecvfd

```
struct strrecvfd {
    long fd;
    unsigned short uid;
    unsigned short gid;
    char fill[8];
};
typedef struct strrecvfd strrecvfd;
```

Fields

`fd`

`uid`

`gid`

`fill`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_addr_ack

```
struct T_addr_ack {
    long PRIM_type;
    long LOCADDR_length;
    long LOCADDR_offset;
    long REMADDR_length;
    long REMADDR_offset;
};
typedef struct T_addr_ack T_addr_ack;
```

Fields

`PRIM_type`

`LOCADDR_length`

`LOCADDR_offset`

`REMADDR_length`

`REMADDR_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_addr_req

```
struct T_addr_req {
    long PRIM_type;
};
typedef struct T_addr_req T_addr_req;
```

Fields
`PRIM_type`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_bind_ack

```
struct T_bind_ack {
    long PRIM_type;
    long ADDR_length;
    long ADDR_offset;
    unsigned long CONIND_number;
};
typedef struct T_bind_ack T_bind_ack;
```

Fields
`PRIM_type`
`ADDR_length`
`ADDR_offset`
`CONIND_number`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_bind_req

```
struct T_bind_req {
    long PRIM_type;
    long ADDR_length;
    long ADDR_offset;
    unsigned long CONIND_number;
};
typedef struct T_bind_req T_bind_req;
```

Fields

`PRIM_type`

`ADDR_length`

`ADDR_offset`

`CONIND_number`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

t_call

Fields

T_cancelreply_req

```
struct T_cancelreply_req {
    long PRIM_type;
    long SEQ_number;
};
typedef struct T_cancelreply_req T_cancelreply_req;
```

Fields

`PRIM_type`

`SEQ_number`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_cancelrequest_req

```
struct T_cancelrequest_req {
    long PRIM_type;
    long SEQ_number;
};
typedef struct T_cancelrequest_req T_cancelrequest_req;
```

Fields

`PRIM_type`

`SEQ_number`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_conn_con

```
struct T_conn_con {
    long PRIM_type;
    long RES_length;
    long RES_offset;
    long OPT_length;
    long OPT_offset;
};
typedef struct T_conn_con T_conn_con;
```

Fields

`PRIM_type`

`RES_length`

`RES_offset`

`OPT_length`

`OPT_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_conn_ind

```
struct T_conn_ind {
    long PRIM_type;
    long SRC_length;
    long SRC_offset;
    long OPT_length;
    long OPT_offset;
    long SEQ_number;
};
typedef struct T_conn_ind T_conn_ind;
```

Fields

`PRIM_type`

`SRC_length`

`SRC_offset`

`OPT_length`

`OPT_offset`

`SEQ_number`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_conn_req

```
struct T_conn_req {
    long PRIM_type;
    long DEST_length;
    long DEST_offset;
    long OPT_length;
    long OPT_offset;
};
typedef struct T_conn_req T_conn_req;
```

Fields

`PRIM_type`

`DEST_length`

`DEST_offset`

`OPT_length`

`OPT_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_conn_res

```
struct T_conn_res {
    long PRIM_type;
    queue_t * QUEUE_ptr;
    long OPT_length;
    long OPT_offset;
    long SEQ_number;
};
typedef struct T_conn_res T_conn_res;
```

Fields

`PRIM_type`

`QUEUE_ptr`

`OPT_length`

`OPT_offset`

`SEQ_number`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_data_ind

```
struct T_data_ind {
    long PRIM_type;
    long MORE_flag;
};
typedef struct T_data_ind T_data_ind;
```

Fields

`PRIM_type`

`MORE_flag`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_data_req

```
struct T_data_req {
    long PRIM_type;
    long MORE_flag;
};
typedef struct T_data_req T_data_req;
```

Fields

`PRIM_type`

`MORE_flag`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_delname_req

```
struct T_delname_req {
    long PRIM_type;
    long SEQ_number;
    long NAME_length;
    long NAME_offset;
};
typedef struct T_delname_req T_delname_req;
```

Fields

`PRIM_type`

`SEQ_number`

`NAME_length`

`NAME_offset`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

t_discon

Fields

T_discon_ind

```
struct T_discon_ind {
    long PRIM_type;
    long DISCON_reason;
    long SEQ_number;
};
typedef struct T_discon_ind T_discon_ind;
```

Fields

`PRIM_type`

`DISCON_reason`

`SEQ_number`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_discon_req

```
struct T_discon_req {
    long PRIM_type;
    long SEQ_number;
};
typedef struct T_discon_req T_discon_req;
```

Fields

`PRIM_type`

`SEQ_number`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_error_ack

```
struct T_error_ack {
    long PRIM_type;
    long ERROR_prim;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_error_ack T_error_ack;
```

Fields

`PRIM_type`

`ERROR_prim`

`TLI_error`

`UNIX_error`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_event_ind

```
struct T_event_ind {
    long PRIM_type;
    long EVENT_code;
    long EVENT_cookie;
};
typedef struct T_event_ind T_event_ind;
```

Fields

`PRIM_type`

`EVENT_code`

`EVENT_cookie`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_exdata_ind

```
struct T_exdata_ind {
    long PRIM_type;
    long MORE_flag;
};
typedef struct T_exdata_ind T_exdata_ind;
```

Fields

`PRIM_type`

`MORE_flag`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_exdata_req

```
struct T_exdata_req {
    long PRIM_type;
    long MORE_flag;
};
typedef struct T_exdata_req T_exdata_req;
```

Fields

`PRIM_type`

`MORE_flag`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

t_info

Fields

T_info_ack

```
struct T_info_ack {
    long PRIM_type;
    long TSDU_size;
    long ETSDU_size;
    long CDATA_size;
    long DDATA_size;
    long ADDR_size;
    long OPT_size;
    long TIDU_size;
    long SERV_type;
    long CURRENT_state;
    long PROVIDER_flag;
};
typedef struct T_info_ack T_info_ack;
```

Fields

PRIM_type

TSDU_size

ETSDU_size

CDATA_size

DDATA_size

ADDR_size

OPT_size

TIDU_size

SERV_type

CURRENT_state

PROVIDER_flag

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_info_req

```
struct T_info_req {
    long PRIM_type;
};
typedef struct T_info_req T_info_req;
```

Fields

PRIM_type

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

The Keepalive Structure

Specifies the value of the `OPT_KEEPALIVE` option.

```
struct t_kpalive {
    SInt32 kp_onoff;
    SInt32 kp_timeout;
};
typedef struct t_kpalive t_kpalive;
```

Fields

`kp_onoff`

A constant specifying whether the option is turned on (T_ON) or off (T_OFF).

`kp_timeout`

A positive integer specifying how many minutes Open Transport should maintain a connection in the absence of traffic.

Discussion

The keepalive structure specifies the value of the OPT_KEEPALIVE option, described in "XTI-Level Options and Generic Options" (page 2718)

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

The Linger Structure

Specifies the value of the `XTI_LINGER` option.

```
struct t_linger {
    SInt32 l_onoff;
    SInt32 l_linger;
};
typedef struct t_linger t_linger;
```

Fields

`l_onoff`

A constant specifying whether the option is turned on (T_ON) or off (T_OFF).

`l_linger`

An integer specifying the linger time, the amount of time in seconds that Open Transport should wait to allow data in an endpoint's internal buffer to be sent before the OTCloseProvider function closes the endpoint.

To request the default value for this option, set the l_linger field to T_UNSPEC.

Discussion

The linger structure specifies the value of the `XTI_LINGER` option, described in "XTI-Level Options and Generic Options" (page 2718).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

T_lkupname_con

```
struct T_lkupname_con {
    long PRIM_type;
    long SEQ_number;
    long NAME_length;
    long NAME_offset;
    long RSP_count;
    long RSP_cumcount;
};
typedef struct T_lkupname_con T_lkupname_con;
```

Fields

`PRIM_type`

`SEQ_number`

`NAME_length`

`NAME_offset`

`RSP_count`

`RSP_cumcount`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_lkupname_req

```
struct T_lkupname_req {
    long PRIM_type;
    long SEQ_number;
    long NAME_length;
    long NAME_offset;
    long ADDR_length;
    long ADDR_offset;
    long MAX_number;
    long MAX_milliseconds;
    long REQ_flags;
};
typedef struct T_lkupname_req T_lkupname_req;
```

Fields

`PRIM_type`

`SEQ_number`

`NAME_length`

`NAME_offset`

`ADDR_length`

`ADDR_offset`

`MAX_number`

`MAX_milliseconds`

`REQ_flags`

Availability

Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_MIB_ack

Fields

T_MIB_req

Fields

T_ok_ack

```
struct T_ok_ack {
    long PRIM_type;
    long CORRECT_prim;
};
typedef struct T_ok_ack T_ok_ack;
```

Fields
PRIM_type
CORRECT_prim

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

t_opthdr

Fields

T_optmgmt_ack

```
struct T_optmgmt_ack {
    long PRIM_type;
    long OPT_length;
    long OPT_offset;
    long MGMT_flags;
};
typedef struct T_optmgmt_ack T_optmgmt_ack;
```

Fields

`PRIM_type`

`OPT_length`

`OPT_offset`

`MGMT_flags`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_optmgmt_req

```
struct T_optmgmt_req {
    long PRIM_type;
    long OPT_length;
    long OPT_offset;
    long MGMT_flags;
};
typedef struct T_optmgmt_req T_optmgmt_req;
```

Fields

`PRIM_type`

`OPT_length`

`OPT_offset`

`MGMT_flags`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_ordrel_ind

```
struct T_ordrel_ind {
    long PRIM_type;
};
typedef struct T_ordrel_ind T_ordrel_ind;
```

Fields
`PRIM_type`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_ordrel_req

```
struct T_ordrel_req {
    long PRIM_type;
};
typedef struct T_ordrel_req T_ordrel_req;
```

Fields
`PRIM_type`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

};
typedef struct T_regname_req T_regname_req;
```

Fields

`PRIM_type`

`SEQ_number`

`NAME_length`

`NAME_offset`

`ADDR_length`

`ADDR_offset`

`REQ_flags`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

t_reply

Fields

T_reply_ack

```
struct T_reply_ack {
    long PRIM_type;
    long SEQ_number;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_reply_ack T_reply_ack;
```

Fields
PRIM_type
SEQ_number
TLI_error
UNIX_error

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_reply_ind

```
struct T_reply_ind {
    long PRIM_type;

    long ORIG_data;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_resolveaddr_ack T_resolveaddr_ack;
```

Fields

`PRIM_type`

`SEQ_number`

`ADDR_length`

`ADDR_offset`

`ORIG_client`

`ORIG_data`

`TLI_error`

`UNIX_error`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProtocol.h`

T_resolveaddr_req

```
struct T_resolveaddr_req {
    long PRIM_type;
    long SEQ_number;
    long ADDR_length;
    long ADDR_offset;
    long ORIG_client;
    long ORIG_data;
    long MAX_milliseconds;
};
typedef struct T_resolveaddr_req T_resolveaddr_req;
```

Fields

`PRIM_type`

`SEQ_number`

`ADDR_length`

`ADDR_offset`

`ORIG_client`

`ORIG_data`

`MAX_milliseconds`

Availability

Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_sequence_ack

```
struct T_sequence_ack {
    long PRIM_type;
    long ORIG_prim;
    long SEQ_number;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_sequence_ack T_sequence_ack;
```

Fields
PRIM_type
ORIG_prim
SEQ_number
TLI_error
UNIX_error

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_stream_timer

Fields

T_stream_timer_1

Fields

t_uderr

Fields

T_uderror_ind

```
struct T_uderror_ind {

};
typedef struct T_unitdata_ind T_unitdata_ind;
```

Fields

`PRIM_type`

`SRC_length`

`SRC_offset`

`OPT_length`

`OPT_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_unitdata_req

```
struct T_unitdata_req {
    long PRIM_type;
    long DEST_length;
    long DEST_offset;
    long OPT_length;
    long OPT_offset;
};
typedef struct T_unitdata_req T_unitdata_req;
```

Fields

`PRIM_type`

`DEST_length`

`DEST_offset`

`OPT_length`

`OPT_offset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

t_unitreply

Fields

T_unitreply_ack

```
struct T_unitreply_ack {
    long PRIM_type;
    long SEQ_number;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_unitreply_ack T_unitreply_ack;
```

Fields

`PRIM_type`

`SEQ_number`

`TLI_error`

`UNIX_error`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

T_unitreply_ind

```
struct T_unitreply_ind {
    long PRIM_type;
    long SEQ_number;
    long OPT_length;
    long OPT_offset;
    long REP_flags;
    long TLI_error;
    long UNIX_error;
};
typedef struct T_unitreply_ind T_unitreply_ind;
```

Fields

`PRIM_type`

`SEQ_number`

`OPT_length`

`OPT_offset`

`REP_flags`

`TLI_error`

`UNIX_error`

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

T_unitreply_req

```
struct T_unitreply_req {
    long PRIM_type;
    long SEQ_number;
    long OPT_length;
    long OPT_offset;
    long REP_flags;
};
typedef struct T_unitreply_req T_unitreply_req;
```

Fields
PRIM_type
SEQ_number
OPT_length
OPT_offset
REP_flags

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransportProtocol.h

t_unitrequest

Fields

T_unitrequest_ind

```
struct T_unitrequest_ind {
    long PRIM_type;
    long SEQ_number;
    long SRC_length;
    long SRC_offset;
    long OPT_length;
    long OPT_offset;
    long REQ_flags;
};
typedef struct T_unitrequest_ind T_unitrequest_ind;
```

Fields

`PRIM_type`

`SEQ_number`

`SRC_length`

`SRC_offset`

`OPT_length`

`OPT_offset`

`REQ_flags`

Availability

Available in Mac OS X v10.0 and later.

`OpenTransportProtocol.h`

T8022Address

```
struct T8022Address {
    OTAddressType fAddrFamily;
    UInt8 fHWAddr[6];
    UInt16 fSAP;
    UInt8 fSNAP[5];
};
typedef struct T8022Address T8022Address;
```

Fields

`fAddrFamily`

`fHWAddr`

`fSAP`

`fSNAP`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

T8022FullPacketHeader

```
struct T8022FullPacketHeader {
    EnetPacketHeader fEnetPart;
    T8022SNAPHeader f8022Part;
};
typedef struct T8022FullPacketHeader T8022FullPacketHeader;
```

Fields

`fEnetPart`

`f8022Part`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

T8022Header

```
struct T8022Header {
    UInt8 fDSAP;
    UInt8 fSSAP;
    UInt8 fCtrl;
};
typedef struct T8022Header T8022Header;
```

Fields

`fDSAP`

`fSSAP`

`fCtrl`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransportProviders.h`

T8022SNAPHeader

```
struct T8022SNAPHeader {
    UInt8 fDSAP;
    UInt8 fSSAP;
    UInt8 fCtrl;
    UInt8 fSNAP[5];
};
typedef struct T8022SNAPHeader T8022SNAPHeader;
```

Fields

`fDSAP`

`fSSAP`

`fCtrl`

`fSNAP`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

TBind

Describes the protocol address to which an endpoint is currently bound or connected, or specifies the protocol address to which you wish to bind or connect the endpoint.

```
struct TBind {
    TNetbuf addr;
    OTQLen qlen;
};
typedef struct TBind TBind;
```

Fields

`addr`

A `TNetbuf` structure that contains information about an address. The `addr.maxlen` field specifies the maximum size of the address, the `addr.len` field specifies the actual length of the address, and the `addr.buf` field points to the buffer containing the address.

When specifying an address, you must allocate a buffer for the address and initialize it; you must set the `addr.buf` field to point to this buffer; and you must set the `addr.len` field to the size of the address.

When requesting an address, you must allocate a buffer in which the address is to be placed; you must set the `addr.buf` field to point to this buffer; and you must set the `addr.maxlen` field to the maximum size of the address that is being returned. You determine this value by examining the `addr` field of the `TEndpointInfo` (page 2542) structure for the endpoint.

`qlen`

For a connection-oriented endpoint, the maximum number of connection requests that can be concurrently outstanding for this endpoint. For more information, see the description of the `OTBind` (page 2319) function. For connectionless endpoints, this field has no meaning.

Discussion
The `TBind` structure describes the protocol address to which an endpoint is currently bound or connected, or specifies the protocol address to which you wish to bind or connect the endpoint. For a connection-oriented endpoint, the `TBind` structure also specifies the actual or desired number of connection requests that can be concurrently outstanding for the endpoint.

You pass the `TBind` structure as a parameter to the `OTBind` (page 2319) function, the `OTGetProtAddress` (page 2348) function, and the `OTResolveAddress` (page 2387) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TCall

Specifies the options and data associated with establishing a connection.

```
struct TCall {
    TNetbuf addr;
    TNetbuf opt;
    TNetbuf udata;
    OTSequence sequence;
};
typedef struct TCall TCall;
```

Fields

`addr`
A TNetbuf structure that specifies the location and size of an address buffer

`opt`
A TNetbuf structure that specifies the location and size of an options buffer.

`udata`
A TNetbuf structure that specifies the location and size of a buffer for data associated with a connection or disconnection request.

`sequence`
A 32-bit value used by the OTListen and OTAccept functions to specify the connection ID.

Discussion
You use the `TCall` structure to specify the options and data associated with establishing a connection. You pass a pointer to this structure as a parameter to the OTConnect function, the OTRcvConnect function, the OTListen function, and the OTAccept function.

If you are using the TCall structure to send information, you must allocate a buffer and initialize it to contain the information. Set the .buf field of each TNetbuf to point to the buffer, and then specify the size of the buffer using the .len field. Set this field to 0 if you are not sending data.

If you are using the TCall structure to receive information, you must allocate a buffer into which the function can place the information when it returns. Then set the .buf field of all the TNetbufs to point to this buffer, and set the .maxlen field to the maximum size of the information. Set this field to 0 if you are not interested in receiving information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TDiscon

Specifies data sent with the OTSndDisconnect function and retrieved by the OTRcvDisconnect function.

```
struct TDiscon {
    TNetbuf udata;
    OTReason reason;
    OTSequence sequence;
};
typedef struct TDiscon TDiscon;
```

Fields

`udata`
A TNetbuf structure that references data sent with the OTSndDisconnect function or received by the OTRcvDisconnect function.

`reason`
A 32-bit value specifying an error code that identifies the reason for the disconnection. These codes are supplied by the protocol. For additional information, consult the documentation provided for the protocol you are using.

`sequence`
A 32-bit value specifying an outstanding connection request that has been rejected. This field is meaningful only when you have issued several connection requests to the same endpoint and are awaiting the results.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TEndpointInfo

Describes the initial characteristics of an endpoint that you opened by calling the `OTOpenEndpointInContext` function; returned by calling `OTGetEndpointInfo`.

```
struct TEndpointInfo {
    OTDataSize addr;
    OTDataSize options;
    OTDataSize tsdu;
    OTDataSize etsdu;
    OTDataSize connect;
    OTDataSize discon;
    OTServiceType servtype;
    UInt32 flags;
};
typedef struct TEndpointInfo TEndpointInfo;
```

Fields

`addr`

`options`

A value greater than or equal to 0 indicates the maximum number of bytes needed to store the protocol-specific options that this endpoint supports, if any. A value of `T_INVALID` (-2) indicates that this endpoint has no protocol-specific options that you can set; they are read-only. A value of -3 specifies that the provider does not support any options.

`tsdu`

For a transactionless endpoint, a positive value indicates the maximum number of bytes in a transport service data unit (TSDU) for this endpoint. A value of `T_INFINITE` (-1) indicates that there is no limit to the size of a TSDU. A value of 0 indicates that the provider does not support the concept of a TSDU. This means that you cannot send data with logical boundaries preserved across a connection. A value of `T_INVALID` indicates that this endpoint cannot transfer normal data (as opposed to expedited data).

For a transaction-based endpoint, this field indicates the maximum number of bytes in a response.

`etsdu`

For a transactionless endpoint, a positive value indicates the maximum number of bytes in an expedited transport service data unit (ETSDU) for this endpoint. A value of `T_INFINITE` indicates that there is no limit to the size of a ETSDU. A value of 0 indicates that this endpoint does not support the concept of an ETSDU. This means that you must not send expedited data with logical boundaries preserved across a connection. A value of `T_INVALID` indicates that this endpoint cannot transfer expedited data.

For a transaction-based endpoint, this field indicates the maximum number of bytes in a request.

`connect`

For a connection-oriented endpoint, a value greater than or equal to 0 indicates the maximum amount of data (in bytes) that you can send with the `OTConnect` (page 2326) function or the `OTAccept` (page 2306) function. A value of `T_INVALID` indicates that this endpoint does not let you send data with these functions. This field is meaningless for other types of endpoints.

`discon`

For a connection-oriented endpoint, a value greater than or equal to 0 indicates the maximum amount of data (in bytes) that you can send using the `OTSndDisconnect` (page 2399) function. A value of `T_INVALID` indicates that this endpoint does not let you send data with disconnection requests. This field is meaningless for other types of endpoints.

`servtype`

A constant that indicates what kind of service the endpoint provides. Possible values are given by the "Endpoint Service Types" (page 2670) enumeration.

`flags`

A bit FIeld that provides additional information about the endpoint. Possible values are given by the "Endpoint Flags" (page 2706) enumeration.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

IP Multicast Address Structure

Supports adding and dropping membership in an IP multicast address.

```
struct TIPAddMulticast {
    InetHost multicastGroupAddress;
    InetHost interfaceAddress;
};
typedef struct TIPAddMulticast TIPAddMulticast;
```

Fields

`multicastGroupAddress`
The IP address of the multicast group for which you want to add or drop membership.

`interfaceAddress`
The IP address of the network interface that you are using for the multicast group.

Discussion
You use the IP multicast address structure with the IP_ADD_MEMBERSHIP and IP_DROP_MEMBERSHIP options when you are adding or dropping membership in an IP multicast address.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProviders.h`

TLookupBuffer

Defines the format of entries in the buffer passed back in the reply parameter of the `OTLookupName` function.

```
struct TLookupBuffer {
    UInt16 fAddressLength;
    UInt16 fNameLength;
    UInt8 fAddressBuffer[1];
};
typedef struct TLookupBuffer TLookupBuffer;
```

Fields

`fAddressLength`
Specifies the size of the address specified by the fAddressBuffer field.

`fNameLength`
Specifies the size of the name that is stored in the buffer following the fAddressBuffer field.

`fAddressBuffer`
The first byte of the address to which the entity whose name follows (in the buffer) is bound.

Discussion
The TLookupBuffer structure defines the format of entries in the buffer passed back in the reply parameter of the OTLookupName function. When you parse the buffer in which the OTLookupName function places the names it has found, you can cast it as a TLookupBuffer structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TLookupReply

Stores information passed back to your application by the OTLookupName function.

```
struct TLookupReply {
    TNetbuf names;
    UInt32 rspcount;
};
typedef struct TLookupReply TLookupReply;
```

Fields

`names`
: A TNetbuf structure that specifies the size and location of a buffer into which the OTLookupName function, on return, places the names it has found. You must allocate the buffer into which the replies are stored when the function returns; you must set the names.buf field to point to it; and you must set the names.maxlen field to the size of the buffer.

`rspcount`
: A long specifying, on return, the number of names found.

Discussion
You use the TLookupReply structure to store information passed back to you by the OTLookupName function. The information includes both a pointer to a buffer (containing registered entity names matching the criterion specified with the TLookupRequest structure) and the number of names found.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TLookupRequest

Specifies the entity name to be looked up by the `OTLookupName` function.

```
struct TLookupRequest {
    TNetbuf name;
    TNetbuf addr;
    UInt32 maxcnt;
    OTTimeout timeout;
    OTFlags flags;
};
typedef struct TLookupRequest TLookupRequest;
```

Fields

`name`

A TNetbuf structure specifying the location and size of a buffer that contains the name to be looked up. You must allocate a buffer that contains the name, set the name.buf field to point to it, and set the name.len field to the length of the name.

`addr`

A TNetbuf structure describing the address of the node where you expect the names to be stored. You should normally supply 0 for addr.len. This causes the provider to use internal defaults for the starting point of the search. For a protocol family such as AppleTalk, in which every node has access to name and address information, this parameter is meaningless.

Specifying an address has meaning for those protocols that use a dedicated server or other device to store name information. In such a case, the name specified would override the protocol's default address. To specify an address, you would need to allocate a buffer containing the address, set the addr.buf field to point to it, and set the addr.len field to the length of the address. Consult the documentation supplied with your protocol to determine whether you can or should specify an address.

`maxcnt`

A long specifying the number of names you expect to be returned. Some protocols allow the use of wildcard characters in specifying a name. As a result, the OTLookupName function might find multiple names matching the specified name pattern. If you expect a specific number of replies for a particular name or do not expect to exceed a specific number, you should specify this number to obtain faster execution. Otherwise, set this field to 0xffff ffff; in this case, the timeout value will control the lookup.

`timeout`

A long specifying the amount of time, in milliseconds, that should elapse before Open Transport gives up searching for a name. Specify 0 to leave the timeout value up to the underlying naming system.

`flags`

Discussion

You use the TLookupRequest structure to specify the entity name to be looked up by the OTLookupName function and to set additional values that the mapper provider uses to circumscribe the search.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

TNetbuf

Specifies the location and size of a buffer that contains an address, option information, or user data.

```
struct TNetbuf {
    ByteCount maxlen;
    ByteCount len;
    UInt8 * buf;
};
typedef struct TNetbuf TNetbuf;
```

Fields

`maxlen`

The size (in bytes) of the buffer to which the `buf` field points. You must set the `maxlen` field before passing a `TNetbuf` structure to a provider function as an output parameter. Open Transport ignores this field if you pass the `TNetbuf` structure as an input parameter.

`len`

The actual length (in bytes) of the information in the buffer to which the `buf` field points. If you are using the `TNetbuf` structure as an input parameter, you must set this field.

If you pass the `TNetbuf` structure as an output parameter, on return the provider function sets this field to the number of bytes the function has actually placed in the buffer referenced by the `buf` field.

`buf`

A pointer to a buffer. You must make sure that the `buf` field points to a valid buffer and that the buffer is large enough to store the information for which it is intended.

Discussion

You use a TNetbuf structure to specify the location and size of a buffer that contains an address, option information, or user data. Provider functions use TNetbuf structures both as input parameters and output parameters. If you use a TNetbuf structure as an input parameter, you specify the location and size of a buffer containing information you want to send. If you use a TNetbuf structure as an output parameter, you specify the location and the maximum size of the buffer used to hold information when the function returns.

You use a TNetbuf structure to describe the location and size of contiguous data. Open Transport allows you to describe noncontiguous data with the OTData structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

The TOption Structure

Stores information about a single option in a buffer.

```
struct TOption {
    ByteCount len;
    OTXTILevel level;
    OTXTIName name;
    UInt32 status;
    UInt32 value[1];
};
typedef struct TOption TOption;
```

Fields

`len`

The size (in bytes) of the option information, including the header.

`level`
The protocol for which the option is defined.

`name`
The name of the option.

`status`
A status code specifying whether the negotiation has succeeded or failed. Possible values are given by the "Open Transport Flags and Status Codes" (page 2702) enumeration

`value`
The option value. To have the endpoint select an appropriate value, you can specify the constant T_UNSPEC.

Discussion
The TOption structure stores information about a single option in a buffer. All functions that you use to change or verify option values use a buffer containing TOption structures to store option information. For each option in the buffer, the TOption structure specifies the total length occupied by the option, the protocol level of the option, the option name, the status of a negotiated value, and the value of the option.

You use the TOption structure with the OPT_NEXTHDR macro, the OTCreateOptionString function, the OTNextOption function, and the OTFindOption function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

The TOptionHeader Structure

Stores information about options in a buffer.

```
struct TOptionHeader {
    ByteCount len;
    OTXTILevel level;
    OTXTIName name;
    UInt32 status;
};
typedef struct TOptionHeader TOptionHeader;
```

Fields
`len`
The size (in bytes) of the option information, including the header.

`level`
The protocol affected.

`name`
The option name.

`status`
The status value. Possible values are given by the "Open Transport Flags and Status Codes" (page 2702).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

The Option Management Structure

Manages the `req` and `ret` parameters of the `OTOptionManagement` function

```
struct TOptMgmt {
    TNetbuf opt;
    OTFlags flags;
};
typedef struct TOptMgmt TOptMgmt;
```

Fields

`opt`

A TNetbuf structure describing the buffer containing option information. The opt.maxlen field specifies the maximum size of the buffer. The opt.len field specifies the actual size of the buffer, and the opt.buf field contains the address of the buffer.

On input, as part of the req parameter, the buffer contains TOption structures describing the options to be negotiated or verified, or contains the names of options whose default or current values you are interested in. You must allocate this buffer, place in it the structures describing the options of interest, and set the opt.len field to the size of the buffer.

On output, as part of the ret parameter, the buffer contains the actual values of the options you described in the req parameter. You must allocate a buffer to hold the option information when the function returns and set the opt.maxlen field to the maximum length of this buffer. When the function returns, the opt.len field is set to the actual length of the buffer.

`flags`

For the req parameter, the flags field indicates the action to be taken as defined by the action flags enumeration (page 570). For the ret parameter, the flags field indicates the overall success or failure of the operation performed by the OTOptionManagement function, as defined by the "Open Transport Flags and Status Codes" (page 2702) enumeration.

Discussion
The option management structure is used for the req and ret parameters of the OTOptionManagement function. The req parameter is used to verify or negotiate option values. The ret parameter returns information about an endpoint's default, current, or negotiated values.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TOTConfiguratorRef

```
typedef struct OpaqueTOTConfiguratorRef * TOTConfiguratorRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

TPortRecord

```
struct TPortRecord {
    OTLink fLink;
    char *fPortName;
    char *fModuleName;
    char *fResourceInfo;
    char *fSlotID;
    TPortRecord *fAlias;
    ItemCount fNumChildren;
    OTPortRef *fChildPorts;
    UInt32 fPortFlags;
    UInt32 fInfoFlags;
    UInt32 fCapabilities;
    OTPortRef fRef;
    streamtab *fStreamtab;
    void *fContext;
    void *fExtra;
};
```

Fields

trace_ids

```
struct trace_ids {
    short ti_mid;
    short ti_sid;
    char ti_level;
};
typedef struct trace_ids trace_ids;
```

Fields

`ti_mid`

`ti_sid`

`ti_level`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransportProtocol.h`

TRegisterReply

Stores information returned by the `OTRegisterName` function.

```
struct TRegisterReply {
    TNetbuf addr;
    OTNameID nameid;
};
typedef struct TRegisterReply TRegisterReply;
```

Fields

`addr`

A TNetbuf structure that specifies the location and size of a buffer containing the actual address of the entity whose name you have just registered. This information is passed back to you when the OTRegisterName function returns. You must allocate a buffer, set the addr.buf field to point to it, and set the addr.maxlen field to the size of the buffer.

`nameid`

A unique identifier passed to you when the OTRegisterName function returns. You can use this identifier when you call the OTDeleteNameByID function to delete the name.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TRegisterRequest

Specifies the entity name you want to register using the OTRegisterName function and, optionally, to specify its address.

```
struct TRegisterRequest {
    TNetbuf name;
    TNetbuf addr;
    OTFlags flags;
};
typedef struct TRegisterRequest TRegisterRequest;
```

Fields

`name`

A TNetbuf structure that specifies the location and size of a buffer containing the entity name you want to register. You must allocate a buffer that contains the name, set the name.buf field to point to that buffer, and set the name.len field to the length of the buffer.

`addr`

A TNetbuf structure that specifies the location and size of a buffer containing the address associated with the entity whose name you want to register. You must allocate a buffer that contains the address, set the addr.buf field to point to that buffer, and set the addr.len field to the length of the buffer. The actual address with which the entity is associated is returned in the addr field of the TRegisterReply structure.

You can set the addr.len field to 0, in which case the underlying protocol finds an appropriate address to associate with the newly registered entity name.

`flags`

A field used to control registration. Normally, this field is set to 0 for default registration behavior. See the documentation for the naming service you are using for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TReply

```
struct TReply {
    TNetbuf data;
    TNetbuf opt;
    OTSequence sequence;
};
typedef struct TReply TReply;
```

Fields
`data`
`opt`
`sequence`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TRequest

```
struct TRequest {
    TNetbuf data;
    TNetbuf opt;
    OTSequence sequence;
};
typedef struct TRequest TRequest;
```

Fields
`data`
`opt`
`sequence`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TUDErr

In the event of failure of the `OTSndUData` function, points to information that explains why it failed.function (page 462) has failed.

```
struct TUDErr {
    TNetbuf addr;
    TNetbuf opt;
    SInt32 error;
};
typedef struct TUDErr TUDErr;
```

Fields

`addr`

A `TNetbuf` (page 2546) structure that contains information about the destination address of the data sent using the `OTSndUData` (page 2400) function. The `OTRcvUData` (page 2381) function fills in the buffer referenced by this structure when the function returns. You must allocate a buffer to contain the address, initialize the `addr.buf` field to point to it, and set the `addr.maxlen` field to specify its maximum size. If you are not interested in address information, set `addr.maxlen` to 0.

`opt`

A `TNetbuf` (page 2546) structure that contains information about the options associated with the data sent using the `OTSndUData` (page 2400)function. The `OTRcvUDErr` (page 2382) function fills in the buffer referenced by this structure when the function returns. If you want to know this information, you must allocate a buffer to contain the option data, initialize the `opt.buf` field to point to it, and initialize the `opt.maxlen` field to specify the maximum size of the buffer. If you are not interested in option information, set the `opt.maxlen` field to 0.

`error`

On return, this specifies a protocol-dependent error code for the `OTSndUData` (page 2400) function that failed.

Discussion

In the event of failure of the `OTSndUData` (page 2400)function, points to information that explains why it failed.You pass this structure as a parameter to the `OTRcvUData` (page 2381) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OpenTransport.h`

TUnitData

Describes the data being sent with the `OTSndUData` function and the data being read with the `OTRcvUData` function.function (page 467)

```
struct TUnitData {
    TNetbuf addr;
    TNetbuf opt;
    TNetbuf udata;
};
typedef struct TUnitData TUnitData;
```

Fields

`addr`

A `TNetbuf` structure for address information.

`opt`

A `TNetbuf` structure for option information.

`udata`
A `TNetbuf` structure for data.

Discussion
You use the `TUnitData` structure to describe the data being sent with the `OTSndUData` (page 2400) function and the data being read with the `OTRcvUData` (page 2381) function; you pass this structure as a parameter to each of these functions. When sending data you must initialize the `buf` and `len` fields of all the `TNetbuf` structures. When receiving data, you must initialize the `buf` and `maxlen` fields of all the `TNetbuf` structures.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TUnitReply

```
struct TUnitReply {
    TNetbuf opt;
    TNetbuf udata;
    OTSequence sequence;
};
typedef struct TUnitReply TUnitReply;
```

Fields
`opt`
`udata`
`sequence`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

TUnitRequest

```
struct TUnitRequest {
    TNetbuf addr;
    TNetbuf opt;
    TNetbuf udata;
    OTSequence sequence;
};
typedef struct TUnitRequest TUnitRequest;
```

Fields

`addr`

`opt`

`udata`

`sequence`

Discussion

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

uchar_p

```
typedef UInt8 uchar_p;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OpenTransport.h`

uid_t

```
typedef UInt32 uid_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`types.h`

uint_t

```
typedef  uint_t;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

ushort_p

```
typedef UInt16 ushort_p;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
OpenTransport.h

Constants

AF_8022

```
enum {
    AF_8022 = 8200
};
```

Constants
AF_8022
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

AF_ATALK_FAMILY

```
enum {
    AF_ATALK_FAMILY = 0x0100,
    AF_ATALK_DDP = 0x0100,
    AF_ATALK_DDPNBP = AF_ATALK_FAMILY + 1,
    AF_ATALK_NBP = AF_ATALK_FAMILY + 2,
    AF_ATALK_MNODE = AF_ATALK_FAMILY + 3
};
```

Constants
AF_ATALK_FAMILY
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

AF_ATALK_DDP
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

AF_ATALK_DDPNBP
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

`AF_ATALK_NBP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`AF_ATALK_MNODE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

AF_DNS

```
enum {
    AF_DNS = 42
};
```

Constants
`AF_DNS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

AF_INET

```
enum {
    AF_INET = 2
};
```

Constants
`AF_INET`

AF_ISDN

```
enum {
    AF_ISDN = 8192
};
```

Constants
`AF_ISDN`

ANYMARK

```
enum {
    ANYMARK = 0x01,
    LASTMARK = 0x02
};
```

Constants
`ANYMARK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`LASTMARK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

ATALK_IOC_FULLSELFSEND

```
enum {
    ATALK_IOC_FULLSELFSEND = ((MIOC_ATALK << 8) | 47),
    ADSP_IOC_FORWARDRESET = ((MIOC_ATALK << 8) | 60)
};
```

Constants

`ATALK_IOC_FULLSELFSEND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ADSP_IOC_FORWARDRESET`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

ATK_DDP

```
enum {
    ATK_DDP = 'DDP ',
    ATK_AARP = 'AARP',
    ATK_ATP = 'ATP ',
    ATK_ADSP = 'ADSP',
    ATK_ASP = 'ASP ',
    ATK_PAP = 'PAP ',
    ATK_NBP = 'NBP ',
    ATK_ZIP = 'ZIP '
};
```

Constants

`ATK_DDP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_AARP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_ATP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_ADSP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_ASP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_PAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_NBP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATK_ZIP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

BPRI_LO

```
enum {
    BPRI_LO = 1,
    BPRI_MED = 2,
    BPRI_HI = 3
};
```

Constants

`BPRI_LO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`BPRI_MED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`BPRI_HI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

CE_CONT

```
enum {
    CE_CONT = 0,
    CE_NOTE = 0,
    CE_WARN = 1,
    CE_PANIC = 2
};
```

Constants
`CE_CONT`
`CE_NOTE`
`CE_WARN`
`CE_PANIC`

CLONEOPEN

```
enum {
    CLONEOPEN = 0x02,
    MODOPEN = 0x01,
    OPENFAIL = -1
};
```

Constants
`CLONEOPEN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.
`MODOPEN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.
`OPENFAIL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

COM_ISDN

```
enum {
    COM_ISDN = 'ISDN'
};
```

Constants
`COM_ISDN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

COM_PPP

```
enum {
    COM_PPP = 'PPPC'
};
```

Constants

`COM_PPP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

COM_SERIAL

```
enum {
    COM_SERIAL = 'SERL'
};
```

Constants

`COM_SERIAL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

DDP_OPT_CHECKSUM

```
enum {
    DDP_OPT_CHECKSUM = 0x0600,
    DDP_OPT_SRCADDR = 0x2101,
    ATP_OPT_REPLYCNT = 0x2110,

    ATP_OPT_RELTIMER = 0x2112,
    ATP_OPT_TRANID = 0x2113,
    PAP_OPT_OPENRETRY = 0x2120
};
```

Constants

`DDP_OPT_CHECKSUM`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`DDP_OPT_SRCADDR`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`ATP_OPT_REPLYCNT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`ATP_OPT_DATALEN`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`ATP_OPT_RELTIMER`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ATP_OPT_TRANID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`PAP_OPT_OPENRETRY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

DDP_OPT_HOPCOUNT

```
enum {
    DDP_OPT_HOPCOUNT = 0x2100
};
```

Constants

`DDP_OPT_HOPCOUNT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

DL_ACCESS

```
enum {

Constants

`DL_INFO_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_INFO_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_ATTACH_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DETACH_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_BIND_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_BIND_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_UNBIND_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_OK_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_ERROR_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SUBS_BIND_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SUBS_BIND_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SUBS_UNBIND_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_ENABMULTI_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISABMULTI_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_PROMISCON_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_PROMISCOFF_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_UNITDATA_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_UNITDATA_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_UDERROR_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_UDQOS_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_CONNECT_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_CONNECT_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_CONNECT_RES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_CONNECT_CON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TOKEN_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TOKEN_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCONNECT_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCONNECT_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_RES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_CON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DATA_ACK_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DATA_ACK_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DATA_ACK_STATUS_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_STATUS_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_UPDATE_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_UPDATE_STATUS_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_XID_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_XID_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_XID_RES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_XID_CON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TEST_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TEST_IND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TEST_RES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_TEST_CON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_PHYS_ADDR_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_PHYS_ADDR_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SET_PHYS_ADDR_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_GET_STATISTICS_REQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_GET_STATISTICS_ACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_REPLY_UPDATE_STATUS_IND_SIZE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DL_IOC_HDR_INFO

```
enum {
    DL_IOC_HDR_INFO = ((MIOC_DLPI << 8) | 10)
};
```

Constants

`DL_IOC_HDR_INFO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DL_NONE

```
enum {
    DL_NONE = 0x0B01,
    DL_MONITOR = 0x0B02,
    DL_MAXIMUM = 0x0B03
};
```

Constants

`DL_NONE`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_MONITOR`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_MAXIMUM`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_PEER_BIND

```
enum {
    DL_PEER_BIND = 0x01,
    DL_HIERARCHICAL_BIND = 0x02
};
```

Constants

`DL_PEER_BIND`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_HIERARCHICAL_BIND`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_POLL_FINAL

```
enum {
    DL_POLL_FINAL = 0x01
};
```

Constants

`DL_POLL_FINAL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_PROMISC_OFF

```
enum {
    DL_PROMISC_OFF = 0
};
```

Constants

`DL_PROMISC_OFF`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

DL_PROMISC_PHYS

```
enum {
    DL_PROMISC_PHYS = 0x01,
    DL_PROMISC_SAP = 0x02,
    DL_PROMISC_MULTI = 0x03
};
```

Constants

`DL_PROMISC_PHYS`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_PROMISC_SAP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_PROMISC_MULTI`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_PROVIDER

```
enum {
    DL_PROVIDER = 0x0700,
    DL_USER = 0x0701
};
```

Constants

`DL_PROVIDER`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_USER`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_QOS_CO_RANGE1

```
enum {
    DL_QOS_CO_RANGE1 = 0x0101,
    DL_QOS_CO_SEL1 = 0x0102,
    DL_QOS_CL_RANGE1 = 0x0103,
    DL_QOS_CL_SEL1 = 0x0104
};
```

Constants

`DL_QOS_CO_RANGE1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_QOS_CO_SEL1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_QOS_CL_RANGE1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_QOS_CL_SEL1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DL_RESET_FLOW_CONTROL

```
enum {
    DL_RESET_FLOW_CONTROL = 0x0900,
    DL_RESET_LINK_ERROR = 0x0901,
    DL_RESET_RESYNCH = 0x0902
};
```

Constants

`DL_RESET_FLOW_CONTROL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_LINK_ERROR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_RESYNCH`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DL_RQST_RSP

```
enum {
    DL_RQST_RSP = 0x01,
    DL_RQST_NORSP = 0x02
};
```

Constants

`DL_RQST_RSP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_RQST_NORSP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_STYLE1

```
enum {
    DL_STYLE1 = 0x0500,
    DL_STYLE2 = 0x0501
};
```

Constants

`DL_STYLE1`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`DL_STYLE2`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

DL_UNATTACHED

```
enum {
    DL_UNATTACHED = 0x04,

Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_OUTCON_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_INCON_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_CONN_RES_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DATAXFER`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_USER_RESET_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_PROV_RESET_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_RESET_RES_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCON8_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCON9_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCON11_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCON12_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_DISCON13_PENDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SUBS_BIND_PND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_SUBS_UNBIND_PND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DL_UNKNOWN

```
enum {
    DL_UNKNOWN = -1,
    DL_QOS_DONT_CARE = -2
};
```

Constants

`DL_UNKNOWN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`DL_QOS_DONT_CARE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

DVMRP_INIT

```
enum {
    DVMRP_INIT = 100,
    DVMRP_DONE = 101,
    DVMRP_ADD_VIF = 102,
    DVMRP_DEL_VIF = 103,
    DVMRP_ADD_LGRP = 104,
    DVMRP_DEL_LGRP = 105,
    DVMRP_ADD_MRT = 106,
    DVMRP_DEL_MRT = 107
};
```

Constants

`DVMRP_INIT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_DONE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_ADD_VIF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_DEL_VIF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_ADD_LGRP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_DEL_LGRP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_ADD_MRT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`DVMRP_DEL_MRT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

EAddrType

```
typedef UInt32 EAddrType;

    keaStandardAddress = 0,
    keaMulticast = 1,
    keaBroadcast = 2,
    keaBadAddress = 3,
    keaRawPacketBit = 0x80000000,
    keaTimeStampBit = 0x40000000
};
```

Constants

`keaStandardAddress`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`keaMulticast`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`keaBroadcast`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`keaBadAddress`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`keaRawPacketBit`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`keaTimeStampBit`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

};
```

Constants

`I_SetSerialDTR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSetDTROff`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSetDTROn`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`I_SetSerialBreak`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSetBreakOn`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSetBreakOff`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`I_SetSerialXOffState`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialForceXOffTrue`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialForceXOffFalse`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`I_SetSerialXOn`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSendXOnAlways`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSendXOnIfXOffTrue`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`I_SetSerialXOff`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSendXOffAlways`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialSendXOffIfXOnTrue`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

I_TRCLOG

```
enum {
    I_TRCLOG = ((MIOC_STRLOG << 8) | 1),
    I_ERRLOG = ((MIOC_STRLOG << 8) | 2)
};
```

Constants

`I_TRCLOG`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`I_ERRLOG`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

INET_IP

```
enum {
    INET_IP = 0x00,
    INET_TCP = 0x06,
    INET_UDP = 0x11
};
```

Constants

`INET_IP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`INET_TCP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`INET_UDP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

INFPSZ

```
enum {
    INFPSZ = -1
};
```

Constants

`INFPSZ`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

INFTIM

```
enum {
    INFTIM = 0xFFFFFFFF
};
```

Constants

`INFTIM`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

IP_OPTIONS

```
enum {
    IP_OPTIONS = 1,
    IP_TOS = 2,
    IP_TTL = 3,
    IP_REUSEADDR = 4,
    IP_DONTROUTE = 16,
    IP_BROADCAST = 32,
    IP_REUSEPORT = 512,
    IP_HDRINCL = 4098,
    IP_RCVOPTS = 4101,
    IP_RCVDSTADDR = 4103,
    IP_MULTICAST_IF = 4112,
    IP_MULTICAST_TTL = 4113,
    IP_MULTICAST_LOOP = 4114,
    IP_ADD_MEMBERSHIP = 4115,
    IP_DROP_MEMBERSHIP = 4116,
    IP_BROADCAST_IFNAME = 4117,
    IP_RCVIFADDR = 4118
};
```

Constants

```
IP_OPTIONS
IP_TOS
IP_TTL
IP_REUSEADDR
IP_DONTROUTE
IP_BROADCAST
IP_REUSEPORT
IP_HDRINCL
IP_RCVOPTS
IP_RCVDSTADDR
IP_MULTICAST_IF
IP_MULTICAST_TTL
IP_MULTICAST_LOOP
IP_ADD_MEMBERSHIP
IP_DROP_MEMBERSHIP
IP_BROADCAST_IFNAME
IP_RCVIFADDR
```

IPCP_OPT_GETREMOTEPROTOADDR

```
enum {
    IPCP_OPT_GETREMOTEPROTOADDR = 0x00007000,

    LCP_OPT_ECHO = 0x00007017,
    CC_OPT_SERIALPORTNAME = 0x00007200
};
```

Constants

`IPCP_OPT_GETREMOTEPROTOADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`IPCP_OPT_GETLOCALPROTOADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`IPCP_OPT_TCPHDRCOMPRESSION`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LCP_OPT_PPPCOMPRESSION`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LCP_OPT_MRU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LCP_OPT_RCACCMAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LCP_OPT_TXACCMAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SEC_OPT_OUTAUTHENTICATION`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SEC_OPT_ID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SEC_OPT_PASSWORD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_REMINDERTIMER`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_IPIDLETIMER`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_DTEADDRESSTYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_DTEADDRESS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_CALLINFO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_GETMISCINFO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`PPP_OPT_GETCURRENTSTATE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LCP_OPT_ECHO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`CC_OPT_SERIALPORTNAME`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

ISDN_OPT_COMMTYPE

```
enum {
    ISDN_OPT_COMMTYPE = 0x0200,
    ISDN_OPT_FRAMINGTYPE = 0x0201,
    ISDN_OPT_56KADAPTATION = 0x0202
};
```

Constants

`ISDN_OPT_COMMTYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ISDN_OPT_FRAMINGTYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`ISDN_OPT_56KADAPTATION`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

k8022BasicAddressLength

```
enum {
    k8022BasicAddressLength = sizeof(OTAddressType) + k48BitAddrLength
+ sizeof(UInt16),
    k8022SNAPAddressLength = sizeof(OTAddressType) + k48BitAddrLength
+ sizeof(UInt16) + k8022SNAPLength
};
```

Constants

`k8022BasicAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`k8022SNAPAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kAF_ISDN

```
enum {
    kAF_ISDN = 0x2000
};
```

Constants

`kAF_ISDN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kAllATalkRoutersDown

```
enum {
    kAllATalkRoutersDown = 0,
    kLocalATalkRoutersDown = -1L,
    kARARouterDisconnected = -2L
};
```

Constants

`kAllATalkRoutersDown`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kLocalATalkRoutersDown`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kARARouterDisconnected`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kAllDHCPOptions

```
enum {
    kAllDHCPOptions = -1,
    kDHCPLongOption = 126,
    kDHCPLongOptionReq = 127
};
```

Constants

`kAllDHCPOptions`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kDHCPLongOption`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kDHCPLongOptionReq`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kAppleTalkEvent

```
enum {
    kAppleTalkEvent = kPROTOCOLEVENT | 0x00010000,
    T_GETMYZONECOMPLETE = kAppleTalkEvent + 1,
    T_GETLOCALZONESCOMPLETE = kAppleTalkEvent + 2,
    T_GETZONELISTCOMPLETE = kAppleTalkEvent + 3,
    T_GETATALKINFOCOMPLETE = kAppleTalkEvent + 4,
    T_ATALKROUTERDOWNEVENT = kAppleTalkEvent + 51,
    T_ATALKROUTERUPEVENT = kAppleTalkEvent + 52,
    T_ATALKZONENAMECHANGEDEVENT = kAppleTalkEvent + 53,
    T_ATALKCONNECTIVITYCHANGEDEVENT = kAppleTalkEvent + 54,
    T_ATALKINTERNETAVAILABLEEVENT = kAppleTalkEvent + 55,
    T_ATALKCABLERANGECHANGEDEVENT = kAppleTalkEvent + 56
};
```

Constants

`kAppleTalkEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_GETMYZONECOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_GETLOCALZONESCOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_GETZONELISTCOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_GETATALKINFOCOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKROUTERDOWNEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKROUTERUPEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKZONENAMECHANGEDEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKCONNECTIVITYCHANGEDEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKINTERNETAVAILABLEEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ATALKCABLERANGECHANGEDEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kARARouterOnline

```
enum {
    kARARouterOnline = -1L,
    kATalkRouterOnline = 0,
    kLocalATalkRouterOnline = -2L
};
```

Constants

`kARARouterOnline`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kATalkRouterOnline`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kLocalATalkRouterOnline`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kATalkInfoIsExtended

```
enum {
    kATalkInfoIsExtended = 0x0001,
    kATalkInfoHasRouter = 0x0002,
    kATalkInfoOneZone = 0x0004
};
```

Constants

`kATalkInfoIsExtended`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kATalkInfoHasRouter`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kATalkInfoOneZone`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kCCReminderTimerDisabled

```
enum {
    kCCReminderTimerDisabled = 0,
    kCCIPIdleTimerDisabled = 0
};
```

Constants

`kCCReminderTimerDisabled`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kCCIPIdleTimerDisabled`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kDDPAddressLength

```
enum {
    kDDPAddressLength = 8,
    kNBPAddressLength = kNBPEntityBufferSize,
    kAppleTalkAddressLength = kDDPAddressLength + kNBPEntityBufferSize
};
```

Constants

`kDDPAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kAppleTalkAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kDefaultAppleTalkServicesPath

```
enum {
    kDefaultAppleTalkServicesPath = -3
};
```

Constants
`kDefaultAppleTalkServicesPath`

kDefaultInetInterface

```
enum {
    kDefaultInetInterface = -1
};
```

Constants
`kDefaultInetInterface`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kDefaultInternetServicesPath

```
enum {
    kDefaultInternetServicesPath = -3
};
```

Constants
`kDefaultInternetServicesPath`

kE164Address

```
enum {
    kE164Address = 1,
    kPhoneAddress = 1,
    kCompoundPhoneAddress = 2,
    kX121Address = 3
};
```

Constants
`kE164Address`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPhoneAddress`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kCompoundPhoneAddress`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kX121Address`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kECHO_TSDU

```
enum {
    kECHO_TSDU = 585
};
```

Constants
`kECHO_TSDU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kEnetPacketHeaderLength

```
enum {
    kEnetPacketHeaderLength = (2 * k48BitAddrLength) + k8022DLSAPLength,
    kEnetTSDU = 1514,
    kTokenRingTSDU = 4458,
    kFDDITSDU = 4458,
    k8022SAPLength = 1,
    k8022BasicHeaderLength = 3,
    k8022SNAPHeaderLength = k8022SNAPLength + k8022BasicHeaderLength
};
```

Constants

`kEnetPacketHeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kEnetTSDU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kTokenRingTSDU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kFDDITSDU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`k8022SAPLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`k8022BasicHeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`k8022SNAPHeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kFirstMinorNumber

```
enum {
    kFirstMinorNumber = 10
};
```

Constants
`kFirstMinorNumber`

kInetInterfaceInfoVersion

```
enum {
    kInetInterfaceInfoVersion = 3
};
```

Constants
`kInetInterfaceInfoVersion`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kIP_OPTIONS

```
enum {
    kIP_OPTIONS = 0x01,
    kIP_TOS = 0x02,
    kIP_TTL = 0x03,
    kIP_REUSEADDR = 0x04,
    kIP_DONTROUTE = 0x10,
    kIP_BROADCAST = 0x20,
    kIP_REUSEPORT = 0x0200,
    kIP_HDRINCL = 0x1002,
    kIP_RCVOPTS = 0x1005,
    kIP_RCVDSTADDR = 0x1007,
    kIP_MULTICAST_IF = 0x1010,
    kIP_MULTICAST_TTL = 0x1011,
    kIP_MULTICAST_LOOP = 0x1012,
    kIP_ADD_MEMBERSHIP = 0x1013,
    kIP_DROP_MEMBERSHIP = 0x1014,
    kIP_BROADCAST_IFNAME = 0x1015,
    kIP_RCVIFADDR = 0x1016
};
```

Constants
`kIP_OPTIONS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_TOS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_TTL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_REUSEADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_DONTROUTE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_BROADCAST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_REUSEPORT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_HDRINCL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_RCVOPTS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_RCVDSTADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_MULTICAST_IF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_MULTICAST_TTL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_MULTICAST_LOOP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_ADD_MEMBERSHIP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_DROP_MEMBERSHIP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_BROADCAST_IFNAME`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIP_RCVIFADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kIPCPTCPHdrCompressionDisabled

```
enum {
    kIPCPTCPHdrCompressionDisabled = 0,
    kIPCPTCPHdrCompressionEnabled = 1
};
```

Constants

`kIPCPTCPHdrCompressionDisabled`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIPCPTCPHdrCompressionEnabled`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kISDNModuleID

```
enum {
    kISDNModuleID = 7300
};
```

Constants

`kISDNModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kMaxHostAddrs

```
enum {
    kMaxHostAddrs = 10,
    kMaxSysStringLen = 32,
    kMaxHostNameLen = 255
};
```

Constants

`kMaxHostAddrs`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kMaxSysStringLen`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kMaxHostNameLen`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Port-Related Constants

Provide length and size values for modules, provider names, and slot IDs.

```
enum {
    kMaxModuleNameLength = 31,
    kMaxModuleNameSize = kMaxModuleNameLength + 1,
    kMaxProviderNameLength = kMaxModuleNameLength + 4,
    kMaxProviderNameSize = kMaxProviderNameLength + 1,
    kMaxSlotIDLength = 7,
    kMaxSlotIDSize = kMaxSlotIDLength + 1,
    kMaxResourceInfoLength = 31,
    kMaxResourceInfoSize = 32,
    kMaxPortNameLength = kMaxModuleNameLength + 4,
    kMaxPortNameSize = kMaxPortNameLength + 1
};
```

Constants

`kMaxModuleNameLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxModuleNameSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxProviderNameLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxProviderNameSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxSlotIDLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxSlotIDSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxResourceInfoLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxResourceInfoSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kMaxPortNameLength`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kMaxPortNameSize`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

Discussion
These constants provide length and size values for modules, provider names, and slot IDs. These fields all end with a byte for the terminating zero. The constant kMaxProviderNameSize permits a length of 36 bytes: 31 bytes for the name, up to 4 bytes of extra characters (called minor numbers in STREAMS specifications, and currently not used), and a byte for the zero that terminates the string.

kMaxServices

```
enum {
    kMaxServices = 20
};
```

Constants
`kMaxServices`

kMulticastLength

```
enum {
    kMulticastLength = 6,
    k48BitAddrLength = 6,
    k8022DLSAPLength = 2,
    k8022SNAPLength = 5,
    kEnetAddressLength = k48BitAddrLength + k8022DLSAPLength,
    kSNAPSAP = 0x00AA,
    kIPXSAP = 0x00FF,
    kMax8022SAP = 0x00FE,
    k8022GlobalSAP = 0x00FF,
    kMinDIXSAP = 1501,
    kMaxDIXSAP = 0xFFFF
};
```

Constants
`kMulticastLength`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`k48BitAddrLength`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`k8022DLSAPLength`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`k8022SNAPLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kEnetAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kSNAPSAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kIPXSAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kMax8022SAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`k8022GlobalSAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kMinDIXSAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kMaxDIXSAP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kNBPMaxNameLength

```
enum {
    kNBPMaxNameLength = 32,
    kNBPMaxTypeLength = 32,
    kNBPMaxZoneLength = 32,
    kNBPSlushLength = 9,
    kNBPMaxEntityLength = (kNBPMaxNameLength + kNBPMaxTypeLength
+ kNBPMaxZoneLength + 3),
    kNBPEntityBufferSize = (kNBPMaxNameLength + kNBPMaxTypeLength
+ kNBPMaxZoneLength + kNBPSlushLength),
    kNBPWildCard = 0x3D,
    kNBPImbeddedWildCard = 0xC5,
    kNBPDefaultZone = 0x2A
};
```

Constants

`kNBPMaxNameLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPMaxTypeLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPMaxZoneLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPSlushLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPMaxEntityLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPEntityBufferSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPWildCard`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPImbeddedWildCard`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kNBPDefaultZone`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kNetbufDataIsOTData

```
enum {
    kNetbufDataIsOTData = 0xFFFFFFFE
};
```

Constants

`kNetbufDataIsOTData`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kO_ASYNC

Constants

kOTAnyInetAddress

```
enum {
    kOTAnyInetAddress = 0
};
```

Constants

`kOTAnyInetAddress`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTAutopushMax

```
enum {
    kOTAutopushMax = 8
};
```

Constants

`kOTAutopushMax`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

kOTCFMClass

```
enum {
    kOTCFMClass = 'otan'
};
```

Constants

`kOTCFMClass`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kOTDefaultConfigurator

```
enum {
    kOTDefaultConfigurator = 0,
    kOTProtocolFamilyConfigurator = 1,
    kOTLinkDriverConfigurator = 2
};
```

Constants

`kOTDefaultConfigurator`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTProtocolFamilyConfigurator`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTLinkDriverConfigurator`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

kOTFLUSHBAND

```
enum {
    kOTFLUSHBAND = 0x40
};
```

Constants
`kOTFLUSHBAND`

Port Framing Capabilities

Describe a port's framing capabilities.

```
enum {
    kOTFramingEthernet = 0x01,
    kOTFramingEthernetIPX = 0x02,
    kOTFraming8023 = 0x04,
    kOTFraming8022 = 0x08
};
```

Constants
`kOTFramingEthernet`
The port can use standard Ethernet framing.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTFramingEthernetIPX`
The port can use IPX Ethernet framing.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTFraming8023`
The port can use 802.3 Ethernet framing.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTFraming8022`
The port can use 802.2 Ethernet framing.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Discussion
This enumeration contains flags indicating the type of framing capability that a port has. If the port can handle only one type of framing, this field is 0. This field is dependent on the ports device type.

kOTGenericName

```
enum {
    kOTGenericName = 0
};
```

Constants

`kOTGenericName`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kOTGetDataSymbol

```
enum {
    kOTGetDataSymbol = 0,
    kOTGetCodeSymbol = 1,
    kOTLoadNewCopy = 2,
    kOTLoadACopy = 4,
    kOTFindACopy = 8,
    kOTLibMask = kOTLoadNewCopy | kOTLoadACopy | kOTFindACopy,
    kOTLoadLibResident = 0x20
};
```

Constants

`kOTGetDataSymbol`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTGetCodeSymbol`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTLoadNewCopy`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTLoadACopy`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTFindACopy`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTLibMask`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTLoadLibResident`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

kOTInitialScan

```
enum {
    kOTInitialScan = 0,
    kOTScanAfterSleep = 1
};
```

Constants

`kOTInitialScan`

`kOTScanAfterSleep`

kOTInvalidPortRef

```
enum {
    kOTInvalidPortRef = 0
};
```

Constants

`kOTInvalidPortRef`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

kOTInvalidRef

```
enum {
    kOTInvalidRef = 0,
    kOTInvalidProviderRef = 0,
    kOTInvalidEndpointRef = 0,
    kOTInvalidMapperRef = 0
};
```

Constants
`kOTInvalidRef`
`kOTInvalidProviderRef`
`kOTInvalidEndpointRef`
`kOTInvalidMapperRef`

kOTInvalidStreamRef

```
enum {
    kOTInvalidStreamRef = 0
};
```

Constants
`kOTInvalidStreamRef`

kOTISDNDefaultCommType

```
enum {
    kOTISDNDefaultCommType = kOTISDNDigital64k,
    kOTISDNDefaultFramingType = kOTISDNFramingHDLC,
    kOTISDNDefault56KAdaptation = kOTISDNNot56KAdaptation
};
```

Constants
`kOTISDNDefaultCommType`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNDefaultFramingType`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNDefault56KAdaptation`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTISDNFramingTransparent

```
enum {
    kOTISDNFramingTransparent = 0x0010,
    kOTISDNFramingHDLC = 0x0020,
    kOTISDNFramingV110 = 0x0040,
    kOTISDNFramingV14E = 0x0080
};
```

Constants

`kOTISDNFramingTransparent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingHDLC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingV110`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingV14E`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTISDNFramingTransparentSupported

```
enum {
    kOTISDNFramingTransparentSupported = 0x0010,
    kOTISDNFramingHDLCSupported = 0x0020,
    kOTISDNFramingV110Supported = 0x0040,
    kOTISDNFramingV14ESupported = 0x0080
};
```

Constants

`kOTISDNFramingTransparentSupported`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingHDLCSupported`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingV110Supported`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFramingV14ESupported`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTISDNMaxPhoneSize

```
enum {
    kOTISDNMaxPhoneSize = 32,
    kOTISDNMaxSubSize = 4
};
```

Constants

`kOTISDNMaxPhoneSize`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNMaxSubSize`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

kOTISDNMaxUserDataSize

```
enum {
    kOTISDNMaxUserDataSize = 32
};
```

Constants

`kOTISDNMaxUserDataSize`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

kOTISDNNot56KAdaptation

```
enum {
    kOTISDNNot56KAdaptation = false,
    kOTISDN56KAdaptation = true
};
```

Constants

`kOTISDNNot56KAdaptation`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDN56KAdaptation`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

kOTISDNTelephoneALaw

```
enum {
    kOTISDNTelephoneALaw = 1,
    kOTISDNTelephoneMuLaw = 26,
    kOTISDNDigital64k = 13,
    kOTISDNDigital56k = 37,
    kOTISDNVideo64k = 41,
    kOTISDNVideo56k = 42
};
```

Constants

`kOTISDNTelephoneALaw`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNTelephoneMuLaw`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNDigital64k`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNDigital56k`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNVideo64k`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNVideo56k`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTISDNUnallocatedNumber

```
enum {
    kOTISDNUnallocatedNumber = 1,
    kOTISDNNoRouteToSpecifiedTransitNetwork = 2,
    kOTISDNNoRouteToDestination = 3,
    kOTISDNChannelUnacceptable = 6,
    kOTISDNNormal = 16,
    kOTISDNUserBusy = 17,
    kOTISDNNoUserResponding = 18,
    kOTISDNNoAnswerFromUser = 19,
    kOTISDNCallRejected = 21,
    kOTISDNNumberChanged = 22,
    kOTISDNNonSelectedUserClearing = 26,
    kOTISDNDestinationOutOfOrder = 27,
    kOTISDNInvalidNumberFormat = 28,
    kOTISDNFacilityRejected = 29,
    kOTISDNNormalUnspecified = 31,
    kOTISDNNoCircuitChannelAvailable = 34,
    kOTISDNNetworkOutOfOrder = 41,
    kOTISDNSwitchingEquipmentCongestion = 42,
    kOTISDNAccessInformationDiscarded = 43,
    kOTISDNRequestedCircuitChannelNotAvailable = 44,
    kOTISDNResourceUnavailableUnspecified = 45,
    kOTISDNQualityOfServiceUnvailable = 49,
    kOTISDNRequestedFacilityNotSubscribed = 50,
    kOTISDNBearerCapabilityNotAuthorized = 57,
    kOTISDNBearerCapabilityNotPresentlyAvailable = 58,
    kOTISDNCallRestricted = 59,
    kOTISDNServiceOrOptionNotAvilableUnspecified = 63,
    kOTISDNBearerCapabilityNotImplemented = 65,
    kOTISDNRequestedFacilityNotImplemented = 69,
    kOTISDNOnlyRestrictedDigitalBearer = 70,
    kOTISDNServiceOrOptionNotImplementedUnspecified = 79,
    kOTISDNCallIdentityNotUsed = 83,
    kOTISDNCallIdentityInUse = 84,
    kOTISDNNoCallSuspended = 85,
    kOTISDNCallIdentityCleared = 86,
    kOTISDNIncompatibleDestination = 88,
    kOTISDNInvalidTransitNetworkSelection = 91,
    kOTISDNInvalidMessageUnspecified = 95,
    kOTISDNMandatoryInformationElementIsMissing = 96,
    kOTISDNMessageTypeNonExistentOrNotImplemented = 97,
    kOTISDNInterworkingUnspecified = 127
};
```

Constants

`kOTISDNUnallocatedNumber`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNNoRouteToSpecifiedTransitNetwork`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNNoRouteToDestination`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNChannelUnacceptable`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNormal`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNUserBusy`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNoUserResponding`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNoAnswerFromUser`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNCallRejected`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNumberChanged`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNonSelectedUserClearing`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNDestinationOutOfOrder`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNInvalidNumberFormat`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNFacilityRejected`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNormalUnspecified`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNoCircuitChannelAvailable`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNNetworkOutOfOrder`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNSwitchingEquipmentCongestion`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNAccessInformationDiscarded`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNRequestedCircuitChannelNotAvailable`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNResourceUnavailableUnspecified`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNQualityOfServiceUnvailable`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNRequestedFacilityNotSubscribed`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNBearerCapabilityNotAuthorized`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNBearerCapabilityNotPresentlyAvailable`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNCallRestricted`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNServiceOrOptionNotAvilableUnspecified`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNBearerCapabilityNotImplemented`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNRequestedFacilityNotImplemented`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNOnlyRestrictedDigitalBearer`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTISDNServiceOrOptionNotImplementedUnspecified`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNCallIdentityNotUsed`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNCallIdentityInUse`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNNoCallSuspended`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNCallIdentityCleared`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNIncompatibleDestination`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNInvalidTransitNetworkSelection`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNInvalidMessageUnspecified`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNMandatoryInformationElementIsMissing`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNMessageTypeNonExistentOrNotImplemented`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTISDNInterworkingUnspecified`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

kOTLastSlotNumber

```
enum {
    kOTLastSlotNumber = 255,
    kOTLastOtherNumber = 255
};
```

Constants

`kOTLastSlotNumber`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTLastOtherNumber`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

kOTLvlFatal

```
enum {
    kOTLvlFatal = 0,
    kOTLvlNonfatal = 1,
    kOTLvlExtFatal = 2,
    kOTLvlExtNonfatal = 3,
    kOTLvlUserErr = 4,
    kOTLvlInfoErr = 5,
    kOTLvlInfoOnly = 6
};
```

Constants
kOTLvlFatal
kOTLvlNonfatal
kOTLvlExtFatal
kOTLvlExtNonfatal
kOTLvlUserErr
kOTLvlInfoErr
kOTLvlInfoOnly

kOTMinimumTimerValue

```
enum {
    kOTMinimumTimerValue = 8
};
```

Constants
kOTMinimumTimerValue

kOTModIsDriver

```
enum {
    kOTModIsDriver = 1,
    kOTModIsModule = 2,
    kOTModNoWriter = 16,
    kOTModUpperIsTPI = 4096,
    kOTModUpperIsDLPI = 8192,
    kOTModLowerIsTPI = 16384,
    kOTModLowerIsDLPI = 32768,
    kOTModGlobalContext = 8388608,
    kOTModUsesInterrupts = 134217728,
    kOTModIsComplexDriver = 536870912,
    kOTModIsFilter = 1073741824
};
```

Constants
kOTModIsDriver
kOTModIsModule
kOTModNoWriter
kOTModUpperIsTPI
kOTModUpperIsDLPI
kOTModLowerIsTPI

```
kOTModLowerIsDLPI
kOTModGlobalContext
kOTModUsesInterrupts
kOTModIsComplexDriver
kOTModIsFilter
```

kOTNetbufDataIsOTBufferStar

```
enum {
    kOTNetbufDataIsOTBufferStar = 0xFFFFFFFD
};
```

Constants

`kOTNetbufDataIsOTBufferStar`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

kOTNetbufIsRawMode

```
enum {
    kOTNetbufIsRawMode = 0xFFFFFFFF
};
```

Constants

`kOTNetbufIsRawMode`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

kOTNoMemoryConfigurationPtr

```
enum {
    kOTNoMemoryConfigurationPtr = 0,
    kOTInvalidConfigurationPtr = -1
};
```

Constants

`kOTNoMemoryConfigurationPtr`

`kOTInvalidConfigurationPtr`

kOTNoMessagesAvailable

```
enum {
    kOTNoMessagesAvailable = 0xFFFFFFFF,
    kOTAnyMsgType = 0xFFFFFFFE,
    kOTDataMsgTypes = 0xFFFFFFFC,
    kOTMProtoMsgTypes = 0xFFFFFFFB,
    kOTOnlyMProtoMsgTypes = 0xFFFFFFFA
};
```

Constants

`kOTNoMessagesAvailable`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`kOTAnyMsgType`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`kOTDataMsgTypes`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`kOTMProtoMsgTypes`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`kOTOnlyMProtoMsgTypes`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

kOTOptionHeaderSize

```
enum {
    kOTOptionHeaderSize = sizeof(TOptionHeader),
    kOTBooleanOptionDataSize = sizeof(UInt32),
    kOTBooleanOptionSize = kOTOptionHeaderSize + kOTBooleanOptionDataSize,
    kOTOneByteOptionSize = kOTOptionHeaderSize + 1,
    kOTTwoByteOptionSize = kOTOptionHeaderSize + 2,
    kOTFourByteOptionSize = kOTOptionHeaderSize + sizeof(UInt32)
};
```

Constants

`kOTOptionHeaderSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTBooleanOptionDataSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTBooleanOptionSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTOneByteOptionSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTTwoByteOptionSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFourByteOptionSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kOTPCINoErrorStayLoaded

```
enum {
    kOTPCINoErrorStayLoaded = 1
};
```

Constants

`kOTPCINoErrorStayLoaded`

Port Flags

Specify a port's status.

```
enum {
    kOTPortIsActive = 0x00000001,
    kOTPortIsDisabled = 0x00000002,
    kOTPortIsUnavailable = 0x00000004,
    kOTPortIsOffline = 0x00000008
};
```

Constants

`kOTPortIsActive`
The port is in use.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsDisabled`
The port may or may not be in use, but no other client can use it.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsUnavailable`
The port is not available for use.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsOffline`
The port is off-line. This bit is typically only set when the port is active, the port autoconnects, and it is currently not connected.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

Port Additional Flags

Specify additional information about a port.

```
enum {
    kOTPortIsDLPI = 0x00000001,
    kOTPortIsTPI = 0x00000002,
    kOTPortCanYield = 0x00000004,
    kOTPortCanArbitrate = 0x00000008,
    kOTPortIsTransitory = 0x00000010,
    kOTPortAutoConnects = 0x00000020,
    kOTPortIsSystemRegistered = 0x00004000,
    kOTPortIsPrivate = 0x00008000,
    kOTPortIsAlias = 0x80000000
};
```

Constants

`kOTPortIsDLPI`
The port driver is a DLPI STREAMS module.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsTPI`
The port driver is a TPI STREAMS module.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortCanYield`
The port can yield when requested.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortCanArbitrate`
Reserved.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsTransitory`
The port has off-line/on-line status.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortAutoConnects`
The port auto connects. The port goes on-line and off-line on demand. ISDN is a typical example.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsSystemRegistered`
The port was registered by the system from the Name Registry
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsPrivate`
The port is private.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortIsAlias`
The port is an alias for another port.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kOTPrintOnly

```
enum {
    kOTPrintOnly = 0,
    kOTPrintThenStop = 1
};
```

Constants

`kOTPrintOnly`

`kOTPrintThenStop`

kOTRawRcvOn

```
enum {
    kOTRawRcvOn = 0,
    kOTRawRcvOff = 1,
    kOTRawRcvOnWithTimeStamp = 2
};
```

Constants

`kOTRawRcvOn`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTRawRcvOff`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTRawRcvOnWithTimeStamp`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

kOTSerialDefaultBaudRate

```
enum {
    kOTSerialDefaultBaudRate = 19200,
    kOTSerialDefaultDataBits = 8,
    kOTSerialDefaultStopBits = 10,
    kOTSerialDefaultParity = kOTSerialNoParity,
    kOTSerialDefaultHandshake = 0,
    kOTSerialDefaultOnChar = ('Q' & 0xFFFFFFBF),
    kOTSerialDefaultOffChar = ('S' & 0xFFFFFFBF),
    kOTSerialDefaultSndBufSize = 1024,
    kOTSerialDefaultRcvBufSize = 1024,
    kOTSerialDefaultSndLoWat = 96,
    kOTSerialDefaultRcvLoWat = 1,
    kOTSerialDefaultRcvTimeout = 10
};
```

Constants

`kOTSerialDefaultBaudRate`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultDataBits`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultStopBits`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultParity`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultHandshake`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultOnChar`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultOffChar`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultSndBufSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultRcvBufSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultSndLoWat`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultRcvLoWat`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDefaultRcvTimeout`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTSerialFramingAsync

```
enum {
    kOTSerialFramingAsync = 0x01,
    kOTSerialFramingHDLC = 0x02,
    kOTSerialFramingSDLC = 0x04,
    kOTSerialFramingAsyncPackets = 0x08,
    kOTSerialFramingPPP = 0x10
};
```

Constants

`kOTSerialFramingAsync`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialFramingHDLC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialFramingSDLC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialFramingAsyncPackets`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialFramingPPP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTSerialSwOverRunErr

```
enum {
    kOTSerialSwOverRunErr = 0x01,
    kOTSerialBreakOn = 0x08,
    kOTSerialParityErr = 0x10,
    kOTSerialOverrunErr = 0x20,
    kOTSerialFramingErr = 0x40,
    kOTSerialXOffSent = 0x00010000,
    kOTSerialDTRNegated = 0x00020000,
    kOTSerialCTLHold = 0x00040000,
    kOTSerialXOffHold = 0x00080000,
    kOTSerialOutputBreakOn = 0x01000000
};
```

Constants

`kOTSerialSwOverRunErr`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialBreakOn`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialParityErr`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialOverrunErr`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialFramingErr`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialXOffSent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDTRNegated`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialCTLHold`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialXOffHold`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialOutputBreakOn`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTSerialXOnOffInputHandshake

```
enum {
    kOTSerialXOnOffInputHandshake = 1,
    kOTSerialXOnOffOutputHandshake = 2,
    kOTSerialCTSInputHandshake = 4,
    kOTSerialDTROutputHandshake = 8
};
```

Constants

`kOTSerialXOnOffInputHandshake`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialXOnOffOutputHandshake`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialCTSInputHandshake`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kOTSerialDTROutputHandshake`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kOTSpecificConfigPass

```
enum {
    kOTSpecificConfigPass = 0,
    kOTGenericConfigPass = 1
};
```

Constants

`kOTSpecificConfigPass`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kOTGenericConfigPass`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

kOTT_BIND_REQ

```
enum {
    kOTT_BIND_REQ = 101,
    kOTT_CONN_REQ = 102,
    kOTT_CONN_RES = 103,

    kOTT_MIB_REQ = 81,
    kOTT_MIB_ACK = 82,
    kOTT_PRIVATE_REQ = 90
```

```
};
```

Constants
kOTT_TIMER_REQ
kOTT_MIB_REQ
kOTT_MIB_ACK
kOTT_PRIVATE_REQ

kOTTRANSPARENT

```
enum {
    kOTTRANSPARENT = 0xFFFFFFFF
};
```

Constants
kOTTRANSPARENT

kPPPAsyncMapCharsNone

```
enum {
    kPPPAsyncMapCharsNone = 0x00000000,
    kPPPAsyncMapCharsXOnXOff = 0x000A0000,
    kPPPAsyncMapCharsAll = 0xFFFFFFFF
};
```

Constants
kPPPAsyncMapCharsNone
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.
kPPPAsyncMapCharsXOnXOff
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.
kPPPAsyncMapCharsAll
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

kPPPCompressionDisabled

```
enum {
    kPPPCompressionDisabled = 0x00000000,
    kPPPProtoCompression = 0x00000001,
    kPPPAddrCompression = 0x00000002
};
```

Constants
kPPPCompressionDisabled
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProviders.h.

`kPPPProtoCompression`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPAddrCompression`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPConnectionStatusDialogsFlag

```
enum {
    kPPPConnectionStatusDialogsFlag = 0x00000001,
    kPPPConnectionRemindersFlag = 0x00000002,
    kPPPConnectionFlashingIconFlag = 0x00000004,
    kPPPOutPasswordDialogsFlag = 0x00000008,
    kPPPAllAlertsDisabledFlag = 0x00000000,
    kPPPAllAlertsEnabledFlag = 0x0000000F
};
```

Constants

`kPPPConnectionStatusDialogsFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectionRemindersFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectionFlashingIconFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPOutPasswordDialogsFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPAllAlertsDisabledFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPAllAlertsEnabledFlag`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPConnectionStatusIdle

```
enum {
    kPPPConnectionStatusIdle = 1,
    kPPPConnectionStatusConnecting = 2,
    kPPPConnectionStatusConnected = 3,
    kPPPConnectionStatusDisconnecting = 4
};
```

Constants

`kPPPConnectionStatusIdle`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectionStatusConnecting`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectionStatusConnected`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectionStatusDisconnecting`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPEvent

```
enum {
    kPPPEvent = kPROTOCOLEVENT | 0x000F0000,
    kPPPConnectCompleteEvent = kPPPEvent + 1,
    kPPPSetScriptCompleteEvent = kPPPEvent + 2,
    kPPPDisconnectCompleteEvent = kPPPEvent + 3,
    kPPPDisconnectEvent = kPPPEvent + 4,
    kPPPIPCPUpEvent = kPPPEvent + 5,
    kPPPIPCPDownEvent = kPPPEvent + 6,
    kPPPLCPUpEvent = kPPPEvent + 7,
    kPPPLCPDownEvent = kPPPEvent + 8,
    kPPPLowerLayerUpEvent = kPPPEvent + 9,
    kPPPLowerLayerDownEvent = kPPPEvent + 10,
    kPPPAuthenticationStartedEvent = kPPPEvent + 11,
    kPPPAuthenticationFinishedEvent = kPPPEvent + 12,
    kPPPDCEInitStartedEvent = kPPPEvent + 13,
    kPPPDCEInitFinishedEvent = kPPPEvent + 14,
    kPPPDCECallStartedEvent = kPPPEvent + 15,
    kPPPDCECallFinishedEvent = kPPPEvent + 16
};
```

Constants

`kPPPEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPConnectCompleteEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPSetScriptCompleteEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDisconnectCompleteEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDisconnectEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPIPCPUpEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPIPCPDownEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPLCPUpEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPLCPDownEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPLowerLayerUpEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPLowerLayerDownEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPAuthenticationStartedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPAuthenticationFinishedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDCEInitStartedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDCEInitFinishedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDCECallStartedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPDCECallFinishedEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPMaxIDLength

```
enum {
    kPPPMaxIDLength = 255,
    kPPPMaxPasswordLength = 255,
    kPPPMaxDTEAddressLength = 127,
    kPPPMaxCallInfoLength = 255
};
```

Constants

`kPPPMaxIDLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPMaxPasswordLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPMaxDTEAddressLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPMaxCallInfoLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPMinMRU

```
enum {
    kPPPMinMRU = 0,
    kPPPMaxMRU = 4500
};
```

Constants

`kPPPMinMRU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPMaxMRU`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPNoOutAuthentication

```
enum {
    kPPPNoOutAuthentication = 0,
    kPPPCHAPOrPAPOutAuthentication = 1
};
```

Constants

`kPPPNoOutAuthentication`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPCHAPOrPAPOutAuthentication`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPScriptTypeModem

```
enum {
    kPPPScriptTypeModem = 1,
    kPPPScriptTypeConnect = 2,
    kPPPMaxScriptSize = 32000
};
```

Constants

`kPPPScriptTypeModem`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPScriptTypeConnect`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPMaxScriptSize`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kPPPStateInitial

```
enum {
    kPPPStateInitial = 1,
    kPPPStateClosed = 2,
    kPPPStateClosing = 3,
    kPPPStateOpening = 4,
    kPPPStateOpened = 5
};
```

Constants

`kPPPStateInitial`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPStateClosed`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPStateClosing`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPStateOpening`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kPPPStateOpened`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kRAProductClientOnly

```
enum {
    kRAProductClientOnly = 2,
    kRAProductOnePortServer = 3,
    kRAProductManyPortServer = 4
};
```

Constants

`kRAProductClientOnly`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kRAProductOnePortServer`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kRAProductManyPortServer`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kSAP_ONE

```
enum {
    kSAP_ONE = 1,
    kSAP_RANGE = 2,
    kSAP_ALL = 3,
    kSAP_CLEAR = 4
};
```

Constants

`kSAP_ONE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kSAP_RANGE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kSAP_ALL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`kSAP_CLEAR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

kSerialABModuleID

```
enum {
    kSerialABModuleID = 7200
};
```

Constants

`kSerialABModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kSIGHUP

```
enum {
    kSIGHUP = 1,
    kSIGURG = 16,
    kSIGPOLL = 30
};
```

Constants

`kSIGHUP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kSIGURG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kSIGPOLL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kT_UNSPEC

```
enum {
    kT_UNSPEC = 0xFFFFFFFD,
    T_ALLOPT = 0
};
```

Constants

`kT_UNSPEC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_ALLOPT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

kT8022HeaderLength

```
enum {
    kT8022HeaderLength = 3,
    kT8022SNAPHeaderLength = 3 + k8022SNAPLength,
   kT8022FullPacketHeaderLength = kEnetPacketHeaderLength + kT8022SNAPHeaderLength
};
```

Constants

`kT8022HeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kT8022SNAPHeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kT8022FullPacketHeaderLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kT8022ModuleID

```
enum {
    kT8022ModuleID = 7100,
    kEnetModuleID = 7101,
    kTokenRingModuleID = 7102,
    kFDDIModuleID = 7103
};
```

Constants

`kT8022ModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kEnetModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kTokenRingModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kFDDIModuleID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

kZIPMaxZoneLength

```
enum {
    kZIPMaxZoneLength = kNBPMaxZoneLength
};
```

Constants
`kZIPMaxZoneLength`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

LNK_ENET

```
enum {
    LNK_ENET = 'ENET',
    LNK_TOKN = 'TOKN',
    LNK_FDDI = 'FDDI',
    LNK_TPI = 'LTPI'
};
```

Constants
`LNK_ENET`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LNK_TOKN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LNK_FDDI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`LNK_TPI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

LOGMSGSZ

```
enum {
    LOGMSGSZ = 128
};
```

Constants

`LOGMSGSZ`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

M_MI

```
enum {
    M_MI = 0x40,
    M_MI_READ_RESET = 1,
    M_MI_READ_SEEK = 2,
    M_MI_READ_END = 4
};
```

Constants

`M_MI`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_MI_READ_RESET`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_MI_READ_SEEK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_MI_READ_END`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

MIOC_ISDN

```
enum {
    MIOC_ISDN = 85
};
```

Constants

`MIOC_ISDN`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

MIOC_STREAMIO

```
enum {
    MIOC_STREAMIO = 65,
    MIOC_TMOD = 'a',
    MIOC_STRLOG = 'b',
    MIOC_ND = 'c',
    MIOC_ECHO = 'd',
    MIOC_TLI = 'e',
    MIOC_RESERVEDf = 'f',
    MIOC_SAD = 'g',
    MIOC_ARP = 'h',
    MIOC_HAVOC = 72,
    MIOC_RESERVEDi = 'i',
    MIOC_SIOC = 'j',
    MIOC_TCP = 'k',
    MIOC_DLPI = 'l',
    MIOC_SOCKETS = 'm',
    MIOC_IPX = 'o',
    MIOC_OT = 79,
    MIOC_ATALK = 84,
    MIOC_SRL = 85,
    MIOC_RESERVEDp = 'p',
    MIOC_RESERVEDr = 'r',
    MIOC_RESERVEDs = 's',
    MIOC_CFIG = 'z'
};
```

Constants

`MIOC_STREAMIO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_TMOD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_STRLOG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_ND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_ECHO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_TLI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_RESERVEDf`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_SAD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_ARP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_HAVOC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_RESERVEDi`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_SIOC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_TCP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_DLPI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_SOCKETS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_IPX`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_OT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_ATALK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_SRL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_RESERVEDp`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_RESERVEDr`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_RESERVEDs`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`MIOC_CFIG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

MORECTL

```
enum {
    MORECTL = 0x01,
    MOREDATA = 0x02
};
```

Constants

`MORECTL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`MOREDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

MSG_HIPRI

```
enum {
    MSG_HIPRI = 0x01,
    MSG_BAND = 0x02,
    MSG_ANY = 0x04
};
```

Constants

`MSG_HIPRI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`MSG_BAND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`MSG_ANY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

MSGMARK

```
enum {
    MSGMARK = 0x01,
    MSGNOLOOP = 0x02,
    MSGDELIM = 0x04,
    MSGNOGET = 0x08
};
```

Constants

`MSGMARK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`MSGNOLOOP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`MSGDELIM`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`MSGNOGET`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

MUXID_ALL

```
enum {
    MUXID_ALL = -1
};
```

Constants

`MUXID_ALL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

NOERROR

```
enum {
    NOERROR = -1
};
```

Constants

`NOERROR`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

O_ASYNC

```
enum {
    O_ASYNC = kO_ASYNC,
    O_NDELAY = kO_NDELAY,
    O_NONBLOCK = kO_NONBLOCK
};
```

Constants

`O_ASYNC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`O_NDELAY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`O_NONBLOCK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

OPT_ADDMCAST

```
enum {
    OPT_ADDMCAST = 0x1000,
    OPT_DELMCAST = 0x1001,
    OPT_RCVPACKETTYPE = 0x1002,
    OPT_RCVDESTADDR = 0x1003,
    OPT_SETRAWMODE = 0x1004,
    OPT_SETPROMISCUOUS = 0x1005
};
```

Constants

`OPT_ADDMCAST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`OPT_DELMCAST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`OPT_RCVPACKETTYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`OPT_RCVDESTADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`OPT_SETRAWMODE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`OPT_SETPROMISCUOUS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Bus Type Constants

Specify the bus type of a port.

```
typedef UInt8 OTBusType;
enum {
    kOTUnknownBusPort = 0,
    kOTMotherboardBus = 1,
    kOTNuBus = 2,
    kOTPCIBus = 3,
    kOTGeoPort = 4,
    kOTPCCardBus = 5,
    kOTFireWireBus = 6,
    kOTLastBusIndex = 15
};
```

Constants

`kOTUnknownBusPort`
The port's bus type is not a known type.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTMotherboardBus`
The port is on the motherboard.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTNuBus`
The port is on a NuBus.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPCIBus`
The port is on a PCI bus.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTGeoPort`
The port is a GeoPort device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPCCardBus`
The port is on a PCCard bus.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFireWireBus`
The port is on a Firewire bus.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTLastBusIndex`
The maximum bus type that the port can support.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

Hardware Device Types

Lists hardware device types for Open Transport ports.

```
typedef UInt16 OTDeviceType;
enum {
    kOTNoDeviceType = 0,
    kOTADEVDevice = 1,
    kOTMDEVDevice = 2,
    kOTLocalTalkDevice = 3,
    kOTIRTalkDevice = 4,
    kOTTokenRingDevice = 5,
    kOTISDNDevice = 6,
    kOTATMDevice = 7,
    kOTSMDSDevice = 8,
    kOTSerialDevice = 9,
    kOTEthernetDevice = 10,
    kOTSLIPDevice = 11,
    kOTPPPDevice = 12,
    kOTModemDevice = 13,
    kOTFastEthernetDevice = 14,
    kOTFDDIDevice = 15,
    kOTIrDADevice = 16,
    kOTATMSNAPDevice = 17,
    kOTFibreChannelDevice = 18,
    kOTFireWireDevice = 19,
    kOTPseudoDevice = 1023,
    kOTLastDeviceIndex = 1022
};
```

Constants

`kOTNoDeviceType`
The port's device type is not specified. This value is illegal.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTADEVDevice`
The port is specified as an 'adev' device, which is a pseudodevice used by AppleTalk.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTMDEVDevice`
The port is specified as an 'mdev' device, which is a pseudodevice used by TCP.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTLocalTalkDevice`
The port is specified as a LocalTalk device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTIRTalkDevice`
The port is specified as an IRTalk device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTTokenRingDevice`
The port is specified as a token ring device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTISDNDevice`
The port is specified as an ISDN device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTATMDevice`
The port is specified as an ATM device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSMDSDevice`
The port is specified as a SMDS device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSerialDevice`
The port is specified as a serial device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTEthernetDevice`
The port is specified as an Ethernet device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSLIPDevice`
The port is specified as a SLIP pseudodevice.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPPPDevice`
The port is specified as a SLIP pseudodevice.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTModemDevice`
The port is specified as a modem pseudodevice.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFastEthernetDevice`
The port is specified as an 100 MB Ethernet device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFDDIDevice`
The port is specified as a FDDI device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTIrDADevice`
The port is specified as an IrDA Infrared device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTATMSNAPDevice`
The port is specified as an ATM pseudodevice simulating a SNAP device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFibreChannelDevice`
The port is specified as a Fibre Channel device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTFireWireDevice`
The port is specified as a Firewire device.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPseudoDevice`
The port is designated as a pseudodevice.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTLastDeviceIndex`
The maximum device types that a port can use.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

Special Considerations

Do not arbitrarily add new device types. Please contact Developer Support at Apple Computer, Inc. to obtain a new, unique device type.

OTInitializationFlags

```
typedef UInt32 OTInitializationFlags;
enum {
    kInitOTForApplicationMask = 1,
    kInitOTForExtensionMask = 2
};
```

Constants

`kInitOTForApplicationMask`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kInitOTForExtensionMask`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

OTOpenFlags

```
typedef UInt32 OTOpenFlags;
enum {
    kO_ASYNC = 0x01,
    kO_NDELAY = 0x04,
    kO_NONBLOCK = 0x04
};
```

Constants

`kO_ASYNC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kO_NDELAY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kO_NONBLOCK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

OTPacketType

```
typedef UInt32 OTPacketType;
enum {
    kETypeStandard = 0,
    kETypeMulticast = 1,
    kETypeBroadcast = 2,
    kETRawPacketBit = 0x80000000,
    kETTimeStampBit = 0x40000000
};
```

Constants

`kETypeStandard`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kETypeMulticast`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kETypeBroadcast`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kETRawPacketBit`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`kETTimeStampBit`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Endpoint Service Types

Contains values that Open Transport can return in the `servtype` field of the `TEndpointInfo` structure.

```
typedef UInt32 OTServiceType;
enum {
    T_COTS = 1,
    T_COTS_ORD = 2,
    T_CLTS = 3,
    T_TRANS = 5,
    T_TRANS_ORD = 6,
    T_TRANS_CLTS = 7
};
```

Constants

`T_COTS`
Connection-oriented transactionless service without orderly release.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_COTS_ORD`
Connection-oriented transactionless service with optional orderly release.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_CLTS`
Connectionless transactionless service.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_TRANS`
Connection-oriented transaction-based service without orderly release.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_TRANS_ORD`
Connection-oriented transaction-based service with optional orderly release.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_TRANS_CLTS`
Connectionless transaction-based service.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

Endpoint States

Define enpoint states for the `OTGetEndpointState` function.

```
typedef UInt32 OTXTIStates;
enum {
    T_UNINIT = 0,
    T_UNBND = 1,
    T_IDLE = 2,
    T_OUTCON = 3,
    T_INCON = 4,
    T_DATAXFER = 5,
    T_OUTREL = 6,
    T_INREL = 7
};
```

Constants

`T_UNINIT`
This endpoint has been closed and destroyed.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UNBND`
This endpoint is initialized but has not yet been bound to an address.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_IDLE`
This endpoint has been bound to an address and is ready for use: connectionless endpoints can send or receive data; connection-oriented endpoints can initiate or listen for a connection.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_OUTCON`
This endpoint has initiated a connection and is waiting for the peer endpoint to accept the connection.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_INCON`
This endpoint has received a connection request but has not yet accepted or rejected the request.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_DATAXFER`
This connection-oriented endpoint can now transfer data because the connection has been established.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_OUTREL`
This endpoint has issued an orderly disconnect that the peer has not acknowledged. The endpoint can continue to read data, but must not send any more data.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_INREL`
This endpoint has received a request for an orderly disconnect, which it has not yet acknowledged. The endpoint can continue to send data until it acknowledges the disconnection request, but it must not read data.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

ParityOptionValues

```
typedef UInt32 ParityOptionValues;
enum {
    kOTSerialNoParity = 0,
    kOTSerialOddParity = 1,
    kOTSerialEvenParity = 2
};
```

Constants

`kOTSerialNoParity`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTSerialOddParity`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`kOTSerialEvenParity`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

QB_FULL

```
enum {
    QB_FULL = 0x01,
    QB_WANTW = 0x02,
    QB_BACK = 0x04
};
```

Constants

`QB_FULL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QB_WANTW`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QB_BACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

qfields

```
typedef SInt32 qfields;
enum {
    QHIWAT = 0,
    QLOWAT = 1,
    QMAXPSZ = 2,
    QMINPSZ = 3,
    QCOUNT = 4,
    QFIRST = 5,
    QLAST = 6,
    QFLAG = 7,
    QBAD = 8
};
```

Constants

`QHIWAT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QLOWAT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QMAXPSZ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QMINPSZ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QCOUNT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QFIRST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QLAST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QFLAG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QBAD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

QNORM

```
enum {
    QNORM = 0,
    M_DATA = 0,
    M_PROTO = 1,
    M_BREAK = 0x08,
    M_PASSFP = 0x09,
    M_SIG = 0x0B,
    M_DELAY = 0x0C,
    M_CTL = 0x0D,
    M_IOCTL = 0x0E,
    M_SETOPTS = 0x10,
    M_RSE = 0x11
};
```

Constants

`QNORM`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_DATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_PROTO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_BREAK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_PASSFP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_SIG`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_DELAY`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_CTL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_IOCTL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_SETOPTS`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_RSE`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

QPCTL

```
enum {
    QPCTL = 0x80,
    M_IOCACK = 0x81,
    M_IOCNAK = 0x82,
    M_PCPROTO = 0x83,
    M_PCSIG = 0x84,
    M_FLUSH = 0x86,
    M_STOP = 0x87,
    M_START = 0x88,
    M_HANGUP = 0x89,
    M_ERROR = 0x8A,
    M_READ = 0x8B,
    M_COPYIN = 0x8C,
    M_COPYOUT = 0x8D,
    M_IOCDATA = 0x8E,
    M_PCRSE = 0x90,
    M_STOPI = 0x91,
    M_STARTI = 0x92,
    M_HPDATA = 0x93
};
```

Constants

`QPCTL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_IOCACK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_IOCNAK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_PCPROTO`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_PCSIG`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_FLUSH`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_STOP`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_START`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`M_HANGUP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_ERROR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_READ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_COPYIN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_COPYOUT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_IOCDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_PCRSE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_STOPI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_STARTI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`M_HPDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

QREADR

```
enum {
    QREADR = 0x01,
    QNOENB = 0x02,
    QFULL = 0x04,
    QWANTR = 0x08,
    QWANTW = 0x10,
    QUSE = 0x20,
    QENAB = 0x40,
    QBACK = 0x80,
    QOLD = 0x0100,
    QHLIST = 0x0200,
    QWELDED = 0x0400,
    QUNWELDING = 0x0800,
    QPROTECTED = 0x1000,
    QEXCOPENCLOSE = 0x2000
};
```

Constants

`QREADR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QNOENB`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QFULL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QWANTR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QWANTW`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QUSE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QENAB`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QBACK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QOLD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QHLIST`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QWELDED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QUNWELDING`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QPROTECTED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`QEXCOPENCLOSE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

RNORM

```
enum {
    RNORM = 0x01,
    RMSGD = 0x02,
    RMSGN = 0x04,
    RFILL = 0x08
};
```

Constants

`RNORM`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RMSGD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RMSGN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RFILL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

RPROTNORM

```
enum {
    RPROTNORM = 0x10,
    RPROTDIS = 0x20,
    RPROTDAT = 0x40
};
```

Constants

`RPROTNORM`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RPROTDIS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RPROTDAT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

RS_EXDATA

```
enum {
    RS_EXDATA = 0x20,
    RS_ALLOWAGAIN = 0x40,
    RS_DELIMITMSG = 0x80
};
```

Constants

`RS_EXDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RS_ALLOWAGAIN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`RS_DELIMITMSG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

RS_HIPRI

```
enum {
    RS_HIPRI = 0x01
};
```

Constants

`RS_HIPRI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

S_INPUT

```
enum {
    S_INPUT = 0x01,
    S_HIPRI = 0x02,
    S_OUTPUT = 0x04,
    S_MSG = 0x08,
    S_RDNORM = 0x10,
    S_RDBAND = 0x20,
    S_WRNORM = 0x40,
    S_WRBAND = 0x80,
    S_ERROR = 0x0100,
    S_HANGUP = 0x0200,
    S_BANDURG = 0x0400
};
```

Constants

`S_INPUT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_HIPRI`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_OUTPUT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_MSG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_RDNORM`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_RDBAND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_WRNORM`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_WRBAND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_ERROR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_HANGUP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`S_BANDURG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

SENDZERO

```
enum {
    SENDZERO = 0x0001,
    XPG4_1 = 0x0002
};
```

Constants

`SENDZERO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`XPG4_1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

SERIAL_OPT_BAUDRATE

```
enum {
    SERIAL_OPT_BAUDRATE = 0x0100,
    SERIAL_OPT_DATABITS = 0x0101,
    SERIAL_OPT_STOPBITS = 0x0102,
    SERIAL_OPT_PARITY = 0x0103,
    SERIAL_OPT_STATUS = 0x0104,
    SERIAL_OPT_HANDSHAKE = 0x0105,
    SERIAL_OPT_RCVTIMEOUT = 0x0106,
    SERIAL_OPT_ERRORCHARACTER = 0x0107,
    SERIAL_OPT_EXTCLOCK = 0x0108,
    SERIAL_OPT_BURSTMODE = 0x0109,
    SERIAL_OPT_DUMMY = 0x010A
};
```

Constants

`SERIAL_OPT_BAUDRATE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_DATABITS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_STOPBITS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_PARITY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_STATUS`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_HANDSHAKE`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_RCVTIMEOUT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_ERRORCHARACTER`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_EXTCLOCK`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_BURSTMODE`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`SERIAL_OPT_DUMMY`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

SIGHUP

```
enum {
    SIGHUP = 1,
    SIGURG = 16,
    SIGPOLL = 30
};
```

Constants
SIGHUP
SIGURG
SIGPOLL

SL_FATAL

```
enum {
    SL_FATAL = 0x01,
    SL_NOTIFY = 0x02,
    SL_ERROR = 0x04,
    SL_TRACE = 0x08,
    SL_CONSOLE = 0x00,
    SL_WARN = 0x20,
    SL_NOTE = 0x40
};
```

Constants

SL_FATAL
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_NOTIFY
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_ERROR
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_TRACE
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_CONSOLE
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_WARN
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SL_NOTE
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

SNDZERO

```
enum {
    SNDZERO = 0x01
};
```

Constants

`SNDZERO`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

SO_ALL

```
enum {
    SO_ALL = 0x7FFF,
    SO_READOPT = 0x0001,
    SO_WROFF = 0x0002,
    SO_MINPSZ = 0x0004,
    SO_MAXPSZ = 0x0008,
    SO_HIWAT = 0x0010,
    SO_LOWAT = 0x0020,
    SO_MREADON = 0x0040,
    SO_MREADOFF = 0x0080,
    SO_NDELON = 0x0100,
    SO_NDELOFF = 0x0200,
    SO_ISTTY = 0x0400,
    SO_ISNTTY = 0x0800,
    SO_TOSTOP = 0x1000,
    SO_TONSTOP = 0x2000,
    SO_BAND = 0x4000,
    SO_POLL_SET = 0x8000,
    SO_POLL_CLR = 0x00010000
};
```

Constants

`SO_ALL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`SO_READOPT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`SO_WROFF`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`SO_MINPSZ`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`SO_MAXPSZ`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProtocol.h`.

`SO_HIWAT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_LOWAT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_MREADON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_MREADOFF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_NDELON`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_NDELOFF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_ISTTY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_ISNTTY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_TOSTOP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_TONSTOP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_BAND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_POLL_SET`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`SO_POLL_CLR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

SQLVL_QUEUE

```
enum {
    SQLVL_QUEUE = 1,
    SQLVL_QUEUEPAIR = 2,
    SQLVL_MODULE = 3,
    SQLVL_GLOBAL = 4,
    SQLVL_DEFAULT = 3
};
```

Constants
SQLVL_QUEUE
SQLVL_QUEUEPAIR
SQLVL_MODULE
SQLVL_GLOBAL
SQLVL_DEFAULT

STRCANON

```
enum {
    STRCANON = 0x01,
    RECOPY = 0x02
};
```

Constants
STRCANON
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.
RECOPY
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

STRCTLSZ

```
enum {
    STRCTLSZ = 256,
    STRMSGSZ = 8192
};
```

Constants
STRCTLSZ
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.
STRMSGSZ
Available in Mac OS X v10.0 and later.
Declared in OpenTransportProtocol.h.

T_ADDR

```
enum {
    T_ADDR = 0x01,
    T_OPT = 0x02,
    T_UDATA = 0x04,
    T_ALL = 0xFFFF
};
typedef UInt32 OTFieldsType;
```

Constants

`T_ADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_OPT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_UDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_ALL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

T_ATALKBADROUTEREVENT

```
enum {
    T_ATALKBADROUTEREVENT = kAppleTalkEvent + 70,
    T_ALLNODESTAKENEVENT = kAppleTalkEvent + 71,
    T_FIXEDNODETAKENEVENT = kAppleTalkEvent + 72,
    T_MPPCOMPATCFIGEVENT = kAppleTalkEvent + 73,
    T_FIXEDNODEBADEVENT = kAppleTalkEvent + 74
};
```

Constants

`T_ATALKBADROUTEREVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_ALLNODESTAKENEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_FIXEDNODETAKENEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_MPPCOMPATCFIGEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_FIXEDNODEBADEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Structure Types

Specify the various Open Transport structure types that can be allocated by the `OTAllocInContext` function.

```
enum {
    T_BIND = 1,
    T_OPTMGMT = 2,
    T_CALL = 3,
    T_DIS = 4,
    T_UNITDATA = 5,
    T_UDERROR = 6,
    T_INFO = 7,
    T_REPLYDATA = 8,
    T_REQUESTDATA = 9,
    T_UNITREQUEST = 10,
    T_UNITREPLY = 11
};
typedef UInt32 OTStructType;
```

Constants

`T_BIND`
Specifies the `TBind` (page 2540) structure.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_OPTMGMT`
Specifies the `The Option Management Structure` (page 2549) structure.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_CALL`
Specifies the `TCall` (page 2541) structure
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_DIS`
Specifies the `TDiscon` (page 2542) structure.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_UNITDATA`
Specifies the `TUnitData` (page 2553) structure.
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_UDERROR`
Specifies the `TUDErr` (page 2552) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_INFO`
Speciifies the `TEndpointInfo` (page 2542) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REPLYDATA`
Specifies the `TReply` (page 2552) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REQUESTDATA`
Specifies the `TRequest` (page 2552) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UNITREQUEST`
Specifies the `TUnitRequest` (page 2555) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UNITREPLY`
Specifies the `TUnitReply` (page 2554) structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

T_DNRSTRINGTOADDRCOMPLETE

```
enum {
    T_DNRSTRINGTOADDRCOMPLETE = kPRIVATEEVENT + 1,
    T_DNRADDRTONAMECOMPLETE = kPRIVATEEVENT + 2,
    T_DNRSYSINFOCOMPLETE = kPRIVATEEVENT + 3,
    T_DNRMAILEXCHANGECOMPLETE = kPRIVATEEVENT + 4,
    T_DNRQUERYCOMPLETE = kPRIVATEEVENT + 5
};
```

Constants

`T_DNRSTRINGTOADDRCOMPLETE`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_DNRADDRTONAMECOMPLETE`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_DNRSYSINFOCOMPLETE`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_DNRMAILEXCHANGECOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_DNRQUERYCOMPLETE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

T_GARBAGE

```
enum {
    T_GARBAGE = 2
};
```

Constants
`T_GARBAGE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

T_INFINITE

```
enum {
    T_INFINITE = -1,
    T_INVALID = -2
};
```

Constants
`T_INFINITE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`T_INVALID`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

Event Codes

Define the constant names that provider functions can use for event codes, or define port-related events Open Transport can send to an client application.

```
typedef UInt32 OTEventCode;
enum {
    T_LISTEN = 0x0001,
    T_CONNECT = 0x0002,
    T_DATA = 0x0004,
    T_EXDATA = 0x0008,
    T_DISCONNECT = 0x0010,
    T_ERROR = 0x0020,
    T_UDERR = 0x0040,
    T_ORDREL = 0x0080,
    T_GODATA = 0x0100,
    T_GOEXDATA = 0x0200,
    T_REQUEST = 0x0400,
    T_REPLY = 0x0800,
    T_PASSCON = 0x1000,
    T_RESET = 0x2000,
    kPRIVATEEVENT = 0x10000000,

```

Constants

`T_LISTEN`

A connection request has arrived. Call the `OTListen` function to read the request.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_CONNECT`

The passive peer has accepted a connection that you requested using the `OTConnect` function. Call the `OTRcvConnect` function to retrieve any data or option information that the passive peer has specified when accepting the connection or to retrieve the address to which you are actually connected. The `cookie` parameter to the notifier function is the `sndCall` parameter that you specified when calling the `OTConnect` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_DATA`

Normal data has arrived. Depending on the type of service of the endpoint you are using, you can call the `OTRcvUData` function or the `OTRcv` function to read it. Continue reading data until the function returns with the `kOTNoDataErr` result; you will not get another indication that data has arrived until you have read all the data and got this error.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_EXDATA`

Expedited data has arrived. Use the `OTRcv` function to read it. Continue reading data by calling the `OTRcv` function until the function returns with the `kOTNoDataErr` result; you will not get another indication that data has arrived until you have read all the data and got this error.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_DISCONNECT`

A connection has been torn down or rejected. Use the `OTRcvDisconnect` function to clear the event.

If the event is used to signify that a connection has been terminated, the cookie parameter to the notifier is `NULL`.

If the event indicates a rejected connection request, the `cookie` parameter to the notification routine is the same as the `sndCall` parameter that you passed to the `OTConnect` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_ERROR`

Obsolete.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UDERR`

The provider was not able to send the data you specified using the `OTSndUData` function even though the function returned successfully. You must call the `OTRcvUDErr` function to clear this event and determine why the function failed.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_ORDREL`

The remote client has called the `OTSndOrderlyDisconnect` function to initiate an orderly disconnect. You must call the `OTRcvOrderlyDisconnect` function to acknowledge receiving the event.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_GODATA`

Flow-control restrictions have been lifted. You can now send normal data.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_GOEXDATA`

Flow-control restrictions have been lifted. You can now send expedited data.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REQUEST`

A request has arrived. Depending on the type of service for the endpoint you are using, you can call the `OTRcvRequest` function or the `OTRcvURequest` function to receive it. You must continue to call the function until it returns with the `kOTNoDataErr` result.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REPLY`

A response to a request has arrived. Depending on the type of service of the endpoint you are using, you can call the `OTRcvReply` function or `OTRcvUReply` function to receive it. You must continue to call the function until it returns with the `kOTNoDataErr` result.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_PASSCON`

When the `OTAccept` function completes, the endpoint provider passes this event to the endpoint receiving the connection (whether that endpoint is the same as or different from the endpoint that calls the `OTAccept` function). The `cookie` parameter contains the `resRef` parameter to the `OTAccept` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_RESET`

A connection-oriented endpoint has received a reset from the remote end and has flushed all unread and unsent data. This only occurs for some types of endpoints, and it generally leaves the endpoint in an unknown state.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kPRIVATEEVENT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kCOMPLETEEVENT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_BINDCOMPLETE`

The `OTBind` function has completed. The `cookie` parameter contains the `retAddr` parameter of the bind call.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UNBINDCOMPLETE`

The `OTUnbind` function has completed. The `cookie` parameter is meaningless.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_ACCEPTCOMPLETE`

The `OTAccept` function has completed. The `cookie` parameter contains the `resRef` parameter to the `OTAccept` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REPLYCOMPLETE`
The `OTSndUReply` or `OTSndReply` functions have completed. The `cookie` parameter contains the sequence number used in the `OTSndUReply` or `OTSndReply` call.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_DISCONNECTCOMPLETE`
The `OTSndDisconnect` function has completed. The `cookie` parameter contains the call parameter of the `OTSndDisconnect` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_OPTMGMTCOMPLETE`
The `OTOptionManagement` function has completed. The `cookie` parameter contains the `ret` parameter that you passed to the function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_OPENCOMPLETE`
An asynchronous call to open a provider has completed. The `cookie` parameter contains the provider reference.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_GETPROTADDRCOMPLETE`
The `OTGetProtAddress` function has completed. The `cookie` parameter contains the `peerAddr` parameter that you passed to the `OTGetProtocolAddress` function. If you passed `NULL` for that parameter, the `cookie` parameter contains the address passed in the `boundAddr` parameter.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_RESOLVEADDRCOMPLETE`
The `OTResolveAddress` function has completed. The `cookie` parameter contains the `retAddr` parameter of the `OTResolveAddress` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_GETINFOCOMPLETE`
The `OTGetEndpointInfo` function has completed. The `cookie` parameter contains the `info` parameter of the `OTGetEndpointInfo` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_SYNCCOMPLETE`
The `OTSync` function has completed. The `cookie` parameter is meaningless.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_MEMORYRELEASED`

You are using an asynchronous endpoint that acknowledges sends and Open Transport is done using the buffers containing the data you are sending. If you called the `OTSnd` function, the `cookie` parameter contains the `buf` parameter. If you called the `OTSndUData` function, the `cookie` parameter contains the `udata` parameter. The `result` parameter contains the number of bytes that were sent. This might be less than the number you meant to send due to flow-control or memory restrictions.

You should not wait for the `T_MEMORYRELEASED` event from a previous send operation to trigger more sends. The exact time this event occurs depends on how the underlying provider is implemented. It might hold on to memory until the next send occurs, or behave in some other way which causes it to delay releasing memory.

Note that `T_MEMORYRELEASED` events can reenter your notifier. See `OTAckSends` (page 2307)for more information.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_REGNAMECOMPLETE`

The `OTRegisterName` function has completed. The `cookie` parameter is the reply parameter, unless it was `NULL`. In this case, it is the `req` parameter.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_DELNAMECOMPLETE`

The `OTDeleteName` function or the `OTDeleteNameByID` function has completed. The `cookie` parameter contains the `name` parameter or the `nameId` parameter of the function, respectively.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_LKUPNAMECOMPLETE`

The `OTLookupName` function has completed. The `cookie` parameter contains the `reply` parameter of the `OTLookUpName` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_LKUPNAMERESULT`

An `OTLookupName` function has found a name and is returning it, but the lookup is not yet complete. The `cookie` parameter contains the `reply` parameter passed to the `OTLookupName` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTSyncIdleEvent`

A synchronous call is waiting to complete.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kSTREAMEVENT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTReservedEvent1`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kGetmsgEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kStreamReadEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kStreamWriteEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kStreamIoctlEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent2`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kStreamOpenEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kPollEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent3`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent4`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent5`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent6`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent7`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTReservedEvent8`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kSIGNALEVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kPROTOCOLEVENT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTProviderIsDisconnected`

Your provider was bound with a `qlen` parameter value greater than 0 and it has been disconnected (is no longer listening). You receive this event after a port has accepted a request to temporarily yield ownership of a port to another provider, which causes this provider to be disconnected from the port in question. This currently only happens with serial ports, but could also happen with other connection-oriented drivers that have characteristics similar to serial ports. You get a `kOTProviderIsReconnected` message when the port reverts back to this provider's ownership.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTProviderIsReconnected`

Your provider has been reconnected, that is, the cause for its disconnection has been relieved.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTProviderWillClose`

When you return from the notifier function, Open Transport will close the provider whose reference is contained in the `cookie` parameter. The `result` parameter contains a result code specifying the reason why the provider had to close. For example, the user may have decided to switch links using the TCP/IP or AppleTalk control panel. The result codes that can be returned are in the range –3280 through –3285; these are documented in "Open Transport Result Codes" (page 2722).

You can only get this event at system task time. Consequently, you are allowed to set the endpoint to synchronous mode (from within the notifier function) and call functions synchronously before you return from the notifier, at which point the provider is closed. After this, any calls other than `OTCloseProvider` will fail with a `kOTOutStateErr` error.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTProviderIsClosed`

The provider has closed. The reason for being closed can be found in the `OTResult` value passed to your notifier. The reasons typically are `kOTPortHasDiedErr`, `kOTPortWasEjectedErr`, or `kOTPortLostConnectionErr`. At this point, any calls other than `OTCloseProvider` will fail with a `kOTOutStateErr` error.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTPortDisabled`

A port has gone off line, as when the user removes a PCMCIA card while the computer is running. The OTResult parameter specifies the reason, if known, and the cookie parameter provides the port reference of the port that went off line. A port going off line often results in providers getting kOTProviderIsClosed events. There is no guarantee in Open Transport as to which of these events will be received first.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTPortEnabled`
A port that had previously been disabled is now reenabled, as when the user reinserts a previously removed PCMCIA card while the computer is running. The cookie parameter is the port reference of the port that is now enabled.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTPortOffline`
The port is now offline.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTPortOnline`
A request has been made to close or yield this port.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTClosePortRequest`
You currently are using a provider that is using a port that some other application wants to use. The OTResult parameter is the reason for the request (normally kOTNoError or kOTUserRequestedErr), and the cookie parameter is a pointer to an OTPortCloseStruct structure.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTYieldPortRequest`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTNewPortRegistered`
A new port has been registered with Open Transport, as when the user inserts a new PCMCIA card. The cookie parameter is the port reference of the new port. Your provider receives this event the first time a new port is enabled. Subsequently, if a port is reenabled after being disabled, you receive the kOTPortEnabled event instead.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTPortNetworkChange`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTConfigurationChanged`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTSystemSleep`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTSystemShutdown`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kOTSystemAwaken`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSystemIdle`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSystemSleepPrep`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSystemShutdownPrep`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTSystemAwakenPrep`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTStackIsLoading`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTStackWasLoaded`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTStackIsUnloading`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTDisablePortEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kStreamCloseEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kBackgroundStreamEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kIoctlRecvFdEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTTryShutdownEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTScheduleTerminationEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTEnablePortEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTNewPortRegisteredEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortOfflineEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortOnlineEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`kOTPortNetworkChangeEvent`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

Open Transport Flags and Status Codes

Specify information about data transmitted with the `OTSnd` or `OTRcv` functions, or specify options for the `OTOptionManagement` function, or indicate the result status of an option negotiation.

```
typedef UInt32 OTFlags;
/*   These flags are used when sending and receiving data.The constants
defined are masks.*/
enum {
    T_MORE = 0x0001,
    T_EXPEDITED = 0x0002,
    T_ACKNOWLEDGED = 0x0004,
    T_PARTIALDATA = 0x0008,
    T_NORECEIPT = 0x0010,
    T_TIMEDOUT = 0x0020
};

/* These flags are used in the TOptMgmt structure to request services.*/
enum {
    T_NEGOTIATE = 0x0004,
    T_CHECK = 0x0008,
    T_DEFAULT = 0x0010,
    T_CURRENT = 0x0080
};
```

```
/*   These flags are used in the TOptMgmt and TOption structures
to   return results.*/
enum {
    T_SUCCESS = 0x0020,
    T_FAILURE = 0x0040,
    T_PARTSUCCESS = 0x0100,
    T_READONLY = 0x0200,
    T_NOTSUPPORT = 0x0400
};
```

Constants

`T_MORE`

There is more data for the current TSDU or ETSDU. The next send or receive operation will handle additional data for this TSDU or ETSDU.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_EXPEDITED`

On sends, the data is sent as expedited data if the endpoint supports expedited data. On receives, the flag indicates that expedited data was sent.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_ACKNOWLEDGED`

The transaction must be acknowledged before the send or receive function can complete.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_PARTIALDATA`

There is more data for the current TSDU or ETSDU. Unlike `T_MORE`, `T_PARTIALDATA` does not guarantee that the next send or receive operation will handle additional data for this TSDU or ETSDU.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_NORECEIPT`

There is no need to send a `T_REPLY_COMPLETE` event to complete the transaction. If you don't need to know when the transaction is actually done, you can set this flag to improve performance.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_TIMEDOUT`

The reply timed out. If a protocol such as ATP loses the acknowledgment for a transaction that needs to be acknowledged, the transaction will eventually time out. Since the reply didn't really fail (it just timed out), Open Transport can send a `T_REPLY_COMPLETE` event to complete the transaction and set this flag to explain what happened.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_NEGOTIATE`
: Negotiate the option values specified in the opt.buf field of the req parameter.

  The overall result of the negotiation is specified by the flags field of the ret parameter. The opt.buf field of the ret parameter points to a buffer where negotiated values for each option are placed.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_CHECK`
: Verify whether the endpoint supports the options referenced by the opt.buf field of the req parameter. The overall result of the verification is specified by the flags field of the ret parameter. Specific verification results are returned in the opt.buf field of the ret parameter.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_DEFAULT`
: Retrieve the default value for those options in the buffer referenced by the req->opt.buf field. To retrieve default values for all the options supported by an endpoint, include just the option T_ALLOPT in the options buffer.Option values are returned in the opt.buf field of the ret parameter.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_CURRENT`
: Retrieve the current value for those options that the endpoint supports and that are specified in the buffer referenced by the req->opt.buf field. To retrieve current values for all the options that an endpoint supports, include just the option T_ALLOPT in the options buffer.Option values are returned in the opt.buf field of the ret parameter.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_SUCCESS`
: The requested value was negotiated.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_FAILURE`
: The negotiation failed.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_PARTSUCCESS`
: A lower requested value was negotiated.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_READONLY`
: The option was read-only.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`T_NOTSUPPORT`
The endpoint does not support the requested value.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

T_NOTOS

```
enum {
    T_NOTOS = 0x00,
    T_LDELAY = (1 << 4),
    T_HITHRPT = (1 << 3),
    T_HIREL = (1 << 2)
};
```

Constants

`T_NOTOS`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_LDELAY`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_HITHRPT`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`T_HIREL`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

T_NULL

```
enum {
    T_NULL = NULL,
    T_UNSPEC = -3
};
```

Constants

`T_NULL`

`T_UNSPEC`
The option does not have a fully specified value at this time. An endpoint provider might return this status code if it cannot currently access the option value. This might happen if the endpoint is in the state T_UNBND in systems where the protocol stack resides on a separate host.

T_ROUTINE

```
enum {
    T_ROUTINE = 0,
    T_PRIORITY = 1,
    T_IMMEDIATE = 2,
    T_FLASH = 3,
    T_OVERRIDEFLASH = 4,
    T_CRITIC_ECP = 5,
    T_INETCONTROL = 6,
    T_NETCONTROL = 7
};
```

Constants

`T_ROUTINE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_PRIORITY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_IMMEDIATE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_FLASH`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_OVERRIDEFLASH`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_CRITIC_ECP`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_INETCONTROL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`T_NETCONTROL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

Endpoint Flags

Specifies information about an endpoint.

```
enum {
    T_SENDZERO = 0x0001,
    T_XPG4_1 = 0x0002,
    T_CAN_SUPPORT_MDATA = 0x10000000,
    T_CAN_RESOLVE_ADDR = 0x40000000,
    T_CAN_SUPPLY_MIB = 0x20000000
};
```

Constants

`T_SENDZERO`

This endpoint lets you send and receive zero-length TSDUs.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_XPG4_1`

This endpoint supports the `OTGetProtAddress` function (conforms to XTI in XPG4).

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_CAN_SUPPORT_MDATA`

This endpoint supports `M_DATA`, that is, it permits receiving and returning raw packets.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_CAN_RESOLVE_ADDR`

This endpoint supports the `OTResolveAddress` function.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_CAN_SUPPLY_MIB`

This endpoint can supply the Management Information Base (MIB) data used by the Simple Network Management Protocol (SNMP). At this time you cannot access this data.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

T_UNSPEC

Constants

T_YES

```
enum {
    T_YES = 1,
    T_NO = 0,
    T_UNUSED = -1,
    kT_NULL = 0,
    T_ABSREQ = 0x8000
};
```

Constants

`T_YES`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_NO`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_UNUSED`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`kT_NULL`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`T_ABSREQ`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

TCP_NODELAY

```
enum {
    TCP_NODELAY = 0x01,
    TCP_MAXSEG = 0x02,
    TCP_NOTIFY_THRESHOLD = 0x10,
    TCP_ABORT_THRESHOLD = 0x11,
    TCP_CONN_NOTIFY_THRESHOLD = 0x12,
    TCP_CONN_ABORT_THRESHOLD = 0x13,
    TCP_OOBINLINE = 0x14,
    TCP_URGENT_PTR_TYPE = 0x15,
    TCP_KEEPALIVE = 0x0008
};
```

Constants

`TCP_NODELAY`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`TCP_MAXSEG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_NOTIFY_THRESHOLD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_ABORT_THRESHOLD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_CONN_NOTIFY_THRESHOLD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_CONN_ABORT_THRESHOLD`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_OOBINLINE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_URGENT_PTR_TYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

`TCP_KEEPALIVE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProviders.h`.

TE_OPENED

```
enum {
    TE_OPENED = 1,
    TE_BIND = 2,
    TE_OPTMGMT = 3,
    TE_UNBIND = 4,
    TE_CLOSED = 5,
    TE_CONNECT1 = 6,
    TE_CONNECT2 = 7,
    TE_ACCEPT1 = 8,
    TE_ACCEPT2 = 9,
    TE_ACCEPT3 = 10,
    TE_SND = 11,
    TE_SNDDIS1 = 12,
    TE_SNDDIS2 = 13,
    TE_SNDREL = 14,
    TE_SNDUDATA = 15,
    TE_LISTEN = 16,
    TE_RCVCONNECT = 17,
    TE_RCV = 18,
    TE_RCVDIS1 = 19,
    TE_RCVDIS2 = 20,
    TE_RCVDIS3 = 21,
    TE_RCVREL = 22,
    TE_RCVUDATA = 23,
    TE_RCVUDERR = 24,
    TE_PASS_CONN = 25,
    TE_BAD_EVENT = 26
};
```

Constants

`TE_OPENED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_BIND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_OPTMGMT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_UNBIND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_CLOSED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_CONNECT1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_CONNECT2`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_ACCEPT1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_ACCEPT2`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_ACCEPT3`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_SND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_SNDDIS1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_SNDDIS2`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_SNDREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_SNDUDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_LISTEN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVCONNECT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCV`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVDIS1`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVDIS2`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVDIS3`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVUDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_RCVUDERR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_PASS_CONN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TE_BAD_EVENT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

TS_UNBND

```
enum {
    TS_UNBND = 1,
    TS_WACK_BREQ = 2,
    TS_WACK_UREQ = 3,
    TS_IDLE = 4,
    TS_WACK_OPTREQ = 5,
    TS_WACK_CREQ = 6,
    TS_WCON_CREQ = 7,
    TS_WRES_CIND = 8,
    TS_WACK_CRES = 9,
    TS_DATA_XFER = 10,
    TS_WIND_ORDREL = 11,
    TS_WREQ_ORDREL = 12,

    TS_WACK_DREQ9 = 15,
    TS_WACK_DREQ10 = 16,
    TS_WACK_DREQ11 = 17,
    TS_WACK_ORDREL = 18,
    TS_NOSTATES = 19,
    TS_BAD_STATE = 19
};
```

Constants

`TS_UNBND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_BREQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_UREQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_IDLE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_OPTREQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_CREQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WCON_CREQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WRES_CIND`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_CRES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_DATA_XFER`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WIND_ORDREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WREQ_ORDREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_DREQ6`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_DREQ7`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_DREQ9`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_DREQ10`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_DREQ11`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_WACK_ORDREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_NOSTATES`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

`TS_BAD_STATE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransportProtocol.h`.

TSUCCESS

```
typedef UInt16 OTXTIErr;
enum {
    TSUCCESS = 0,
    TBADADDR = 1,
    TBADOPT = 2,
    TACCES = 3,
    TBADF = 4,
    TNOADDR = 5,
    TOUTSTATE = 6,
    TBADSEQ = 7,
    TSYSERR = 8,
    TLOOK = 9,
    TBADDATA = 10,
    TBUFOVFLW = 11,
    TFLOW = 12,
    TNODATA = 13,
    TNODIS = 14,
    TNOUDERR = 15,
    TBADFLAG = 16,
    TNOREL = 17,
    TNOTSUPPORT = 18,
    TSTATECHNG = 19,
    TNOSTRUCTYPE = 20,
    TBADNAME = 21,
    TBADQLEN = 22,

    TRESADDR = 27,
    TQFULL = 28,
    TPROTO = 29,
    TBADSYNC = 30,
    TCANCELED = 31,
    TLASTXTIERROR = 31
};
```

Constants

`TSUCCESS`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`TBADADDR`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`TBADOPT`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`TACCES`

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`TBADF`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNOADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TOUTSTATE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADSEQ`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TSYSERR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TLOOK`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADDATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBUFOVFLW`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TFLOW`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNODATA`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNODIS`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNOUDERR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADFLAG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNOREL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNOTSUPPORT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TSTATECHNG`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TNOSTRUCTYPE`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADNAME`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADQLEN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TADDRBUSY`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TINDOUT`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TPROVMISMATCH`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TRESQLEN`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TRESADDR`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TQFULL`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TPROTO`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TBADSYNC`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TCANCELED`
Available in Mac OS X v10.0 and later.
Declared in `OpenTransport.h`.

`TLASTXTIERROR`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

UDP_CHECKSUM

```
enum {
    UDP_CHECKSUM = 0x0600,
    UDP_RX_ICMP = 0x02
};
```

Constants

`UDP_CHECKSUM`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

`UDP_RX_ICMP`
Available in Mac OS X v10.0 and later.

Declared in `OpenTransportProviders.h`.

XTI-Level Options and Generic Options

Specifies constant names for XTI-level options.

```
enum {
    XTI_DEBUG = 0x0001,
    XTI_LINGER = 0x0080,
    XTI_RCVBUF = 0x1002,
    XTI_RCVLOWAT = 0x1004,
    XTI_SNDBUF = 0x1001,
    XTI_SNDLOWAT = 0x1003,
    XTI_PROTOTYPE = 0x1005,
    OPT_CHECKSUM = 0x0600,
    OPT_RETRYCNT = 0x0601,
    OPT_INTERVAL = 0x0602,
    OPT_ENABLEEOM = 0x0603,
    OPT_SELFSEND = 0x0604,
    OPT_SERVERSTATUS = 0x0605,
    OPT_ALERTENABLE = 0x0606,
    OPT_KEEPALIVE = 0x0008
};
```

Constants

`XTI_DEBUG`
A 32 bit constant specifying whether debugging is enabled. Debugging is disabled if the option is specified with no value. This option is an absolute requirement.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_LINGER`

A value defined by a linger structure (page 571) that specifies whether the option is turned on (T_YES) or off (T_NO) and specifies a linger period in seconds. This option is an absolute requirement; however, you do not have to specify a value for the l_linger field of the linger structure.

You use this option to extend the execution of the OTCloseProvider function for some specified amount of time. The delay allows data still queued in the endpoint's internal send buffer to be sent before the endpoint provider is closed. If you call the OTCloseProvider function and the send buffer is not empty, the endpoint provider attempts to send the remaining data during the linger period, before closing. Open Transport discards any data remaining in the send buffer after the linger period has elapsed.

Consult the documentation for your protocol to determine the valid range of values for the linger period.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_RCVBUF`

A 32-bit integer specifying the size of the endpoint's internal buffer allocated for receiving data. You can increase the size of this buffer for high-volume connections or decrease the buffer to limit the possible backlog of incoming data.

This option is not an absolute requirement. Consult the documentation for your protocol to determine the valid range of values for the buffer size.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_RCVLOWAT`

A 32-bit integer specifying the low-water mark for the receive buffer—that is, the number of bytes that must accumulate in the endpoint's internal receive buffer before you are advised that data has arrived via a T_DATA event. Choosing a value that is too low might result in your application's getting an excessive number of T_DATA events and doing unnecessary reads. Choosing a value that is too high might result in Open Transport running out of memory and disabling incoming data packets.

This option is not an absolute requirement. Consult the documentation for your protocol to determine the valid range of values for the low-water mark.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_SNDBUF`

A 32-bit integer specifying the size of the endpoint's internal buffer allocated for sending data. Specifying a value that is too low might result in Open Transport doing more sends than necessary and wasting processor time; specifying a value that is too high might cause flow control problems.

This option is not an absolute requirement. Consult the documentation for your protocol to determine the valid range of values for the buffer size.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_SNDLOWAT`

A 32-bit integer specifying the low-water mark for the send buffer—that is, the number of bytes that must accumulate in the endpoint's internal send buffer before Open Transport actually sends the data. Choosing a value that is too low might result in Open Transport's doing too many sends and wasting processor time. Choosing a value that is too high might result in flow control problems. A value that is slightly lower than the largest packet size defined for the endpoint is a good choice.

This option is not an absolute requirement. Consult the documentation for your protocol to determine the valid range of values for the low-water mark.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`XTI_PROTOTYPE`

The protocol type used by the endpoint. The option is supported by the RawIP endpoint.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`OPT_CHECKSUM`

A 32-bit constant specifying whether checksums are performed. Specify 1 to turn the option on and 0 to turn it off. If you turn it on, a checksum is calculated when a packet is sent and recalculated when the packet is received. If the checksum values match, the client receiving the packet can be fairly certain that data has not been corrupted or lost during transmission. If the checksum values don't match, the receiver discards the packet.

This option is usually implemented by the lowest-level protocol, although you might be allowed to set it at a higher level. For example, if you use an ATP endpoint, you can set checksumming at the ATP level, even though it is implemented by the underlying DDP protocol.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`OPT_RETRYCNT`

A 32-bit integer specifying the number of times a function can attempt packet delivery before returning with an error. A value of 0 means that the function should attempt packet delivery an infinite number of times.

This option is usually implemented by connection-oriented endpoints or connectionless transaction-based endpoints to enable reliable delivery of data. Such protocols normally set a default value for this option.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`OPT_INTERVAL`

A 32-bit integer specifying the interval of time in milliseconds that should elapse between attempts to deliver a packet. The number of attempts is defined by the OPT_RETRYCNT option.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`OPT_ENABLEEOM`

An 32-bit integer specifying end-of-message capability. If you set this option, you enable the use of the T_MORE flag with the OTSnd function to mark the end of a logical unit. This option has meaning only for connection-oriented protocols. A value of 0 clears the option; a value of 1 sets it.

This option is not association-related.

Available in Mac OS X v10.0 and later.

Declared in `OpenTransport.h`.

`OPT_SELFSEND`
: A 32-bit integer allowing you to send broadcast packets to yourself. A value of 0 clears the option; a value of 1 sets it.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`OPT_SERVERSTATUS`
: A string that sets the server's status. The maximum length is protocol dependent. For more information, consult the documentation for the protocol you are using.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`OPT_ALERTENABLE`
: A keepalive structure that specifies whether "keep alive" is turned on (T_YES) or off (T_NO) and specifies the timeout period in minutes.

  Connection-oriented protocols can use this option to check that the connection is maintained. If a connection is established but there is no data being transferred, you can specify a time limit within which Open Transport checks to see that the remote end of the connection is still alive. If it is not, Open Transport tears down the connection.

  This option is association-related.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

`OPT_KEEPALIVE`
: Enables or disables protocol alerts.

  Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

Discussion
Open Transport defines XTI-level options. These options are not association-related. If the protocol you are using supports these options, you can negotiate them while the endpoint is in any state. The protocol level for all of these options is XTI_GENERIC.

Open Transport also defines some generic options that you can use with any protocol that supports them, listed in this enumeration starting with `OPT_CHECKSUM`. The protocol level for each of these options is the same as the name of the protocol that supports them.

XTI_GENERIC

```
enum {
    XTI_GENERIC = 0xFFFF
};
```

Constants
`XTI_GENERIC`
: Available in Mac OS X v10.0 and later.

  Declared in `OpenTransport.h`.

Result Codes

The most common result codes returned by Open Transport are listed below.

Result Code	Value	Description
kOTNoError	0	No Error occurred Available in Mac OS X v10.0 and later.
kOTBadAddressErr	-3150	XTI2OSStatus(TBADADDR) A Bad address was specified Available in Mac OS X v10.0 and later.
kOTBadOptionErr	-3151	XTI2OSStatus(TBADOPT) A Bad option was specified Available in Mac OS X v10.0 and later.
kOTAccessErr	-3152	XTI2OSStatus(TACCES) Missing access permission Available in Mac OS X v10.0 and later.
kOTBadReferenceErr	-3153	XTI2OSStatus(TBADF) Bad provider reference Available in Mac OS X v10.0 and later.
kOTNoAddressErr	-3154	XTI2OSStatus(TNOADDR) No address was specified Available in Mac OS X v10.0 and later.
kOTOutStateErr	-3155	XTI2OSStatus(TOUTSTATE) Call issued in wrong state Available in Mac OS X v10.0 and later.
kOTBadSequenceErr	-3156	XTI2OSStatus(TBADSEQ) Sequence specified does not exist Available in Mac OS X v10.0 and later.
kOTSysErrorErr	-3157	XTI2OSStatus(TSYSERR) A system error occurred Available in Mac OS X v10.0 and later.
kOTLookErr	-3158	XTI2OSStatus(TLOOK) An event occurred - call Look() Available in Mac OS X v10.0 and later.
kOTBadDataErr	-3159	XTI2OSStatus(TBADDATA) An illegal amount of data was specified Available in Mac OS X v10.0 and later.
kOTBufferOverflowErr	-3160	XTI2OSStatus(TBUFOVFLW) Passed buffer not big enough Available in Mac OS X v10.0 and later.
kOTFlowErr	-3161	XTI2OSStatus(TFLOW) Provider is flow-controlled Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kOTNoDataErr	-3162	XTI2OSStatus(TNODATA) No data available for reading Available in Mac OS X v10.0 and later.
kOTNoDisconnectErr	-3163	XTI2OSStatus(TNODIS) No disconnect indication available Available in Mac OS X v10.0 and later.
kOTNoUDErrErr	-3164	XTI2OSStatus(TNOUDERR) No Unit Data Error indication available Available in Mac OS X v10.0 and later.
kOTBadFlagErr	-3165	XTI2OSStatus(TBADFLAG) A Bad flag value was supplied Available in Mac OS X v10.0 and later.
kOTNoReleaseErr	-3166	XTI2OSStatus(TNOREL) No orderly release indication available Available in Mac OS X v10.0 and later.
kOTNotSupportedErr	-3167	XTI2OSStatus(TNOTSUPPORT) Command is not supported Available in Mac OS X v10.0 and later.
kOTStateChangeErr	-3168	XTI2OSStatus(TSTATECHNG) State is changing - try again later Available in Mac OS X v10.0 and later.
kOTNoStructureTypeErr	-3169	XTI2OSStatus(TNOSTRUCTYPE) Bad structure type requested for OTAlloc Available in Mac OS X v10.0 and later.
kOTBadNameErr	-3170	XTI2OSStatus(TBADNAME) A bad endpoint name was supplied Available in Mac OS X v10.0 and later.
kOTBadQLenErr	-3171	XTI2OSStatus(TBADQLEN) A Bind to an in-use addr with qlen > 0 Available in Mac OS X v10.0 and later.
kOTAddressBusyErr	-3172	XTI2OSStatus(TADDRBUSY) Address requested is already in use Available in Mac OS X v10.0 and later.
kOTIndOutErr	-3173	XTI2OSStatus(TINDOUT) Accept failed because of pending listen Available in Mac OS X v10.0 and later.
kOTProviderMismatchErr	-3174	XTI2OSStatus(TPROVMISMATCH) Tried to accept on incompatible endpoint Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kOTResQLenErr	-3175	XTI2OSStatus(TRESQLEN) Available in Mac OS X v10.0 and later.
kOTResAddressErr	-3176	XTI2OSStatus(TRESADDR) Available in Mac OS X v10.0 and later.
kOTQFullErr	-3177	XTI2OSStatus(TQFULL) Available in Mac OS X v10.0 and later.
kOTProtocolErr	-3178	XTI2OSStatus(TPROTO) An unspecified provider error occurred Available in Mac OS X v10.0 and later.
kOTBadSyncErr	-3179	XTI2OSStatus(TBADSYNC) A synchronous call at interrupt time Available in Mac OS X v10.0 and later.
kOTCanceledErr	-3180	XTI2OSStatus(TCANCELED) The command was cancelled Available in Mac OS X v10.0 and later.
kEPERMErr	-3200	Permission denied Available in Mac OS X v10.0 and later.
kENOENTErr	-3201	No such file or directory Available in Mac OS X v10.0 and later.
kOTNotFoundErr	-3201	OT generic not found error Available in Mac OS X v10.0 and later.
kENORSRCErr	-3202	No such resource Available in Mac OS X v10.0 and later.
kEINTRErr	-3203	Interrupted system service Available in Mac OS X v10.0 and later.
kEIOErr	-3204	I/O error Available in Mac OS X v10.0 and later.
kENXIOErr	-3205	No such device or address Available in Mac OS X v10.0 and later.
kEBADFErr	-3208	Bad file number Available in Mac OS X v10.0 and later.
kEAGAINErr	-3210	Try operation again later Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kENOMEMErr	-3211	Not enough space Available in Mac OS X v10.0 and later.
kOTOutOfMemoryErr	-3211	OT ran out of memory, may be a temporary Available in Mac OS X v10.0 and later.
kEACCESErr	-3212	Permission denied Available in Mac OS X v10.0 and later.
kEFAULTErr	-3213	Bad address Available in Mac OS X v10.0 and later.
kEBUSYErr	-3215	Device or resource busy Available in Mac OS X v10.0 and later.
kEEXISTErr	-3216	File exists Available in Mac OS X v10.0 and later.
kOTDuplicateFoundErr	-3216	OT generic duplicate found error Available in Mac OS X v10.0 and later.
kENODEVErr	-3218	No such device Available in Mac OS X v10.0 and later.
kEINVALErr	-3221	Invalid argument Available in Mac OS X v10.0 and later.
kENOTTYErr	-3224	Not a character device Available in Mac OS X v10.0 and later.
kEPIPEErr	-3231	Broken pipe Available in Mac OS X v10.0 and later.
kERANGEErr	-3233	Message size too large for STREAM Available in Mac OS X v10.0 and later.
kEDEADLKErr	-3234	or a deadlock would occur Available in Mac OS X v10.0 and later.
kEWOULDBLOCKErr	-3234	Call would block, so was aborted Available in Mac OS X v10.0 and later.
kEALREADYErr	-3236	Available in Mac OS X v10.0 and later.
kENOTSOCKErr	-3237	Socket operation on non-socket Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kEDESTADDRREQErr	-3238	Destination address required Available in Mac OS X v10.0 and later.
kEMSGSIZEErr	-3239	Message too long Available in Mac OS X v10.0 and later.
kEPROTOTYPEErr	-3240	Protocol wrong type for socket Available in Mac OS X v10.0 and later.
kENOPROTOOPTErr	-3241	Protocol not available Available in Mac OS X v10.0 and later.
kEPROTONOSUPPORTErr	-3242	Protocol not supported Available in Mac OS X v10.0 and later.
kESOCKTNOSUPPORTErr	-3243	Socket type not supported Available in Mac OS X v10.0 and later.
kEOPNOTSUPPErr	-3244	Operation not supported on socket Available in Mac OS X v10.0 and later.
kEADDRINUSEErr	-3247	Address already in use Available in Mac OS X v10.0 and later.
kEADDRNOTAVAILErr	-3248	Can't assign requested address Available in Mac OS X v10.0 and later.
kENETDOWNErr	-3249	Network is down Available in Mac OS X v10.0 and later.
kENETUNREACHErr	-3250	Network is unreachable Available in Mac OS X v10.0 and later.
kENETRESETErr	-3251	Network dropped connection on reset Available in Mac OS X v10.0 and later.
kECONNABORTEDErr	-3252	Software caused connection abort Available in Mac OS X v10.0 and later.
kECONNRESETErr	-3253	Connection reset by peer Available in Mac OS X v10.0 and later.
kENOBUFSErr	-3254	No buffer space available Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kEISCONNErr	-3255	Socket is already connected Available in Mac OS X v10.0 and later.
kENOTCONNErr	-3256	Socket is not connected Available in Mac OS X v10.0 and later.
kESHUTDOWNErr	-3257	Can't send after socket shutdown Available in Mac OS X v10.0 and later.
kETOOMANYREFSErr	-3258	Too many references: can't splice Available in Mac OS X v10.0 and later.
kETIMEDOUTErr	-3259	Connection timed out Available in Mac OS X v10.0 and later.
kECONNREFUSEDErr	-3260	Connection refused Available in Mac OS X v10.0 and later.
kEHOSTDOWNErr	-3263	Host is down Available in Mac OS X v10.0 and later.
kEHOSTUNREACHErr	-3264	No route to host Available in Mac OS X v10.0 and later.
kEPROTOErr	-3269	Available in Mac OS X v10.0 and later.
kETIMEErr	-3270	Available in Mac OS X v10.0 and later.
kENOSRErr	-3271	Available in Mac OS X v10.0 and later.
kEBADMSGErr	-3272	Available in Mac OS X v10.0 and later.
kECANCELErr	-3273	Available in Mac OS X v10.0 and later.
kENOSTRErr	-3274	Available in Mac OS X v10.0 and later.
kENODATAErr	-3275	Available in Mac OS X v10.0 and later.
kEINPROGRESSErr	-3276	Available in Mac OS X v10.0 and later.
kESRCHErr	-3277	Available in Mac OS X v10.0 and later.
kENOMSGErr	-3278	Available in Mac OS X v10.0 and later.
kOTClientNotInittedErr	-3279	Available in Mac OS X v10.0 and later.
kOTPortHasDiedErr	-3280	Available in Mac OS X v10.0 and later.
kOTPortWasEjectedErr	-3281	Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kOTBadConfigurationErr	-3282	Available in Mac OS X v10.0 and later.
kOTConfigurationChangedErr	-3283	Available in Mac OS X v10.0 and later.
kOTUserRequestedErr	-3284	Available in Mac OS X v10.0 and later.
kOTPortLostConnection	-3285	Available in Mac OS X v10.0 and later.
kModemOutOfMemory	-14000	Available in Mac OS X v10.0 and later.
kModemPreferencesMissing	-14001	Available in Mac OS X v10.0 and later.
kModemScriptMissing	-14002	Available in Mac OS X v10.0 and later.

Search Kit Reference

Framework: CoreServices/CoreServices.h

Declared in SearchKit.h
SKAnalysis.h
SKDocument.h
SKIndex.h
SKSearch.h
SKSummary.h

Overview

Search Kit is a powerful and streamlined C language framework for indexing and searching text in most human languages. It provides fast information retrieval in System Preferences, Address Book, Help Viewer, and Xcode. Apple's Spotlight technology is built on top of Search Kit to provide content searching in Finder, Mail, and the Spotlight menu.

You can use Search Kit or Spotlight to provide similar functionality and powerful information-access capabilities within your Mac OS X application. The Search Kit API is appropriate when you want your application to have full control over indexing and searching, and when your focus is file content. Search Kit is thread-safe and works with Cocoa, Carbon, and command-line tools.

Beginning with Mac OS X version 10.4, Search Kit supports phrase searches, prefix/suffix/substring searches, improved Boolean searches, and improved relevance ranking. Search Kit now uses Spotlight's metadata importers when indexing documents, and takes advantage of any additional importers available on a system. Searching and indexing are much faster with Search Kit's new asynchronous search APIs. And, starting in Mac OS X v10.4, Search Kit provides a summarization API that supplants Find By Content.

Functions by Task

Functions are grouped according to the tasks you perform using them. For an alphabetical list of functions, go to the API index at the end of the document.

Creating, Opening, and Closing Indexes

Search Kit performs its searches not on documents but on its indexes of documents. The functions in this group let your application create memory-based and persistent indexes. Indexes are initially empty. Functions in "Managing Indexes" (page 2730) let you add document content to these indexes.

SKIndexCreateWithURL (page 2747)
Creates a named index in a file whose location is specified with a CFURL object.

SKIndexCreateWithMutableData (page 2746)
Creates a named index stored in a CFMutableData object.

SKIndexOpenWithData (page 2758)
Opens an existing, named index for searching only.

SKIndexOpenWithMutableData (page 2759)
Opens an existing, named index for searching and updating.

SKIndexOpenWithURL (page 2760)
Opens an existing, named index stored in a file whose location is specified with a CFURL object.

SKIndexClose (page 2740)
Closes an index.

SKIndexGetIndexType (page 2754)
Gets the category of an index.

SKIndexGetTypeID (page 2757)
Gets the type identifier for Search Kit indexes.

Managing Indexes

The functions in this section let your application add document content to (and remove document content from) indexes, work with memory- and disk-based indexes, and retrieve metadata from indexes.

SKIndexAddDocumentWithText (page 2739)
Adds a document URL object, and the associated document's textual content, to an index.

SKIndexAddDocument (page 2738)
Adds location information for a file-based document, and the document's textual content, to an index.

SKIndexFlush (page 2750)
Invokes all pending updates associated with an index and commits them to backing store.

SKIndexCompact (page 2741)
Invokes all pending updates associated with an index, compacts the index if compaction is needed, and commits all changes to backing store.

SKIndexGetDocumentCount (page 2751)
Gets the total number of documents represented in an index.

SKIndexGetMaximumDocumentID (page 2755)
Gets the highest-numbered document ID in an index.

SKIndexGetMaximumTermID (page 2756)
Gets the highest-numbered term ID in an index.

SKIndexDocumentIteratorCreate (page 2749)
Creates an index-based iterator for document URL objects owned by a parent document URL object.

SKIndexDocumentIteratorCopyNext (page 2748)
Obtains the next document URL object from an index using a document iterator.

SKIndexGetAnalysisProperties (page 2751)
Gets the text analysis properties of an index.

SKIndexMoveDocument (page 2758)
Changes the parent of a document URL object in an index.

`SKIndexRemoveDocument` (page 2761)
Removes a document URL object and its children, if any, from an index.

`SKIndexRenameDocument` (page 2761)
Changes the name of a document URL object in an index.

`SKIndexSetMaximumBytesBeforeFlush` (page 2763)
Not recommended. Sets the memory size limit for updates to an index, measured in bytes.

`SKIndexGetMaximumBytesBeforeFlush` (page 2755)
Not recommended. Gets the memory size limit for updates to an index, measured in bytes.

`SKIndexDocumentIteratorGetTypeID` (page 2750) Deprecated in Mac OS X v10.5
Gets the type identifier for Search Kit document iterators.

Working With Text Importers

Search Kit can import the textual content of file-based documents into indexes using the Spotlight metadata importers.

`SKLoadDefaultExtractorPlugIns` (page 2763)
Tells Search Kit to use the Spotlight metadata importers.

Working with Documents and Terms

From Search Kit's perspective, a document is anything that contains text—an RTF document, a PDF file, a Mail message, an Address Book entry, an Internet URL, the result of a database query, and so on.

The functions in this section let your application create new document URL objects (SKDocumentRefs), retrieve metadata from documents, get information on document hierarchies, and work with documents and their terms in the context of Search Kit indexes.

`SKDocumentCreateWithURL` (page 2735)
Creates a document URL object from a CFURL object.

`SKDocumentCreate` (page 2734)
Creates a document URL object based on a scheme, parent, and name.

`SKDocumentCopyURL` (page 2734)
Builds a CFURL object from a document URL object.

`SKDocumentGetName` (page 2736)
Gets the name of a document URL object.

`SKDocumentGetParent` (page 2736)
Gets a document URL object's parent.

`SKDocumentGetSchemeName` (page 2737)
Gets the scheme name for a document URL object.

`SKDocumentGetTypeID` (page 2737)
Gets the type identifier for Search Kit document URL objects.

`SKIndexCopyDocumentForDocumentID` (page 2741)
Obtains a document URL object from an index.

`SKIndexCopyInfoForDocumentIDs` (page 2744)
Gets document names and parent IDs based on document IDs.

SKIndexCopyDocumentRefsForDocumentIDs (page 2743)
Gets document URL objects based on document IDs.

SKIndexCopyDocumentURLsForDocumentIDs (page 2744)
Gets document URLs based on document IDs.

SKIndexCopyDocumentIDArrayForTermID (page 2742)
Obtains document IDs for documents that contain a given term.

SKIndexCopyTermIDArrayForDocumentID (page 2745)
Obtains the IDs for the terms of an indexed document.

SKIndexCopyTermStringForTermID (page 2746)
Obtains a term, specified by ID, from an index.

SKIndexGetTermIDForTermString (page 2757)
Gets the ID for a term in an index.

SKIndexSetDocumentProperties (page 2762)
Sets the application-defined properties of a document URL object.

SKIndexCopyDocumentProperties (page 2742)
Obtains the application-defined properties of an indexed document.

SKIndexGetDocumentState (page 2753)
Gets the current indexing state of a document URL object in an index.

SKIndexGetDocumentTermCount (page 2753)
Gets the number of terms for a document in an index.

SKIndexGetDocumentTermFrequency (page 2754)
Gets the number of occurrences of a term in a document.

SKIndexGetTermDocumentCount (page 2756)
Gets the number of documents containing a given term represented in an index.

SKIndexGetDocumentID (page 2752)
Gets the ID of a document URL object in an index.

Fast Asynchronous Searching

In Mac OS X v10.4 and later, Search Kit's fast asynchronous searching replaces synchronous searching. Synchronous searching, which relied on search groups, is deprecated.

SKSearchCreate (page 2764)
Creates an asynchronous search object for querying an index, and initiates search.

SKSearchFindMatches (page 2766)
Extracts search result information from a search object.

SKSearchCancel (page 2764)
Cancels an asynchronous search request.

SKSearchGetTypeID (page 2768)
Gets the type identifier for Search Kit search objects.

Working With Summarization

Search Kit's Summarization functions supplant those in Apple's Find by Content API.

`SKSummaryCreateWithString` (page 2777)
Creates a summary object based on a text string.

`SKSummaryGetSentenceSummaryInfo` (page 2779)
Gets detailed information about a body of text for constructing a custom sentence-based summary string.

`SKSummaryGetParagraphSummaryInfo` (page 2777)
Gets detailed information about a body of text for constructing a custom paragraph-based summary string.

`SKSummaryGetSentenceCount` (page 2778)
Gets the number of sentences in a summarization object.

`SKSummaryGetParagraphCount` (page 2777)
Gets the number of paragraphs in a summarization object.

`SKSummaryCopySentenceAtIndex` (page 2776)
Gets a specified sentence from the text in a summarization object.

`SKSummaryCopyParagraphAtIndex` (page 2775)
Gets a specified paragraph from the text in a summarization object.

`SKSummaryCopySentenceSummaryString` (page 2776)
Gets a text string consisting of a summary with, at most, the requested number of sentences.

`SKSummaryCopyParagraphSummaryString` (page 2775)
Gets a text string consisting of a summary with, at most, the requested number of paragraphs.

`SKSummaryGetTypeID` (page 2779)
Gets the type identifier for Search Kit summarization objects.

Legacy Support for Synchronous Searching

Developers should avoid using the functions listed in this section; instead, use the replacement functions that are recommended. Search Kit retains the functions in this section for backward compatibility.

`SKSearchGroupGetTypeID` (page 2769)
Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.

`SKSearchResultsGetTypeID` (page 2774)
Gets the type identifier for Search Kit search results. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

`SKSearchGroupCopyIndexes` (page 2768) Deprecated in Mac OS X v10.4
Obtains the indexes for a search group. (Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.)

`SKSearchGroupCreate` (page 2769) Deprecated in Mac OS X v10.4
Creates a search group as an array of references to indexes. (Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.)

`SKSearchResultsCopyMatchingTerms` (page 2770) Deprecated in Mac OS X v10.4
Obtains the terms in a document that match a query. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

`SKSearchResultsCreateWithDocuments` (page 2770) Deprecated in Mac OS X v10.4
Finds documents similar to given example documents. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

`SKSearchResultsCreateWithQuery` (page 2772) Deprecated in Mac OS X v10.4
Queries the indexes in a search group. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

`SKSearchResultsGetCount` (page 2773) Deprecated in Mac OS X v10.4
Gets the total number of found items in a search. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

`SKSearchResultsGetInfoInRange` (page 2773) Deprecated in Mac OS X v10.4
Extracts information from a Search Kit query result. (Deprecated. Use `SKSearchCreate` (page 2764) instead.)

Functions

SKDocumentCopyURL

Builds a CFURL object from a document URL object.

```
CFURLRef SKDocumentCopyURL (
    SKDocumentRef   inDocument
);
```

Parameters

inDocument
The document URL object (SKDocumentRef) that you want a `CFURLRef` object for.

Return Value

A `CFURLRef` object representing a document location, or `NULL` on failure.

Discussion

You can use this function to create a *CFURL Reference* object to represent a document's location. Do this to gain access to the Core Foundation functionality provided by CFURL. This functionality includes accessing parts of the URL string, getting properties of the URL, and converting the URL to other representations.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKDocument.h`

SKDocumentCreate

Creates a document URL object based on a scheme, parent, and name.

```
SKDocumentRef SKDocumentCreate (
CFStringRef     inScheme,
SKDocumentRef   inParent,
CFStringRef     inName
);
```

Parameters

inScheme

The scheme to use—analogous to the scheme of a URL. Only documents referenced with the "file" scheme can be read by the SKIndexAddDocument (page 2738) function. The scheme can be anything you like if you use the SKIndexAddDocumentWithText (page 2739) function. The scheme can be NULL, in which case it will be set to be the same scheme as the document URL object's (SKDocumentRef's) parent. For more information on schemes, see http://www.iana.org/assignments/uri-schemes.html.

inParent

The document URL object one step up in the document hierarchy. Can be NULL.

inName

The name of the document that you're creating a document URL object for. For the "file" scheme, it is the name of the file or the container, not its path. The path can be constructed by following parent links. The maximum length for a document name is 256 bytes.

Return Value

The new document URL object, or NULL on failure.

Discussion

The new document URL object's (SKDocumentRef's) parent can be NULL, but you must specify either a scheme or a parent. When your application no longer needs the document URL object, dispose of it by calling CFRelease.

Availability

Available in Mac OS X v10.3 and later.

Declared In

SKDocument.h

SKDocumentCreateWithURL

Creates a document URL object from a CFURL object.

```
SKDocumentRef SKDocumentCreateWithURL (
    CFURLRef    inURL
);
```

Parameters

inURL

The URL for the document URL object (SKDocumentRef) you are creating. The scheme of the document URL object gets set to the scheme of the URL used. Only URLs with a scheme of "file" can be used with the SKIndexAddDocument (page 2738) function, but the URL scheme may be anything you like if you use the SKIndexAddDocumentWithText (page 2739) function. For more information on schemes, see http://www.iana.org/assignments/uri-schemes.html.

Return Value

The new document URL object (SKDocumentRef), or NULL if the document URL object could not be created.

Discussion
Use `SKDocumentCreateWithURL` to create a unique reference to a file or to another, arbitrary URL that your application will use as a document URL object (SKDocumentRef). When your application no longer needs the document URL object, dispose of it by calling `CFRelease`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKDocument.h`

SKDocumentGetName

Gets the name of a document URL object.

```
CFStringRef SKDocumentGetName (
    SKDocumentRef   inDocument
);
```

Parameters
`inDocument`
The document URL object (SKDocumentRef) whose name you want to get.

Return Value
A `CFStringRef` object containing the document URL object's name, or `NULL` on failure.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKDocument.h`

SKDocumentGetParent

Gets a document URL object's parent.

```
SKDocumentRef SKDocumentGetParent (
    SKDocumentRef   inDocument
);
```

Parameters
`inDocument`
The document URL object (SKDocumentRef) whose parent you want to get.

Return Value
The parent document URL object, or `NULL` on failure.

Discussion
As described in `SKDocumentRef` (page 2781), Search Kit manages document locations in terms of URLs as Document URL objects (SKDocumentRefs). The parent document URL object typically contains the document's URL up to but not including the document name.

Typically, document URL objects contain the complete URL to a file-based document. But you can use this function iteratively to build up the complete file-system path for a document that you are managing as part of a document hierarchy. See `SKDocumentRef` (page 2781) for more on this.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKDocument.h`

SKDocumentGetSchemeName

Gets the scheme name for a document URL object.

```
CFStringRef SKDocumentGetSchemeName (
    SKDocumentRef   inDocument
);
```

Parameters

`inDocument`
The document URL object (SKDocumentRef) whose scheme you want to get.

Return Value
A `CFStringRef` object containing the document URL object's scheme name, or `NULL` on failure.

Discussion
The scheme of a document URL object (SKDocumentRef), which represents how it can be accessed, can be any character string but is typically "`file`" or "`http`". The scheme is one of a Search Kit document URL object's three properties—see `SKDocumentRef` (page 2781) for details.

For more information on schemes, see http://www.iana.org/assignments/uri-schemes.html

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKDocument.h`

SKDocumentGetTypeID

Gets the type identifier for Search Kit document URL objects.

```
CFTypeID SKDocumentGetTypeID (void);
```

Return Value
A `CFTypeID` object containing the type identifier for the document URL object (SKDocumentRef).

Discussion
Search Kit represents document URL objects with the `SKDocumentRef` (page 2781) opaque type. If your code needs to determine whether a particular data type is a document URL object, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the document URL object type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKDocument.h

SKIndexAddDocument

Adds location information for a file-based document, and the document's textual content, to an index.

```
Boolean SKIndexAddDocument (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument,
    CFStringRef     inMIMETypeHint,
    Boolean         inCanReplace
);
```

Parameters

inIndex

The index you are adding the document URL object to.

inDocument

The document URL object (SKDocumentRef), containing a file-based document's location information, to add to the index. You can release the document URL object immediately after adding it to the index.

inMIMETypeHint

The MIME type hint for the specified file-based document. Can be NULL. In Search Kit, common MIME type hints include text/plain, text/rtf, text/html, text/pdf, and application/msword.

Specify a MIME type hint to help Spotlight determine which of its metadata importers to use when Search Kit is indexing a file-based document. Search Kit uses filename extensions and type/creator codes in attempting to determine file types when indexing files. See SKLoadDefaultExtractorPlugIns (page 2763). You can circumvent Search Kit's file type determination process, or override it, by using a MIME type hint.

inCanReplace

A Boolean value specifying whether Search Kit will overwrite a document's index entry (true, indicated by 1 or kCFBooleanTrue), or retain the entry if it exists (false, indicated by 0 or kCFBoolenFalse).

Return Value
A Boolean value of true on success, or false on failure. Also returns false if the document has an entry in the index and *inCanReplace* is set to false.

Discussion
The document scheme must be of type "file" to use this function. If it's not, call SKIndexAddDocumentWithText (page 2739) instead. For more information on schemes, see http://www.iana.org/assignments/uri-schemes.html.

This function uses the referenced document and the optional MIME type hint to get the document's textual content using the Spotlight metadata importers. If you do not supply a MIME type hint, Spotlight's importers will use filename extensions and type/creator codes to guess file types.

Search Kit indexes any nonexecutable file associated with a document URL object (SKDocumentRef) that you hand to this function, even nontext files such as images. Your application takes responsibility for ensuring that the document URL objects you pass to SKIndexAddDocument are in fact the locations of files you want to index.

If your application did not call SKLoadDefaultExtractorPlugIns (page 2763), Search Kit indexes the first 10 MB of a document. Otherwise, Search Kit indexes the entire document up to the index file size limit of 4 GB.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

A single Search Kit index can hold up to 4 billion document URL objects and their associated textual content.

Special Considerations

In the current implementation of Search Kit, some functions do not provide expected results unless you follow SKIndexAddDocument with a call to SKIndexFlush (page 2750). The affected functions include SKIndexGetDocumentCount (page 2751), SKIndexGetDocumentTermCount (page 2753), SKIndexGetDocumentTermFrequency (page 2754), and SKIndexGetTermDocumentCount (page 2756). However, in typical use this won't be an issue, because applications call these functions after a search, and you must call SKIndexFlush before a search.

Version Notes

In versions of Mac OS X prior to Mac OS X v10.4, Search Kit used its own text extractor plug-ins rather than using the Spotlight metadata importers. See SKLoadDefaultExtractorPlugIns (page 2763) and http://developer.apple.com/macosx/tiger/spotlight.html.

Availability

Available in Mac OS X v10.3 and later.

Declared In

SKIndex.h

SKIndexAddDocumentWithText

Adds a document URL object, and the associated document's textual content, to an index.

```
Boolean SKIndexAddDocumentWithText (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument,
    CFStringRef     inDocumentText,
    Boolean         inCanReplace
);
```

Parameters

inIndex

The index to which you are adding the document URL object (SKDocumentRef).

inDocument

The document URL object to add.

inDocumentText

The document text. Can be NULL.

inCanReplace

A Boolean value specifying whether Search Kit will overwrite a document's index entry (true, indicated by 1 or kCFBooleanTrue), or retain the entry if it exists (false, indicated by 0 or kCFBoolenFalse).

Return Value

A Boolean value of true on success, or false on failure. Also returns false if the document has an entry in the index and *inCanReplace* is set to false.

Discussion
Use this function to add the textual contents of arbitrary document types to an index. With this function, your application takes responsibility for getting textual content and handing it to the index as a CFString object. Because of this, your application can define what it considers to be a document—a database record, a tagged field in an XML document, an object in memory, a text file, and so on.

Search Kit will index any size text string that you give it, up to its 4 GB index file size limit.

To add the textual content of file-based documents to a Search Kit index, you can use this function or take advantage of Search Kit's ability to locate and read certain on-disk, file-based document types—see `SKIndexAddDocument` (page 2738).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

A single Search Kit index file can be up to 4 GB in size.

Special Considerations

In Mac OS X v10.3, some functions do not provide expected results unless you follow a call to `SKIndexAddDocumentWithText` with a call to `SKIndexFlush` (page 2750). The affected functions include `SKIndexGetDocumentCount` (page 2751), `SKIndexGetDocumentTermCount` (page 2753), `SKIndexGetDocumentTermFrequency` (page 2754), and `SKIndexGetTermDocumentCount` (page 2756). However, in typical use this won't be an issue, because applications call these functions after a search, and you must call `SKIndexFlush` before a search.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexClose

Closes an index.

```
void SKIndexClose (
    SKIndexRef      inIndex
);
```

Parameters

inIndex
The index to close.

Discussion
When your application no longer needs an index that it has opened or created, call `SKIndexClose`. Calling this function is equivalent to calling `CFRelease` on an index.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKIndex.h`

SKIndexCompact

Invokes all pending updates associated with an index, compacts the index if compaction is needed, and commits all changes to backing store.

```
Boolean SKIndexCompact (
    SKIndexRef  inIndex
);
```

Parameters

inIndex

The index you want to compact.

Return Value

A Boolean value of `true` on success, or `false` on failure.

Discussion

Over time, as document URL objects (SKDocumentRefs) and associated contents get added to and removed from an index, the index's disk or memory footprint may grow due to fragmentation.

Compacting can take a significant amount of time. Do not call `SKIndexCompact` on the main thread in an application with a user interface. Call it only if the index is significantly fragmented and according to the needs of your application.

Calling `SKIndexCompact` changes the block allocation for an index's backing store. Close all clients of an index before calling this function.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKIndex.h`

SKIndexCopyDocumentForDocumentID

Obtains a document URL object from an index.

```
SKDocumentRef SKIndexCopyDocumentForDocumentID (
    SKIndexRef      inIndex,
    SKDocumentID    inDocumentID
);
```

Parameters

inIndex

The index containing the document URL object (SKDocumentRef).

inDocumentID

The ID of the document URL object you want to copy.

Return Value

A Search Kit document URL object.

Version Notes

In versions of Mac OS X prior to Mac OS X v10.4, the parameter type for *inDocumentID* was `CFIndex`. The parameter type in Mac OS X v10.4 and later is `SKDocumentID`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexCopyDocumentIDArrayForTermID

Obtains document IDs for documents that contain a given term.

```
CFArrayRef SKIndexCopyDocumentIDArrayForTermID (
    SKIndexRef      inIndex,
    CFIndex         inTermID
);
```

Parameters

inIndex

The index to search.

inTermID

The ID of the term to search for.

Return Value
An array of CFNumbers, each the ID for a document URL object that points to a document containing the search term.

Discussion
SKIndexCopyDocumentIDArrayForTermID searches a single index for documents that contain a given term. The search uses a term ID, not a term string. To get the ID of a term, use SKIndexGetTermIDForTermString (page 2757).

Term IDs are index-specific; that is, a term has a different ID in each index in which it appears. If you want to search for all the documents containing a term in a set of indexes, call this function in turn for each index, using the index-specific term ID in each case.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexCopyDocumentProperties

Obtains the application-defined properties of an indexed document.

```
CFDictionaryRef SKIndexCopyDocumentProperties (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument
);
```

Parameters

inIndex

The index containing the document URL object (SKDocumentRef) whose properties you want to copy.

inDocument
The document URL object whose properties you want to copy.

Return Value
A CFDictionary object containing the document URL object's (SKDocumentRef's) properties, or `NULL` on failure.

Discussion
Search Kit document URL objects (SKDocumentRefs) can have an optional, application-defined properties dictionary to hold any information you'd like to associate with the document represented by a document URL object—such as timestamp, keywords, and so on. Use `SKIndexSetDocumentProperties` (page 2762) to add a properties dictionary to a document URL object, and this function to obtain a copy of the dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexCopyDocumentRefsForDocumentIDs

Gets document URL objects based on document IDs.

```
void SKIndexCopyDocumentRefsForDocumentIDs (
    SKIndexRef      inIndex,
    CFIndex         inCount,
    SKDocumentID    *inDocumentIDsArray,
    SKDocumentRef   *outDocumentRefsArray
);
```

Parameters

inIndex
The index containing the document information.

inCount
The number of document IDs in *inDocumentIDsArray*.

inDocumentIDsArray
Points to an array of document IDs corresponding to the document URL objects (SKDocumentRefs) you want.

outDocumentRefsArray
On input, a pointer to an array for document URL objects. On output, points to the previously allocated array, which now contains document URL objects corresponding to the document IDs in `inDocumentIDsArray`.

When finished with the document URL objects array, dispose of it by calling `CFRelease` on each array element.

Discussion
The `SKIndexCopyDocumentRefsForDocumentIDs` function lets you get a batch of document URL objects (SKDocumentRef objects) in one step, based on a list of document IDs.

If you want to get lightweight URLs in the form of CFURL objects instead, use `SKIndexCopyDocumentURLsForDocumentIDs` (page 2744).

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSearch.h

SKIndexCopyDocumentURLsForDocumentIDs

Gets document URLs based on document IDs.

```
void SKIndexCopyDocumentURLsForDocumentIDs (
    SKIndexRef      inIndex,
    CFIndex         inCount,
    SKDocumentID    *inDocumentIDsArray,
    CFURLRef        *outDocumentURLsArray
);
```

Parameters

inIndex
The index containing the document information.

inCount
The number of document IDs in *inDocumentIDsArray*.

inDocumentIDsArray
Points to an array of document IDs corresponding to the document URLs (CFURL objects) you want.

outDocumentURLsArray
On input, a pointer to an array for document URLs (CFURL objects). On output, points to the previously allocated array, which now contains document URLs corresponding to the document IDs in `inDocumentIDArray`.

When finished with the document URL array, dispose of it by calling `CFRelease` on each array element.

Discussion
The `SKIndexCopyDocumentURLsForDocumentIDs` function lets you get a batch of document URLs (CFURL objects) in one step, based on a list of document IDs.

If you want to get Search Kit Document URL objects (SKDocumentRefs) instead, use `SKIndexCopyDocumentRefsForDocumentIDs` (page 2743).

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSearch.h

SKIndexCopyInfoForDocumentIDs

Gets document names and parent IDs based on document IDs.

```
void SKIndexCopyInfoForDocumentIDs (
    SKIndexRef      inIndex,
    CFIndex         inCount,
    SKDocumentID    *inDocumentIDsArray,
    CFStringRef     *outNamesArray,
    SKDocumentID    *outParentIDsArray
);
```

Parameters

inIndex

The index containing the document information.

inCount

The number of document IDs in *inDocumentIDsArray*.

inDocumentIDsArray

Points to an array of document IDs representing the documents whose names and parent IDs you want.

outNamesArray

On input, a pointer to an array for document names. On output, points to the previously allocated array, which now contains the document names corresponding to the document IDs in *inDocumentIDsArray*. May be `NULL` on input if you don't want to get the document names.

When finished with the names array, dispose of it by calling `CFRelease` on each array element.

outParentIDsArray

On input, a pointer to an array for parent document IDs. On output, points to the previously allocated array, which now contains document IDs representing the parents of the documents whose IDs are in *inDocumentIDsArray*. May be `NULL` on input if you don't want to get the parent document IDs.

Discussion

The `SKIndexCopyInfoForDocumentIDs` function lets you get a batch of document names and parent document IDs in one step, based on a list of document IDs.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`SKSearch.h`

SKIndexCopyTermIDArrayForDocumentID

Obtains the IDs for the terms of an indexed document.

```
CFArrayRef SKIndexCopyTermIDArrayForDocumentID (
    SKIndexRef      inIndex,
    SKDocumentID    inDocumentID
);
```

Parameters

inIndex

The index containing the document URL object (SKDocumentRef) and associated textual content.

inDocumentID

The ID of the document whose term IDs you are copying.

Return Value
A CFArray containing CFNumbers, each of which represents the ID for a term in a document.

Discussion
To derive the list of terms contained in a document, use this function to obtain an array of the term IDs, then convert each ID into the corresponding term with the `SKIndexCopyTermStringForTermID` (page 2746) function.

Version Notes
In versions of Mac OS X prior to Mac OS X v10.4, the parameter type for `inDocumentID` was `CFIndex`. In Mac OS X v10.4 and later, the parameter type is `SKDocumentID`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexCopyTermStringForTermID

Obtains a term, specified by ID, from an index.

```
CFStringRef SKIndexCopyTermStringForTermID (
    SKIndexRef      inIndex,
    CFIndex         inTermID
);
```

Parameters

`inIndex`
The index whose terms you are searching.

`inTermID`
The ID of the term whose string you want.

Return Value
A CFString containing the term specified by `inTermID`.

Discussion
When your application has the ID of a term, perhaps as a result of calling `SKIndexCopyTermIDArrayForDocumentID` (page 2745), use this function to derive the term's text string.

To perform the inverse operation of deriving a term ID from a term string in a given index, use `SKIndexGetTermIDForTermString` (page 2757).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexCreateWithMutableData

Creates a named index stored in a CFMutableData object.

```
SKIndexRef SKIndexCreateWithMutableData (
    CFMutableDataRef    inData,
    CFStringRef         inIndexName,
    SKIndexType         inIndexType,
    CFDictionaryRef     inAnalysisProperties
);
```

Parameters

inData

An empty CFMutableData object to contain the index being created.

inIndexName

The name of the index. If you call this function with `inIndexName` set to `NULL`, Search Kit assigns the index the default index name `IADefaultIndex`. If you then attempt to create a second index in the same file without assigning a name, no second index is created and this function returns `NULL`. Search Kit does not currently support retrieving index names from an index.

inIndexType

The index type. See "`SKIndexType`" (page 2788).

inAnalysisProperties

The text analysis properties dictionary, which optionally sets the minimum term length, stopwords, term substitutions, maximum unique terms to index, and proximity support (for phrase-based searches) when creating the index. See "`Text Analysis Keys`" (page 2784). The `inAnalysisProperties` parameter can be `NULL`, in which case Search Kit applies the default dictionary, which is `NULL`.

Return Value
The newly created index.

Discussion
`SKIndexCreateWithMutableData` creates an index in memory as a CFMutableData object. Search Kit indexes are initially empty. A memory-based index is useful for quick searching and when your application doesn't need persistent storage. To create a disk-based, persistent index, use `SKIndexCreateWithURL` (page 2747).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

When your application no longer needs the index, dispose of it by calling `SKIndexClose` (page 2740).

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexCreateWithURL

Creates a named index in a file whose location is specified with a CFURL object.

```
SKIndexRef SKIndexCreateWithURL (
    CFURLRef            inURL,
    CFStringRef         inIndexName,
    SKIndexType         inIndexType,
    CFDictionaryRef     inAnalysisProperties
);
```

Parameters

inURL

The location of the index.

inIndexName

The name of the index. If you call this function with `inIndexName` set to `NULL`, Search Kit assigns the index the default index name `IADefaultIndex`. If you then attempt to create a second index in the same file without assigning a name, no second index is created and this function returns `NULL`. Search Kit does not currently support retrieving index names from an index.

inIndexType

The index type. See "SKIndexType" (page 2788).

inAnalysisProperties

The text analysis properties dictionary, which optionally sets the minimum term length, stopwords, term substitutions, maximum unique terms to index, and proximity support (for phrase-based searches) when creating the index. See "Text Analysis Keys" (page 2784). To get the analysis properties of an index, use the `SKIndexGetAnalysisProperties` (page 2751) function. The `inAnalysisProperties` parameter can be `NULL`, in which case Search Kit applies the default dictionary, which is `NULL`.

Return Value

A unique reference to the newly created index.

Discussion

`SKIndexCreateWithURL` creates an index in a file. Search Kit indexes are initially empty. Use this function when your application needs persistent storage of an index. To create a memory-based, nonpersistent index, use `SKIndexCreateWithMutableData` (page 2746).

A file can contain more than one index. To add a new index to an existing file, use the same value for `inURL` and supply a new name for `inIndexName`.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

When your application no longer needs the index, dispose of it by calling `SKIndexClose` (page 2740).

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKIndex.h`

SKIndexDocumentIteratorCopyNext

Obtains the next document URL object from an index using a document iterator.

```
SKDocumentRef SKIndexDocumentIteratorCopyNext (
    SKIndexDocumentIteratorRef  inIterator
);
```

Parameters

inIterator

The index-based document iterator. See `SKIndexDocumentIteratorCreate` (page 2749) for information on creating an document iterator, and `SKIndexDocumentIteratorRef` (page 2781) for more about iterators.

Return Value
The next document URL object (SKDocumentRef) in the index.

Discussion
This function returns `NULL` when there are no more document URL objects (SKDocumentRefs) in the index. When finished iterating, your application must call `CFRelease` on all retrieved document URL objects that are non-`NULL`.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexDocumentIteratorCreate

Creates an index-based iterator for document URL objects owned by a parent document URL object.

```
SKIndexDocumentIteratorRef SKIndexDocumentIteratorCreate (
    SKIndexRef      inIndex,
    SKDocumentRef   inParentDocument
);
```

Parameters

inIndex

The index you want to iterate across.

inParentDocument

The document URL object (SKDocumentRef) that is the parent of the document URL objects you want to examine. Pass `NULL` to get the top item in an index. See `SKDocumentRef` (page 2781) for a discussion of how to get the full URL for a document URL object.

Return Value
An index-based document iterator.

Discussion
When you want to iterate across all the documents represented in an index, use this function to create an iterator and then call `SKIndexDocumentIteratorCopyNext` (page 2748) in turn for each document URL object (SKDocumentRef) in the index.

Document iterators iterate over a single level of an index. Your code is responsible for descending through a hierarchy of documents in an index.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

When your application no longer needs the iterator, dispose of it by calling `CFRelease`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexDocumentIteratorGetTypeID

Gets the type identifier for Search Kit document iterators.

```
CFTypeID SKIndexDocumentIteratorGetTypeID (void);
```

Return Value
A CFTypeID object containing the type identifier for the SKIndexDocumentIterator opaque type.

Discussion
Search Kit represents document iterators with the `SKIndexDocumentIteratorRef` (page 2781) opaque type. If your code needs to determine whether a particular data type is a document iterator, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Never hard-code the document iterator type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexFlush

Invokes all pending updates associated with an index and commits them to backing store.

```
Boolean SKIndexFlush (
    SKIndexRef  inIndex
);
```

Parameters

inIndex
The index you want to update and commit to backing store.

Return Value
A Boolean value of `true` on success, or `false` on failure.

Discussion
An on-disk or memory-based index becomes stale when your application updates it by adding or removing a document entry. A search on an index in such a state won't have access to the nonflushed updates. The solution is to call this function before searching. `SKIndexFlush` flushes index-update information and commits memory-based index caches to disk, in the case of an on-disk index, or to a memory object, in the case of a memory-based index. In both cases, calling this function makes the state of the index consistent.

Before searching an index, always call `SKIndexFlush`, even though the flush process may take up to several seconds. If there are no updates to commit, a call to `SKIndexFlush` does nothing and takes minimal time.

A new Search Kit index does not have term IDs until it is flushed.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetAnalysisProperties

Gets the text analysis properties of an index.

```
CFDictionaryRef SKIndexGetAnalysisProperties (
    SKIndexRef      inIndex
);
```

Parameters
inIndex
The index whose text-analysis properties you want to get.

Return Value
A CFDictionary object containing the index's text-analysis properties. On failure, returns `NULL`.

Discussion
The text analysis properties of an index determine how searches behave when querying the index. You set the analysis properties when creating an index with the `SKIndexCreateWithURL` (page 2747) or `SKIndexCreateWithMutableData` (page 2746) functions. For more information on text-analysis properties, see "`Text Analysis Keys`" (page 2784).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetDocumentCount

Gets the total number of documents represented in an index.

```
CFIndex SKIndexGetDocumentCount (
    SKIndexRef      inIndex
);
```

Parameters

inIndex

The index whose document URL objects (SKDocumentRefs) you want to count.

Return Value
A CFIndex object containing the number of document URL objects in the index. On failure, returns 0.

Discussion
Document URL objects (SKDocumentRefs) added to an index have an indexing state of `kSKDocumentStateIndexed`. See the "`SKDocumentIndexState`" (page 2786) enumeration.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Special Considerations

In the current implementation of Search Kit, `SKIndexGetDocumentCount` returns the number of documents represented in the on-disk index. If your application has added document URL objects to the index but has not yet called `SKIndexFlush` (page 2750), the document count may not be correct.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetDocumentID

Gets the ID of a document URL object in an index.

```
SKDocumentID SKIndexGetDocumentID (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument
);
```

Parameters

inIndex

The index containing the text of the document whose document URL object (SKDocumentRef) ID you want.

inDocument

The document URL object whose ID you want.

Return Value
A document ID object.

Discussion
The document ID identifies a document URL object (SKDocumentRef) in an index. The ID is available as soon as you add a document URL object to an index using `SKIndexAddDocumentWithText` (page 2739) or `SKIndexAddDocument` (page 2738).

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexGetDocumentState

Gets the current indexing state of a document URL object in an index.

```
SKDocumentIndexState SKIndexGetDocumentState (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument
);
```

Parameters

inIndex

The index containing the document URL object (SKDocumentRef) whose indexing state you want.

inDocument

The document URL object whose indexing state you want.

Return Value
A value indicating the document URL object's indexing state.

Discussion
A document URL object (SKDocumentRef) can be in one of four states, as defined by the "SKDocumentIndexState" (page 2786) enumeration: not indexed, indexed, not in the index but will be added after the index is flushed or closed, and in the index but will be deleted after the index is flushed or closed.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexGetDocumentTermCount

Gets the number of terms for a document in an index.

```
CFIndex SKIndexGetDocumentTermCount (
    SKIndexRef      inIndex,
    SKDocumentID    inDocumentID
);
```

Parameters

inIndex

The index containing the text of the document whose term count you want.

inDocumentID

The ID of the document URL object (SKDocumentRef) whose term count you want. Obtain a document ID by calling SKIndexGetDocumentID (page 2752).

Return Value
A CFIndex object containing the number of terms in a document.

Version Notes
versions of Mac OS X prior to Mac OS X v10.4, the parameter type for *inDocumentID* was `CFIndex`. In Mac OS X v10.4 and later, the parameter type is `SKDocumentID`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetDocumentTermFrequency

Gets the number of occurrences of a term in a document.

```
CFIndex SKIndexGetDocumentTermFrequency (
    SKIndexRef      inIndex,
    SKDocumentID    inDocumentID,
    CFIndex         inTermID
);
```

Parameters

inIndex
The index containing the text of the document whose term count you are interested in.

inDocumentID
The ID of the document URL object whose associated term count you are interested in. Obtain a document ID by calling `SKIndexGetDocumentID` (page 2752).

inTermID
The ID of the term whose number of occurrences you want.

Return Value
A CFIndex object containing the number of occurrences of a term in a document.

Version Notes
In versions of Mac OS X prior to Mac OS X v10.4, the parameter type for `inDocumentID` was `CFIndex`. In Mac OS X v10.4 and later, the parameter type is `SKDocumentID`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetIndexType

Gets the category of an index.

```
SKIndexType SKIndexGetIndexType (
    SKIndexRef      inIndex
);
```

Parameters

inIndex
The index whose category you want to know.

Return Value
The category of the index. See the "SKIndexType" (page 2788) enumeration for a list of the various index categories. On failure, returns a value of kSKIndexUnknown.

Discussion
As described in "SKIndexType" (page 2788), Search Kit offers four categories of index, each optimized for one or more types of searching.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexGetMaximumBytesBeforeFlush

Not recommended. Gets the memory size limit for updates to an index, measured in bytes.

```
CFIndex SKIndexGetMaximumBytesBeforeFlush (
    SKIndexRef      inIndex
);
```

Special Considerations

This function is rarely needed and is likely to be deprecated. Apple recommends using the SKIndexFlush (page 2750) function along with the default memory size limit for index updates. Refer to the SKIndexSetMaximumBytesBeforeFlush function for more information.

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKIndexGetMaximumDocumentID

Gets the highest-numbered document ID in an index.

```
SKDocumentID SKIndexGetMaximumDocumentID (
    SKIndexRef  inIndex
);
```

Parameters

inIndex
An index.

Return Value
A document ID object containing the highest-numbered document ID in the index.

Discussion
Use this function with SKIndexGetDocumentCount (page 2751) to determine whether an index is fragmented and in need of compaction. See SKIndexCompact (page 2741).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Version Notes
In versions of Mac OS X prior to Mac OS X v10.4, the return type for `SKIndexGetMaximumDocumentID` was `CFIndex`. The return type in Mac OS X v10.4 and later is `SKDocumentID`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetMaximumTermID

Gets the highest-numbered term ID in an index.

```
CFIndex SKIndexGetMaximumTermID (
    SKIndexRef  inIndex
);
```

Parameters

inIndex
An index.

Return Value
A CFIndex object containing the highest-numbered term ID in an index.

Discussion
A new Search Kit index does not have term IDs until it is flushed.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetTermDocumentCount

Gets the number of documents containing a given term represented in an index.

```
CFIndex SKIndexGetTermDocumentCount (
    SKIndexRef      inIndex,
    CFIndex         inTermID
);
```

Parameters

inIndex
The index containing the text of the documents you want to examine.

inTermID
The terms whose occurrences you want to know.

Return Value
A CFIndex object containing the number of documents represented in an index that contain a given term.

Discussion
If you want to know in which documents a term appears across multiple indexes, call this function separately on each index. Before querying each index, get the index-specific term ID using `SKIndexGetTermIDForTermString` (page 2757).

To ensure that this function takes into account document URL objects (SKDocumentRefs) recently added to indexes, call `SKIndexFlush` (page 2750) on each index before calling this function.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetTermIDForTermString

Gets the ID for a term in an index.

```
CFIndex SKIndexGetTermIDForTermString (
    SKIndexRef      inIndex,
    CFStringRef     inTermString
);
```

Parameters

inIndex
The index you want to examine.

inTermString
The term string whose corresponding ID you want.

Return Value
A CFIndex object containing the term ID for a given term in an index. If the term isn't found, this function returns a value of `kCFNotFound`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexGetTypeID

Gets the type identifier for Search Kit indexes.

```
CFTypeID SKIndexGetTypeID (void);
```

Return Value
A CFTypeID object containing the type identifier for the SKIndex opaque type.

Discussion
Search Kit represents indexes with the `SKIndexRef` (page 2782) opaque type. If your code needs to determine whether a particular data type is an index, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the index type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexMoveDocument

Changes the parent of a document URL object in an index.

```
Boolean SKIndexMoveDocument (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument,
    SKDocumentRef   inNewParent
);
```

Parameters

inIndex
The index containing the document URL object (SKDocumentRef) you want to move.

inDocument
The document URL object you want to move.

inNewParent
The new parent document URL object for the document URL object you want to move.

Return Value
A Boolean value of `true` for a successful move, or `false` on failure.

Discussion
When your application moves a document, use this function to update the index to reflect the change.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexOpenWithData

Opens an existing, named index for searching only.

```
SKIndexRef SKIndexOpenWithData (
    CFDataRef       inData,
    CFStringRef     inIndexName
);
```

Parameters

inData

The index to open.

inIndexName

The name of the index. Can be `NULL`, in which case this function attempts to open the index with the default name of `IADefaultIndex`.

Return Value

The named index, or `NULL` on failure.

Discussion

An index opened by `SKIndexOpenWithData` can be searched but not updated. To open an index for updating, use `SKIndexOpenWithMutableData` (page 2759).

If `inIndexName` is `NULL` and `inData` does not contain an index with the default name, this function returns `NULL`.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

A call to `SKIndexOpenWithData` retains the opened index. When your application no longer needs the index, dispose of it by calling `SKIndexClose` (page 2740).

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKIndex.h`

SKIndexOpenWithMutableData

Opens an existing, named index for searching and updating.

```
SKIndexRef SKIndexOpenWithMutableData (
    CFMutableDataRef    inData,
    CFStringRef         inIndexName
);
```

Parameters

inData

The index to open.

inIndexName

The name of the index. Can be `NULL`, in which case this function attempts to open the index with the default name of `IADefaultIndex`.

Return Value
The named index, or `NULL` on failure.

Discussion
An index opened by `SKIndexOpenWithMutableData` may be searched or updated. To open an index for search only, use the `SKIndexOpenWithData` (page 2758) function.

If `inIndexName` is `NULL` and `inData` does not contain an index with the default name, this function returns `NULL`.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

A call to `SKIndexOpenWithMutableData` retains the opened index. When your application no longer needs the index, dispose of it by calling `SKIndexClose` (page 2740).

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexOpenWithURL

Opens an existing, named index stored in a file whose location is specified with a CFURL object.

```
SKIndexRef SKIndexOpenWithURL (
    CFURLRef        inURL,
    CFStringRef     inIndexName,
    Boolean         inWriteAccess
);
```

Parameters

inURL

The location of the index.

inIndexName

The name of the index. Can be `NULL`.

inWriteAccess

A Boolean value indicating whether the index is open for updating. To open an index for searching only, pass `false` (`0` or `kCFBoolenFalse`). To open it for searching and updating, pass `true` (`1` or `kCFBooleanTrue`).

Return Value
The named index.

Discussion
A call to `SKIndexOpenWithURL` retains the opened index. When your application no longer needs the index, dispose of it by calling `SKIndexClose` (page 2740).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexRemoveDocument

Removes a document URL object and its children, if any, from an index.

```
Boolean SKIndexRemoveDocument (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument
);
```

Parameters

inIndex

The index from which you want to remove the document URL object (SKDocumentRef).

inDocument

The document URL object to remove.

Return Value
A Boolean value of `true` on success, or `false` on failure.

Discussion
When your application deletes a document, use this function to update the index to reflect the change.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexRenameDocument

Changes the name of a document URL object in an index.

```
Boolean SKIndexRenameDocument (
    SKIndexRef      inIndex,
    SKDocumentRef   inDocument,
    CFStringRef     inNewName
);
```

Parameters

inIndex

The index containing the document URL object (SKDocumentRef) whose name you want to change.

inDocument
The document URL object whose name you want to change.

inNewName
The new name for the document URL object.

Return Value
A Boolean value of `true` if the document URL object name was successfully changed, or `false` on failure.

Discussion
When your application changes the name of a document, use this function to update the index to reflect the change.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexSetDocumentProperties

Sets the application-defined properties of a document URL object.

```
void SKIndexSetDocumentProperties (
    SKIndexRef          inIndex,
    SKDocumentRef       inDocument,
    CFDictionaryRef     inProperties
);
```

Parameters
inIndex
An index containing the document URL object (SKDocumentRef) whose properties you want to set.

inDocument
The document URL object whose properties you want to set.

inProperties
A CFDictionary object containing the properties to apply to the document URL object.

Discussion
Search Kit document URL objects (SKDocumentRefs) can have an optional, application-defined properties dictionary to hold any information you'd like to associate with the document represented by a document URL object—such as timestamp, keywords, and so on.

Use `SKIndexSetDocumentProperties` to persistently set application-defined properties for a document URL object in an index. This function replaces a document URL object's existing properties dictionary with the new one. To obtain a copy of a document URL object's properties dictionary, use `SKIndexCopyDocumentProperties` (page 2742).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexSetMaximumBytesBeforeFlush

Not recommended. Sets the memory size limit for updates to an index, measured in bytes.

```
void SKIndexSetMaximumBytesBeforeFlush (
    SKIndexRef  inIndex
    CFIndex     inBytesForUpdate
);
```

Discussion

This function is rarely needed and is likely to be deprecated. Search Kit keeps track of index updates that are not yet committed to disk. Apple recommends using the default memory size limit for index updates, which is currently 2 million bytes.

Special Considerations

Apple recommends use of the `SKIndexFlush` (page 2750) function instead of `SKIndexSetMaximumBytesBeforeFlush`.

Version Notes

In Mac OS X v10.3, the default memory size limit for index updates was 1 million bytes.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKIndex.h`

SKLoadDefaultExtractorPlugIns

Tells Search Kit to use the Spotlight metadata importers.

```
void SKLoadDefaultExtractorPlugIns (void);
```

Discussion

The Spotlight metadata importers determine the `kMDItemTextContent` property for each document passed to the `SKIndexAddDocument` (page 2738) function. See http://developer.apple.com/macosx/tiger/spotlight.html.

Call the `SKLoadDefaultExtractorPlugIns` function once at application launch to tell Search Kit to use the Spotlight metadata importers. The function `SKIndexAddDocument` (page 2738) will then use Spotlight's importers to extract the text from supported files and place that text into an index, leaving the markup behind.

Version Notes

In versions of Mac OS X prior to Mac OS X v10.4, Search Kit used its own set of default text extractor plug-ins. The file types supported by Search Kit's default text extractor plug-ins were:

- plaintext
- PDF
- HTML
- RTF
- Microsoft Word (.doc)

Availability
Available in Mac OS X v10.3 and later.

Declared In
SKIndex.h

SKSearchCancel

Cancels an asynchronous search request.

```
void SKSearchCancel (
    SKSearchRef                 inSearch
);
```

Parameters

inSearch

The search object whose associated asynchronous search you want to cancel.

Discussion
Call this function when you want to cancel an asynchronous search that you initiated with SKSearchCreate (page 2764). This function stops the search process if it is still in progress at the time. It does not dispose of the search object (SKSearchRef).

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSearch.h

SKSearchCreate

Creates an asynchronous search object for querying an index, and initiates search.

```
SKSearchRef SKSearchCreate (
    SKIndexRef              inIndex,
    CFStringRef             inQuery,
    SKSearchOptions         inSearchOptions
);
```

Parameters

inIndex

The index to query.

inQuery

The query string to search for.

inSearchOptions

The search options. May be NULL. See the "SKSearchOptions" (page 2787) enumeration for a description of the available options.

Return Value
A search object.

Discussion
This function creates an asynchronous search object for querying the document contents in an index. It also initiates the search on a separate thread.

After you create the search object, call `SKSearchFindMatches` (page 2766) to retrieve results. You can call `SKSearchFindMatches` immediately. To cancel a search, call `SKSearchCancel` (page 2764).

For normal (non-similarity-based) queries, Search Kit discerns the type of query—Boolean, prefix, phrase, and so on—from the syntax of the query itself. Moreover, Search Kit supports multiple query types within a single search. For example, the following query includes Boolean, prefix, and suffix searching:

```
appl* OR *ing
```

This query will return documents containing words that begin with "appl" as well as documents that contain words that end with "ing".

For similarity searches, specified with the `kSKSearchOptionFindSimilar` flag in the *`inSearchOptions`* parameter, `SKSearchCreate` ignores all query operators.

The query operators that `SKSearchCreate` recognizes for non-similarity searching are:

Table 45-1 Search Kit query operators for non-similarity searches

Operator	meaning
`AND`	Boolean `AND`
`&`	Boolean `AND`
`<space>`	Boolean `AND` by default when no other operator is present, or Boolean `OR` if specified by `kSKSearchOptionSpaceMeansOR`.
`OR`	Boolean inclusive `OR`
`|`	Boolean inclusive `OR`
`NOT`	Boolean `NOT` (see Special Considerations)
`!`	Boolean `NOT` (see Special Considerations)
*	Wildcard for prefix or suffix; surround term with wildcard characters for substring search. Ignored in phrase searching.
(	Begin logical grouping
)	End logical grouping
"	delimiter for phrase searching

The operators `AND`, `OR`, and `NOT` are case sensitive.

Search Kit performs Unicode normalization on query strings and on the text placed into indexes. It uses Unicode Normalization Form KC (NFKC, compatibility decomposition followed by canonical composition) as documented in Unicode Standard Annex #15. For example, the a-grave character, 'à', can be written as the

two Unicode characters (0x0061, 0x0300) or as the single Unicode character 0x00E0. Search Kit will normalize (0x0061, 0x0300) to 0x00E0. For more information on Unicode normalization, see http://unicode.org/reports/tr15 .

Search Kit further normalizes query strings and indexes by stripping diacritical marks and by forcing characters to lowercase. For example, Search Kit normalizes each of the following characters to 'a': 'a', 'à', 'A', and 'À'.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

When your application no longer needs the search object, dispose of it by calling CFRelease.

Special Considerations

Search Kit supports logical exclusion. The NOT and ! operators behave as though they were EXCLUDE operators. For example, a search for 'red NOT blue' returns all documents that contain the word 'red' and do not contain the word 'blue'.

Unary Boolean operators, however, are not currently implemented in Search Kit. A search, for example, for 'NOT blue', returns zero documents no matter what their content.

You cannot use CFMakeCollectable with SKSearch objects. In a garbage-collected environment, you must use CFRelease to dispose of an SKSearch object.

Version Notes

Mac OS X version 10.4 uses a completely revised, and far more powerful, query approach than did earlier versions of Mac OS X. Refer to the Discussion in this function for details. Refer to SKSearchResultsCreateWithQuery (page 2772) (deprecated) for a description of Search Kit's behavior in earlier versions of Mac OS X.

In versions of Mac OS X prior to version 10.4, Search Kit did not perform Unicode normalization, and did not remove diacritical marks.

Availability

Available in Mac OS X v10.4 and later.

Declared In

SKSearch.h

SKSearchFindMatches

Extracts search result information from a search object.

```
Boolean SKSearchFindMatches (
    SKSearchRef         inSearch,
    CFIndex             inMaximumCount,
    SKDocumentID        *outDocumentIDsArray,
    float               *outScoresArray,
    CFTimeInterval      maximumTime
    CFIndex             *outFoundCount
);
```

Parameters

inSearch

A reference to a search object (SKSearchRef) previously created with SKSearchCreate.

inMaximumCount

The maximum number of items to find. For each item found, `SKSearchFindMatches` places the associated document ID into the *outDocumentIDsArray* array. Specify an *inMaximumCount* of 0 to find as many items as possible within *maximumTime*.

outDocumentIDsArray

On input, a pointer to an array for document IDs. On output, points to points to the previously allocated array, which now contains the found document IDs. The size of this array must be equal to *inMaximumCount*.

outScoresArray

On input, a pointer to an array for scores. On output, points to the previously allocated array, which now contains relevance scores for the found items. The size of this array, if not `NULL`, must be equal to *inMaximumCount*. Can be `NULL` on input, provided that your application doesn't need this information. Search Kit does not normalize relevance scores, so they can be very large.

maximumTime

The maximum number of seconds before this function returns, whether or not *inMaximumCount* items have been found. Setting maximumTime to 0 tells the search to return quickly

outFoundCount

On input, a pointer to a CFIndex object that will hold the number of items found. On output, points to the CFIndex object that now contains the actual number of items found.

Return Value
A logical value indicating whether the search is still in progress. Returns false when the search is exhausted.

Discussion
The `SKSearchFindMatches` extracts results from a find operation initiated by a search object (SKSearchRef).

This function provides results to its output parameters simply in the order in which they are found. This reduces latency to support search-as-you-type functionality. Larger scores mean greater relevance.

You can call this function on a search object repeatedly to get additional sets of search results. For example, if you call this function twice with an *inMaximumCount* value of 10, the first call will put the first 10 items found into the output arrays and the second call will put the second 10 items found into the output arrays.

Applications are free to display relevance scores in any appropriate manner. One simple way is to divide each relevance score by the largest number returned to get relevance numbers scaled linearly from 0.0 to 1.0. Search Kit does not scale the relevance scores for you, because you may want to combine the scores from several calls on a search object or the scores from calls to more than one search object.

Search Kit is thread-safe. You can use separate indexing and searching threads. Your application is responsible for ensuring that no more than one process is open at a time for writing to an index.

Before invoking a search, call `SKIndexFlush` (page 2750) on all indexes you will query to ensure that updates to the indexes have been flushed to disk.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSearch.h`

SKSearchGetTypeID

Gets the type identifier for Search Kit search objects.

```
CFTypeID SKSearchGetTypeID (void);
```

Return Value
A CFTypeID object containing the type identifier for the SKSearch opaque type.

Discussion
Search Kit represents searches with search objects (`SKSearchRef` (page 2782) opaque types). If your code needs to determine whether a particular data type is a search object, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the search type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSearch.h`

SKSearchGroupCopyIndexes

Obtains the indexes for a search group. (Deprecated in Mac OS X v10.4. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.)

```
CFArrayRef SKSearchGroupCopyIndexes (
    SKSearchGroupRef    inSearchGroup
);
```

Parameters

inSearchGroup
The search group whose indexes you want to copy.

Return Value
A CFArray object containing the indexes in the search group.

Discussion
Although the search functions `SKSearchResultsCreateWithQuery` (page 2772) and `SKSearchResultsCreateWithDocuments` (page 2770) operate directly on search groups, many Search Kit functions, such as `SKIndexCompact` (page 2741), operate on one index at a time. When you want to examine or manage all the indexes in a search group, use `SKSearchGroupCopyIndexes` to get the search group's list of indexes.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.

Declared In
`SKSearch.h`

SKSearchGroupCreate

Creates a search group as an array of references to indexes. (Deprecated in Mac OS X v10.4. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.)

```
SKSearchGroupRef SKSearchGroupCreate (
    CFArrayRef      inArrayOfInIndexes
);
```

Parameters

inArrayOfInIndexes

A CFArray object containing the indexes to put into the search group.

Return Value

An SKSearchGroup opaque type.

Discussion

Creates a search group as an array of references to indexes.

You create a search group to search one or more indexes, and then typically use the resulting `SKSearchGroupRef` opaque type with `SKSearchResultsCreateWithQuery` (page 2772) or `SKSearchResultsCreateWithDocuments` (page 2770).

When your application no longer needs the search group, dispose of it by calling `CFRelease`.

Availability

Available in Mac OS X v10.3 and later.

Deprecated in Mac OS X v10.4.

Declared In

`SKSearch.h`

SKSearchGroupGetTypeID

Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.

```
CFTypeID SKSearchGroupGetTypeID (void);
```

Return Value

A CFTypeID object containing the type identifier for the SKSearchGroup opaque type.

Discussion

Gets the type identifier for Search Kit search groups.

Search Kit represents search groups with the `SKSearchGroupRef` (page 2784) opaque type. If your code needs to determine whether a particular data type is a search group, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the search group type ID because it can change from one release of Mac OS X to another.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`SKSearch.h`

SKSearchResultsCopyMatchingTerms

Obtains the terms in a document that match a query. (Deprecated in Mac OS X v10.4. Use SKSearchCreate (page 2764) instead.)

```
CFArrayRef SKSearchResultsCopyMatchingTerms (
    SKSearchResultsRef  inSearchResults,
    CFIndex             inItem
);
```

Parameters

inSearchResults

The search results to examine.

inItem

An integer that corresponds to a document URL object (SKDocumentRef) in the search results. A value of '1' identifies the first document URL object in the search results, a value of '2' identifies the second, and so on.

If you've created the search results using SKSearchResultsCreateWithQuery (page 2772), the document URL objects are sorted in ranking order with the top-ranked one first. See SKSearchResultsGetInfoInRange (page 2773) for a description of how to get a particular document URL object, or set of them, from a search result.

Return Value

A CFArray object containing term IDs.

Discussion

When using a prefix search, or a search for which the user entered more than one word, there may be multiple terms that match the query. This function returns an array of the term IDs corresponding to these matches.

For example, a user could enter 'App' when performing a prefix search. If a document represented in the search group contains the words 'Apple,' 'application,' and 'appendectomy,' the IDs for all of these terms would then appear in the CFArray object that SKSearchResultsCopyMatchingTerms returns.

See SKSearchResultsCreateWithQuery (page 2772) for a description of how to perform a search and get search results. See SKSearchResultsGetInfoInRange (page 2773) for how to extract information, including document URL objects, from a search result. See "Deprecated Search Keys" (page 2789) for a description of the various categories of search.

Availability

Available in Mac OS X v10.3 and later.

Deprecated in Mac OS X v10.4.

Declared In

SKSearch.h

SKSearchResultsCreateWithDocuments

Finds documents similar to given example documents. (Deprecated in Mac OS X v10.4. Use SKSearchCreate (page 2764) instead.)

```
SKSearchResultsRef SKSearchResultsCreateWithDocuments (
    SKSearchGroupRef                inSearchGroup,
    CFArrayRef                      inExampleDocuments,
    CFIndex                         inMaxFoundDocuments,
    void                            *inContext,
    SKSearchResultsFilterCallBack   inFilterCallBack
);
```

Parameters

inSearchGroup

A search group containing the indexes which, in turn, contain the document URL objects (SKDocumentRefs) representing the documents you want to search by similarity. The search group must also contains the indexes that contain the textual content of the example documents.

inExampleDocuments

An array of document URL objects (SKDocumentRefs), each representing an example document.

inMaxFoundDocuments

The maximum number of found items to return. Your application must pass in a positive value.

inContext

An application-specified context for use by the `SKSearchResultsFilterCallBack` (page 2780) callback function. Can be `NULL`.

inFilterCallBack

A callback function for hit testing during searching—see `SKSearchResultsFilterCallBack` (page 2780). In a similarity search, your application would typically use this function to exclude the example documents from the search results. This parameter can be `NULL`, in which case your application receives the returned results directly and without any custom postprocessing.

Return Value

A search results object containing a list of document URL objects (SKDocumentRefs) representing documents similar to the example documents.

Discussion

This function searches the on-disk indexes in a search group for document URL objects (SKDocumentRefs) representing documents similar to those provided as examples. Build the search group in three steps:

1. Collect the index IDs from the search groups you want to search: for each search group, call the `SKSearchGroupCopyIndexes` (page 2768) function.

2. Add the document URL objects representing the example documents to a memory-based index (if they're not already in an index) by calling `SKIndexCreateWithMutableData` (page 2746), and get that index's ID.

3. Create a new search group that contains the indexes to search, and also containing the example-documents index, using `SKSearchGroupCreate` (page 2769).

Before invoking a search, call `SKIndexFlush` (page 2750) on all indexes in the search group to ensure that changes to the indexes have been written to disk.

Once you've obtained the results of a search, get the specifics—including which documents match the user's similarity query, and the ranking scores for each document—by calling `SKSearchResultsGetInfoInRange` (page 2773).

When your application no longer needs the search result, dispose of it by calling `CFRelease`.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.

Declared In
SKSearch.h

SKSearchResultsCreateWithQuery

Queries the indexes in a search group. (Deprecated in Mac OS X v10.4. Use SKSearchCreate (page 2764) instead.)

```
SKSearchResultsRef SKSearchResultsCreateWithQuery (
    SKSearchGroupRef        inSearchGroup,
    CFStringRef             inQuery,
    SKSearchType            inSearchType,
    CFIndex                 inMaxFoundDocuments,
    void                    *inContext,
    SKSearchResultsFilterCallBackinFilterCallBack
);
```

Parameters

inSearchGroup
The search group to query.

inQuery
The query string to search for.

inSearchType
The category of search to perform. See the "Deprecated Search Keys" (page 2789) enumeration for options.

inMaxFoundDocuments
The maximum number of found items to return. Your application must pass in a positive integer value.

inContext
An application-specified context for use by the SKSearchResultsFilterCallBack (page 2780). Can be NULL, but if you want to use the callback you must supply a context.

inFilterCallBack
A callback function for hit testing during searching. Can be NULL, in which case your application receives the returned results directly and without any custom postprocessing. If non-NULL, you must supply a context. See SKSearchResultsFilterCallBack (page 2780).

Return Value
A search results object.

Discussion
This function searches the on-disk indexes in a search group. Before invoking a search, call SKIndexFlush (page 2750) on all indexes in the search group to ensure that changes to the indexes have been flushed to disk.

Once you've obtained the results of a search, get the specifics—including which documents match the user's query, and the ranking scores for each document—by calling SKSearchResultsGetInfoInRange (page 2773). You can extract other information by calling SKSearchResultsCopyMatchingTerms (page 2770) and SKSearchResultsGetCount (page 2773).

When your application no longer needs the search result, dispose of it by calling `CFRelease`.

Special Considerations

This deprecated function performs searches synchronously. Apple recommends using the asynchronous `SKSearchCreate` function instead.

In the current implementation of Search Kit, unary Boolean operators are not implemented. A search, for example, for 'not blue', returns zero documents no matter what their content.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.

Declared In
`SKSearch.h`

SKSearchResultsGetCount

Gets the total number of found items in a search. (Deprecated in Mac OS X v10.4. Use `SKSearchCreate` (page 2764) instead.)

```
CFIndex SKSearchResultsGetCount (
    SKSearchResultsRef  inSearchResults
);
```

Parameters

`inSearchResults`
A search results object containing the results of a query.

Return Value
A CFIndex object containing the total number of found items in a search.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.

Declared In
`SKSearch.h`

SKSearchResultsGetInfoInRange

Extracts information from a Search Kit query result. (Deprecated in Mac OS X v10.4. Use `SKSearchCreate` (page 2764) instead.)

```
CFIndex SKSearchResultsGetInfoInRange (
    SKSearchResultsRef  inSearchResults,
    CFRange             inRange,
    SKDocumentRef       *outDocumentsArray,
    SKIndexRef          *outIndexesArray,
    float               *outScoresArray
);
```

Parameters

inSearchResults

The search results whose information you want to extract.

inRange

The starting ranking and total number of found items to obtain, specified as `(Location, Length)`. 'Location' specifies the starting item by ranking, with the top-ranked item having a location of 0. 'Length' specifies the total number of items to include in the results. For example, (0,1) indicates the first item, which is also the highest-ranking item. (1,1) indicates the second item, which is also the second-highest-ranking item. (0,5) means to get the first 5 items.

outDocumentsArray

On output, points to an array of found document URL objects (SKDocumentRefs).

outIndexesArray

On output, points to an array of indexes in which the found document URL objects reside. Can be `NULL` on input, provided that your application doesn't need this information.

outScoresArray

On output, points to an array of correspondence scores for found items. Can be `NULL` on input, provided that your application doesn't need this information.

Return Value

The number of items returned—usually the same number as specified by the length item in the `inRange` parameter.

Discussion

This function provides results to its output parameters in the order in which they are found, to reduce latency and to support search-as-you-type functionality.

Availability

Available in Mac OS X v10.3 and later.

Deprecated in Mac OS X v10.4.

Declared In

`SKSearch.h`

SKSearchResultsGetTypeID

Gets the type identifier for Search Kit search results. (**Deprecated.** Use `SKSearchCreate` (page 2764) instead.)

```
CFTypeID SKSearchResultsGetTypeID (void);
```

Return Value

A CFTypeID object containing the type identifier for the SKSearchResults opaque type.

Discussion
Search Kit represents search results with search results objects (`SKSearchResultsRef` (page 2783) opaque types). If your code needs to determine whether a particular data type is a search result, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the search result type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKSearch.h`

SKSummaryCopyParagraphAtIndex

Gets a specified paragraph from the text in a summarization object.

```
CFStringRef SKSummaryCopyParagraphAtIndex (
    SKSummaryRef        summary,
    CFIndex             i,
);
```

Parameters

summary
The summarization object containing the text from which you want a paragraph.

i
The ordinal number of the paragraph in the original text, with the first paragraph designated by zero (this function uses zero-based indexing).

Return Value
A CFString object containing the specified paragraph, or `NULL` on failure.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSummary.h`

SKSummaryCopyParagraphSummaryString

Gets a text string consisting of a summary with, at most, the requested number of paragraphs.

```
CFStringRef SKSummaryCopyParagraphSummaryString (
    SKSummaryRef        summary,
    CFIndex             numParagraphs
);
```

Parameters

summary
The summarization object containing the text from which you want a summarization.

numParagraphs
The maximum number of paragraphs you want in the summary.

Return Value
A CFString object containing the requested summary.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSummary.h`

SKSummaryCopySentenceAtIndex

Gets a specified sentence from the text in a summarization object.

```
CFStringRef SKSummaryCopySentenceAtIndex (
    SKSummaryRef        summary,
    CFIndex             i,
);
```

Parameters

summary
The summarization object containing the text from which you want a sentence.

i
The ordinal number of the sentence in the original text, with the first sentence designated by zero (this function uses zero-based indexing).

Return Value
A CFString object containing the specified sentence, or `NULL` on failure.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSummary.h`

SKSummaryCopySentenceSummaryString

Gets a text string consisting of a summary with, at most, the requested number of sentences.

```
CFStringRef SKSummaryCopySentenceSummaryString (
    SKSummaryRef        summary,
    CFIndex             numSentences
);
```

Parameters

summary
The summarization object containing the text from which you want a summarization.

numSentences
The maximum number of sentences you want in the summary.

Return Value
A CFString object containing the requested summary.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKSummaryCreateWithString

Creates a summary object based on a text string.

```
SKSummaryRef SKSummaryCreateWithString (
    CFStringRef     inString
);
```

Parameters

inString
The text string that you want to summarize.

Return Value
Returns a summarization object, or NULL on failure.

Discussion
The SKSummaryCreateWithString function creates a summarization object that pre-analyzes a text string to support fast summarization. When your application no longer needs the summarization object, dispose of it by calling CFRelease.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKSummaryGetParagraphCount

Gets the number of paragraphs in a summarization object.

```
CFIndex SKSummaryGetParagraphCount (
    SKSummaryRef    summary
);
```

Parameters

summary
The summarization object whose paragraphs you want to count.

Return Value
A CFIndex object containing the number of paragraphs in the summarization object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKSummaryGetParagraphSummaryInfo

Gets detailed information about a body of text for constructing a custom paragraph-based summary string.

```
CFIndex SKSummaryGetParagraphSummaryInfo (
    SKSummaryRef            summary,
    CFIndex                 numParagraphsInSummary,
    CFIndex                 *outRankOrderOfParagraphs,
    CFIndex                 *outParagraphIndexOfParagraphs
);
```

Parameters

summary

The summarization object containing the text from which you want to build a summary.

numParagraphsInSummary

The maximum number of paragraphs you want in the summary.

outRankOrderOfParagraphs

On input, a pointer to an array of CFIndex objects. On output, points to the previously allocated array, which now lists the summarization relevance rank of each paragraph in the original text. The most important paragraph gets a rank of 1. The array size must equal *numParagraphsInSummary*, or else be NULL if you don't want to get the relevance ranks.

outParagraphIndexOfParagraphs

On output, points to an array containing the ordinal number for each paragraph in the original text. Use the SKSummaryCopyParagraphAtIndex (page 2775) function with one of these numbers to get the corresponding paragraph. The array size must equal *numParagraphsInSummary*, or else be NULL if you don't want to get the ordinal numbers of the paragraphs.

Return Value
The number of paragraphs in the summary.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKSummaryGetSentenceCount

Gets the number of sentences in a summarization object.

```
CFIndex SKSummaryGetSentenceCount (
    SKSummaryRef    summary
);
```

Parameters

summary

The summarization object whose sentences you want to count.

Return Value
A CFIndex object containing the number of sentences in the summarization object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKSummaryGetSentenceSummaryInfo

Gets detailed information about a body of text for constructing a custom sentence-based summary string.

```
CFIndex SKSummaryGetSentenceSummaryInfo (
    SKSummaryRef            summary,
    CFIndex                 numSentencesInSummary,
    CFIndex                 *outRankOrderOfSentences,
    CFIndex                 *outSentenceIndexOfSentences,
    CFIndex                 *outParagraphIndexOfSentences
);
```

Parameters

summary

The summarization object containing the text from which you want to build a summary.

numSentencesInSummary

The maximum number of sentences you want in the summary.

outRankOrderOfSentences

On input, a pointer to an array of CFIndex objects. On output, points to the previously allocated array, which now lists the summarization relevance rank of each sentence in the original text. The most important sentence gets a rank of 1. The array size must equal *numSentencesInSummary*, or else be NULL if you don't want to get the rank orders.

outSentenceIndexOfSentences

On input, a pointer to an array of CFIndex objects. On output, points to the previously allocated array, which now contains the ordinal number for each sentence in the original text. Use the SKSummaryCopySentenceAtIndex (page 2776) function with one of these numbers to get the corresponding sentence. The array size must equal *numSentencesInSummary*, or else be NULL if you don't want to get the ordinal numbers of the sentences.

outParagraphIndexOfSentences

On input, a pointer to an array of CFIndex objects. On output, points to the previously allocated array, which now contains the ordinal number for the paragraph that each corresponding sentence, referenced in *outSentenceIndexOfSentences*, appears in. The array size must equal *numSentencesInSummary*, or else be NULL if you don't want to get the ordinal numbers of the sentences.

Return Value

The number of sentences in the summary.

Availability

Available in Mac OS X v10.4 and later.

Declared In

SKSummary.h

SKSummaryGetTypeID

Gets the type identifier for Search Kit summarization objects.

```
CFTypeID SKSummaryGetTypeID (void);
```

Return Value

A CFTypeID object, or NULL on failure.

Discussion
Search Kit represents summarization results with summarization objects (`SKSummaryRef` (page 2783) opaque types). If your code needs to determine whether a particular data type is a summary, you can use this function along with the `CFGetTypeID` function and perform a comparison.

Never hard-code the summarization type ID because it can change from one release of Mac OS X to another.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`SKSummary.h`

Callbacks

Developers should avoid using the callbacks listed in this section; instead, use `SKSearchCreate` (page 2764) and `SKSearchFindMatches` (page 2766).

SKSearchResultsFilterCallBack

Deprecated. Use `SKSearchCreate` and `SKSearchFindMatches` instead, which do not use a callback.

```
typedef Boolean (SKSearchResultsFilterCallBack) (
    SKIndexRef     inIndex,
    SKDocumentRef     inDocument,
    void      *inContext
```

If you name your function `MySearchResultsFilter`, you would declare it like this:

```
Boolean MySearchResultsFilter (
    SKIndexRef     inIndex,
    SKDocumentRef     inDocument,
    void      *inContext
);
```

Parameters

inIndex
The index you are searching.

inDocument
The document URL object within the index you are searching.

inContext
An application-specified context which you set when calling `SKSearchResultsCreateWithQuery` (page 2772) or `SKSearchResultsCreateWithDocuments` (page 2770).

Return Value
A Boolean value of `true` for a successful search hit, or `false` otherwise.

Discussion
Deprecated. Defines a pointer to a search-results filtering callback function for hit testing and processing during a search. Use this callback function to perform custom filtering on the search hits returned by the `SKSearchResultsCreateWithQuery` (page 2772) and `SKSearchResultsCreateWithDocuments` (page 2770) functions. Return `true` to keep this document URL object (SKDocumentRef) in the results, `false` to filter it out.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKSearch.h`

Data Types

SKDocumentRef

Defines an opaque data type representing a document's URL.

```
typedef struct __SKDocument *SKDocumentRef;
```

Discussion
A document URL object is a generic location specification for a document. It is built from a document scheme, a parent document, and a document name. You can convert back and forth between document URL objects and `CFURL` objects using Search Kit's `SKDocumentCreateWithURL` (page 2735) and `SKDocumentCopyURL` (page 2734) functions.

To create a Search Kit document URL object, use `SKDocumentCreateWithURL` (page 2735) when you can provide a complete URL, or use `SKDocumentCreate` (page 2734) when you want to specify document location indirectly using a parent document URL object. For other operations on documents, see "Working with Documents and Terms" (page 2731).

If you create document URL objects with indirect locations using the `SKDocumentCreate` (page 2734) function, you can resolve the locations by assembling them piece by piece, starting with a document URL object and going up step by step, parent to parent.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKDocument.h`

SKIndexDocumentIteratorRef

Defines an opaque data type representing an index-based document iterator.

```
typedef struct __SKIndexDocumentIterator *SKIndexDocumentIteratorRef;
```

Discussion
A Search Kit document iterator lets your application loop through all the document URL objects owned by a given parent document URL object. To create an iterator, use `SKIndexDocumentIteratorCreate` (page 2749). To get a copy of the next document in the set owned by the iterator, use `SKIndexDocumentIteratorCopyNext` (page 2748).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKIndexRef

Defines an opaque data type representing an index.

```
typedef struct __SKIndex *SKIndexRef;
```

Discussion
A Search Kit index object contains the textual contents of one or more documents, as well as document URL objects (SKDocumentRefs) representing those documents' locations.

To create a new disk-based Search Kit index object, use `SKIndexCreateWithURL` (page 2747). To create a memory-based index, use `SKIndexCreateWithMutableData` (page 2746). For other operations on indexes, see "Creating, Opening, and Closing Indexes" (page 2729) and "Managing Indexes" (page 2730). Also see"Fast Asynchronous Searching" (page 2732).

Special Considerations

You cannot use `CFMakeCollectable` with SKIndex objects. In a garbage-collected environment, you must use `SKIndexClose` (page 2740) to dispose of an SKIndex object.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKIndex.h`

SKSearchRef

Defines an opaque data type representing a an asynchronous search.

```
typedef struct __SKSearch *SKSearchRef;
```

Discussion
A search object is created when you call the `SKSearchCreate` (page 2764) function.

Special Considerations

You cannot use `CFMakeCollectable` with SKSearch objects. In a garbage-collected environment, you must use `CFRelease` to dispose of an SKSearch object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSearch.h

SKSummaryRef

Defines an opaque data type representing summarization information.

```
typedef struct __SKSummary *SKSummaryRef;
```

Discussion
A summarization object contains summarization information, including summary text.

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKSummary.h

SKDocumentID

Defines an opaque data type representing a lightweight document identifier.

```
typedef CFIndex SKDocumentID;
```

Discussion
Use document IDs rather than document URL objects (SKDocumentRefs) whenever possible. Using document IDs results in faster searching.

You can work with document IDs using a variety of Search Kit functions. See SKIndexGetMaximumDocumentID (page 2755), SKIndexCopyDocumentForDocumentID (page 2741), SKIndexCopyInfoForDocumentIDs (page 2744), SKIndexCopyDocumentRefsForDocumentIDs (page 2743), SKIndexCopyDocumentURLsForDocumentIDs (page 2744), SKIndexCopyDocumentIDArrayForTermID (page 2742), and SKIndexCopyTermIDArrayForDocumentID (page 2745).

Availability
Available in Mac OS X v10.4 and later.

Declared In
SKIndex.h

SKSearchResultsRef

Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.

```
typedef struct __SKSearchResults *SKSearchResultsRef;
```

Discussion
Defines an opaque data type representing the result of a search. To perform a query and generate search results, use `SKSearchResultsCreateWithQuery` (page 2772) or `SKSearchResultsCreateWithDocuments` (page 2770). To examine the result of a search, use `SKSearchResultsGetInfoInRange` (page 2773). For other operations on search results, see "Legacy Support for Synchronous Searching" (page 2733).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKSearch.h`

SKSearchGroupRef

Deprecated. Use asynchronous searching with SKSearchCreate instead, which does not employ search groups.

```
typedef struct __SKSearchGroup *SKSearchGroupRef;
```

Discussion
Defines an opaque data type representing a search group.

A search group is a group of one or more indexes to be searched. To create a search group, use `SKSearchGroupCreate` (page 2769). For other operations with search groups, see "Fast Asynchronous Searching" (page 2732).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`SKSearch.h`

Constants

Text Analysis Keys

Each of these constants is an optional key in a Search Kit index's text analysis properties dictionary. The constant descriptions describe the corresponding values for each of these keys. These keys are declared in the `Analysis.h` header file.

```
const CFStringRef kSKMinTermLength;
const CFStringRef kSKStopWords;
const CFStringRef kSKSubstitutions;
const CFStringRef kSKMaximumTerms;
const CFStringRef kSKProximityIndexing;
const CFStringRef kSKTermChars;
const CFStringRef kSKStartTermChars;
const CFStringRef kSKEndTermChars;
```

Constants

`kSKMinTermLength`

The minimum term length to index. Specified as a CFNumber object. If this optional key is not present, Search Kit indexing defaults to a minimum term length of 1.

Available in Mac OS X v10.3 and later.

Declared in `SKAnalysis.h`.

`kSKStopWords`

A set of stopwords—words not to index. Specified as a CFSet object. There is no default stopword list. You must supply your own.

Available in Mac OS X v10.3 and later.

Declared in `SKAnalysis.h`.

`kSKSubstitutions`

A dictionary of term substitutions—terms that differ in their character strings but that match during a search. Specified as a CFDictionary object.

Available in Mac OS X v10.3 and later.

Declared in `SKAnalysis.h`.

`kSKMaximumTerms`

The maximum number of number unique terms to index in each document. Specified as a CFNumber object.

Search Kit indexes from the beginning of a document. When it has indexed the first n unique terms, it stops.

The default number of maximum terms, which applies if you do not provide a number, is 2000.

To tell Search Kit to index all the terms in each document without limit, specify a value of 0.

Available in Mac OS X v10.4 and later.

Declared in `SKAnalysis.h`.

`kSKProximityIndexing`

A Boolean flag indicating whether or not Search Kit should use proximity indexing. The flag can be a `0` or `kCFBoolenFalse` value (for false) or a `1` or `kCFBooleanTrue` value for true.

Proximity indexing supports phrase searching. If this key is not present in an index's text analysis properties dictionary, Search Kit defaults to not adding proximity information to the index.

Available in Mac OS X v10.4 and later.

Declared in `SKAnalysis.h`.

`kSKTermChars`

Additional valid starting-position "word" characters for indexing and querying. The corresponding value, a CFString object, specifies the additional valid "word" characters that you want to be considered as valid starting characters of terms for indexing and querying. "Word" characters are contrasted with nonword characters, such as spaces.

The value of `kSKStartTermChars`, if this key is present, overrides the value of `kSKTermChars` for the first character of a term.

By default, Search Kit considers alphanumeric characters as valid starting characters for terms, and considers all others (including the underscore character) to be nonword characters.

Available in Mac OS X v10.4 and later.

Declared in `SKAnalysis.h`.

`kSKStartTermChars`

Additional valid starting-position "word" characters for indexing and querying. The corresponding value, a CFString object, specifies the additional valid "word" characters that you want to be considered as valid starting characters of terms for indexing and querying. "Word" characters are contrasted with nonword characters, such as spaces.

The value of `kSKStartTermChars`, if this key is present, overrides the value of `kSKTermChars` for the first character of a term.

By default, Search Kit considers alphanumeric characters as valid starting characters for terms, and considers all others (including the underscore character) to be nonword characters.

Available in Mac OS X v10.4 and later.

Declared in `SKAnalysis.h`.

`kSKEndTermChars`

Additional valid last-position "word" characters for indexing and querying. The corresponding value, a CFString object, specifies the additional valid "word" characters that you want to be considered as valid ending characters of terms for indexing and querying. "Word" characters are contrasted with nonword characters, such as spaces.

The value of `kSKEndTermChars`, if this key is present, overrides the value of `kSKTermChars` for the last character of a term.

By default, Search Kit considers alphanumeric characters as valid ending characters for terms, and considers all others (including the underscore character) to be nonword characters.

Available in Mac OS X v10.4 and later.

Declared in `SKAnalysis.h`.

SKDocumentIndexState

The indexing state of a document.

```
enum SKDocumentIndexState {
    kSKDocumentStateNotIndexed  = 0,
    kSKDocumentStateIndexed     = 1,
    kSKDocumentStateAddPending  = 2,
    kSKDocumentStateDeletePending= 3
};
```

Constants

`kSKDocumentStateNotIndexed`

Specifies that the document is not indexed.

Available in Mac OS X v10.3 and later.

Declared in `SKIndex.h`.

`kSKDocumentStateIndexed`

Specifies that the document is indexed.

Available in Mac OS X v10.3 and later.

Declared in `SKIndex.h`.

`kSKDocumentStateAddPending`

Specifies that the document is not in the index but will be added after the index is flushed or closed.

Available in Mac OS X v10.3 and later.

Declared in `SKIndex.h`.

`kSKDocumentStateDeletePending`

Specifies that the document is in the index but will be deleted after the index is flushed or closed.

Available in Mac OS X v10.3 and later.

Declared in `SKIndex.h`.

Declared In

`SKIndex.h`

SKSearchOptions

Specifies the search options available for the `SKSearchCreate` (page 2764) function.

```
typedef UInt32 SKSearchOptions;
enum SKSearchType {
    kSKSearchOptionDefault = 0,
    kSKSearchOptionNoRelevanceScores = 1L << 0,
    kSKSearchOptionSpaceMeansOR = 1L << 1
    kSKSearchOptionFindSimilar = 1L << 2
};
```

Constants

`kSKSearchOptionDefault`

Default search options include:

- Relevance scores will be computed
- Spaces in a query are interpreted as Boolean `AND` operators.
- Do not use similarity searching.

Available in Mac OS X v10.4 and later.

Declared in `SKSearch.h`.

`kSKSearchOptionNoRelevanceScores`
: This option saves time during a search by suppressing the computation of relevance scores.

  Available in Mac OS X v10.4 and later.

  Declared in `SKSearch.h`.

`kSKSearchOptionSpaceMeansOR`
: This option alters query behavior so that spaces are interpreted as Boolean `OR` operators.

  Available in Mac OS X v10.4 and later.

  Declared in `SKSearch.h`.

`kSKSearchOptionFindSimilar`
: This option alters query behavior so that Search Kit returns references to documents that are similar to an example text string. When this option is specified, Search Kit ignores all query operators.

  Available in Mac OS X v10.4 and later.

  Declared in `SKSearch.h`.

Declared In
`SKSearch.h`

SKIndexType

Specifies the category of an index.

```
enum SKIndexType {
    kSKIndexUnknown         = 0,
    kSKIndexInverted        = 1,
    kSKIndexVector          = 2,
    kSKIndexInvertedVector  = 3
};
```

Constants
`kSKIndexUnknown`
: Specifies an unknown index type.

  Available in Mac OS X v10.3 and later.

  Declared in `SKIndex.h`.

`kSKIndexInverted`
: Specifies an inverted index, mapping terms to documents.

  Available in Mac OS X v10.3 and later.

  Declared in `SKIndex.h`.

`kSKIndexVector`
: Specifies a vector index, mapping documents to terms.

  Available in Mac OS X v10.3 and later.

  Declared in `SKIndex.h`.

`kSKIndexInvertedVector`
: Specifies an index type with all the capabilities of an inverted and a vector index.

  Available in Mac OS X v10.3 and later.

  Declared in `SKIndex.h`.

Declared In
`SKIndex.h`

Deprecated Text Analysis Keys

Search Kit ignores the `kSKLanguageTypes` constant. It determines language directly by document content.

```
const CFStringRef kSKLanguageTypes;
```

Constants

`kSKLanguageTypes`

Deprecated—Search Kit ignores this constant.

In releases of Mac OS X previous to version 10.4, each string in this key's corresponding value specifies a language to use for indexing. Each such string is a two character ISO 639-1 code. For example, `'en'` for English, `'ja'` for Japanese, and so on. If this key is not present, Search Kit uses the Mac OS X preferences system to determine the primary language from the user's locale.

Available in Mac OS X v10.3 and later.

Declared in `SKAnalysis.h`.

Version Notes

In releases of Mac OS X prior to version 10.4, the `kSKLanguageTypes` constant was an optional key in an index's text analysis properties dictionary. Starting in Mac OS X v10.4, Search Kit ignores this constant and determines language directly by the document content. A document may use multiple languages.

Deprecated Search Keys

Search Kit ignores the constants in this group. Use asynchronous searching with `SKSearchCreate` instead, which uses query syntax to determine search type.

```
enum SKSearchType {
    kSKSearchRanked         = 0,
    kSKSearchBooleanRanked  = 1,
    kSKSearchRequiredRanked = 2,
    kSKSearchPrefixRanked   = 3
};
```

Constants

`kSKSearchRanked`

Deprecated. Specifies a basic ranked search.

Available in Mac OS X v10.3 and later.

Declared in `SKSearch.h`.

`kSKSearchBooleanRanked`

Deprecated. Specifies a query that can include Boolean operators including `'|'`, `'&'`, `'!'`, `'('`, and `')'`.

Available in Mac OS X v10.3 and later.

Declared in `SKSearch.h`.

`kSKSearchRequiredRanked`

Deprecated. Specifies a query that can include required (`'+'`) or excluded (`'-'`) terms.

Available in Mac OS X v10.3 and later.

Declared in `SKSearch.h`.

`kSKSearchPrefixRanked`

Deprecated. Specifies a prefix-based search, which matches terms that begin with the query string.

Available in Mac OS X v10.3 and later.

Declared in `SKSearch.h`.

Version Notes

In releases of Mac OS X prior to version 10.4, these constants specify the category of search to perform. Starting with Mac OS X v10.4, use asynchronous searching with `SKSearchCreate` instead, which uses query syntax to determine search type.

In older versions of Mac OS X, these constants specify the various search types you can use with `SKSearchResultsCreateWithQuery`. Each of these specifies a set of ranked search hits. The `kSKSearchRanked` and `kSKSearchPrefixRanked` constants can be used for all index types. The `kSKSearchBooleanRanked` and `kSKSearchRequiredRanked` constants cannot be used for vector indexes.

Declared In

`SKSearch.h`

Spotlight Metadata Attributes

Common Metadata Attribute Keys

Metadata attribute keys that are common to many file types.

kMDItemAttributeChangeDate

Date and time of the last change made to a metadata attribute.

Value Type: CFDate

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAudiences

The audience for which the file is intended. The audience may be determined by the creator or the publisher or by a third party.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAuthors

The author, or authors, of the contents of the file. The order of the authors is preserved, but does not represent the main author or relative importance of the authors.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemCity

Identifies city of origin according to guidelines established by the provider. For example, "New York", "Cupertino", or "Toronto".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemComment

A comment related to the file. This comment is not displayed by the Finder.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemContactKeywords

A list of contacts that are associated with this document, not including the authors.

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemContentCreationDate

The date and time that the content was created.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemContentModificationDate

Date and time when the content of this item was modified.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemContentType

Uniform Type Identifier of the file. For example, a jpeg image file will have a value of public.jpeg. The value of this attribute is set by the Spotlight importer. Changes to this value are lost when the file attributes are next imported.

This attribute is marked as nosearch. You must specify this attribute key explicitly in a query in order for its contents to be searched.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemContentTypeTree

Uniform Type Identifier hierarchy of the file. For example, a jpeg image file will return an array containing "public.jpeg", "public.image", and "public.data". The value of this attribute is set by the Spotlight importer. Changes to this value are lost when the file attributes are next imported.

This attribute is marked as nosearch. You must specify this attribute key explicitly in a query in order for its contents to be searched.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemContributors

Entities responsible for making contributions to the content of the resource. Examples of a contributor include a person, an organization or a service.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemCopyright

Copyright owner of the file contents.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemCountry

The full, publishable name of the country or primary location where the intellectual property of the item was created, according to guidelines of the provider.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemCoverage

Extent or scope of the content of the resource. Coverage will typically include spatial location (a place name or geographic co-ordinates), temporal period (a period label, date, or date range) or jurisdiction (such as a named administrative entity). Recommended best practice is to select a value from a controlled vocabulary, and that, where appropriate, named places or time periods be used in preference to numeric identifiers such as sets of co-ordinates or date ranges.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemCreator

Name of the application used to create the document content. For example, "Pages" or "Keynote".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemDescription

Description of the kind of item this file represents.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemDisplayName

Localized version of the file name. This is the localized version of the LaunchServices call `LSCopyDisplayNameForURL()`/ `LSCopyDisplayNameForRef()`.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemDueDate

Date this item is due.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemDurationSeconds

The duration, in seconds, of the content of the item. A value of 10.5 represents media that is 10 and 1/2 seconds long.

Value Type: CFNumber
Units: seconds
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemEmailAddresses

Email addresses related to this item.

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemEncodingApplications

Applications used to convert the original content into it's current form. For example, a PDF file might have an encoding application set to "Distiller".

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFinderComment

Finder comments for this item.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemFonts

Fonts used by this item. You should store the font's full name, the postscript name, or the font family name, based on the available information.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemHeadline

Publishable entry providing a synopsis of the contents of the item. For example, "Apple Introduces the iPod Photo".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemIdentifier

Formal identifier used to reference the resource within a given context. For example, the Message-ID of a mail message.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemInstantMessageAddresses

Instant message addresses related to this item.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemInstructions

Instructions concerning the use of the item, such as embargoes and warnings. For example, "Second of four stories".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemKeywords

Keywords associated with this file. For example, "Birthday", "Important", etc.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemKind

Description of the kind of item this file represents.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemLanguages

Indicates the languages used by the item. The recommended best practice for the values of this attribute are defined by RFC 3066.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemLastUsedDate

Date and time that the file was last used. This value is updated automatically by LaunchServices everytime a file is opened by double clicking, or by asking LaunchServices to open a file.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemNumberOfPages

Number of pages in the document.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemOrganizations

Companies or organizations that created the document.

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemPageHeight

Height of the document page, in points (72 points per inch). For PDF files this indicates the height of the first page only.

Value Type: CFNumber
Units: points
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemPageWidth

Width of the document page, in points (72 points per inch). For PDF files this indicates the width of the first page only.

Value Type: CFNumber

Units: points

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemPhoneNumbers

Phone numbers related to this item.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemProjects

List of projects related to this item. For example, if you were working on a movie, all of the files could be marked as belonging to the project "My Movie".

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemPublishers

Publishers of the item. For example, a person, an organization, or a service.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemRecipients

Recipients of this item.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemRights

Provides a link to information about rights held on the document. Contains a rights management statement for the document, or reference a service providing such information. Rights information often encompasses Intellectual Property Rights (IPR), copyright, and various property rights. If this attribute is absent, no assumptions can be made about the status of these and other rights with respect to the document.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemSecurityMethod

Encryption method used to make the item secure. PDF files return "None" or "Password Encrypted".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemStarRating

User rating of this item. For example, the user rating (number of stars) of an iTunes track.

Value Type: CFNumber

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemStateOrProvince

Province or state of origin according to guidelines established by the provider. For example, "CA", "Ontario", or "Sussex".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemTextContent

Contains a text representation of the content of the document. Data in multiple fields should be combined using a whitespace character as a separator. An application's Spotlight importer provides the content of this attribute.

Applications can create queries using this attribute, but are not able to read the value of this attribute directly.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemTitle

Title of the item. For example, this could be the title of a document, the name of an song, or the subject of an email message.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemVersion

Version number of the item.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemWhereFroms

Describes where the item was obtained from. For example, a downloaded file may refer to the URL, files received by email may indicate the sender's email address, message subject, etc.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

Image Metadata Attribute Keys

Metadata attribute keys that are common to image files.

kMDItemAcquisitionMake

Manufacturer of the device used to acquire the document contents.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemAcquisitionModel

Model of the device used to acquire the document contents.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemAlbum

Title for the collection containing this item. This is analogous to a record label or photo album.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemAperture

Aperture setting used to aqure the document contents. This unit is the APEX value.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemBitsPerSample

Number of bits per sample. For example, the bit depth of an image (8-bit, 16-bit etc...) or the bit depth per audio sample of uncompressed audio data (8, 16, 24, 32, 64, etc..).

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemColorSpace

Color space model used by the document contents. For example, “RGB”, “CMYK”, “YUV”, or “YCbCr”.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemEXIFVersion

Version of the EXIF header used to generate the metadata.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemExposureMode

Exposure mode used to acquire the document contents.

Value Type: CFNumber

Expected Values: 0 (auto exposure), 1 (manual exposure), 2 (auto bracket)

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemExposureProgram

Type of exposure program used by the camera to acquire the document contents. Possible values include: Manual, Normal, Aperture priority, etc.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemExposureTimeSeconds

Exposure time used to capture the document contents.

Value Type: CFNumber

Units: seconds

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemExposureTimeString

Time when the document contents were captured. Typically this corresponds to when a photograph is exposed.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemFNumber

Diameter of the aperture relative to the effective focal length of the lens.

Value Type: CFNumber

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemFlashOnOff

Whether a camera flash was used to capture the document contents.

Value Type: CFBoolean

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemFocalLength

Actual focal length of the lens, in millimeters.

Value Type: CFNumber

Units: millimeters

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemHasAlphaChannel

Whether the image has an alpha channel.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemISOSpeed

ISO speed used to acquire the document contents. For example, 100, 200, 400, etc.

Value Type: CFNumber
Units: ISO Speed
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemLayerNames

Names of the layers in the file.

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemMaxAperture

Smallest F number of the lens in APEX value units, usually in the range of 00.00 to 99.99.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemMeteringMode

Metering mode used to acquire the image.

Value Type: CFString
Expected Values: Unknown, Average, CenterWeightedAverage, Spot, MultiSpot, Pattern, Partial
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemOrientation

Orientation of the document contents.

Value Type: CFNumber
Expected Values: 0 (landscape), 1 (portrait)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemPixelHeight

Height, in pixels, of the contents. For example, the image height or the video frame height.

Value Type: CFNumber
Units: pixels
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemPixelWidth

Width, in pixels, of the contents. For example, the image width or the video frame width.

Value Type: CFNumber
Units: pixels
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemProfileName

Name of the color profile used by the document contents.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemRedEyeOnOff

Whether red-eye reduction was used to take the picture.

Value Type: CFBoolean

Expected Values: 0 (no red-eye reduction mode or unknown), 1 (red-eye reduction used)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemResolutionHeightDPI

Resolution height, in DPI, of the item.

Value Type: CFNumber
Units: dots per inch (DPI)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemResolutionWidthDPI

Resolution width, in DPI, of the item.

Value Type: CFNumber
Units: dots per inch (DPI)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemWhiteBalance

White balance setting of the camera when the picture was taken.

Value Type: CFNumber
Expected Values: 0 (auto white balance), 1 (manual)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

Video Metadata Attribute Keys

Metadata attribute keys that are common to video files.

kMDItemAudioBitRate

Bit rate of the audio in the media.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemCodecs

Codecs used to encode/decode the media.

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemDeliveryType

Method used to deliver streaming media.

Value Type: CFString
Expected Values: "Fast Start", "RTSP"
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemMediaTypes

Media types present in the content. For example, a QuickTime movie may return:

```
kMDItemMediaTypes = (Sound, Video, "Hinted Video Track", "Hinted Sound Track")
kMDItemMediaTypes = (Sound, Video)
kMDItemMediaTypes = ("MPEG1 Muxed")
```

Value Type: Array of CFStrings
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemStreamable

Whether the content is prepared for streaming.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemTotalBitRate

Total bit rate, audio and video combined, of the media.

Value Type: CFNumber

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemVideoBitRate

Bit rate of the video in the media.

Value Type: CFNumber

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

Audio Metadata Attribute Keys

Metadata attribute keys that describe an audio file.

kMDItemAppleLoopDescriptors

Specifies multiple pieces of descriptive information about a loop. Besides genre and instrument, files can contain descriptive information that help users in refining searches.

Value Type: Array of CFStrings

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAppleLoopsKeyFilterType

Specifies key filtering information about a loop. Loops are matched against projects that often differ in a major or minor key. To assist users in identifying loops that will "fit" with their compositions, loops can be tagged with one of the following key filters: "AnyKey", "Minor", "Major", "NeitherKey", or "BothKeys". "AnyKey" means that it fits with anything (whether in a major key, minor key or neither). "Minor" fits with compositions in a minor key. "NeitherKey" doesn't work well with compositions that are in major or minor key. "BothKeys" means it fits with compositions that are in major or minor key.

Value Type: CFString

Expected Values: "AnyKey", "Minor", "Major" , "NeitherKey", "BothKeys"

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAppleLoopsLoopMode

Specifies how a file should be played. Tagged files can either be loops or non-loops (e.g., a cymbal crash). "Looping" indicates if the file should be treated as a loop. "Non-looping" indicates the file should not be treated as a loop.

Value Type: CFString

Expected Values: "Looping", "Non-looping"

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAppleLoopsRootKey

Specifies the loop's original key. The key is the root note or tonic for the loop, and does not include the scale type

Value Type: CFString

Expected Values: "C", "C#/Db", "D", "D#/Eb", "E", "F", "F#/Gb", "G", "G#/Ab", "A", "A#/Bb", "B", "NoKey"

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAudioChannelCount

Number of channels in the audio data contained in the file. This integer value only represents the number of discrete channels of audio data found in the file. It does not indicate any configuration of the data in regards to a user's speaker setup.

Value Type: CFNumber

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAudioEncodingApplication

Name of the application that encoded the audio of the document.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemAudioSampleRate

Sample rate of the item's audio data. The sample rate is a float value representing hz (audio_frames/second). For example: 44100.0, 22254.54.

Value Type: CFNumber
Units: hz (audio_frames/second)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemAudioTrackNumber

Track number of a song or composition when it is part of an album.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemComposer

Composer of the song in the audio file.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemIsGeneralMIDISequence

Whether the MIDI sequence contained in the file is set up for use with a General MIDI device.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemKeySignature

Musical key of the song in the audio file. For example: "C", "Dm", "F#m", "Bb".

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemLyricist

Lyricist of the song in the audio file.

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemMusicalGenre

Musical genre of the song or composition contained in the audio file. For example: "Jazz", "Pop", "Rock", "Classical".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemMusicalInstrumentCategory

Specifies the category of an instrument. Files should have an instrument associated with them ("Other Instrument" is provided as a catch-all). For some categories, such as "Keyboards", there are instrument names which provide a more detailed instrument definition, for example "Piano" or "Organ".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemMusicalInstrumentName

Specifies the name of instrument relative to the instrument category. Files can have an instrument name associated with them if they have certain instrument categories. For example, the "Percussion" category has multiple instruments, including "Conga" and "Bongo".

Value Type: CFString

Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemRecordingDate

Recording date of the song or composition. This is in contrast to `kMDItemContentCreationDate` which, could indicate the creation date of an edited or "mastered" version of the original art.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemRecordingYear

Year the item was recorded. For example: 1964, 1995, 1997, or 2003.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemTempo

Tempo of the music in the audio file. A floating point value.

Value Type: CFNumber
Units: Beats per Minute (BPM)
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemTimeSignature

Time signature of the musical composition contained in the audio/MIDI file. For example: "4/4", "7/8".

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

File System Metadata Attribute Keys

Metadata attribute keys that describe the file system attributes for a file. These attributes are available for files on any mounted volume.

kMDItemFSContentChangeDate

Date the file contents last changed.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSCreationDate

Date that the contents of the file were created.

Value Type: CFDate
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSInvisible

Whether the file is invisible.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSIsExtensionHidden

Whether the file extension of the file is hidden.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSLabel

Index of the Finder label of the file. Possible values are 0 through 7.

Value Type: CFNumber
Expected Values: 0 through 7
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h

Availability: Available in Mac OS X v10.4 and later.

kMDItemFSName

File name of the item.

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSNodeCount

Number of files in a directory.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSOwnerGroupID

Group ID of the owner of the file.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSOwnerUserID

User ID of the owner of the file.

Value Type: CFNumber
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemFSSize

Size, in bytes, of the file on disk.

Value Type: CFNumber
Units: bytes

Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

kMDItemPath

Complete path to the file. This value of this attribute can be retrieved, but can't be used in a query or to sort search results. This attribute can't be used as a member of the `valueListAttrs` array parameter for `MDQueryCreate` (page 155) or `MDQueryCreateSubset` (page 155).

Value Type: CFString
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Available in Mac OS X v10.4 and later.

Deprecated Metadata Attribute Keys

Metadata attribute keys that have been deprecated.

kMDItemFSExists

This attribute is deprecated and was never implemented.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Deprecated in Mac OS X v10.4 and later.

kMDItemFSIsReadable

This attribute is deprecated and was never implemented.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h
Header: MDItem.h
Availability: Deprecated in Mac OS X v10.4 and later.

kMDItemFSIsWriteable

This attribute is deprecated and was never implemented.

Value Type: CFBoolean
Framework Path: CoreServices/CoreServices.h

Header: MDItem.h

Availability: Deprecated in Mac OS X v10.4 and later.

Document Revision History

This table describes the changes to *Core Services Framework Reference*.

Date	Notes
2007-10-31	Added three documents (Folder Manager, Launch Services, and CFStream Socket Additions) and removed one (Device Manager).
2006-07-31	Added information about Identity Services and the Backup Core API.
2006-05-23	First publication of this content as a collection of previously published documents.
