# NSMethodSignature Class Reference

---

<b>Inherits from</b>	NSObject
<b>Conforms to</b>	NSObject (NSObject)
<b>Framework</b>	/System/Library/Frameworks/Foundation.framework
<b>Availability</b>	Available in Mac OS X v10.0 and later.
<b>Declared in</b>	NSMethodSignature.h
<b>Companion guides</b>	Distributed Objects Programming Topics The Objective-C 2.0 Programming Language

## Overview

An `NSMethodSignature` object records type information for the arguments and return value of a method. It is used to forward messages that the receiving object does not respond to—most notably in the case of distributed objects. You typically create an `NSMethodSignature` object using `NSObject`'s `methodSignatureForSelector:` instance method (on Mac OS X v10.5 and later you can also use `signatureWithObjCTypes:` (page 6)). It is then used to create an `NSInvocation` object, which is passed as the argument to a `forwardInvocation:` message to send the invocation on to whatever other object can handle the message. In the default case, `NSObject` invokes `doesNotRecognizeSelector:`, which raises an exception. For distributed objects, the `NSInvocation` object is encoded using the information in the `NSMethodSignature` object and sent to the real object represented by the receiver of the message.

An `NSMethodSignature` object presents its argument types by index with the `getArgumentTypeAtIndex:` (page 7) method. The hidden arguments for every method, `self` and `_cmd`, are at indices 0 and 1, respectively. The arguments normally specified in a message invocation follow these. In addition to the argument types, an `NSMethodSignature` object offers the total number of arguments with `numberOfArguments` (page 9), the total stack frame length occupied by all arguments with `frameLength` (page 7) (this varies with hardware architecture), and the length and type of the return value with `methodReturnLength` (page 8) and `methodReturnType` (page 9). Finally, applications using distributed objects can determine if the method is asynchronous with the `isOneway` (page 8) method.

For more information about the nature of a method, including the hidden arguments, see “How Messaging Works” in *The Objective-C 2.0 Programming Language*.

## Tasks

### Creating a Method Signature Object

- + [signatureWithObjCTypes:](#) (page 6)  
Returns an `NSMethodSignature` object for the given Objective C method type string.

### Getting Information on Argument Types

- [getArgumentTypeAtIndex:](#) (page 7)  
Returns the type encoding for the argument at a given index.
- [numberOfArguments](#) (page 9)  
Returns the number of arguments recorded in the receiver.
- [frameLength](#) (page 7)  
Returns the number of bytes that the arguments, taken together, occupy on the stack.

### Getting Information on Return Types

- [methodReturnType](#) (page 9)  
Returns a C string encoding the return type of the method in Objective-C type encoding.
- [methodReturnLength](#) (page 8)  
Returns the number of bytes required for the return value.

### Determining Synchronous Status

- [isOneway](#) (page 8)  
Returns a Boolean value that indicates whether the receiver is asynchronous when invoked through distributed objects.

## Class Methods

### **signatureWithObjCTypes:**

Returns an `NSMethodSignature` object for the given Objective C method type string.

```
+ (NSMethodSignature *)signatureWithObjCTypes:(const char *)types
```

#### Parameters

*types*

An array of characters containing the type encodings for the method arguments.

Indices begin with 0. The hidden arguments *self* (of type `id`) and *\_cmd* (of type `SEL`) are at indices 0 and 1; method-specific arguments begin at index 2.

**Return Value**

An `NSMethodSignature` object for the given Objective C method type string in *types*.

**Discussion****Special Considerations**

This method, available since Mac OS X v10.0, is exposed in Mac OS X v10.5. Only type encoding strings of the style of the runtime that the application is running against are supported. In exposing this method there is no commitment to binary compatibility supporting any "old-style" type encoding strings after such changes occur.

It is your responsibility to pass in type strings which are either from the current runtime data or match the style of type string in use by the runtime that the application is running on.

**Availability**

Available in Mac OS X v10.5 and later.

**Declared In**

`NSMethodSignature.h`

## Instance Methods

**frameLength**

Returns the number of bytes that the arguments, taken together, occupy on the stack.

- (NSUInteger)frameLength

**Return Value**

The number of bytes that the arguments, taken together, occupy on the stack.

**Discussion**

This number varies with the hardware architecture the application runs on.

**Availability**

Available in Mac OS X v10.0 and later.

**Declared In**

`NSMethodSignature.h`

**getArgumentTypeAtIndex:**

Returns the type encoding for the argument at a given index.

- (const char \*)getArgumentTypeAtIndex:(NSUInteger) *index*

**Parameters**

*index*

The index of the argument to get.

**Return Value**

The type encoding for the argument at *index*.

**Discussion**

Indices begin with 0. The hidden arguments *self* (of type `id`) and *\_cmd* (of type `SEL`) are at indices 0 and 1; method-specific arguments begin at index 2. Raises `NSInvalidArgumentException` if *index* is too large for the actual number of arguments.

Argument types are given as C strings with Objective-C type encoding. This encoding is implementation-specific, so applications should use it with caution.

**Availability**

Available in Mac OS X v10.0 and later.

**Declared In**

`NSMethodSignature.h`

**isOneway**

Returns a Boolean value that indicates whether the receiver is asynchronous when invoked through distributed objects.

- (BOOL)isOneway

**Return Value**

YES if the receiver is asynchronous when invoked through distributed objects, otherwise NO.

**Discussion**

If the method is *oneway*, the sender of the remote message doesn't block awaiting a reply.

**Availability**

Available in Mac OS X v10.0 and later.

**Declared In**

`NSMethodSignature.h`

**methodReturnLength**

Returns the number of bytes required for the return value.

- (NSUInteger)methodReturnLength

**Return Value**

The number of bytes required for the return value.

**Availability**

Available in Mac OS X v10.0 and later.

**See Also**

- [methodReturnType](#) (page 9)

**Declared In**

`NSMethodSignature.h`

## methodReturnType

Returns a C string encoding the return type of the method in Objective-C type encoding.

- (const char \*)methodReturnType

### Return Value

A C string encoding the return type of the method in Objective-C type encoding.

### Discussion

This encoding is implementation-specific, so applications should use it with caution.

### Availability

Available in Mac OS X v10.0 and later.

### See Also

- [methodReturnLength](#) (page 8)

### Declared In

NSMethodSignature.h

## numberOfArguments

Returns the number of arguments recorded in the receiver.

- (NSUInteger)numberOfArguments

### Return Value

The number of arguments recorded in the receiver.

### Discussion

There are always at least 2 arguments, because an `NSMethodSignature` object includes the hidden arguments `self` and `_cmd`, which are the first two arguments passed to every method implementation.

### Availability

Available in Mac OS X v10.0 and later.

### Declared In

NSMethodSignature.h

# Document Revision History

---

This table describes the changes to *NSMethodSignature Class Reference*.

Date	Notes
2008-10-15	Added declaration of signatureWithObjCTypes:.
2008-03-11	Added a live link to a cross-reference in the Overview section.
2007-02-23	Revised task heading.
2006-05-23	First publication of this content as a separate document.
