The WebObjects Framework

Introduction

The WebObjects class hierarchy is rooted in the Foundation Framework's NSObject class (see Figure 1). The remainder of the WebObjects Framework consists of several related groups of classes as well as a few individual classes.

Figure 1 The WebObjects Framework class hierarchy
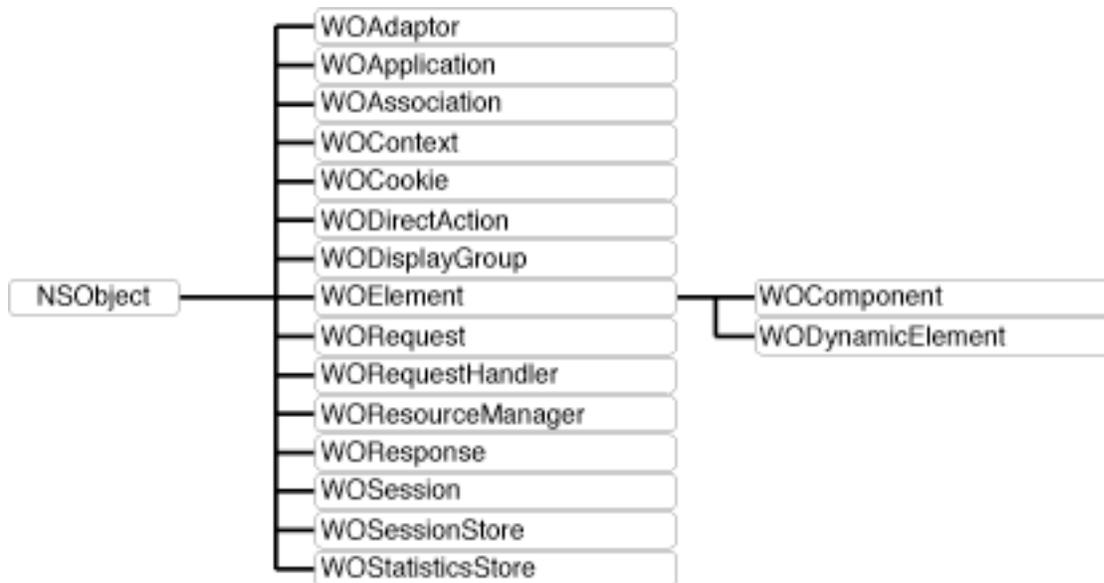

The more commonly-used classes within the WebObjects framework can be grouped as follows:

- **Server and Application Level Classes**. WOAdaptor defines the interface for objects mediating the exchange of data between an HTTP server and a WebObjects application. WOApplication receives requests from the adaptor and initiates and coordinates the request-handling process, after which it returns a response to the adaptor.

- **Session Level Classes**. WOSession encapsulates the state of a session; WOSession objects persiste between the cycles of the request-response loop. WOSessionStore provides the strategy or mechanism through which WOSession objects are made persistent.

- **Request Level Classes**. WORequest stores essential data about an HTTP request, such as header information, form values, HTTP version, host and page name, and session, context, and sender IDs. WOResponse stores and allows the modification of HTTP response data, such as header information, status, and HTTP version. WOContext provides access to the objects involved in the current cycle, such as the current request, response, session, and application objects.

- **Page Level Classes**. WOComponent represents and integral, reusable page (or portion of a page) for display in a web browser. WOElement declares the three request-handling methods: takeValuesFromRequest:inContext:, invokeActionForRequest:inContext:, and appendToResponse: inContext:. WODynamicElement is an abstract class for subclasses that generate particular dynamic elements. WOAssociation knows how to find and set a value by reference to a key.

- **Database Integration Level Classes**. WODisplayGroup performs fetches, queries, creations, and deletions of records from one table in the database.

WOAdaptor

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOAdaptor is an abstract class that represents objects that can receive events from a WebObjects adaptor. A WebObjects adaptor is a process that handles communication between the server and a WebObjects application. The WebObjects application (a WOApplication instance) communicates with the adaptor using messages defined in the WOAdaptor class.

The purpose of the WOAdaptor class is to perform these tasks:

- Register with the application's run loop to begin receiving events.
- Receive incoming events from the run loop and package them as WORequest objects.
- Forward the WORequest to the WOApplication by sending it the message **dispatchRequest**.
- Receive the WOResponse object from the WOApplication and send it to the client using an RPC mechanism.

Method Types

Constructors

    WOAdaptor

Obtaining attributes

    doesBusyRunOnce
    dispatchesRequestsConcurrently

Event registering

    registerForEvents
    unregisterForEvents

Running

    runOnce

Constructors

WOAdaptor

public **WOAdaptor**(java.lang.String *aName*, NSDictionary *someArguments*)

Initializes a WOAdaptor with the name *aName* and arguments *someArguments*. *aName* is the name of the WOAdaptor subclass. *someArguments* are the default options specified for this adaptor (such as port number and listen queue depth).

The WOApplication method **adaptorWithName:arguments:** invokes this message when it encounters an **WOAdaptor** option on the command line. The WOApplication retains each of its WOAdaptors.

See also: **adaptorWithName** (WOApplication)

Instance Methods

doesBusyRunOnce

public boolean **doesBusyRunOnce**()

Returns whether repeatedly invoking **runOnce** would result in busy waiting.

dispatchesRequestsConcurrently

public boolean **dispatchesRequestsConcurrently**()

Returns true if the adaptor is multi-threaded, false otherwise. If the adaptor is multi-threaded, the adaptor may dispatch requests to the application concurrently in separate threads.

See also: **adaptorsDispatchRequestsConcurrently** (WOApplication)

registerForEvents

public void **registerForEvents**()

Performs any actions necessary to have the WOAdaptor start receiving events.

See also: **runLoop** in WOApplication

runOnce

public void **runOnce**()

Invoked by the application's main loop

See also: doesBusyRunOnce

unregisterForEvents

public void **unregisterForEvents**()

Undoes the actions performed in **registerForEvents** so that the WOAdaptor stops receiving events.

WOApplication

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

The primary role of the WOApplication class is to coordinate the handling of HTTP requests. Each application must have exactly one WOApplication object (or, simply, application object). The application object receives client requests from an HTTP server adaptor, manages the processing that generates a response, and returns that response—typically an object representing a web page—to the adaptor. The adaptor, in turn, forwards the response in a suitable form to the HTTP server that originated the request.

In handling requests, an application object creates and manages one or more sessions; a session (represented by a WOSession object) dedicates resources to a period of access by a single user and stores persistent state during that period. Conceptually, each cycle of the request-response loop (or transaction) takes place within a session.

Besides acting as a facilitator between the adaptor and the rest of the application during request handling, WOApplication performs many secondary functions. It returns pages based on component name, caches page instances and component definitions, provides some facilities for error handling and script debugging, coordinates the different levels of multi-threaded execution, and furnishes a variety of data.

Typical deployment schemes balance the processing load by having multiple application instances per server adaptor. A single application, in turn, can interact with multiple adaptors; for example, an application can simultaneously communicate with secure-socket and Distributed Object adaptors as well as HTTP adaptors.

You can instantiate ready-made application objects from the WOApplication class or you can obtain the application object from a custom subclass of WOApplication. Custom WOApplication subclasses are common in WebObjects applications since there is often a need to override the **awake**, **sleep**, and request-handling methods. Compiled WOApplication subclasses can take any name, but if the name is anything other than "Application" you must implement your own **main** function to instantiate the application object from this class. However, if the class name is "Application," you don't need to modify **main**. In scripted applications, the code in the **Application.wos** file becomes the implementation logic of a WOApplication subclass automatically created at run time; the application object is instantiated from this subclass.

Managing sessions

                setSessionStore
                sessionStore
                saveSessionForContext
                restoreSessionWithID
                createSessionForRequest

Managing pages

                setPageCacheSize
                pageCacheSize
                permanentPageCacheSize
                setPermanentPageCacheSize
                setPageRefreshOnBacktrackEnabled
                isPageRefreshOnBacktrackEnabled
                pageWithName
                pageWithName

Creating elements

                dynamicElementWithName

Running

           runLoop
           run
           setTimeOut
           timeOut
           terminate
           isTerminating

Handling requests

           dispatchRequest
           awake
           takeValuesFromRequest
           invokeActionForRequest
           appendToResponse
           sleep

Handling errors

           handleSessionCreationErrorInContext
           handlePageRestorationErrorInContext
           handleSessionRestorationErrorInContext
           handleException

Backward compatibility

           requiresWOF35RequestHandling
           requiresWOF35TemplateParser

Scripted class support

           scriptedClassNameWithPath
           scriptedClassNameWithPathEncoding

Script debugging

           logString
           debugWithString
           trace
           traceAssignments
           traceObjectiveCMessages
           traceScriptedMessages
           traceStatements
           logTakeValueForDeclarationNamed
           logSetValueForDeclarationNamed

Statistics report

           setStatisticsStore
           statisticsStore
           statistics

Monitor support

        monitoringEnabled
        activeSessionsCount
        refuseNewSessions:
        isRefusingNewSessions
        setMinimumActiveSessionsCount
        minimumActiveSessionsCount
        terminateAfterTimeInterval
        logToMonitorString

Resource manager support

        setResourceManager
        resourceManager

Request handling

        defaultRequestHandler
        setDefaultRequestHandler
        registerRequestHandler
        removeRequestHandlerForKey
        registeredRequestHandlerKeys
        requestHandlerForKey:
        handlerForRequest

Constructors

WOApplication

public **WOApplication**()

Creates and initializes application attributes and initializes the adaptor or adaptors specified on the command line. If no adaptor is specified, WODefaultAdaptor is made the default adaptor. Some of the more interesting attribute initializations are:

- Session store is in the server.
- Page cache size is 30 pages.
- Client caching of pages is enabled (**isPageRefreshOnBacktrackEnabled** returns false).

A exception is thrown if initialization does not succeed.

Note: The global variable "WOApp" is initialized in this method.

Static Methods

adaptor

public static java.lang.String **adaptor**()

Returns the class name of the primary adaptor. This is the cover method for the user default WOAdaptor.

See also: **setAdaptorpublic static void setAdaptor(java.lang.String anAdaptorName)**

additionalAdaptors

public static NSArray **additionalAdaptors**()

Returns an array of adaptor description dictionaries. This is the cover method for the user default WOAdditionalAdaptors.

See also: **setAdditionalAdaptors**

application

public static WOApplication **application**()

Returns a WOApplication object. You may call this method, but do not override it.

applicationBaseURL

public static java.lang.String **applicationBaseURL**()

Returns a path to where the current application may be found under the document root (either the project or the **.woa** wrapper). This is the cover method for the user default WOApplicationBaseURL.

See also: **setApplicationBaseURL**

autoOpenInBrowser

public static boolean **autoOpenInBrowser**()

Returns whether automatic browser launching is enabled. By default, automatic browser launching is enabled.

cgiAdaptorURL

public static java.lang.String **cgiAdaptorURL**()

Returns the URL for the web server including the path to the WebObjects CGI adaptor (for example, **http://localhost/cgi-bin/WebObjects**). This URL is used by the direct connect feature only. This is the cover for the user default WOCGIAdaptorURL.

See also: **setCGIAdaptorURL**

componentRequestHandlerKey

public static java.lang.String **componentRequestHandlerKey**()

Returns the key which identifies URLs directed at component-action-based requests. By default, this method returns the string "wo".

directActionRequestHandlerKey

public static java.lang.String **directActionRequestHandlerKey**()

Returns the key which identifies URLs directed at component-based requests. By default, this method returns the string "wa".

frameworksBaseURL

public static java.lang.String **frameworksBaseURL**()

Returns a path to where all frameworks may be found under the document root. This value is used to determine URLs that should be generated to reference Web Server Resources in those frameworks. This is the cover method for the user default WOFrameworksBaseURL.

See also: setFrameworksBaseURL

includeCommentsInResponses

public static boolean **includeCommentsInResponses**()

Returns whether or not HTML comments are appended to the response. This is the cover method for the user default WOIncludeCommentsInResponses.

See also: setIncludeCommentsInResponses:

isCachingEnabled

public static boolean **isCachingEnabled**()

Returns whether or not component caching is enabled. If this is enabled, changes to a component will be reparsed after being saved (assuming the project is under the NSProjectSearchPath). Note that this has no effect on page caching. This is the cover method for the user default WOCachingEnabled.

See also: setCachingEnabled, **pageCacheSize**

isDebuggingEnabled

public static boolean **isDebuggingEnabled**()

Returns whether or not debugging is enabled. If true, **debugWithString** prints out. Most startup-time status message are supressed if this method returns false. By default, debugging is enabled. This is the cover method for the user default WODebuggingEnabled.

See also: setDebuggingEnabled, **debugWithString**

isDirectConnectEnabled

public static boolean **isDirectConnectEnabled**()

Returns whether or not direct connect is enabled. By default it is enabled. For more information, see **setDirectConnectEnabled**.

See also: cgiAdaptorURL

isMonitorEnabled

public static boolean **isMonitorEnabled**()

Returns whether or not the application can communicate with a Monitor application. It returns true if the application can contact Monitor upon startup and subsequently let Monitor gather statistics. It returns false if no comunication with Monitor can take place. By default, it can communicate with a Monitor application. 'This is a cover method for the user default WOMonitorEnabled.

See also: setMonitorEnabled, **monitorHost**, **setMonitorHost**

listenQueueSize

public static java.lang.Number **listenQueueSize**()

Returns the size of the listen queue which will created by the primary adaptor (usually WODefaultAdaptor). This is the cover method for the user default WOListenQueueSize.

See also: setListenQueueSize

loadFrameworks

public static NSArray **loadFrameworks**()

Returns the array of frameworks to be loaded during application initialization.

See also: setLoadFrameworks

logString

public static void **logString**(java.lang.String *aString*)

Prints a message to the standard error device (stderr). The message can include formatted variable data using String's concatenation feature, for example:

```
int i = 500;
float f = 2.045;
```

```
WOApplication.logString("Amount = " + i + ", Rate = " + f ", Total = " + i*f);
```

See also: logToMonitorString

monitorHost

   public static java.lang.String **monitorHost**()

Returns the host on which Monitor is assumed to be running. This value is used during initialization if **isMonitorEnabled** returns true. This is a cover for the user default WOMonitorHost.

See also: setMonitorHost, **isMonitorEnabled**

port

   public static java.lang.Number **port**()

Returns the port number on which the primary adaptor will listen (usually WODefaultAdaptor). This is the cover method for the user default WOPort.

See also: setPort

projectSearchPath

   public static NSArray **projectSearchPath**()

Returns an array of file system paths which are searched for projects for rapid turnaround mode. This is the cover method for the user default NSProjectSearchPath.

See also: setProjectSearchPath

recordingPath

   public static java.lang.String **recordingPath**()

Returns a file system path which is where the recording information should be saved. By default, this method returns nil.

If this method returns a path, all requests and responses are recorded in the HTTP format in numbered files (**0000-request**, **0000-response**, **0001-request**, **0001-response**, and so on), and saved under the recording path specified. This directory is then used by the Playback tool to test the application. You will most likely set this as a command line argument (-WORecordingPath pathname), exercise your application to record a scenario you would like to test, and then stop the application. Afterward you can restart the

application without the WORecordingPath argument, and point Playback to the recording directory just created to replay your sequence of requests and compare the responses received with the ones recorded.

See also: setRecordingPath

resourceRequestHandlerKey

   public static java.lang.String **resourceRequestHandlerKey**()

Returns the key which identifies URLs directed through the resource request handler. Resource requests are only used during development of an application when the application is being run without an HTTP server.

See also: setResourceRequestHandlerKey

sessionTimeout

   public static java.lang.Number **sessionTimeOut**()

Returns the number (of seconds) which will be used as the default timeout for each newly created session. You may either override this method, change the user default WOSessionTimeOut, or set the session timeout in your session's **init** method.

See also: setSessionTimeOutpublic void setSessionTImeOut(java.lang.Number aTimeOut)

   setAdaptorpublic static void **setAdaptor**(java.lang.String *anAdaptorName*)

Sets the the class name of the primary adaptor to *anAdaptorName*.

See also: adaptor

setAdditionalAdaptors

   public static void **setAdditionalAdaptors**(NSArray *anAdaptorPlist*)

Sets the array of adaptor description dictionaries to *anAdaptorPlist*. Each adaptor description dictionary must have "WOAdaptor" defined, which is the name of the adaptor class. Other attributes such as WOPort may also be specified, but are adaptor specific. For example WOWorkerThreadCount is specific to the WODefaultAdaptor class and may not apply for all adaptors.

See also: additionalAdaptors

setApplicationBaseURL

    public static void **setApplicationBaseURL**(java.lang.String *aBaseURL*)

Sets to *aBaseURL* the path to which the current application may be found under the document root (either the project or the **.woa** wrapper).

See also: applicationBaseURL

setAutoOpenInBrowser

    public static void **setAutoOpenInBrowser**(boolean *isEnabled*)

Controls whether starting up this application also launches a web browser. If *isEnabled* is **true**, the application launches the web browser. If **false**, the application does not launch the browser. Browser launching is enabled by default as long as there is a WOAdaptorURL key in the file **NeXT_ROOT/NextLibrary/WOAdaptors/Configuration/WebServerConfig.plist**.

To disable web browser launching, you must send this message in your subclass's constructor.

See also: autoOpenInBrowser

setCGIAdaptorURL

    public static void **setCGIAdaptorURL**(java.lang.String *aURL*)

Sets the URL for the web server to *aURL*. The URL must include the path to the WebObjects CGI adaptor (for example, **http://localhost/cgi-bin/WebObjects**). This URL is used by the direct connect feature only..

See also: cgiAdaptorURL

setCachingEnabled

    public static void **setCachingEnabled**(boolean *flag*)

Sets whether or not component caching is enabled. If this is enabled, changes to a component will be reparsed after being saved (assuming the project is under the NSProjectSearchPath). Note that this has no effect on page caching.

See also: isCachingEnabled, **pageCacheSize**

setComponentRequestHandlerKey

> public static void **setComponentRequestHandlerKey**(java.lang.String *key*)

Sets the component request handler key. This affects all URLs generated during **appendToResponse**: of component-based actions.

See also: componentRequestHandlerKey

setDebuggingEnabled

> public static void **setDebuggingEnabled**(boolean *flag*)

Sets whether or not debugging is enabled. If true, **debugWithString** prints out. Most startup-time status message are supressed if this method returns false. By default, debugging is enabled.

See also: isDebuggingEnabled, **debugWithString**

setDirectActionRequestHandlerKey

> public static void **setDirectActionRequestHandlerKey**(java.lang.String *key*)

Sets the Direct Action request handler key. This affects all URLs generated during **appendToResponse**: of direct actions.

See also: directActionRequestHandlerKey

setDirectConnectEnabled

> public static void **setDirectConnectEnabled**(boolean *flag*)

Sets whether or not direct connect is enabled. By default it is enabled.

Direct connect actually transforms your application in a simple web server of its own. In particular, it is then able to find and return its images and resources as if it were a web server. It is very useful in development mode: You don't need a web server. Just point your URL to the port where your application is listening, and the application will handle all urls.

If this flag is true, the following happens:

- When using **autoOpenInBrowser**, a direct connect URL will be used.
- When using WOMailDelivery to mail pages with dynamic links in them, these links will be generated with a complete direct connect URL format. People receiving these mails will be able to access the application with direct connect.

- *All files on the system are accessible through the resource request handler.* On the other hand, if this flag is false, the resource request handler can be used to retrieve data objects from memory only, and no more reading in the file system is permitted (secure mode for deployment).

See also: isDirectConnectEnabled, **cgiAdaptorURL**

setFrameworksBaseURL

   public static void **setFrameworksBaseURL**(java.lang.String *aString*)

Sets to *aString* the path to where all frameworks may be found under the document root. This value is used to determine URLs that should be generated to reference Web Server Resources in those frameworks.

See also: frameworksBaseURL

setIncludeCommentsInResponses:

   public static void **setIncludeCommentsInResponses**(boolean *flag*)

Sets whether or not HTML comments are appended to the response.

See also: includeCommentsInResponses

setListenQueueSize

   public static void **setListenQueueSize**(java.lang.Number *aListenQueueSize*)

Sets the size of the listen queue which will created by the primary adaptor (usually WODefaultAdaptor).

See also: listenQueueSize

setLoadFrameworks

   public static void **setLoadFrameworks**(NSArray *frameworkList*)

Sets the array of frameworks to be loaded during application initialization.

See also: loadFrameworks

setMonitorEnabled

    public static void **setMonitorEnabled**(boolean *flag*)

Sets whether or not the application will communicate with a Monitor application. If *flag* is true, the application can contact Monitor upon startup and subsequently let Monitor gather statistics. If *flag* is false, no comunication with Monitor can take place. By default, it can communicate with a Monitor application.

See also: isMonitorEnabled

setMonitorHost

    public static void **setMonitorHost**(java.lang.String *hostName*)

Sets the host on which Monitor is assumed to be running. This value is used during initialization if **isMonitorEnabled** returns true.

See also: monitorHost, **isMonitorEnabled**

setPort

    public static void **setPort**(java.lang.Number *port*)

Sets the port number on which the primary adaptor will listen (usually WODefaultAdaptor).

See also: port

setProjectSearchPath

    public static void **setProjectSearchPath**(NSArray *searchPath*)

Sets the array of file system paths which are searched for projects for rapid turnaround mode.

See also: projectSearchPath

setRecordingPath

    public static void **setRecordingPath**(java.lang.String *path*)

Sets the file system path where the recording information should be saved. Use nil as the path if you don't want to save recording information. By default, recording information is not saved.

If you save recording information, all requests and responses are recorded in the HTTP format in numbered files (**0000-request**, **0000-response**, **0001-request**, **0001-response**, and so on), and saved under the recording path specified. This directory is then used by the Playback tool to test the application. You will most likely set this as a command line argument (`-WORecordingPath pathname`), exercise your

application to record a scenario you would like to test, and then stop the application. Afterward you can restart the application without the WORecordingPath argument, and point Playback to the recording directory just created to replay your sequence of requests and compare the responses received with the ones recorded.

See also: recordingPath

setResourceRequestHandlerKey

    public static void **setResourceRequestHandlerKey**(java.lang.String *key*)

Sets the resource request handler key. This affects all URLs generated during **appendToResponse**: of resources.

See also: resourceRequestHandlerKey

    setSessionTimeOutpublic void **setSessionTImeOut**(java.lang.Number *aTimeOut*)
    (void)**setSessionTimeOut:**(NSNumber*)*aTimeOut*

Accessor to set the default session timeOut.

See also: sessionTimeout

setSMTPHost

    public static void **setSMTPHost**(java.lang.String *hostName*)

Sets the name of the host that will be used to send e-mail messages created by WOMailDelivery.

See also: SMTPHost

setWorkerThreadCount

    public static void **setWorkerThreadCount**(java.lang.Number *aWorkerThreadCount*)

SEts the count of worker threads which will created by the primary adaptor (usually WODefaultAdaptor). A worker thread count of 0 implies single-threaded mode.

See also: workerThreadCount

SMTPHost

   public static java.lang.String **SMTPHost**()

Returns the name of the host that will be used to send e-mail messages created by WOMailDelivery. This is the cover method for the user default WOSMTPHost.

See also: **setSMTPHost**

workerThreadCount

   public static java.lang.Number **workerThreadCount**()

Returns the count of worker threads which will created by the primary adaptor (usually WODefaultAdaptor). A worker thread count of 0 implies single-threaded mode. This is the cover method for the user default WOWorkerThreadCount.

See also: **setWorkerThreadCount**

Instance Methods

activeSessionsCount

   public int **activeSessionsCount**()

Returns the number of sessions that are currently active. (A session is active if it has not yet timed out.)

The number returned here is only accurate if the application stores state in memory in the server, which is the default. If you use a custom state-storage strategy, there may be no way to tell how many sessions are active for a given application instance.

See also: **minimumActiveSessionsCount**, **setMinimumActiveSessionsCount**

adaptorWithName

   public WOAdaptor **adaptorWithName**(java.lang.String *aName*, NSDictionary *someArguments*)

Invoked during the constructor to create an adaptor. If you subclass WOAdaptor, you specify the WOAdaptor subclass you want the application to use with the **-a** option on the application's command line. When WOApplication encounters the **-a** option, it invokes this method. This method looks for a subclass of WOAdaptor with the name *aName* (which was supplied as the **-a** option's argument), and if such a class exists, a new instance is created. The *someArguments* array is populated with any adaptor-specific options (such as **-p** or **-q**) that follow the adaptor name on the command line. See the WOAdaptor class for more information.

See also: **adaptors**

adaptors

public NSArray **adaptors**()

Returns the current list of application adaptors. A WOApplication can have multiple adaptors. (To associate the WOApplication with multiple adaptors, you specify each adaptor on the application's command line using the **-a** option.) This allows you to design an application that can not only listen to a socket for incoming HTTP requests (using the WODefaultAdaptor), but can also receive remote request messages using more advanced RPC mechanisms such as DO, CORBA, and DCOM.

adaptorsDispatchRequestsConcurrently

public boolean **adaptorsDispatchRequestsConcurrently**()

Returns true if at least one adaptor contains multiple threads and will attempt to concurrently invoke the request handlers.

allowsConcurrentRequestHandling

public boolean **allowsConcurrentRequestHandling**()

Override to return true if concurrent request handling is allowed.

appendToResponse

public void **appendToResponse**(WOResponse *aResponse*, WOContext *aContext*)

The WOApplication object sends this message to itself to initiate the last phase of request handling. This occurs right after the **invokeActionForRequest:inContext:**: method has completed, typically with the return a response page. In the append-to-response phase, the application objects (particularly the response component itself) generate the HTML content of the page. WOApplication's default implementation of this method forwards the message to the session object.

See also: invokeActionForRequest

awake

public void **awake**()

Invoked at the beginning of each cycle of the request-response loop, affording the opportunity to perform initializations with application-wide scope. Since the default implementation does nothing, overridden implementations do not have to call **super**.

See also: sleep

baseURL

public java.lang.String **baseURL**()

Returns the application URL relative to the server's document root, for example:

```
WebObjects/Examples/HelloWorld.woa.
```

See also: **name**, **path**

createSessionForRequest

public WOSession **createSessionForRequest**(WORequest *aRequest*)

Creates and returns a WOSession object to manage a session for the application. The method goes through several steps to locate the class to use for instantiating this object:

1. First it looks for a compiled class of name "Session" that is a subclass of WOSession.

2. If such a class does not exist, it looks for a "**.wos**" script with the name of "Session" in the application wrapper ("**.woa**" directory).

3. If the **Session.wos** script exists, the method parses the script and dynamically adds a scripted-class subclass of WOSession to the runtime.

The method then returns an allocated and initialized (using the default WOSession constructor) session instance of the selected class. It throws an exception if it is unable to create a new session.

Note: An implication of the foregoing description is that the names of compiled WOSession subclasses should be "Session"; if not, you will have to override this method to use the proper class to create the session object.

See also: **restoreSessionWithID**, **saveSessionForContext**

debugWithString

public void **debugWithString**(java.lang.String *aFormatString*)

Prints a message to the standard error device (stderr), if **WODebuggingEnabled** is true. The message can include formatted variable data using String's concatenation feature.

You control whether this method displays output with the **WODebuggingEnabled** user default option. If **WODebuggingEnabled** is true, then the **debugWithStringFormat:** messages display their output. If **WODebuggingEnabled** is false, the **debugWithStringFormat:** messages don't display their output.

defaultRequestHandler

public WORequestHandler **defaultRequestHandler**()

Returns the request handler to be used when no request handler key was found in the URL or WORequest. This method returns the WOComponent request handler by default. When an application is contacted for the first time it is usually via a URL like the following:

```
http://somehost/cgi-bin/WebObjects/AppName.woa
```

The way that URLs of that type are handled is determined by the default request handler.

dispatchRequest

public WOResponse **dispatchRequest**(WORequest *aRequest*)

The main entry point for any given interaction. Invoked by the adaptor.

dynamicElementWithName

public WODynamicElement **dynamicElementWithName**(java.lang.String *aName*,
    NSDictionary *someAssociations*,
    WOElement *anElement*
    NSArray *languages*)

Creates and returns a WODynamicElement object based on the element's name, a dictionary of associations, and a template of elements. This method is invoked automatically to provide a WODynamicElement object that represents a WEBOBJECT element in the HTML template. You don't ordinarily invoke **dynamicElementWithName:associations:template:languages:**, but you might override it to substitute your own WODynamicElement or reusable component for one of the built-in WODynamicElements.

The arguments *aName* and *someAssociations* are derived from a corresponding line in the declarations file. *aName* is a String that identifies the kind of element to create. Generally *aName* specifies a built-in WODynamicElement such as WOString, but it may also identify a reusable component. (For more information, see the chapter "Using Reusable Components" in the *WebObjects Developer's Guide*.) For example, in the **dynamicElementWithName:associations:template:languages:** message for the following declaration:

```
APP_STRING: WOString {value = applicationString;};
```

aName contains the string "WOString".

The *someAssociations* dictionary contains an entry for each attribute specified in the corresponding declaration. For the declaration above, *someAssociations* contains a single entry for WOString's value attribute. The keys of *someAssociations* are the attribute names and the values are WOAssociation objects.

WOApplication's implementation of **dynamicElementWithName:associations:template:languages:** first searches for a WODynamicElement named *aName*. If a WODynamicElement is found, the method creates an instance and returns it. Otherwise, it searches for a component—either scripted or compiled—to return instead. If neither are found, this method returns **null**.

handleException

public WOResponse **handleException**(java.lang.Throwable *anException*, WOContext *aContext*)

Invoked when an exception occurs within the request-response loop. The default behavior displays a page with debugging information. You can override this method to catch exceptions and display a "friendlier" error page.

See also: **handleSessionCreationErrorInContext**, **handleSessionRestorationErrorInContext**

handlePageRestorationErrorInContext

public WOResponse **handlePageRestorationErrorInContext**(WOContext *aContext*)

Invoked when a page (WOComponent) instance cannot be restored, which typically happens when a user backtracks too far. Specifically, this method is invoked when the following occurs: the request is not the first of a session, page restoration by context ID fails, and page re-creation is disabled. The default behavior displays a page with debugging information. You can override this method to display a "friendlier" error page.

See also: **handleException**, **handleSessionCreationErrorInContext**, **handleSessionRestorationErrorInContext**

handleSessionCreationErrorInContext

public WOResponse **handleSessionCreationErrorInContext**(WOContext *aContext*)

Invoked when a session (WOSession) instance cannot be created. The default behavior displays a page with debugging information. You can override this method to display a "friendlier" error page.

See also: **handleException**, **handlePageRestorationErrorInContext**, **handleSessionRestorationErrorInContext**

handleSessionRestorationErrorInContext

> public WOResponse **handleSessionRestorationErrorInContext**(WOContext *aContext*)

Invoked when a session (WOSession) instance cannot be restored, which typically happens when the session times out. The default behavior displays a page with debugging information. You can override this method to display a "friendlier" error page.

See also: **handleException**, **handlePageRestorationErrorInContext**,
handleSessionCreationErrorInContext

handlerForRequest

> public WORequestHandler **handlerForRequest**(WORequest *aRequest*)

Returns the request handler used to handle a given request.

See also: **registerRequestHandler**, **registeredRequestHandlerKeys**, **requestHandlerForKey:**

invokeActionForRequest

> public WOElement **invokeAction**(WORequest *aRequest*, WOContext *aContext*)

The WOApplication object sends this message to itself to initiate the middle phase of request handling. In this phase, the message is propagated through the objects of the application until the dynamic element that has received the user action (for instance, a click on a button) responds to the message by triggering the method in the request component that is bound to the action. The default WOApplication implementation of this method forwards the message to the session object.

See also: **appendToResponse**

isConcurrentRequestHandlingEnabled

> public boolean **isConcurrentRequestHandlingEnabled**()

Returns whether component-definition caching is enabled. The default is **false**.

isPageRefreshOnBacktrackEnabled

> public boolean **isPageRefreshOnBacktrackEnabled**()

Returns whether caching of pages is disabled in the client. If so, the client does not restore request pages from its cache but re-creates them "from scratch" by resending the URL to the server. This flag is set to **false** by default.

See also: **setPageRefreshOnBacktrackEnabled**

isRefusingNewSessions

> public boolean **isRefusingNewSessions**()

Returns **true** if the application instance is refusing new sessions, and **false** otherwise. When the application instance refuses new sessions, the WebObjects adaptor tries to start the session in another instance of the same application. If no other instance is running and accepting new sessions, the user receives an error message.

isTerminating

> public boolean **isTerminating**()

Returns whether the application will terminate at the end of the current request-response loop.

See also: **setTimeOut**, **terminate**, **terminateAfterTimeInterval**, **timeOut**

lock

> public void **lock**()

Locks the application object.

lockRequestHandling

> public void **lockRequestHandling**()

Serializes request handler access if concurrent request handling isn't enabled.

logSetValueForDeclarationNamed

> public void **logSetValueForDeclarationNamed**(java.lang.String *aDeclarationName*, java.lang.String *aDeclarationType*, java.lang.String *aBindingName*, java.lang.String *anAssociationDescription*, java.lang.Object *aValue*)

Formats and logs a message anytime a value is set through a WOAssociation, when WODebug is set to true for the declaration in which the association appears. (Setting a value means the child component/element is setting a value in the parent). See **logTakeValueForDeclarationNamed** for a description of each of the arguments to this method.

logTakeValueForDeclarationNamed

public void **logTakeValueForDeclarationNamed**(java.lang.String *aDeclarationName*,
java.lang.String *aDeclarationType*, java.lang.String *aBindingName*, java.lang.String
anAssociationDescription, java.lang.Object *aValue*)

Formats and logs a message anytime a value is "taken" through a WOAssociation , when WODebug is set
to true for the declaration in which the association appears. (Taking a value means the child
component/element is taking a value from the parent). Override this method to alter the format of the log
message. The arguments of this method are defined in the following example of a WebObjects declaration.

```
aDeclarationName : aDeclarationType {
aBindingName = anAssociationDescription;
}
```

Also, *aValue* is the value which is being pushed to or pulled from the child to the parent.

logToMonitorString

public void **logToMonitorString**(java.lang.String *aFormat*)

Same as **logString** but prints the string to the Monitor application's standard error. That is, the message is
displayed in the command-shell window that was used to launch the Monitor application.

You use this method to log messages about significant events when the application is ready to be deployed
and you will use Monitor regularly to monitor the application. Otherwise, use **logString**. If the Monitor
application is not running or if this application instance is not being monitored, this method does nothing.

minimumActiveSessionsCount

public int **minimumActiveSessionsCount**()

Returns the minimum number of active sessions allowed. If the number of active sessions is less than or
equal to this number and **isRefusingNewSessions** is **true**, the application instance terminates. The default
is 0.

See also: **activeSessionsCount**, **refuseNewSessions:**, **setMinimumActiveSessionsCount**

monitoringEnabled

public boolean **monitoringEnabled**()

Returns **true** if the application is "monitorable" by the Monitor application, and **false** otherwise. An
application is "monitorable" if it was able to find a running Monitor upon startup and it is able to
successfully communicate with that Monitor.

By default, all applications are monitorable if the Monitor application is running on the same machine as the application. You can specifically disable monitoring using the `-WOMonitorEnabled NO` option on the application command line. If you want the application to be monitorable and the Monitor is running on another host, you can start up the application through Monitor, or you can specify Monitor's host on the application command line this way:

```
MyApp.exe -WOMonitorEnabled YES -WOMonitorHost monitorHost ...
```

See also: **logToMonitorString**, the online document *ServingWebObjects*

name

public java.lang.String **name**()

Returns the name of the application, which is the name of the executable (without the `.exe` extension).

See also: **baseURL**, **path**

number

public java.lang.String **number**()

Returns `"-1"`. This is provided for backwards compatibility only.

pageCacheSize

public int **pageCacheSize**()

Returns the size of the internal cache for page instances. The default size is 30 instances.

See also: : **setPageCacheSize**

pageWithName

public WOComponent **pageWithName**(java.lang.String *aName*, WORequest *aRequest*)

Returns a new page instance (a WOComponent object) identified by *aName*. If *aName* is **null**, the "Main" component is assumed. If the method cannot create a valid page instance, it throws an exception.

As part of its implementation, this method creates a context with *aRequest* and calls **pageWithName**.

See also: **restorePageForContextID** (WOSession), **savePage** (WOSession)

pageWithName

public WOComponent **pageWithName**(java.lang.String *aName*, WOContext *aContext*)

Returns a new page instance (a WOComponent object) identified by *aName*. If *aName* is **null**, the "Main" component is assumed. If the method cannot create a valid page instance, it throws an exception.

See also: **pageWithName**, **restorePageForContextID** (WOSession), **savePage** (WOSession)

path

public java.lang.String **path**()

Returns the filesystem path of the application, which is an absolute path and includes the "**.woa**" extension; for example "**C:/NETSCAPE/ns-home/docs/WebObjects/Examples/HelloWorld.woa**" is a typical application path.

See also: **baseURL**, **name**

permanentPageCacheSize

public int **permanentPageCacheSize**()

Returns the permanent page cache size. The default is 30. The permanent page cache holds pages which should not fall out of the regular page cache. For example, a control page in a frameset should exist for the duration of a session.

See also: **savePageInPermanentCache** (WOApplication)

refuseNewSessions:

public void **refuseNewSessions**(boolean *flag*)

Controls whether this application instance will create a session when it receives an HTTP request from a new user. If *flag* is **true**, the application does not create new sessions; when it receives a request from a new user, it refuses that request, and the adaptor must try to find another application instance that can process the request. If *flag* is **false**, the application creates new sessions. **false** is the default.

You use this method with **setMinimumActiveSessionsCount:** to gracefully shut down application instances. Use **setMinimumActiveSessionsCount:** to set the active session minimum to a certain number. When number of active sessions reaches the number you set and **isRefusingNewSessions** returns **true**, the application terminates.

See also: **activeSessionsCount**, **isRefusingNewSessions**, **minimumActiveSessionsCount**, **setMinimumActiveSessionsCount**

registerRequestHandler

public void **registerRequestHandler**(WORequestHandler *aHandler*, java.lang.String *aKey*)

Registers a new request handler. *aKey* must specify a key which can be found in the URLs following the instance number or application name.

See also: **removeRequestHandlerForKey**, **registeredRequestHandlerKeys**, **requestHandlerForKey:**

registeredRequestHandlerKeys

public NSArray **registeredRequestHandlerKeys**()

Returns an array of strings containing the keys of all of the registered request handlers.

See also: **handlerForRequest**, **requestHandlerForKey:**

removeRequestHandlerForKey

public WORequestHandler **removeRequestHandlerForKey**(java.lang.String *aRequestHandlerKey*)

Removes the specified request handler from the application.

See also: **registerRequestHandler**, **requestHandlerForKey:**

requestHandlerForKey:

public WORequestHandler **requestHandlerForKey**(java.lang.String *key*)

Returns the request handler used to handle requests containing the specified key.

See also: **handlerForRequest**, **registerRequestHandler**, **registeredRequestHandlerKeys**

requiresWOF35RequestHandling

public boolean **requiresWOF35RequestHandling**()

For backward compatibility, if your project depends upon features or side effects of the old request handling, you will want to override this method and return true. By default, it returns false.

requiresWOF35TemplateParser

    public boolean **requiresWOF35TemplateParser**()

For backward compatibility, if your project depends upon features or side effects removed from the new, 4.0 template parser, you will want to override this method and return true. By default, it returns false.

resourceManager

    public WOResourceManager **resourceManager**()

Returns the WOResourceManager object that the application uses to manage resources.

See also: **setResourceManager**

restoreSessionWithID

    public void **restoreSessionWithID**(java.lang.String *aSessionID*, WOContext *aContext*)

Restores the WOSession object representing a session. In normal request handling, this method is invoked at the start of a cycle of the request-response loop. The default implementation simply invokes WOSessionStore's **checkoutSessionWithID** method, but raises an exception if the WOSessionStore object is missing.

See also: **createSessionForRequest**, **saveSessionForContext**

run

    public void **run**()

Runs the application in a near-indefinite run loop in the default run-loop mode. Before starting the run loop, the method sends **registerForEvents** to the application's adaptors so that they can begin receiving run-loop events. Normally, **run** is invoked in the main function.

See also: **setTimeOut**, **terminate**, **terminateAfterTimeInterval**

runLoop

    public NSRunLoop runLoop()

Returns the application's run loop. Use this method when you need a run loop for such things as registering timers.

saveSessionForContext

public void **saveSessionForContext**(WOContext *aContext*)

Called at the end of the request handling loop, when the current session object needs to be saved. The default implementation simply invokes WOSessionStore's **checkinSessionForContext** method, but throws an exception if the WOSessionStore object is missing.

See also: restoreSessionWithID

scriptedClassNameWithPath

public java.lang.String **scriptedClassNameWithPath**(java.lang.String *aPath*)

Loads a Webscript-based class with the pathname *aPath* into the application. The specified script is parsed assuming the default string encoding, and the class and categories found in the script file are dynamically added to the runtime.

scriptedClassNameWithPathEncoding

public java.lang.String **scriptedClassNameWithPathEncoding**(java.lang.String *aPath*,
    int *anEncoding*)

Loads a scripted class with the pathname *aPath* using the encoding *anEncoding*. The class and categories found in the script file are dynamically added to the runtime. The script must use the
`@interface`/`@implementation` syntax.

sessionStore

public WOSessionStore **sessionStore**()

Returns the application's current WOSessionStore object (which, by default, stores state in the server).

See also: setSessionStore

setDefaultRequestHandler

public void **setDefaultRequestHandler**(WORequestHandler *aHandler*)
```
Sets the default request handler.
```

See also: defaultRequestHandler

setMinimumActiveSessionsCount

public void **setMinimumActiveSessionsCount**(int *anInt*)

Sets the minimum number of active sessions to *anInt*. The default is 0.

You use this method to gracefully shut down application instances. If the active sessions count reaches this number and isRefusingNewSessions returns **true**, the application terminates. You might want to terminate application instances periodically for performance reasons; some applications leak a certain amount of memory per transaction, and shutting down and restarting instances of those applications can free up that memory.

See also: **activeSessionsCount**, **isRefusingNewSessions**, **minimumActiveSessionsCount**, **refuseNewSessions:**

setPageCacheSize

public void **setPageCacheSize**(int *anInt*)

Sets whether caching of page instances will occur and the number of pages the cache will hold. When page-instance caching is enabled, the application stores the WOComponent instance corresponding to the response page in the session. When the page is backtracked to, it restores it from the session and makes it the request page. The state of the page is retained. By default, page-instance caching is enabled, with a cache limit of 30 pages.

You turn page-instance caching off by invoking this method with an argument of zero. In this case, when the user backtracks to a page, the page is not stored in the session and so must be re-created "from scratch."

See also: **pageCacheSize**

setPageRefreshOnBacktrackEnabled

public void **setPageRefreshOnBacktrackEnabled**(boolean *flag*)

When *flag* is **true**, disables caching of pages by the client by setting the page's expiration-time header to the current date and time. (By default, this attribute is set to **false**.) Disabling of client caching affects what happens during backtracking. With client caching turned off, the browser resends the URL to the server for the page requested by backtracking. The application must return a new page to the browser (corresponding to a new WOComponent instance). This behavior is desirable when you do not want the user to backtrack to a page that might be obsolete because of changes that have occurred in the session.

When this flag is turned on and a request corresponding to a client backtrack occurs, the retrieved page will only be asked to regenerate its response. The first two phases of a normal request-response loop (value extraction from the request and action invocation) do not occur.

See Caching Strategies in the class description for further details.

See also: isPageRefreshOnBacktrackEnabled

setPermanentPageCacheSize

   public void **setPermanentPageCacheSize**(int *aSize*)

Sets the permanentPageCacheSize to aSize

See also: permanentPageCacheSize

setResourceManager

   public void **setResourceManager**(WOResourceManager *aResourceManager*)

Sets the WOResourceManager object to *aResourceManager*. WOResourceManager objects search for and retrieve resources from the application directory and from shared framework directories.

See also: resourceManager

setSessionStore

   public void **setSessionStore**(WOSessionStore *aSessionStore*)

Set the session-store object for the application. By default, an object that stores session state in process memory (that is, in the server) is used. The session-store object specifies the state storage strategy for the whole application. This object is responsible for making session objects persistent. You should set the session store object when the application starts up, before the first request is handled.

See also: sessionStore

setStatisticsStore

   public void **setStatisticsStore**(WOStatisticsStore *aStatisticsStore*)

Sets the WOStatisticsStore object to *aStatisticsStore*. WOStatisticsStore objects record application statistics while the application runs.

See also: statisticsStore

setTimeOut

    public void **setTimeOut**(double *aTimeInterval*)

Sets the number of seconds the application can experience inactivity (no HTTP requests) before it terminates execution.

This method differs from **terminateAfterTimeInterval** in that with this method, the application must be idle for *aTimeInterval* seconds for the application to terminate. **terminateAfterTimeInterval** terminates the application whether it is active or not.

See also: timeOut

sleep

    public void **sleep**()

Invoked at the conclusion of a request-handling cycle to give an application the opportunity for deallocating objects created and initialized in its awake method. The default implementation does nothing.

statistics

    public NSDictionary **statistics**()

Returns a copy of the dictionary containing the application statistics maintained by WOStatisticsStore. This method is used by the Monitor application to retrieve application statistics. If you need to access the statistics internally, use this message instead:

```
WOApplication.application().statisticsStore().statistics()
```

statisticsStore

    public WOStatisticsStore **statisticsStore**()

Returns the WOStatisticsStore object, which records statistics while the application runs.

See also: setStatisticsStore

takeValuesFromRequest

    public void **takeValuesFromRequest**(WORequest *aRequest*, WOContext *aContext*)

The component action request handler sends this message to the WOApplication to start the first phase of request handling. In this phase, the message is propagated to the session and component objects involved in the request as well as the request page's dynamic elements. Each dynamic element acquires any entered data or changed state (such as a check in a check box) associated with an attribute and assigns the value to

the variable bound to the attribute. The default WOApplication implementation of this method forwards the message to the session object.

See also: **appendToResponse**, **invokeActionForRequest**

terminate

    public void **terminate**()

Terminates the application process. Termination does not take place until the handling of the current request has completed.

See also: **isTerminating**, **setTimeOut**

terminateAfterTimeInterval

    public void **terminateAfterTimeInterval**(double *aTimeInterval*)

Sets the application to terminate itself after *aTimeInterval* seconds has elapsed. After the specified time interval has elapsed, the application immediately stops all current processing. If any sessions are active, users may lose information.

This method differs from **setTimeOut** in that it does not set idle time; **terminateAfterTimeInterval:**: shuts down the application regardless of whether it is idle.

timeOut

    public double **timeOut**()

Returns the application's time-out interval: a period (in seconds) of inactivity before the application terminates execution. The default application time-out interval is a very large number.

See also: **setTimeOut**

trace

    public void **trace**(boolean *flag*)

If *flag* is **true**, prints all trace messages (messages for scripted messages, compiled messages, and all statements in the application) to the standard error device. If *flag* is **false**, stops printing all trace messages.

See also: **traceAssignments**, **traceObjectiveCMessages**:, **traceScriptedMessages**, **traceStatements**

traceAssignments

public void **traceAssignments**(boolean *flag*)

If *flag* is **true**, prints a message to the standard error device every time an assignment statement is executed. If *flag* is **false**, stops printing trace assignment messages.

See also: **trace**, **traceObjectiveCMessages**:, **traceScriptedMessages**, **traceStatements**

traceObjectiveCMessages

public void **traceObjectiveCMessages**(boolean *flag*)

If *flag* is **true**, prints a message to the standard error device every time a message is sent to a compiled class from Webscript. If *flag* is **false**, stops printing these messages.

See also: **trace**, **traceAssignments**, **traceScriptedMessages**, **traceStatements**

traceScriptedMessages

public void **traceScriptedMessages**(boolean *flag*)

If *flag* is **true**, prints a message to the standard error device every time a message is sent to a scripted class from Webscript. If *flag* is **false**, stops printing trace scripted method messages.

See also: **trace**, **traceAssignments**, **traceObjectiveCMessages**, **traceStatements**

traceStatements

public void **traceStatements**(boolean *flag*)

If *flag* is **true**, prints a message to the standard error device every time a statement in the application is executed from Webscript. If *flag* is **false**, stops printing trace statement messages.

See also: **trace**, **traceAssignments**, **traceObjectiveCMessages**, **traceScriptedMessages**

unlock

public void **unlock**()

Unlocks the application object.

unlockRequestHandling

public void **unlockRequestHandling**()

Disables serialized request handler access if concurrent request handling isn't enabled.

Notifications

WOApplicationDidFinishLaunchingNotification

Posted just before the application begins waiting for requests. The notification contains the application instance.

WOApplicationWillFinishLaunchingNotification

Posted when an application has finished its **init** method. Register to receive this notification if you have an object that wishes to set various setting in the application. For example, if you have a WORequestHandler implemented in a framework and you want to register it with the WOApplication, you would register to receive this notification and then implement a method that register your WORequestHandler with the application.

The notification contains the application instance.

WOAssociation

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

The WOAssociation class declares the programmatic interface to objects that represent the values of WebObject attributes, as specified in a declarations file. You rarely need to create subclasses of WOAssociation, except in situations where you need to subclass WODynamicElement.

The purpose of a WOAssociation object is to provide a unified interface to values of different types. For example, consider these declarations:

```
TREENAME1:WOString {value = "Ash"};
TREENAME2:WOString {value = treeName};
TREENAME3:WOString {value = selectedTree.name};
```

At runtime, the WebObjects parser scans an HTML template and these declarations and creates three WOString dynamic element objects. In the first case, the WOString's **value** attribute is assigned a constant string. In the second, it's associated with the **treeName** variable of the component in which the dynamic element is declared. In the third, **value** is associated with the **name** attribute of the component's **selectedTree** variable. The search path for the value can be arbitrarily deep, depending on the needs of your application:

```
MAYOR:WOString {value = country.state.city.mayor.name};
```

To resolve a path such as this, WebObjects accesses each part in turn. First, it looks for the component's **country** variable. If the component responds to a **country** message, it sends one to determine the value; otherwise, it directly accesses the component's **country** instance variable to determine the value. Next, it checks the **country** object for a **state** attribute, using the same strategy of looking for an accessor method named **state** and then, if necessary, accessing the **state** variable's value directly. It continues in this way until the ultimate value is determined.

WOAssociation objects present the WebObjects framework with a unified interface to attribute values, whether their values are static or dynamic. The value attribute for TREENAME1 in the example above will never change during the course of program execution, but the other WOStrings have values that are potentially dynamic, and so will have to be determined at runtime. Since the value of any WOAssociation can be determined by sending it a **valueInComponent** message, objects that use WOAssociation objects don't have to be concerned with how values are resolved. The WODynamicElement class makes extensive use of this feature. See the WODynamicElement class specification for more information.

Method Types

Creation

> associationWithKeyPath
> associationWithValue

Obtaining association attributes

> isValueConstant
> isValueSettable

Setting and retrieving value

> setValue
> valueInComponent

Static Methods

associationWithKeyPath

> public static WOAssociation **associationWithKeyPath**(java.lang.String *aKeyPath*)

Creates and returns a WOAssociation object whose value is determined by evaluating *aKeyPath*. This method is used when a dynamic element's attribute is set to a variable from the component's script. For example, when the WebObjects parser sees a declaration of this sort,

```
TREENAME3:WOString {value = selectedTree.name};
```

it invokes **associationWithKeyPath:** to create a WOAssociation whose key is "selectedTree.name". When the resulting WOAssociation is asked for its value, it searches for the value of the **name** attribute of in the current component's **selectedTree** attribute.

If *aKeyPath* is **null**, the value of the WOAssociation is also **null**.

See also: `associationWithValue`

associationWithValue

> public static WOAssociation **associationWithValue**(java.lang.Object *aValue*)

Creates and returns a WOAssociation object whose value is *aValue*, a constant value. This method is used when a dynamic element's attribute is set to a constant. For example, when the WebObjects parser sees a declaration of this sort,

```
TREENAME3:WOString {value = "Time Flies!"};
```

it invokes this method to create a WOAssociation whose value is "Time Flies!".

See also: associationWithKeyPath

Instance Methods

isValueConstant

public boolean **isValueConstant**()

Returns true if the WOAssociation's value is a constant, false otherwise.

See also: `associationWithValue`, **isValueSettable**

isValueSettable

public boolean **isValueSettable**()

Returns false if the receiver's value is constant, true otherwise.

See also: `associationWithKeyPath`, **isValueConstant**

setValue

public void **setValue**(java.lang.Object *aValue*)
public void **setValue**(java.lang.Object *aValue*, WOComponent *aComponent*)

Finds the attribute of *aComponent* pointed to by the left-hand-side of the receiver and set its value to *aValue*. If *aComponent* is not given, this method fins the attribute in the current component association with the receiver. This method throws an exception if the receiver's value is not settable. For example, sending a **setValue:inComponent:** message to a WOAssociation created from this declaration,

```
USER:WOTextField {value = userName};
```

sets the current component's **userName** variable to the value typed into the WOTextField.

One way in which the WebObjects framework uses this method is to synchronize the values of nested components. When attributes in child and parent components are associated with one another and changes occur in one component, this method is invoked to migrate those changes to the other component. See the reusable components chapter in the *WebObjects Developer's Guide* for more information.

See also: **valueInComponent**

valueInComponent

public java.lang.Object **valueInComponent**(WOComponent *aComponent*)

Returns a value based on the receiver's association and the current component. For example, sending a **value** message to a WOAssociation created from this declaration,

```
DOWNPAYMENT:WOString {value = downpayment};
```

returns the value of the current component's **downpayment** variable.

Sending a **value** message to a WOAssociation created from this declaration,

```
DOWNPAYMENT:WOString {value = "$5000.00"};
```

returns the value "$5000.00" (independent of the current component).

This method raises an exception if it cannot resolve the WOAssociation's value with the current component.

One way in which the WebObjects framework uses this method is to synchronize the values of nested components. When attributes in child and parent components are associated with one another and changes occur in one component, this method is invoked to migrate those changes to the other component. See the reusable components chapter in the *WebObjects Developer's Guide* for more information.

See also: **setValue**

WOComponent

Inherits From:	WOElement : NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOComponent objects dynamically render web pages (or sections of pages) at run time. They provide custom navigation and other logic for the page, provide a framework for organizing constituent objects (static and dynamic HTML elements and subcomponents), and enable the attribute bindings of dynamic elements.

The WOComponent class has many methods that have the same names as methods of the WOApplication class. However, the scope of the WOComponent methods is limited to a component rather than being application-wide. For example, you can control component-definition caching on a per-component basis using **setCachingEnabled**, which has a WOApplication counterpart. When this kind of caching is enabled for a component, the application parses the contents of the component directory the first time the component is requested, creates the component definition, stores this object in memory, and restores it for subsequent requests.

WOComponent objects also respond to **awake**, **sleep**, and the three request-handling messages: **takeValuesFromRequest**, **invokeActionForRequest**,and **appendToResponse**. You can override these methods in your compiled subclasses, and thereby integrate your custom behavior into the request-response loop. (You can also override these methods in component scripts using WebScript.)

Subcomponents

A WOComponent object can represent a dynamic fragment of a Web page as well as an entire page. Such *subcomponents*, or *reusable components*, are nested within a parent component representing the page *or* another subcomponent. Each component keeps track of its parent and subcomponents—when a component receives a request-handling message, such as **takeValuesFromRequest**, it forwards that message to its subcomponents

The WOComponent class also provides a child-parent callback mechanism to allow a child component to communicate with its parent. In the parent's declaration file, bind an arbitrary attribute of the child to an action method of the parent. Then, as the last step in the child's action method, invoke **performParentAction** with the argument being the arbitrary attribute, returning the object received back as the response page. See the method description for **performParentAction** for details.

Method Types

Constructors

      WOComponent

Obtaining attributes

      application
      baseURL
      context
      frameworkName
      hasSession
      name
      pageWithName
      path

synchronizesVariablesWithBindings
valueForBinding:

Other

generateResponse

Constructors

WOComponent

public **WOComponent**()

WebObjects Builder archive file exists in the component directory, it initializes component variables from this archive. This constructor throws exceptions if it cannot determine the name of the component or if it cannot initialize the object for any other reason. Override **WOComponent**() in compiled subclasses to perform custom initializations; as always, invoke **super**'s default constructor as the first thing.

Static Methods

debugString

public static void **logString**(java.lang.String *aString*)

Like **logString**, prints a message to the standard error device (stderr), but only prints the message if the WODebuggingEnabled user default option is **true**. If WODebuggingEnabled is **false**, the **debugString** messages aren't printed. See **logString** for information on the format of *aString*.

logString

public static void **logString**(java.lang.String *aString*)

Prints a message to the standard error device (stderr). The message can include formatted variable data using String's concatenation feature, for example:

```
int i = 500;
float f = 2.045;
WOComponent.logString("Amount = " + i + ", Rate = " + f ", Total = " + i*f);
```

templateWithHTMLString

> public static WOElement **templateWithHTMLString**(java.lang.String *anHTMLString*,
> java.lang.String *aDeclarationString,* NSArray *languages*)

Programmatically creates the component's template using *anHTMLString* as the HTML template contents and *aDeclarationString* as the declarations file contents. Returns (as a WOElement object) the graph of static and dynamic elements build by parsing the HTML and declaration strings. You can then use the returned WOElement as the component's template.

See also: `templateWithName`

Instance Methods

appendToResponse

> public void **appendToResponse**(WOResponse *aResponse*, WOContext *aContext*)

Component objects associated with a response receive this message during the last phase of the request-response loop. In the append-to-response phase, the application objects (particularly the response page instance itself) generate the HTML content of the page. WOComponent's default implementation of this method forwards the message to the root WOElement object of the component template. Compiled or scripted subclasses of WOComponent can override this method to replace or supplement the default behavior with custom logic.

See also: `invokeActionForRequest`, `takeValuesFromRequest`

application

> public WOApplication **application**()

Returns the WOApplication object for the current application.

See also: WOApplication class, **`context`**, **`session`**

awake

> public void **awake**()

Invoked at the beginning of a WOComponent's involvement in a cycle of the request-response loop, giving the WOComponent an opportunity to initialize its instance variables or perform setup operations. The default implementation does nothing.

See also: `, sleep`

baseURL

public java.lang.String **baseURL**()

Returns the component URL relative to the server's document root, for example:
"/WebObjects/MyApp.woa/Resources/Main.wo"

See also: `name`, `path`

context

public WOContext **context**()

Returns the WOContext object for the current transaction.

See also: WOContext `class`, **`application`, `session`**

descriptionForResponse

public java.lang.String **descriptionForResponse**(WOResponse *aResponse*, WOContext *aContext*)

Records information about the component if it is the response component in the current request-response loop transaction. The default implementation records the component's name. You might override this method if you want to record more information about the component. For example, you might want to record the values of some instance variables as well as the component name.

This message is sent only to the top-level response component, that is, the one representing the entire page. Components nested inside of that top-level component do not receive this message.

If a CLFF log file is kept for this application, the string returned by this method is recorded in that log file. Thus, you must ensure that the string you return can be analyzed by a CLFF-analysis tool.

See also: WOStatisticsStore class

frameworkName

public java.lang.String **frameworkName**()

If the component is stored in a framework, this method returns the name of that framework. For example, if the component is in the framework
NeXT_ROOT/**System/Library/Frameworks/WOExtensions.framework**, then this method returns the string "WOExtensions".

If the component is not stored in a framework, this method returns **null**.

See also: WOResourceManager class

generateResponse

public WOResponse **generateResponse**()

Returns a newly-created WOResponse object. WOComponent's implementation of this method translates the receiving component into a WOResponse object by sending itself an **appendToResponse** message.

hasBinding:

public boolean **hasBinding**(java.lang.String *aBindingName*)

 Returns whether the component has a binding named *aBindingName*.

hasSession

public boolean **hasSession**()

Returns whether the component is already in a session. For example, in direct actions, sessions are lazily created and you can avoid creating another one unnecessarily by calling **hasSession** before **session**.

See also: session

invokeActionForRequest

public WOElement **invokeAction**(WORequest *aRequest*, WOContext *aContext*)

WOComponent objects associated with a request page receive this message during the middle phase of request handling. In this middle phase, the **invokeActionForRequest** message is propagated through the WOElement objects of the page; the dynamic element on which the user has acted (by, for example, clicking a button) responds by triggering the method in the request component that is bound to the action. WOComponent's default implementation of this method forwards the message to the root WOElement object of the component template.Compiled or scripted subclasses of WOComponent can override this method to replace or supplement the default behavior with custom logic. (Scripted subclasses must use the Objective-C form of this method: **invokeActionForRequest:inContext:**).

See also: appendToResponse, **takeValuesFromRequest**

isCachingEnabled

public boolean **isCachingEnabled**()

Returns whether component-definition caching is enabled for this component. **false** is the default.

See also: `setCachingEnabled`

name

    public java.lang.String **name**()

Returns the name of the component, which includes a path of all directories under *DOCUMENTROOT*/**WebObjects** and is minus the ".wo" extension; for example "Main" is a typical component name.

See also: `baseURL, path`

pageWithName

    public WOComponent **pageWithName**(java.lang.String *aName*)

Returns a new page instance (a WOComponent object) identified by *aName*. If *aName* is **null**, the "Main" component is assumed. If the method cannot create a valid page instance, it throws an exception.

See also: **restorePageForContextID** (WOSession), **savePage** (WOSession)

parent

    public WOComponent **parent()**

Returns the parent component of the receiver.

path

    public java.lang.String **path**()

Returns the file-system path of the component, which is an absolute path and includes the ".wo" extension; for example "C:\Apple\Library\WOApps\MyApp.woa\Resources\Main.wo" is a typical path.

See also: `baseURL, name`

pathForResource

    public java.lang.String **pathForResource**(java.lang.String *aName*, java.lang.String *aType*)

Returns the absolute path to the component resource having the name of *aName* and an extension of *aType*. The method searches all localized ".lproj" directories of the component before searching directly under the ".wo" component directory for a non-localized resource of the given name and extension.

This method is provided for backwards compatibility only. For WebObjects 3.5 and above, you should use the WOResourceManager API to retrieve resources. WOResourceManager is not able to retrieve resources stored inside component directories.

performParentAction

>   public java.lang.Object **performParentAction**(java.lang.String *anActionName*)

Allows a subcomponent to invoke an action method of its parent component bound to the child component (*attribute*). Parent and child components are "synchronized" when this method returns: the variables that are bound by a declaration of the child component in the parent component's declaration file have the same value.

An example best illustrates this mechanism. Let's say you have a Palette subcomponent, and this WOComponent is nested in a parent component with a "displaySelection" action method. When the user selects an item in the palette (perhaps a color), you want to invoke "displaySelection" to show the result of the new selection (perhaps a car in the new color). The declaration in the parent's ".wod" file would look like this:

```
PALETTE: Palette {
selection = number;
callBack = "displaySelection";
};
```

The "callBack" item is an arbitrary attribute of the child component bound in this declaration to the parent component's "displaySelection" method.The **performParentAction:** method is used to activate this binding. Let's assume the child component has an action method called "click"; the implementation would look like this:

```
public WOComponent click() {              /* this is the child's action */
selection = /* some value */;
/* now invoke the parent's action */
return performParentAction(callBack);
}
```

session

>   public WOSession **session**()

Returns the current WOSession object. This method creates a new one if there isn't one.

See also: WOSession class, **application**, **context**, **hasSession**

setCachingEnabled

>   public void **setCachingEnabled**(boolean *flag*)

Enables or disables the caching of component definitions for the receiving component. WOComponent definitions contain templates and other common information related to components, and are used to generate instances of those components.When this attribute is set to **true**, the application parses the HTML template and the declaration (".wod") file of a component once and then stores the resulting component

definition for future requests. By default, this kind of caching is disabled so that you can edit a *scripted* component without having to relaunch the application every time to check the results.(Note that this does not apply to Java subclasses of WOComponent; in this case, you still have to kill and relaunch the application.)

With WOApplication's method of the same name, you can turn component-definition caching off globally. You can then control caching of individual component definitions using WOComponent's version of this method. Selective caching is an especially valuable technique for very large applications where only the most frequently requested components should be cached.

See also: isCachingEnabled

setValue:forBinding:

> public void **setValueForBinding**(java.lang.Object *aValue*, java.lang.String *aBindingName*)

Sets the value of the binding specified by *aBindingName* in the parent component to *aValue*. If the parent doesn't provide *aBindingName* in its declarations file, this method attempts to set the value in the current component using **takeValueForKey:**. If the current component doesn't define this key, this method silently returns.

See also: synchronizesVariablesWithBindings, **valueForBinding:**

sleep

> public void **sleep**()

Invoked at the conclusion of a request-handling cycle to give component the opportunity for deallocating objects created and initialized in its **awake** method. The default implementation does nothing.

synchronizesVariablesWithBindings

> public boolean **synchronizesVariablesWithBindings**()

Returns whether a nested component pulls all values down from its parent and pushes all values to its parent before and after each phase of the request-response loop. By default, this method returns **true**. Override this method to create a non-synchronizing component.

See also: setValue:forBinding:, **valueForBinding:**

takeValuesFromRequest

public void **takeValuesFromRequest**(WORequest *aRequest*, WOContext *aContext*)

WOComponent objects associated with a request receive this message during the first phase of the request-response loop. The default WOComponent behavior is to send the message to the root object of the component's template.In this phase, each dynamic element in the template extracts any entered data or changed state (such as a check in a check box) associated with an attribute and assigns the value to the component variable bound to the attribute.Compiled or scripted subclasses of Component can override this method to replace or supplement the default behavior with custom logic. (Scripted subclasses must use the Objective-C form of this method: **takeValuesFromRequest:inContext:**).

See also: appendToResponse, **invokeActionForRequest**

templateWithName

public WOElement **templateWithName**(java.lang.String *aName*)

Returns the root object of the graph of static and dynamic HTML elements and subcomponents that is used to graphically render the component identified by *aName*. This template is constructed from the ".html" and ".wod" file found in the component directory. You identify the template by specifying the component directory, which consists of the component name plus the "wo" extension: for example, "HelloWorld.wo." If the template is not cached, the application will parse the HTML and declaration files of the specified component to create the template.

See also: setCachingEnabled

validationFailedWithException
public void **validationFailedWithException**(java.lang.Throwable *exception*, java.lang.Object *value*, java.lang.String *keyPath*)

Called when an Enterprise Object or formatter failed validation during an assignment. The default implementation ignores the error. Subclassers can override to record the error and possibly return a different page for the current action.

valueForBinding:

public java.lang.Object **valueForBinding**(java.lang.String *aBindingName*)

Gets the value for the specified binding from the parent component. If the parent doesn't provide *aBindingName* in its delcarations file, this method attempts to get the value from the current component using **valueForKey**. If the current component doesn't define this key, this method returns null. This cascading lookup makes it easy to provide default values for optional bindings.

See also: setValue:forBinding:, **synchronizesVariablesWithBindings**

WOContext

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

A WOContext object lets you access objects and information that define the *context* of a transaction. In a typical request-response loop (a transaction), several objects have a hand in what is going on: the WOApplication and WOSession objects, the page involved in the request or response (a WOComponent object), the page's subcomponents (also WOComponents), plus the dynamic elements on the page. The WOContext object passed as an argument in the **takeValuesFromRequest**, **invokeActionForRequest**, and **appendToResponse** messages allows access to these objects. A context is identified by the *context ID*, which appears in the URL after the session ID and page name. Each context ID is an integer that the session increments each time a new context is created.

WOContext objects provide other information and services related to the current transaction. From them you can get the entire URL currently in effect as well as portions of that URL, such as the element ID, the context ID, and the URL up to and including the session ID.

A WOContext object plays a further role behind the scenes. For the benefit of a page's dynamic elements, it keeps track of the *current component*, that is, the WOComponent associated with the current element in the request-handling cycle. The current component can be the WOComponent that represents one of the page's subcomponents or the page itself. By reference to the current component (accessed through WOContext's **component** method), a dynamic element can exchange values associatively between itself and the WOComponent that contains it.

Method Types

Constructors

    WOContext

Creating new object instances

    contextWithRequest

Obtaining attributes

         component
         contextID
         elementID
         hasSession
         isInForm
         page
         request
         response
         session
         senderID
         setInForm

Manipulating element ID

         appendElementIDComponent
         appendZeroElementIDComponent
         deleteAllElementIDComponents
         deleteLastElementIDComponent
         incrementLastElementIDComponent

Generating URLs

         directActionURLForActionNamed
         completeURLWithRequestHandlerKey
         componentActionURL
         urlWithRequestHandlerKey

Constructors

WOContext

public **WOContext**()

Returns a WOContext instance initialized with a unique context ID.

Class Methods

contextWithRequest

public static WOContext **contextWithRequest**(WORequest *aRequest*)

Creates and returns a WOContext with *aRequest*. This is the preferred way to create a WOContext. All other constructors call this one, so if you subclass WOContext, you need to override only this one.

Instance Methods

appendElementIDComponent

public void **appendElementIDComponent**(java.lang.String *aString*)

Appends a string to the current element ID to create an identifier of an HTML element. For example, if the current element ID is "0.1.1" and you send this message with an argument of "NameField," the element ID for that field becomes "0.1.1.NameField".

See also: `deleteAllElementIDComponents`, `deleteLastElementIDComponent`, `incrementLastElementIDComponent`

appendZeroElementIDComponent

public void **appendZeroElementIDComponent**()

Appends a ".0" to the current element ID to create an identifier of the first "child" HTML element. For example, if the current element ID is "0.1.1", after you send this message the element ID becomes "0.1.1.0".

See also: `deleteAllElementIDComponents`, `deleteLastElementIDComponent`, `incrementLastElementIDComponent`

completeURLWithRequestHandlerKey

public java.lang.String **completeURLWithRequestHandlerKey**(java.lang.String *requestHandlerKey*,
java.lang.String *aRequestHandlerPath*,
java.lang.String *aQueryString*,
boolean *isSecure*,
int *somePort*)

Returns the complete URL for the specified request handler. The *requestHandlerKey* is one of the keys provided by WOApplication. The *requestHandlerPath* is any URL encoded string. The *queryString* is added at the end of the URL behind a "?". If *isSecure* is true, this method uses "https" instead of "http." If *somePort* is 0 (zero), this method uses the default port.

See also: **urlWithRequestHandlerKey**

component

public WOComponent **component**()

Returns the component that dynamic elements are currently using to push and pull values associatively. This component could represent the current request or response page or a subcomponent of that page.

See also: WOComponent class, **page**, **request**, **response**, **senderID**

componentActionURL

> public java.lang.String **componentActionURL**()

Returns the complete URL for the component action.

contextID

> public java.lang.String **contextID**()

Returns the context ID of the receiver.

deleteAllElementIDComponents

> public void **deleteAllElementIDComponents**()

Deletes all components of the current element ID.

See also: `appendElementIDComponent`, `appendZeroElementIDComponent`,
`incrementLastElementIDComponent`

deleteLastElementIDComponent

> public void **deleteLastElementIDComponent**()

Deletes the last digit (or name) of the current element ID, along with its dot separator. Thus, after sending this message, "0.0.1.1" becomes "0.0.1".

See also: `appendElementIDComponent`, `appendZeroElementIDComponent`,
`incrementLastElementIDComponent`

directActionURLForActionNamed

> public java.lang.String **directActionURLForActionNamed**(java.lang.String *anActionName*,
> NSDictionary *aQueryDict*)

Returns the complete URL for the specified action. You can specify *aQueryDict*, and *anActionName* can be "ActionClass/ActionName" or "ActionName".

See also: WODirectAction class specification

elementID

public java.lang.String **elementID**()

Returns the element ID identifying the current WOElement. This method helps you avoid creating a session in direct actions.

hasSession

public boolean **hasSession**()

Returns whether a session exists for the receiving context.

See also: **senderID**

incrementLastElementIDComponent

public void **incrementLastElementIDComponent**()

Increments the last digit of the current element ID. For example, after this message is sent, "0.0.1.2" becomes "0.0.1.3".

See also: **appendElementIDComponent**, **appendZeroElementIDComponent**, **deleteAllElementIDComponents**, **deleteLastElementIDComponent**

isInForm

public boolean **isInForm**()

Returns true when in the context of a WOForm.

See also: **setInForm**

page

public WOComponent **page**()

Returns the WOComponent object that represents the request or response page.

See also: **component**, **request**, **response**, **senderID**

request

  public WORequest **request**()

Returns the transaction's WORequest object.

See also: **component**, **page**, **response**, **senderID**

response

  public WOResponse **response**()

Returns the transaction's WOResponse object.

See also: **component**, **page**, **response**, **senderID**

senderID

  public java.lang.String **senderID**()

Returns the part of the WORequest's URI that identifies the dynamic element on the page (such as a form or an active image) responsible for submitting the request. The sender ID is the same as the element ID used to identify the dynamic element. A request's sender ID may be **null**, as it always is on the first request of a session.

See also: **request** , **uri (WORequest)**

session

  public WOSession **session**()

Returns the object representing the receiving context's session, if one exists. If the receiver does not have a session, this method creates a new session object and returns it. Note that not all contexts have a session: Direct Actions, for instance, don't always need a session. Use **hasSession** to determine whether a context has a session associated with it.

See also: **component**, **page**, **request**, **response**, WOSession class

setInForm

  public void **setInForm**(boolean *flag*)

If you write something that behaves like a WOForm, set this to notify WODynamicElements that they are in a form.

See also: **isInForm**

urlWithRequestHandlerKey

public java.lang.String **urlWithRequestHandlerKey**(java.lang.String *requestHandlerKey*,
 java.lang.String *aRequestHandlerPath*,
 java.lang.String *aQueryString*)

Returns a URL relative to `cgi-bin/WebObjects` for the specified request handler. The
requestHandlerKey is one of the keys provided by WOApplication. The *requestHandlerPath* is any URL
encoded string. The *queryString* is added at the end of the URL behind a "?".

completeURLWithRequestHandlerKey

WOCookie

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOCookie is used for the creation and setting of cookies in your response objects. A cookie allows for the persistent storage of client state. Instead of using a WOSession object (which can potentially have a shorter life span), a cookie allows server-side applications to store state in client browsers for a specific or indeterminate amount of time. An advantage to cookies is that the data will be stored on the client and not on the server, allowing the server to maintain less state information. A specific advantage in WebObjects applications is that cookies allow the server to put state into the browser that is not bound to a session. Hence, the client can "leave" your application and return with its cookie's state intact.

A WOCookie object defines a cookie that can be added to the HTTP header for your response. You create a cookie using the static method **cookieWithName**. To add or remove cookies from the response, use the WOResponse methods **addCookie** and **removeCookie**. To retrieve cookie data, use the WORequest methods **cookieValues**, **cookieValueForKey**, and **cookieValuesForKey**. WORequest returns the data as name/value pairs and not as WOCookie objects, since browsers don't return the additional data WOCookies provide, such as path name and expiration date.

For more information about cookies and their implementation details, see Netscape's preliminary specification at **http://www.netscape.com/newsref/std/cookie_spec.html** and RFC 2109 - HTTP State Management Mechanism at **http://www.cis.ohio-state.edu/htbin/rfc/rfc2109.html**.

If and when new details evolve in the implementation of cookies, you can subclass WOCookie and implement new behaviors. Pay particular attention to how you override **headerString**, which WOResponse uses to fill the HTTP response with a header string.

Method Types

Constructors

WOCookie

Creation

cookieWithName

Obtaining a cookie's attributes

> domain
> expires
> headerString
> isSecure
> name
> path
> value

Setting a cookie's attributes

> setDomain
> setExpires
> setIsSecure
> setName
> setPath
> setValue

Constructors

WOCookie

public **WOCookie**()

Creates and returns a new empty cookie. To set its attributes, use the appropriate **set** methods.

See also: **cookieWithName**, **setDomain**, **setExpires**, **setIsSecure**, **setName**, **setPath**, **setValue**

Class Methods

cookieWithName

public static WOCookie **cookieWithName**(java.lang.String *aName*, java.lang.String *aValue*)

Creates and returns a cookie with just a name and its value. This method sets the path attribute to your application's path.

public static WOCookie **cookieWithName**(java.lang.String *aName*,
    java.lang.String *aValue*,
    java.lang.String *aPath*,
    java.lang.String *aDomain*,
    NSDate *expirationDate*,
    boolean *flag*)

Creates and returns a cookie, specifying all its attributes. For more information, see the descriptions of the methods that return attribute values.

See also: **domain**, **expires**, **isSecure**, **name**, **path**, **value**

Instance Methods

domain

public java.lang.String **domain**()

Returns the value of the cookie's "domain" attribute. It's of the form "companyname.com".

expires

public NSDate **expires**()

Returns the value of the cookie's "expires" attribute as an NSDate. The expiration date tells the browser how long to keep the cookie in its cache. To have the browser remove the cookie from its cache, set the expiration date to a date in the past.

headerString

public java.lang.String **headerString**()

Returns the string that will be used in the HTTP header. The returned string has the format:

```
Set-cookie: name=value; expires=date; path=path; domain=domain; secure;
```

The calendar format for the expiration date is:

```
@"%A, %d-%b-%Y %H:%M:%S GMT"
```

where all times are converted relative to Greenwich Mean Time.

This method is called by WOResponse when generating the response.

isSecure

public boolean **isSecure**()

Returns the cookie's "secure" attribute. This attribute specifies whether the cookie should be transmitted only with secure HTTP. The default value is false.

name

public java.lang.String **name**()

Returns the cookie's "name" attribute. The name is similar to the key of a dictionary or hash table. Together, the name and value form the cookie's data.

path

public java.lang.String **path**()

Returns the value of the cookie's "path" attribute. Cookies for a specific path are sent only when accessing URLs within that path. For more information on cookies and their paths, see Netscape's preliminary specification at **http://www.netscape.com/newsref/std/cookie_spec.html** and RFC 2109 - HTTP State Management Mechanism at **http://www.cis.ohio-state.edu/htbin/rfc/rfc2109.html**.

setDomain

public void **setDomain**(java.lang.String *aDomain*)

Sets the cookie's "domain" attribute to *aDomain*. For more information, see **domain**.

See also: cookieWithName

setExpires

public void **setExpires**(NSDate *expirationDate*)

Sets the cookie's "expires" attribute to *expirationDate*. For more information, see **expires**.

See also: cookieWithName

setIsSecure

    public void **setIsSecure**(boolean *flag*)

Sets the cookie's "secure" attribute to *flag*. For more information, see **isSecure**.

See also: **cookieWithName**

setName

    public void **setName**(java.lang.String *aName*)

Sets the cookie's "name" attribute to *aName*. For more information, see *name*.

See also: **cookieWithName**

setPath

    public void **setPath**(java.lang.String *aPath*)

Sets the cookie's "path" attribute to *aPath*. For more information, see *path*.

See also: **cookieWithName**

setValue

    public void **setValue**(java.lang.String *aValue*)

Sets the cookie's "value" attribute to *aValue*. For more information, see *value*.

See also: **cookieWithName**

value

    public java.lang.String **value**()

Returns the value of the cookie's value attribute. This attribute is similar to the value of a dictionary or hash table. Together, the name and value form the cookie's data.

WODirectAction

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WODirectAction is an abstract class that defines the interface for direct action classes. You subclass WODirectAction to provide an object that is a repository for action methods.

WODirectAction provides the simplest interface for addig logic and custom code to your WebObjects application. WODirectAction objects are instantiated when a URL requested by a client browser is sent to your WebObjects application. The WODirectActionRequestHandler determines the proper class and action to be invoked and then passes control to your WODirectAction subclass.

In contrast to a WOComponent-based action, a direct action is well-defined by the URL that invokes it. For example, the following URL will invoke the method **findEmployeeAction** on the subclass of WODirectAtion called Common:

```
http://localhost/cgi-bin/WebObjects/Myapp.woa/wa/Common/findEmployee
```

A subclass of WODirectAction is a repository for action methods. New WebObjects applications contain a default implementation of the WODirectAction subclass called DirectAction. The DirectAction class is used when no class is specified in the URL.

In summary, here are some URLs and the actions they invoke:

This URL...	Invokes this method...
../MyApp.woa/wa/	**defaultAction** on class DirectAction
../MyApp.woa/wa/ find	**findAction** on classDirectAction , if it exists **defaultAction** on class find , otherwise
../MyApp.woa/wa/Common/find	**findAction** on class Common

WODirectActionRequestHandler invokes methods only on subclasses on WODirectAction. If the specified class or action doesn't exist, WODirectActionRequestHandler throwsraises an exception.

Method Types

Constructors

      WODirectAction

Obtaining attributes

      request

Obtaining a session

      existingSession
      session

Obtaining a page

      pageWithName

Performing an action

      performActionNamed

Value assignment

      takeFormValueArraysForKeyArray
      takeFormValuesForKeyArray

Debugging

      debugString
      logString

Constructors

WODirectAction

public **WODirectAction**()
public **WODirectAction**(WORequest *aWORequest*)

Subclasses must override to provide any additional initialization.

Static Methods

debugString

public static void **debugString**(java.lang.String *aString*)

This method is similar to **logString** except that you can control whether it displays output with the **WODebuggingEnabled** user default option. If **WODebuggingEnabled** is YES, then the **debugString** messages display their output. If **WODebuggingEnabled** is NO, the **debugString** messages don't display their output.

logString

> public static void **logString**(java.lang.String *aString*)

Prints a message to the standard error device (stderr). The message can include formatted variable data using String's concatenation feature, for example:

```
int i = 500;
float f = 2.045;
WOComponent.logString("Amount = " + i + ", Rate = " + f ", Total = " + i*f);
```

Instance Methods

existingSession

> public WOSession **existingSession**()

Restores the session based on the request. If the request did not have a session ID or the session ID referred to a non-existent session, then this method returns **null**. To determine if a session failed to restore, check the request's session ID to see if it non-**null** and if so, call this method to check its result.

See also: session

pageWithName

> public WOComponent **pageWithName**(java.lang.String *aComponentName*)

Returns the WOComponent with the specified name.

performActionNamed

> public WOActionResults **performActionNamed**(java.lang.String *anActionName*)

Performs the action with the specified name and returns the result of that action. The default implementation appends "Action" to *anActionName* and tries to invoke resulting method name. Override this method to change how actions are dispatched.

request

> public WORequest **request**()

Returns the WORequest object that initiated the action.

session

>   public WOSession **session**()

Returns the current session. If there is no session, this method first tries to restore the session that the request's session ID refers to. If the request has no session ID—which is a possibility if the application is written entirely with direct actions—this method creates a new session and returns it. If the session ID refers to a session that doesn't exist or cannot be restored, this method throws an exception.

See also: existingSession

takeFormValueArraysForKeyArray

>   public void **takeFormValueArraysForKeyArray**(NSArray *aKeyArray*)

Performs takeValueForKey on each key in *aKeyArray* using values from the receiver's request.

This method uses an NSArray for each form value. This is useful when a user can select multiple items for a form value, such as a WOBrowser. If a form value contains only one item, this method uses an NSArray with one object. To use single objects as form values, use **takeFormValuesForKeyArray**.

takeFormValuesForKeyArray

>   public void **takeFormValuesForKeyArray**(NSArray *aKeyArray*)

Performs takeValueForKey on the each key in *aKeyArray* using values from the receiver's request.

This method uses an a single object for each form value. If a form value contains more than one item, such as a WOBrowser, this method uses the first item in the array. To use arrays of objects as form values, use **takeFormValueArraysForKeyArray**.

WODisplayGroup

Inherits From:	NSObject
Implements:	NSCoding
Package:	com.apple.yellow.webobjects

Class Description

A WODisplayGroup is the basic user interface manager for a WebObjects application that accesses a database. It collects objects from an EODataSource (defined in EOControl), filters and sorts them, and maintains a selection in the filtered subset. You bind WebObjects dynamic elements to WODisplayGroup attributes and methods to display information from the database on your web page.

A WODisplayGroup manipulates its EODataSource by sending it **fetchObjects**, **insertObject:**, and other messages, and registers itself as an editor and message handler of the EODataSource's EOEditingContext (also defined in EOControl). The EOEditingContext then monitors the WODisplayGroup for changes to objects.

Most of a WODisplayGroup's interactions are with its EODataSource and its EOEditingContext. See the EODataSource, and EOEditingContext class specifications in the *Enterprise Objects Framework Reference* for more information on these interactions.

The Delegate

The WODisplayGroup delegate offers a number of methods, and WODisplayGroup invokes them as appropriate. Besides **displayArrayForObjects**, there are methods that inform the delegate that the WODisplayGroup has fetched, created an object (or failed to create one), inserted or deleted an object, changed the selection, or set a value for a property. There are also methods that request permission from the delegate to perform most of these same actions. The delegate can return **true** to permit the action or **false** to deny it. See each method's description in the WODisplayGroup.Delegates interface specification for more information.

Method Types

        detailKey

Working with named fetch specifications

        queryBindings

Setting the delegate

        setDelegate
        delegate

Constructors

WODisplayGroup

 public **WODisplayGroup**()

Creates and returns a new WODisplayGroup. The WODisplayGroup then needs to have an EODataSource
(defined in EOControl) set with **setDataSource**.

Instance Methods

allObjects

 public NSArray **allObjects**()

Returns all of the objects collected by the receiver.

See also: **displayedObjects**, **fetch**

allQualifierOperators

 public NSArray **allQualifierOperators**()

Returns an array containing all of the relational operators supported by EOControl's EOQualifier: =, !=, <,
<=, >, >=, "**like**" and "**caseInsensitiveLike**".

See also: **queryOperator**, **relationalQualifierOperators**

batchCount

public int **batchCount**()

The number of batches to display. For example, if the displayed objects array contains two hundred records and the batch size is ten, **batchCount** returns twenty (twenty batches of ten records each).

See also: **currentBatchIndex**, **displayNextBatch**, **displayPreviousBatch**, **hasMultipleBatches**, **numberOfObjectsPerBatch**

clearSelection

public boolean **clearSelection**()

Invokes **setSelectionIndexes** to clear the selection, returning **true** on success and **false** on failure.

currentBatchIndex

public int **currentBatchIndex**()

Returns the index of the batch currently being displayed. The total batch count equals the number of displayed objects divided by the batch size. For example, if the WODisplayGroup has one hundred objects to display and the batch size is twenty, there are five batches. The first batch has a batch index of 1.

See also: **batchCount**, **numberOfObjectsPerBatch**, **setCurrentBatchIndex**

dataSource

public com.apple.yellow.eocontrol.EODataSource **dataSource**()

Returns the receiver's EODataSource (defined in the EOControl framework).

See also: **hasDetailDataSource**, **setDataSource**

defaultStringMatchFormat

public java.lang.String **defaultStringMatchFormat**()

Returns the format string that specifies how pattern matching will be performed on string values in the **queryMatch** dictionary. If a key in the **queryMatch** dictionary does not have an associated operator in the **queryOperator** dictionary, then its value is matched using pattern matching, and the format string returned by this method specifies how it will be matched.

See also: **defaultStringMatchOperator**, **setDefaultStringMatchFormat**

defaultStringMatchOperator

   public java.lang.String **defaultStringMatchOperator**()

Returns the operator used to perform pattern matching for string values in the **queryMatch** dictionary. If a key in the **queryMatch** dictionary does not have an associated operator in the **queryOperator** dictionary, then the operator returned by this method is used to perform pattern matching. Unless the default is changed, this method returns caseInsensitiveLike.

See also: defaultStringMatchFormat, **setDefaultStringMatchOperator**

delegate

   public java.lang.Object **delegate**()

Returns the receiver's delegate.

See also: setDelegate

delete

   public java.lang.Object **delete**()

Uses **deleteSelection** to attempt to delete the selected objects and then causes the page to reload. Returns **null** to force reloading of the web page.

See also: deleteObjectAtIndex

deleteObjectAtIndex

   public boolean **deleteObjectAtIndex**(int *index*)

Attempts to delete the object at *index*, returning **true** if successful and **false** if not. Checks with the delegate using the method **shouldDeleteObject**. If the delegate returns **false**, this method fails and returns **false**. If successful, it sends the delegate a **didDeleteObject** message.

This method performs the delete by sending **deleteObject** to the EODataSource (defined in the EOControl framework). If that message raises an exception, this method fails and returns **false**.

See also: delete, **deleteSelection**

deleteSelection

public boolean **deleteSelection**()

Attempts to delete the selected objects, returning **true** if successful and **false** if not.

See also: **delete**, **deleteObjectAtIndex**

detailKey

public java.lang.String **detailKey**()

For detail display groups, returns the key to the master object that specifies what this detail display group represents. That is, if you send the object returned by the **masterObject** method a **valueForKey:** message with this key, you obtain the objects controlled by this display group.

This method returns **null** if the receiver is not a detail display group or if the detail key has not yet been set. You typically create a detail display group by dragging a to-many relationship from EOModeler to an open component in WebObjects Builder.

See also: **hasDetailDataSource**, **masterObject**, **setDetailKey**

displayBatchContainingSelectedObject

public java.lang.Object **displayBatchContainingSelectedObject**()

Displays the batch containing the selection and sets the current batch index to that batch's index. Returns **null** to force the page to reload.

See also: : **displayNextBatch**, **displayPreviousBatch**, **setCurrentBatchIndex**

displayedObjects

public NSArray **displayedObjects**()

Returns the objects that should be displayed or otherwise made available to the user, as filtered by the receiver's delegate, by the receiver's qualifier and sort ordering.

If batching is in effect, **displayedObjects** returns the current batch of objects.

See also: **allObjects**, **updateDisplayedObjects**, **qualifier**, **setSortOrderings**, **displayArrayForObjects** (delegate method)

displayNextBatch

   public java.lang.Object **displayNextBatch**()

Increments the current batch index, displays that batch of objects, and clears the selection. If the batch currently being displayed is the last batch, this method displays the first batch of objects. Returns **null** to force the page to reload.

See also: **batchCount**, **currentBatchIndex**, **displayBatchContainingSelectedObject**, **displayPreviousBatch**

displayPreviousBatch

   public java.lang.Object **displayPreviousBatch**()

Decrements the current batch index, displays that batch of objects, and clears the selection. If the batch currently being displayed is the first batch, this method displays the last batch of objects. Returns **null** to force the page to reload.

See also: **batchCount**, **currentBatchIndex**, **displayBatchContainingSelectedObject**, **displayNextBatch**

fetch

   public java.lang.Object **fetch**()

Attempts to fetch objects from the EODataSource (defined in the EOControl framework).

Before fetching, this method sends **displayGroupShouldFetch** to the delegate. If this method was successful, it then sends a **fetchObjects** message to the receiver's EODataSource to replace the object array, and if successful sends the delegate a **didFetchObjects** message.

This method returns **null** to force the page to reload.

See also: **allObjects**, **updateDisplayedObjects**

fetchesOnLoad

   public boolean **fetchesOnLoad**()

Returns **true** if the receiver fetches automatically after the component that contains it is loaded, **false** if it must be told explicitly to fetch. The default is **true**. You can set this behavior in WebObjects Builder using the Display Group Options panel. Note that if the display group fetches on load, it performs the fetch each time the component is loaded into the web browser.

See also: **fetch**, **setFetchesOnLoad**

hasDetailDataSource

public boolean **hasDetailDataSource**()

Returns **true** if the display group's data source is an EODetailDataSource (defined in the EOControl framework), and **false** otherwise. If you drag a to-many relationship from EOModeler to an open component in WebObjects Builder, you create a display group that has an EODetailDataSource. You can also set this up using the Display Group Options panel in WebObjects Builder.

See also: **detailKey**, **masterObject**

hasMultipleBatches

public boolean **hasMultipleBatches**()

Returns **true** if the batch count is greater than 1. A display group displays its objects in batches if the **numberOfObjectsPerBatch** method returns a number that is less than the number of objects in the **displayedObjects** array.

See also: **batchCount**, **setNumberOfObjectsPerBatch**

indexOfFirstDisplayedObject

public int **indexOfFirstDisplayedObject**()

Returns the index of the first object displayed by the current batch. For example, if the current batch is displaying items 11 through 20, this method returns 11.

See also: **indexOfLastDisplayedObject**

indexOfLastDisplayedObject

public int **indexOfLastDisplayedObject**()

Returns the index of the last object display by the current batch. For example, if the current batch is displaying items 11 through 20, this method returns 20.

See also: **indexOfFirstDisplayedObject**

inQueryMode

public boolean **inQueryMode**()

Returns **true** to indicate that the receiver is in query mode, **false** otherwise. In query mode, controls in the user interface that normally display values become empty, allowing users to type queries directly into them (this is also known as a "Query by Example" interface). In effect, the receiver's "displayedObjects" are

replaced with an empty **queryMatch** dictionary. When **qualifyDisplayGroup** or **qualifyDataSource** is subsequently invoked, the query is performed and the display reverts to displaying values—this time, the objects returned by the query.

See also: setInQueryMode

insert

public java.lang.Object **insert**()

Invokes **insertNewObjectAtIndex** with an index just past the first index in the selection, or at the end if there's no selection.

This method returns **null** to force the page to reload.

insertedObjectDefaultValues

public NSDictionary **insertedObjectDefaultValues**()

Returns the default values to be used for newly inserted objects. The keys into the dictionary are the properties of the entity that the display group manages. If the dictionary returned by this method is empty, the **insert** method adds an object that is initially empty. Because the object is empty, the display group has no value to display on the HTML page for that object, meaning that there is nothing for the user to select and modify. Use the **setInsertedObjectDefaultValues** method to set up a default value so that there is something to display on the page.

insertNewObjectAtIndex

public java.lang.Object **insertNewObjectAtIndex**(int *index*)

Asks the receiver's EODataSource (defined in the EOControl framework) to create a new object by sending it a **createObject** message, then inserts the new object . If a new object can't be created, this method sends the delegate a **createObjectFailedForDataSource** message.

If the object is successfully created, this method then sets the default values specified by **insertedObjectDefaultValues**.

See also: insert

masterObject

public java.lang.Object **masterObject**()

Returns the master object for a detail display group (a display group that represents a detail in a master-detail relationship). A detail display group is one that uses an EODetailDataSource (defined in the EOControl framework). You create a detail display group by dragging a to-many relationship from EOModeler to an open component in WebObjects Builder. If the display group is not a detail display group or does not have a master object set, this method returns **null**.

See also: **detailKey**, **hasDetailDataSource**, **setMasterObject**

numberOfObjectsPerBatch

public int **numberOfObjectsPerBatch**()

Returns the batch size. You can set the batch size using **setNumberOfObjectsPerBatch** or using WebObjects Builder's Display Group Options panel.

qualifier

public com.apple.yellow.eocontrol.EOQualifier **qualifier**()

Returns the receiver's qualifier, which it uses to filter its array of objects for display when the delegate doesn't do so itself.

See also: **displayedObjects**, **setQualifier**:,**updateDisplayedObjects**

qualifierFromQueryValues

public com.apple.yellow.eocontrol.EOQualifier **qualifierFromQueryValues**()

Builds a qualifier constructed from entries in these query dictionaries: **queryMatch**, **queryMax**, **queryMin**, and **queryOperator**.

See also: **qualifyDataSource**, **qualifyDisplayGroup**

qualifyDataSource

public void **qualifyDataSource**()

Takes the result of **qualifierFromQueryValues** and applies to the receiver's data source. The receiver then sends itself a **fetch** message. If the receiver is in query mode, query mode is exited. This method differs

from **qualifyDisplayGroup** as follows: whereas **qualifyDisplayGroup** performs in-memory filtering of already fetched objects, **qualifyDataSource** triggers a new qualified fetch against the database.

See also: **queryMatch**, **queryMax**,, **queryMin**,**queryOperator**

qualifyDisplayGroup

public void **qualifyDisplayGroup**()

Takes the result of the **qualifierFromQueryValues** and applies to the receiver using **setQualifier**. The method **updateDisplayedObjects** is invoked to refresh the display. If the receiver is in query mode, query mode is exited.

See also: **qualifyDataSource**, **queryMatch**, **queryMax**, -**queryMin**, **queryOperator**

queryBindings

public NSMutableDictionary **queryBindings**()

Returns a dictionary containing the actual values that the user wants to query upon. You use this method to perform a query stored in the model file. Bind keys in this dictionary to elements on your component that specify query values, then pass this dictionary to the fetch specification that performs the fetch.

queryMatch

public NSMutableDictionary **queryMatch**()

Returns a dictionary of query values to match. The **qualifierFromQueryValues** method uses this dictionary along with the **queryMax** and **queryMin** dictionaries to construct qualifiers.

Use the **queryOperator** dictionary to specify the type of matching (=, <, >, **like**, and so on) for each key in the **queryMatch** dictionary.

If the **queryOperator** dictionary does not contain a key contained in the **queryMatch** dictionary, the default is to match the value exactly (=) if the value is a number or a date and to perform pattern matching if the value is a String. In the case of string values, the **defaultStringMatchFormat** and **defaultStringMatchOperator** specify exactly how the pattern matching will be performed.

See also: **allQualifierOperators**, **qualifyDataSource**, **qualifyDisplayGroup**, **relationalQualifierOperators**

queryMax

public NSMutableDictionary **queryMax**()

Returns a dictionary of "less than" query values. The **qualifierFromQueryValues** method uses this dictionary along with the **queryMatch** and **queryMin** dictionaries to construct qualifiers.

See also: **qualifyDataSource**, **qualifyDisplayGroup**, **queryOperator**

queryMin

public NSMutableDictionary **queryMin**()

Returns a dictionary of "greater than" query values. The **qualifierFromQueryValues** method uses this dictionary along with the **queryMatch** and **queryMin** dictionaries to construct qualifiers.

See also: **qualifyDataSource**, **qualifyDisplayGroup**, **queryOperator**

queryOperator

public NSMutableDictionary **queryOperator**()

Returns a dictionary of operators to use on items in the **queryMatch** dictionary. If a key in the **queryMatch** dictionary also exists in **queryOperator**, that operator for that key is used. The **allQualifierOperators** method returns the operator strings you can use as values in this dictionary.

See also: **qualifierFromQueryValues**, **queryMax**, **queryMin**, **relationalQualifierOperators**

redisplay

public void **redisplay**()

Sends out a contents changed notification.

relationalQualifierOperators

public NSArray **relationalQualifierOperators**()

Returns an array containing all of the relational operators supported by EOControl's EOQualifier: =, !=, <, <=, >, and >=. In other words, returns all of the EOQualifier operators except for the ones that work exclusively on strings: "**like**" and "**caseInsensitiveLike**".

See also: **allQualifierOperators**, **queryOperator**

selectedObject

public java.lang.Object **selectedObject**()

Returns the first selected object in the displayed objects array, or **null** if there's no such object.

See also: **displayedObjects**, **selectionIndexes**, **selectedObjects**

selectedObjects

public NSArray **selectedObjects**()

Returns the objects selected in the receiver's displayed objects array.

See also: **displayedObjects**, **selectionIndexes**, **selectedObject**

selectionIndexes

public NSArray **selectionIndexes**()

Returns the selection as an array of integers. The integers are indexes into the array returned by **displayedObjects**.

See also: **selectedObject**, **selectedObjects**, **setSelectionIndexes**

selectNext

public java.lang.Object **selectNext**()

Attempts to select the object just after the currently selected one. The selection is altered in this way:

- If there are no objects, does nothing.
- If there's no selection, selects the object at index zero.
- If the first selected object is the last object in the displayed objects array, selects the first object.
- Otherwise selects the object after the first selected object.

This method returns **null** to force the page to reload.

See also: **selectPrevious**, **setSelectionIndexes**

selectObject

public boolean **selectObject**(java.lang.Object *anObject*)

Attempts to select the object equal to *anObject* in the receiver's displayed objects array, returning **true** if successful and **false** otherwise. *anObject* is equal to an object in the displayed objects array if its address is the same as the object in the array.

See also: **selectNext**, **selectPrevious**

selectObjectsIdenticalTo

public boolean **selectObjectsIdenticalTo**(NSArray *objectSelection*)

Attempts to select the objects in the receiver's displayed objects array whose addresses are equal to those of objects, returning **true** if successful and **false** otherwise.

See also: **setSelectionIndexes**, **selectObjectsIdenticalToAndSelectFirstOnNoMatch**

selectObjectsIdenticalToAndSelectFirstOnNoMatch

public boolean **selectObjectsIdenticalToAndSelectFirstOnNoMatch**(NSArray *objects*, boolean *flag*)

Selects the objects in the receiver's displayed objects array whose addresses are equal to those of *objects*, returning **true** if successful and **false** otherwise. If no objects in the displayed objects array match objects and *flag* is **true**, attempts to select the first object in the displayed objects array.

See also: **setSelectionIndexes**, **selectObjectsIdenticalTo**

selectPrevious

public java.lang.Object **selectPrevious**()

Attempts to select the object just before the presently selected one. The selection is altered in this way:

- If there are no objects, does nothing.
- If there's no selection, selects the object at index zero.
- If the first selected object is at index zero, selects the last object.
- Otherwise selects the object before the first selected object.

This method returns **null** to force the page to reload.

See also: **selectNext**, **redisplay**

selectsFirstObjectAfterFetch

>public boolean **selectsFirstObjectAfterFetch**()

Returns **true** if the receiver automatically selects its first displayed object after a fetch if there was no selection, **false** if it leaves an empty selection as-is.

WODisplayGroups by default do select the first object after a fetch when there was no previous selection.

See also: displayedObjects, **fetch**, **setSelectsFirstObjectAfterFetch**

setCurrentBatchIndex

>public void **setCurrentBatchIndex**(int *anInt*)

Displays the *anInt* batch of objects. The total batch count equals the number of displayed objects divided by the batch size. For example, if the WODisplayGroup has one hundred objects to display and the batch size is twenty, there are five batches. The first batch has a batch index of 1. **setCurrentBatchIndex(3)** would display the third batch of objects (objects 41 to 60 in this example).

If *anInt* is greater than the number of batches, this method displays the first batch.

See also: batchCount, **currentBatchIndex**, **displayBatchContainingSelectedObject**,**displayNextBatch**, **displayPreviousBatch**,**numberOfObjectsPerBatch**

setDataSource

>public void **setDataSource**(com.apple.yellow.eocontrol.EODataSource *aDataSource*)

Sets the receiver's EODataSource (defined in the EOControl framework) to *aDataSource*. In the process, it performs these actions:

Unregisters itself as an editor and message handler for the previous EODataSource's EOEditingContext (also defined in EOControl), if necessary, and registers itself with *aDataSource*'s EOEditingContext. If the new EOEditingContext already has a message handler, however, the receiver doesn't assume that role.

Clears the receiver's array of objects.

Sends **displayGroupDidChangeDataSource** to the delegate if there is one.

See also: dataSource

setDefaultStringMatchFormat

>public void **setDefaultStringMatchFormat**(java.lang.String *format*)

Sets how pattern matching will be performed on String values in the **queryMatch** dictionary. This format is used for properties listed in the **queryMatch** dictionary that have String values and that do not have an

associated entry in the **queryOperator** dictionary. In these cases, the value is matched using pattern matching and *format* specifies how it will be matched.

The default format string for pattern matching is "**%@***" which means that the string value in the **queryMatch** dictionary is used as a prefix. For example, if the **queryMatch** dictionary contains a value "Jo" for the key "Name", the query returns all records whose name values begin with "Jo".

See also: **defaultStringMatchFormat**, **setDefaultStringMatchOperator**

setDefaultStringMatchOperator

public void **setDefaultStringMatchOperator**(java.lang.String *operator*)

Sets the operator used to perform pattern matching for String values in the **queryMatch** dictionary. This operator is used for properties listed in the **queryMatch** dictionary that have String values and that do not have an associated entry in the **queryOperator** dictionary. In these cases, the operator *operator* is used to perform pattern matching.

The default value for the query match operator is **caseInsensitiveLike**, which means that the query does not consider case when matching letters. The other possible value for this operator is **like**, which matches the case of the letters exactly.

See also: **allQualifierOperators**, **defaultStringMatchOperator**, **relationalQualifierOperators**, **setDefaultStringMatchFormat**

setDelegate

public void **setDelegate**(java.lang.Object *anObject*)

Sets the receiver's delegate to *anObject*.

See also: **delegate**, WODisplayGroup.Delegate

setDetailKey

public void **setDetailKey**(java.lang.String *detailKey*)

Sets the detail key to *detailKey* for a detail display group. The detail key is the key that retrieves from the master object the objects that this display group manages. You must set a detail key before you set a master object.

If the receiver is not a detail display group, this method has no effect. A display group is a detail display group if its data source is an EODetailDataSource (defined in the EOControl framework). You typically

create a detail display group by dragging a to-many relationship from EOModeler to an open component in WebObjects Builder. Doing so sets the detail key and master object, so you rarely need to use this method.

See also: **hasDetailDataSource**, **detailKey**, **setMasterObject**

setFetchesOnLoad

   public void **setFetchesOnLoad**(boolean *flag*)

Controls whether the receiver automatically fetches its objects after being loaded. If *flag* is **true** it does; if *flag* is **false** the receiver must be told explicitly to fetch. The default is **false**. You can also set this behavior in WebObjects Builder in the Display Group Options panel.

See also: **fetch**, **fetchesOnLoad**

setInQueryMode

   public void **setInQueryMode**(boolean *flag*)

Sets according to *flag* whether the receiver is in query mode. In query mode, controls in the user interface that normally display values become empty, allowing users to type queries directly into them (this is also known as a "Query by Example" interface). In effect, the receiver's "displayedObjects" are replaced with an empty **queryMatch** dictionary. When **qualifyDisplayGroup** or **qualifyDataSource** is subsequently invoked, the query is performed and the display reverts to displaying values—this time, the objects returned by the query.

See also: **inQueryMode**

setInsertedObjectDefaultValues

   public void **setInsertedObjectDefaultValues**(NSDictionary *defaultValues*)

Sets default values to be used for newly inserted objects. When you use the **insert** method to add an object, that object is initially empty. Because the object is empty, there is no value to be displayed on the HTML page, meaning there is nothing for the user to select and modify. You use this method to provide at least one field that can be displayed for the newly inserted object. The possible keys into the dictionary are the properties of the entity managed by this display group. For example, a component that displays a list of movie titles and allows the user to insert new movie titles might contain these statements to ensure that all new objects have something to display as a movie title:

```
[defaultValues setObject:@"New title" forKey:@"title"];
[movies setInsertedObjectDefaultValues:defaultValues];
```

See also: **insertedObjectDefaultValues**

setMasterObject

   public void **setMasterObject**(java.lang.Object *masterObject*)

Sets the master object to *masterObject* for detail display groups and then performs a fetch if the display group is set to fetch on load. The master object owns the objects controlled by this display group.

Before you use this method, you should use the **setDetailKey** to set the key to this relationship. You typically create a detail display group by dragging a to-Many relationship from EOModeler to an open component in WebObjects Builder. Doing so sets the master object and detail key, so you typically do not have to use this method.

If the receiver is not a detail display group, this method has no effect.

See also: hasDetailDataSource, **masterObject**

setNumberOfObjectsPerBatch

   public void **setNumberOfObjectsPerBatch**(int *count*)

Sets the number of objects the receiver displays at a time. For example, suppose you are displaying one hundred records. Instead of displaying all of these at once, you can set the batch size so that the page displays a more manageable number (for example, 10). WebObjects Builder allows you to set the number of objects per batch on the Display Group Options panel.

See also: batchCount, **displayNextBatch**, **displayPreviousBatch**, **numberOfObjectsPerBatch**

setObjectArray

   public void **setObjectArray**(NSArray *objects*)

Sets the receiver's objects to *objects*, regardless of what its EODataSource (defined in the EOControl framework) provides. This method doesn't affect the EODataSource's objects at all; specifically, it results in neither inserts nor deletes of objects in the EODataSource. *objects* should contain objects with the same property names or methods as those accessed by the receiver. This method is used by **fetch** to set the array of fetched objects; you should rarely need to invoke it directly.

After setting the object array, this method restores as much of the original selection as possible. If there's no match and the receiver selects after fetching, then the first object is selected.

See also: allObjects, **displayedObjects**, **fetch**, **selectsFirstObjectAfterFetch**

setQualifier

public void **setQualifier**(com.apple.yellow.eocontrol.EOQualifier *aQualifier*)

Sets the receiver's qualifier to *aQualifier*. This qualifier is used to filter the receiver's array of objects for display. Use **updateDisplayedObjects** to apply the qualifier.

If the receiver's delegate responds to **displayArrayForObjects**, that method is used instead of the qualifier to filter the objects.

See also: displayedObjects, **qualifier**

setSelectionIndexes

public boolean **setSelectionIndexes**(NSArray *selection*)

Selects the objects at *selection* in the receiver's array if possible, returning **true** if successful and **false** if not (in which case the selection remains unaltered). *selection* is an array of java.lang.Integers. This method is the primitive method for altering the selection; all other such methods invoke this one to make the change.

This method checks the delegate with a **shouldChangeSelectionToIndexes** message. If the delegate returns **false**, this method also fails and returns **false**. If the receiver successfully changes the selection, its observers each receive a **subjectChanged** message and, if necessary, a **displayGroupDidChangeSelectedObjects** message.

Note: The selection set here is only a programmatic selection; the objects on the screen are not highlighted in any way.

See also: allObjects

setSelectsFirstObjectAfterFetch

public void **setSelectsFirstObjectAfterFetch**(boolean *flag*)

Controls whether the receiver automatically selects its first displayed object after a fetch when there were no selected objects before the fetch. If *flag* is **true** it does; if *flag* is **false** then no objects are selected.

WODisplayGroups by default do select the first object after a fetch when there was no previous selection.

See also: displayedObjects, **fetch**, **selectsFirstObjectAfterFetch**

setSortOrderings

> public void **setSortOrderings**(NSArray *keySortOrderArray*)

Sets the EOSortOrdering objects (defined in the EOControl framework) that **updateDisplayedObjects** uses to sort the displayed objects to orderings. Use **updateDisplayedObjects** to apply the sort orderings.You can also set this value using the WebObjects Builder Display Group Options panel.

If the receiver's delegate responds to **displayGroup:displayArrayForObjects:**, that method is used instead of the sort orderings to order the objects.

See also: **displayedObjects**, **sortOrderings**, **updateDisplayedObjects**

setValidatesChangesImmediately

> public void **setValidatesChangesImmediately**(boolean *flag*)

Controls the receiver's behavior on encountering a validation error. In the Web context, this method has no effect.

WODisplayGroups by default don't validate changes immediately.

See also: – **saveChanges** (in EOControl's EOEditingContext), - tryToSaveChanges (EOEditingContext Additions), **validatesChangesImmediately**

sortOrderings

> public NSArray **sortOrderings**()

Returns an array of EOSortOrdering objects (defined in the EOControl framework) that **updateDisplayedObjects** uses to sort the displayed objects, as returned by the **displayedObjects** method.

See also: **setSortOrderings**

updateDisplayedObjects

> public void **updateDisplayedObjects**()

Recalculates the receiver's displayed objects arrays and redisplays. If the delegate responds to **displayArrayForObjects**, it's sent this message and the returned array is set as the WODisplayGroup's displayed objects. Otherwise, the receiver applies its qualifier and sort ordering to its array of objects. In either case, any objects that were selected before remain selected in the new displayed object's array.

See also: **redisplay**, **allObjects**, **displayedObjects**, **qualifier**, **selectedObjects**, **sortOrderings**

validatesChangesImmediately

public boolean **validatesChangesImmediately**()

Returns **true** if the receiver immediately handles validation errors, or leaves them for the EOEditingContext (defined in the EOControl framework) to handle when saving changes.

By default, WODisplayGroups don't validate changes immediately.

See also: setValidatesChangesImmediately

WODynamicElement

Inherits From:	WOElement : NSObject
Package:	com.apple.yellow.webobjects

Class Description

WODynamicElement is an abstract superclass for classes that generate dynamic elements: objects representing HTML or PDF elements whose values can programmatically change at run time. Dynamic elements have a name and one or more *properties*, instance variables holding such things as user-entered data or user-triggerable actions. The properties of a dynamic element are associated with, or "bound" to, the properties of the WOComponent object that represents the page (or portion of a page) in which the dynamic element appears.

At runtime, a dynamic element can extract values from the request, feed those values across the bindings to the owning component, receive back new data, and include that data in the next representation of the page. A dynamic element can also detect if the user has manipulated it (for instance, clicking a button) to signal some intention and then trigger the appropriate action method in the owning WOComponent. The bindings between properties of a dynamic element and properties of a WOComponent are made possible by *associations*, objects that know how to "push" and "pull" values to and from another object using keys. All objects that inherit from NextObject have associative capabilities through NextObjects's implementation of the KeyValueCoding interface.

WODynamicElements must implement the default constructor to initialize their instance variables with the appropriate association objects (passed in). As WOElement objects, they must also implement one or more of the three request-handling methods. In the context of request handling, a dynamic element can use its associations to:

- Push request values into the associated properties of their WOComponent (**takeValuesFromRequest**)

- Invoke action methods of the WOComponent (**invokeActionForRequest**)

- Extract values from the WOComponent when composing a dynamic HTML response (**appendToResponse**)

All dynamic elements must implement **appendToResponse**. If they accept user input or respond to user actions (such as mouse clicks), they should implement **takeValuesFromRequest** and **invokeActionForRequest**, respectively.

Note: If you write a dynamic element that appends content to the response (this is typically done by overriding **appendToResponse**), be sure to verify that the request is not client-side:

```
public void appendToResponse(WOResponse r, WOContext c){
if(!c.request().isFromClientComponent()){
```

```
    // append content here
    }
    }
```

Dynamic elements do not know about their WOComponent object until run time. During request-handling, the application stores components (representing a page and subcomponents on the page) on a stack maintained by the WOContext object, with the currently referenced WOComponent on top of the stack. A dynamic element's WOAssociation retrieves the current WOComponent (through an invocation of WOContext's **component** method) and reads and writes values from and to the WOComponent using KeyValueCoding methods.

A dynamic element can represent a single HTML or PDF element (such as an editable text field) or a compound element, such as the LoginPanel whose implementation is described below. WebObjects includes a suite of ready-made dynamic elements and the WebObjects Builder application makes these objects available on its palettes. The *Dynamic Elements Reference* describes WebObjects' dynamic elements and provides examples showing how to use them.

Method Types

Constructors

WODynamicElement

Constructors

WODynamicElement

public **WODynamicElement**()
public **WODynamicElement**(java.lang.String *aName*,
      com.apple.yellow.foundation.NSDictionary *associations*, WOElement *anElement*)

Returns a dynamic element identified by class *aName* and initialized with the objects in dictionary *associations*. The dictionary contains WOAssociation objects, which know how to take values from, and set values in, an "owning" WOComponent. To properly initialize a dynamic element, you should use the published keys of the dynamic element to get the associations that belong to the dynamic element; then assign these objects to instance variables. The *anElement* argument, if not **null**, is the root object of a graph of WOElements associated with the dynamic element.

Typically, a key in the *associations* dictionary is identified with a property of the element, and the value of this key is the name of a property of the associated Component. For example, the value of key "userName" might be bound to "employee.name" in the WOComponent; this designation means that WOComponent has a property called "employee" (possibly referring to an "Employee" object) which in turn has a property called "name". In this case, the binding is two-way; changes in the dynamic element are reflected in the WOComponent property, and changes in the WOComponent property are communicated to the dynamic

element. The value of an association can also be a constant, in which case the binding is one-way: WOComponent to dynamic element.

WOElement

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

The WOElement class is the abstract superclass of all objects that represent static and dynamic UI elements on a World Wide Web page (currently, HTML and PDF elements). You cannot directly instantiate objects from WOElement; you must create a concrete subclass of WOElement and generate objects from it.

Note: For custom dynamic elements, you need to create a subclass of WODynamicElement.

WOElement declares the three methods corresponding to the phases of the request-response loop (invoked in the following order), but WOElement's implementations do nothing:

- **takeValuesFromRequest**
- **invokeActionForRequest**
- **appendToResponse**

The first argument of these messages is an object that represents the HTTP request or response (WORequest or WOResponse). The second argument is a WOContext object that represents the context of the transaction.

Concrete subclasses of WOElement (or WODynamicElement) must, at minimum, implement **appendToResponse**. Subclasses of WODynamicElement must implement one or both of the remaining methods.

Method Types

Constructors

                                    WOElement

Handling requests

                                    appendToResponse
                                    invokeActionForRequest
                                    takeValuesFromRequest

Constructors

WOElement

public **WOElement**()

Returns an initialized WOElement.

Instance Methods

appendToResponse

public void **appendToResponse**(WOResponse *aResponse*, WOContext *aContext*)

This method is invoked in WOElement objects in the request-handling phase when objects involved in the current transaction append their HTML content to the transaction's WOResponse object. If the WOElement has child WOElements, it should forward the message to them. WOElement's default implementation of this method does nothing.

See also: WOResponse class for methods used to append HTML content

invokeActionForRequest

public WOElement **invokeAction**(WORequest *aRequest*, WOContext *aContext*)

This method is invoked in WOElements in the phase of request handling that results in the triggering of an action method and the return of a response WOComponent. In this phase, the message is propagated through the objects of the application until the dynamic element for the activated HTML control (for instance, a custom button) responds to the message by invoking the method in the request component that is bound to the action. To see if it has been activated, the dynamic element should check its element ID (obtained from its WOContext) against the sender ID in the request and context. To invoke the action method, the dynamic element should return the value of the action. The default WOElement implementation of this method returns null

See also: WOContext class for a description of element IDs

takeValuesFromRequest

public void **takeValuesFromRequest**(WORequest *aRequest*, WOContext *aContext*)

This method is invoked in (dynamic) WOElement objects during the phase of request handling that extracts user-entered data. Each dynamic element acquires any entered data (such as HTML form data) or changed state (such as a check in a check box) associated with an attribute and assigns the value to the

WOComponent variable bound to the attribute. In this way, even back-end business objects are updated. The default WOElement implementation of this method does nothing.

See also: WORequest class for methods used to extract form data

WOMailDelivery

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOMailDelivery uses a tool compiled on all platforms:
`/System/Library/WebObjects/Executables/WOSendMail[.exe]`. This tool constructs an email message from a file and uses SMTP to send it. It requires an SMTP server to be set. There is a default value for this SMTP hostname: "smtp". To change this value, use the following command:

```
defaults write NSGlobalDomain WOSMTPHost "aHostName"
```

Note that this default can be handled by WOApplication as a command-line argument.

There is only one instance of WOMailDelivery, which you access with the **sharedInstance** static. You cannot create one of your own.

Method Types

Obtaining an instance

        sharedInstance

Composing mail

        composeComponentEmail
        composePlainTextEmail

Sending mail

        sendEmail

Static Methods

sharedInstance

public static WOMailDelivery **sharedInstance**()

Instance Methods
Returns the current application's WOMailDelivery instance. Use this method instead of creating an instance of your own.

composeComponentEmail

public java.lang.String **composeComponentEmail**(java.lang.String *sender*,
   com.apple.yellow.foundation.NSArray *destination*,
   com.apple.yellow.foundation.NSArray *ccAddresses*,
   java.lang.String *subject*,
   WOComponent *aComponent*,
   boolean *flag*)

Composes an email message to *destination* with "from," "cc," and "subject" lines. The body of the message is the HTML generated when this method invokes **generateResponse** on *aComponent*. WOMailDelivery uses the WOCGIAdaptorURL default to complete all URLs in the message to be mailed, so the email's reader can click on the URLs to visit them.

If *flag* is true, the message is sent immediately.

composePlainTextEmail

public java.lang.String **composePlainTextEmail**(java.lang.String *sender*,
   com.apple.yellow.foundation.NSArray *destination*,
   com.apple.yellow.foundation.NSArray *ccAddresses*,
   java.lang.String *subject*,
   java.lang.String *message*,
   boolean *flag*)

Composes an email message to *destination* with "from," "cc," and "subject" lines, setting the content type of the email as (Content-type: TEXT/PLAIN; CHARSET=US-ASCII). If *flag* is YES, the message is sent immediately.

sendEmail

public void **sendEmail**(java.lang.String *mailString*)

Sends *anEmail*, with *anEmail* being a String following the SMTP format. The **compose...Email** methods return such Strings and this method lets you modify those strings before sending them.

WORequest

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

A WORequest object typically represents an HTTP request and thus constitutes an event that requires a reaction from a WebObjects application. WORequest objects encapsulate the data transmitted to a HTTP server in a request. Requests originate from user actions in a browser, such as the submission of a URL or a mouse click on a hyperlink, button, or active image in a page; from the perspective of WebObjects, the URL identifies a WebObjects application and the click on a control usually results in the display of a page of a WebObjects application. Such actions cause the browser to send an HTTP request to an HTTP server, which forwards the request to a WebObjects adaptor, which converts it to a WORequest object and sends that object to the appropriate request handler.

WORequest objects can also be created from HTTP requests sent by client-side components (Java applets specially modified to interact with the server side of a WebObjects application), and from HTTP requests submitted by custom client-side programs that don't use the Java client-side components. More rarely, WORequest objects can originate from custom adaptors that handle HTTP requests *or* non-HTTP events. (All the adaptors shipped with WebObjects handle HTTP events only).

Since adaptors usually create WORequest objects, and since you can usually use WebObjects' adaptors without modifications, you probably won't have to create your own instances of WORequest in your code (although you can if you need to). More typically, your code will obtain information from WORequest objects as they become available during certain points in the request-response loop. The application supplies WORequest objects as arguments in the **takeValuesFromRequest:inContext:** and **invokeActionForRequest:inContext:** methods, which are implementable by WOApplication, WOSession, WOComponent, and WOElement objects. You can also obtain the current WORequest object at any time during request handling through WOContext's **request** method.

Note: Because WORequest objects usually correspond to HTTP requests, the data they encapsulate is almost the same as what you would find in an HTTP request. Thus an understanding of HTTP requests is important for understanding the data vended by WORequest objects. A recommended prerequisite therefore is to review the current HTTP specification or HTTP documentation.

Constructors

WORequest

>   public **WORequest**()
>   public **WORequest**(java.lang.String *aMethod*,
>   java.lang.String *anURL*,
>   java.lang.String *anHTTPVersion*,
>   NSDictionary *someHeaders*,
>   NSData *aContent*,
>   NSDictionary *userInfo*)

Returns a WORequest object initialized with the specified parameters. The first two arguments are required:

- *aMethod* must be either "GET" or "POST"; anything else causes an exception to be thrown.

- *aURL* must be a valid URL; if the URL is invalid, an exception is thrown.

If either argument is omitted, the constructor throws an exception.

The remaining arguments are optional; if you specify **null** for these, the constructor substitutes default values or initializes them to **null**. The *someHeaders* argument (if not **null**) should be a dictionary whose String keys correspond to header names and whose values are arrays of one or more strings corresponding to the values of each header. The *userInfo* dictionary can contain any information that the WORequest object wants to pass along to other objects involved in handling the request.

For more information on each argument, see the description of the corresponding accessor method.

See also: method, **httpVersion**, **content**, **userInfo**

Instance Methods

adaptorPrefix

>   public java.lang.String **adaptorPrefix**()

Returns the part of the request's URI that is specific to a particular adaptor. This is typically a URL ending in "/WebObjects", "/WebObjects.exe", "/WebObjects.dll", or uppercase versions of these strings. WebObjects uses a request's adaptor prefix to set the adaptor prefix in the generated response's URL. A WORequest must always have an adaptor prefix.

See also: applicationName, **applicationNumber**, **uri**

applicationName

public java.lang.String **applicationName**()

Returns the part of the request's URI that identifies the application the request is intended for. This name does not include the ".woa" extension of an application directory. A WORequest must always have an application name specified.

See also: **adaptorPrefix**, **applicationNumber**, **uri**

applicationNumber

public int **applicationNumber**()

Returns the part of the request's URI that identifies the particular application instance the request is intended for. This attribute is -1 if the request can be handled by any instance of the application, which is always the case for the first request in a session.

See also: **applicationName**, **uri**

browserLanguages

public NSArray **browserLanguages**()

Returns the language preference list from the user's browser.

content

public NSData **content**()

Returns the content the WORequest was initialized with (which defaults to **null**). The format of the data is undefined, but you can usually identify it by the value of the "content-type" header.

See also: **httpVersion**, **method**

cookieValueForKey

public java.lang.String **cookieValueForKey**(java.lang.String *aKey*)

Returns a string value for the cookie key specified by *aKey*.

See also: **cookieValues**, **cookieValuesForKey**, WOCookie class specification

cookieValues

public NSDictionary **cookieValues**()

Returns a dictionary of cookie values and cookie keys.

See also: **cookieValueForKey**, **cookieValuesForKey**, WOCookie class specification

cookieValuesForKey

public NSArray **cookieValuesForKey**(java.lang.String *aKey*)

Returns an array of values for the cookie key specified by *aKey*. Use this method to retrieve information stored in a cookie in an HTTP header. Valid keys are specified in the cookie specification.

See also: **cookieValueForKey**, **cookieValues**, WOCookie class specification

defaultFormValueEncoding

public int **defaultFormValueEncoding**()

Returns the *default* string encoding the WORequest object uses for converting form values from ASCII to Unicode. It uses the default encoding only when it can detect no encoding from the ASCII form values or if encoding detection is disabled. If no default form-value encoding is set, NSISOLatin1StringEncoding is used.

See also: **setDefaultFormValueEncoding**

formValueEncoding

public int **formValueEncoding**()

Returns the encoding last used to convert form values from ASCII to Unicode. This encoding is either the result of an earlier detection of form-value encoding or the default form value encoding.

See also: **defaultFormValueEncoding**, **isFormValueEncodingDetectionEnabled**

formValueForKey

public java.lang.Object **formValueForKey**(java.lang.String *aKey*)

Returns a form value identified by the name *aKey*. If there are multiple form values identified by the same name, only one of the values is returned, and which of these values is not defined. You should use this method for names that you know occur only once in the name/value pairs of form data.

formValueKeys

    public NSArray **formValueKeys**()

Returns an array of NSStrings corresponding to the names (or keys) used to access values of a form. The array is not sorted in any particular order, and is not necessarily sorted in the same order on successive invocations of this method.

formValues

    public NSDictionary **formValues**()

Returns an NSDictionary containing all of the form data name/value pairs.

formValuesForKey

    public NSArray **formValuesForKey**(java.lang.String *aKey*)

Returns an array of all values (as Strings) of the form identified by the name *aKey*. This array is not sorted in any particular order, and is not necessarily sorted in the same order on successive invocations of this method. You should use this method when you know that a name (key) used for accessing form data can be matched with more than one value.

headerForKey

    public java.lang.String **headerForKey**(java.lang.String *aKey*)

Returns one value of a particular header in the header dictionary the request was initialized with. This will be a string corresponding to one of the values of the header whose name is passed in as the key argument. If the specified header has multiple values, only one of these values is returned, and which one of them this is is not defined. However, on successive calls to this method, the same value will always be returned. This method is intended to be used for headers that are known to have only one value.

headerKeys

    public NSArray **headerKeys**()

Returns an array of the keys of the header dictionary the request was initialized with (which default to an empty dictionary). This will be an array of strings corresponding to the headers' names. The array is not sorted in any particular order, and not necessarily sorted in the same order on successive calls to this method.

headersForKey

    public NSArray **headersForKey**(java.lang.String *aKey*)

Returns the values of a particular header that is identified by *aKey*. The returned object contains Strings sorted in no particular order, but which will always be sorted in the same order on successive calls to this method. Use this method for headers that you know have (or can have) multiple values.

httpVersion

    public java.lang.String **httpVersion**()

Returns the HTTP version the request was initialized with. An application uses the WORequest's HTTP version to initialize the HTTP version of the response that is generated by request handling. The WORequest's HTTP version typically derives from the HTTP version of the client (for example, the browser) that initiated the request.

isFormValueEncodingDetectionEnabled

    public boolean **isFormValueEncodingDetectionEnabled**()

Returns whether detection of form-value encoding is allowed to take place when form values are obtained.

See also: setFormValueEncodingDetectionEnabled

isFromClientComponent

    public boolean **isFromClientComponent**()

Returns whether the request originated from an event in a client-side component (that is, a Java applet that can interact with the server side of a WebObjects application).

If you use dynamic elements and write write HTML code in the response, you should check that the request is not from a client-side component before writing into the response.

method

    public java.lang.String **method**()

Returns the method the WORequest object was initialized with. A WORequest's method defines where it will look for form values. The only currently supported methods are "GET" and "PUT", which have the same meaning as the HTTP request method tokens of the same name.

See also: content, **httpVersion**

requestHandlerKey

public java.lang.String **requestHandlerKey**()

Returns the part of the request's URI which identifies the request handler. This identifies the request handle which will process the reuquest and cannot be **nil**.

requestHandlerPath

public java.lang.String **requestHandlerPath**()

Returns the part of the URL which identifies, for a given request handler, which information is requested. Different request handlers use this part of the URL in different ways.

requestHandlerPathArray

public NSArray **requestHandlerPathArray**()

Returns the request handler path decomposed into elements.

sessionID

public native java.lang.String **sessionID**()

Returns the session ID, or **null** if no session ID is found. This method first looks for the session ID in the URL, then checks the form values, and finally checks to see if the session ID is stored in a cookie.

setDefaultFormValueEncoding

public void **setDefaultFormValueEncoding**(int *anEncoding*)

Sets the default string encoding for the receiver to use when converting its form values from ASCII to Unicode. The default string encoding is called into play if the WORequest cannot detect an encoding from the ASCII form values or if encoding detection is disabled. If no default form value encoding is explicitly set, the WORequest uses NSISOLatin1StringEncoding.

See also: defaultFormValueEncoding, **setFormValueEncodingDetectionEnabled**

setFormValueEncodingDetectionEnabled

public void **setFormValueEncodingDetectionEnabled**(boolean *flag*)

Enables or disables automatic detection of the best encoding for the receiver to use when it converts form values from ASCII to Unicode. When detection is enabled, a WORequest object scans the ASCII form

values and applies heuristics to decide which is the best encoding to use. If no specific encoding is discernible, or if detection is disabled, the WORequest uses the default form value encoding for the conversion.

See also: isFormValueEncodingDetectionEnabled,setDefaultFormValueEncoding

uri

> public java.lang.String **uri**()

Returns the Uniform Resource Identifier (URI) the WORequest was initialized with. For a session's first request, the URI indicates the resource that the request is seeking (such as a WebObjects application); for subsequent requests in the session, the URI indicates which page of the application should handle the request. If the request was caused (as is usually the case) by a web browser submitting a URL to an HTTP server, the URI is that part of the URL that follows the port number. Because the format of WebObjects URLs and the corresponding request URI might change between different versions of WebObjects, you should not attempt to parse the URI returned by this method. Instead, use WORequest's accessor methods to access particular URI/URL components.

See also: adaptorPrefix, **applicationName**, **applicationNumber**

userInfo

> public NSDictionary **userInfo**()

Returns the value of the user information the receiver was initialized with (**null** by default). WebObjects imposes no restrictions on the format or content of the user information dictionary. In fact, WebObjects classes do not themselves use the dictionary, but just pass it around as the request is handled. Custom adaptors, for example, could initialize the dictionary with special information for other objects of an application.

WORequestHandler

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WORequestHandler is an abstract class that defines request handlers. A request handler is an object that can handle requests received by the WebObjects adaptor. All WebObjects applications have multiple request handlers that can handle certain types of requests. Three private request handlers are defined in the WebObjects framework:

- WOComponentRequestHandler, which handles requests for actions implemented in a component.
- WODirectActionRequestHandler, which handles requests for actions implemented in a WODirectAction class.
- WOResourceRequestHandler, which handles requests for resources.

These three request handlers handle most styles of requests that an application can typically receive. If you want to create your own style of request, then you should write your own WORequestHandler. Unless you write your own request handler, your code typically won't have to directly interact with WORequestHandler objects at all.

Method Types

Constructor

WORequestHandler

Handling Requests

handleRequest

Constructors

WORequestHandler

    public **WORequestHandler**()

Returns an initialized WORequestHandler.

Instance Methods

handleRequest

public WOResponse **handleRequest**(WORequest *aRequest*)

Request handlers must implement this method and perform all request-specific handling. By default, a request is an HTTP request. You must supply your own server-side adaptor to accept anything other than HTTP.

WOResourceManager

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOResourceManager manages an application's resources. It defines methods that retrieve resources from standard directories. Each WebObjects application contains a resource manager object, which you can access by sending **resourceManager** to the WOApplication class

Method Types

Retrieving resources

> pathForResourceNamed
> urlForResourceNamed

Retrieving localized strings

> stringForKey

Managing the application-wide data cache

> flushDataCache
> removeDataForKeypublic void removeDataForKey(java.lang.String key, WOSession aSession)
> setData

Controlling access

> lock
> unlock

Instance Methods

flushDataCache

public void **flushDataCache**()

Removes all data from the image data cache. Use this method if you are storing data in the application-wide cache that you no longer need.

Access to the WOResourceManager object is locked at the beginning of this method and unlocked at the end.

lock

   public void **lock**()

Locks access to the WOResourceManager object. When the WOResourceManager is locked, no other threads may access it.

Usually, you don't need to invoke this method in your own code. All messages that you send to a WOResourceManager object lock access to the object at the beginning of the method and unlock access at the end. You only need to use this method if you're subclassing WOResourceManager. In that case, you should lock access to the WOResourceManager object in methods that load resources.

pathForResourceNamed

   public java.lang.String **pathForResourceNamed**(java.lang.String *aResourceFile*,
        java.lang.String *aFrameworkName*,
        NSArray *languagesList*)

Returns the absolute path for the resource *aResourceFile*. Include the file's extension when specifying *aResourceFile*. If the file is in the application, specify **null** for the framework argument.

This method always returns a path like **/Local/Library/WebObjects/Applications/MyApp.woa/WebServerResources/MyResource**. It does not return the path relative to the HTTP server's document root unless the entire application is located in the document root.

Access to the WOResourceManager object is locked at the beginning of this method and unlocked at the end.

   removeDataForKeypublic void **removeDataForKey**(java.lang.String *key*, WOSession *aSession*)

Removes the data stored in the data cache under the key *key*. The session argument is currently ignored; specify **null** to have WOResourceManager use the application-wide cache.

This method is used by default when a dynamic element requests an image or embedded object from a database and the **key** attribute is not set for that dynamic element. If the **key** attribute isn't set, the data retrieved from the database is stored in the cache using **setData**, sent to the dynamic element, and then

removed from the cache using **removeDataForKey:session:**. If the **key** attribute is set, **removeDataForKey:session:** is not invoked.

You rarely need to invoke this method yourself. Use it only if you need to limit the amount of memory your application uses, if your application has data stored in the cache, and you know that the data is no longer needed.

Access to the WOResourceManager object is locked at the beginning of this method and unlocked at the end.

See also: **flushDataCache**

setData

> public void **setData**(NSData *someData*,
>   java.lang.String *key*,
>   java.lang.String *mimeType*,
>   WOSession *aSession*)

Adds the image or embbedded object *someData* of MIME type *type* to the data cache for the session specify by *aSession*. The data is stored under the key *key*. The session argument is currently ignored; specify **null** to have WOResourceManager use the application-wide cache.

This method is invoked any time a dynamic element requests an image or embedded object from a database. You rarely need to invoke it yourself.

By default when a dynamic element requests an image from the database, WOResourceManager fetches the image, stores it in the cache using **setData:forKey:mimeType:session:**, sends it to the dynamic element, and then removes it from the cache using **removeDataForKeypublic void removeDataForKey(java.lang.String key, WOSession aSession)**. However, if the dynamic element has a **key** attribute defined, then the image is stored in the database under that key, and it is not removed from the database.

Access to the WOResourceManager object is locked at the beginning of this method and unlocked at the end.

See also: **flushDataCache**

stringForKey

> public java.lang.String **stringForKey**(java.lang.String *aKey*,
> java.lang.String *aTableName*,
> java.lang.String *aDefaultValue*,
> java.lang.String *aFrameworkName*,
> NSArray *languagesList*)

Returns a localized string from string table *aTable*.**strings** using *aKey* to look it up. If no string value for the key is found in the table, *aDefaultValue* (optional) is returned. The method first searches the *aTable*.**strings** file, if it exists, in each of the localized (**.lproj**) subdirectories of the application wrapper; searching proceeds in the order specified by the array *languagesList*. If no string value matching the key is found, the search then continues to the *aTable*.**strings** file (if it exists) directly under the Resources directory (inside the directory with the **.woa** extension).

unlock

> public void **unlock**()

Removes the lock on the WOResourceManager object, allowing other threads to access it.

Usually, you don't need to invoke this method in your own code. All messages that you send to a WOResourceManager object lock access to the object at the beginning of the method and unlock access at the end. You only need to use this method if you're subclassing WOResourceManager. In that case, you should lock access to the WOResourceManager object in methods that load resources and unlock when the method is finished accessing the WOResourceManager object.

See also: lock

urlForResourceNamed

> public java.lang.String **urlForResourceNamed**(java.lang.String *aResourceFile*,
> java.lang.String *aFrameworkName*,
> NSArray *languagesList*,
> WORequest *aRequest*)

Returns the URL associated with a resource named *aResourceFile*. The URL returned is of the following form:

WebObjects/MyApp.woa/WebServerResources/English.lproj/*aResourceFile*

Include the file's extension when specifying *aResourceFile*. If the file is in the application, specify **null** for the framework argument.

This method locates resources under the application or framework. The URL returned is computed by concatenating the application's base URL (returned by WOApplication's **baseURL** method and settable

using the WOApplicationBaseURL user default) and the relative path of the resource. This method does not check to see if the file is actually under the document root. For example, if your application is installed in **/Local/Library/WebObjects/Applications**, and the method finds *aResourceFile* in the **Resources** directory, it returns:

/WebObjects/MyApp.woa/Resources/*aResourceFile*

even though the **Resources** directory is not under the document root.

Access to the WOResourceManager object is locked at the beginning of this method and unlocked at the end.

See also: **pathForResourceNamed**

124

WOResponse

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

A WOResponse object represents an HTTP response that an application returns to a Web server to complete a cycle of the request-response loop. The composition of a response occurs during the third and final phase of this loop, a phase marked by the propagation of the **appendToResponse** message through the objects of the application. The WOApplication object first sends this message, passing in a newly-created WOResponse object as an argument. WOElement objects, which represent the dynamic and static HTML elements on a page, respond to the message by appending their HTML representation to the content of the WOResponse object. WOApplication, WOSession, and WOComponent objects can also respond to the message by adding information to the WOResponse object.

A WOResponse has two major parts: HTML content and HTTP information. The content is what is displayed in a Web browser; it can include *escaped* HTML, which is HTML code shown "as is," uninterpreted. The other information encapsulated by a WOResponse object is in the handling the response. This HTTP data includes headers, status codes, and version string. See the HTTP specification or HTTP documentation for descriptions of these items.

As you might expect, the methods of the WOResponse class can be divided into two groups, those that add to a response's HTML content and those that read and set HTTP information. The former group consists of methods that escape HTML (**appendContentHTMLAttributeValue** and **appendContentHTMLString**) and those that don't. For images and other binary data, you can use the **appendContentData**. You can obtain and set the entire content of the response with **content** and **setContent**. The following example shows a sequence of "appendContent" messages that compose an HTTP "POST" message:

```
aResponse.appendContentString("<form method=\"POST\" action=\"");
aResponse.appendContentHTMLAttributeValue(aContext.url());
aResponse.appendContentCharacter('"');
aResponse.appendContentString(">");
```

Most of the remaining WOResponse methods set and read the response's HTTP headers, the HTTP status code, and the HTTP version.

Content Encodings

You can set the string encoding used for the response content with **setContentEncoding** and you find out what the current encoding is with **contentEncoding**. An integer represents the type of encoding. The following table lists these integer values along with their OPENSTEP string-constant names.

int Value	OPENSTEP Name	Notes
1	NSASCIIStringEncoding	0 through 127
2	NSNEXTSTEPStringEncoding	
3	NSJapaneseEUCStringEncoding	
4	NSUTF8StringEncoding	
5	NSISOLatin1StringEncoding	default
6	NSSymbolStringEncoding	
7	NSNonLossyASCIIStringEncoding	7-bit verbose ASCII to represent all unichars
8	NSShiftJISStringEncoding	
9	NSISOLatin2StringEncoding	
10	NSUnicodeStringEncoding	
11	NSWindowsCP1251StringEncoding	Cyrillic; same as AdobeStandardCyrillic
12	NSWindowsCP1252StringEncoding	Windows Latin1
13	NSWindowsCP1253StringEncoding	Windows Greek
14	NSWindowsCP1254StringEncoding	Windows Turkish
15	NSWindowsCP1250StringEncoding	Windows Latin2
21	NSISO2022JPStringEncoding	ISO 2022 Japanese encoding for electronic mail

Interfaces Implemented

Method Types

Constructors

    WOResponse

Obtaining attributes

    defaultEncoding
    content
    headerForKey
    headerKeys
    headersForKey
    httpVersion
    status
    userInfo

Setting attributes

    setDefaultEncoding
    setContent
    setHeader
    setHeaders
    setHTTPVersion
    setStatus
    setUserInfo

Appending response content

    appendContentData
    appendContentString
    setContentEncoding
    contentEncoding

Working with HTML content

    appendContentHTMLAttributeValue
    appendContentHTMLString
    stringByEscapingHTMLString
    stringByEscapingHTMLAttributeValue

Working with cookies

    addCookie
    cookies
    removeCookie

Constructors

WOResponse

public **WOResponse**()

Returns an initialized WOResponse instance. HTTP status is set to 200 (OK), client caching is enabled, and the default string encoding is made ISO Latin 1.

Static Methods

defaultEncoding

public static int **defaultEncoding**()

Returns the default character encoding used to construct a new WOResponse. By default, this encoding is NSISOLatin1. For more information, see "Content Encodings".

setDefaultEncoding

public static void **setDefaultEncoding**(int *aStringEncoding*)

Lets you specify the character encoding used by default when construcing a new WOResponse. For more information, see "Content Encodings".

stringByEscapingHTMLString

public static java.lang.String **stringByEscapingHTMLString**(java.lang.String *aString*)

This method takes a string and, if escaping is required, returns a new string with certain characters escaped out. If escaping is not required, no conversion is performed and *aString* is returned. Use this method to escape strings which will appear in the visible part of an HTML file (that is, not inside a tag). The escaped characters are:

&	&
"	"
<	<
>	>

stringByEscapingHTMLAttributeValue

public static java.lang.String **stringByEscapingHTMLAttributeValue**(java.lang.String *aString*)

This method takes astring and, if escaping is required, returns a new string with certain characters escaped out. If escaping is not required, no conversion is performed and *aString* is returned. Use this method to escape strings which will appear as attribute values of a tag. The escaped characters are:

&	&
"	"
\t		
\n	

\r	
<	<
>	>

Instance Methods

addCookie

public void **addCookie**(WOCookie *aCookie*)

Adds the specified WOCookie object to the response.

See also: **cookies**, **removeCookie**, WOCookie class specification

appendContentCharacter

public void **appendContentCharacter**(byte *aChar*)

Appends a single ASCII character (*aChar*) to the HTTP response.

appendContentData

public void **appendContentData**(NSData *dataObject*)

Appends a data-encapsulating object (*dataObject*) to the HTTP response.

appendContentHTMLAttributeValue

public void **appendContentHTMLAttributeValue**(java.lang.String *aValue*)

Appends an HTML attribute value to the HTTP content after transforming the string *aValue* into an NSData object using the receiver's content encoding. Special HTML characters ("<", ">", "&", and double quote) are *escaped* so that the browser does not interpret them. In other words, the message

```
aResponse.appendContentHTMLAttributeValue("<B>");
```

would transform the argument to "<B>".

See also: **setContentEncoding**

appendContentHTMLString

public void **appendContentHTMLString**(java.lang.String *aString*)

Appends an HTML string to the HTTP response after transforming the string *aString* into an NSData object using the receiver's content encoding. Special HTML characters ("<", ">", "&", and double quote) are *escaped* so that the browser does not interpret them. For example, "<P>" becomes "&ltP&gt".

See also: **setContentEncoding**

appendContentString

public void **appendContentString**(java.lang.String *aString*)

Appends a string to the content of the HTTP response. The string is transformed into an NSData object using the receiver's content encoding. The special HTML characters "<", ">", "&", and double-quote are not escaped so the browser can interpret them as HTML.

content

public NSData **content**()

Returns the HTML content of the receiver as an NSData object.

An exception is raised if you attempt to get the content when all elements of the page have not had their chance to append HTML to the response. Thus, you should invoke this method in the application object's **handleRequest:** method, after super's **handleRequest:** has been invoked. (For scripted applications, **handleRequest:** is implemented in Application.wos). Note that at this point in the request-handling process, the components, pages, and session have already been put to sleep, so you won't have access to any context, session, or page information. If you need such information for your response, store it

somewhere--such as in WOResponse's "user info" dictionary—at a point when you do have access to it. You may want to do this in your application's **appendToResponse** method, for example.

See also: setContent, **setContentEncoding**

contentEncoding

> public int **contentEncoding**()

Returns an integer representing the encoding used for the response content. See "Content Encodings" in the class description for a mapped list of supported encodings and their Objective-C names. Usually, you will want the response encoding to be the same as that used by the submitting form on the client browser. In this case it is preferable to use WORequest's **formValueEncoding**.

```
NSStringEncoding theEncoding = [[aContext request] formValueEncoding];
```

The default string encoding is ISO Latin1.

See also: setContent, **setContentEncoding**

cookies

> public NSArray **cookies**()

Returns an array of WOCookie objects to be included in the response.

See also: addCookie, **removeCookie**, WOCookie class specification

headerForKey

> public java.lang.String **headerForKey**(java.lang.String *aKey*)

Returns the HTTP header information identified by *aKey*. If there are multiple headers associated with the one key, only the first one is returned. Returns **null** if there are no headers for the key.

See also: setHeader

headerKeys

> public NSArray **headerKeys**()

Returns an array of string keys associated with the receiver's HTTP headers. Returns **null** if there are no headers. You could easily test to see if a header is included by doing something similar to this:

```
ImmutableVector hKeys =  aResponse.headerKeys();
if (hKeys.contains("expires")) {
```

```
    // do something
    }
```

See also: **setHeaders**

headersForKey

    public NSArray **headersForKey**(java.lang.String *aKey*)

Returns *all* HTTP headers identified by *aKey*.

See also: **setHeaders**

httpVersion

    public java.lang.String **httpVersion**()

Returns the version of HTTP used for the response (for example, "HTTP/1.0").

See also: **setHTTPVersion**

removeCookie

    public void **removeCookie**(WOCookie *aCookie*)

Removes the specified WOCookie object from the response.

See also: **cookies**, **removeCookie**, WOCookie class specification

setContent

    public void **setContent**(NSData *someData*)

Sets the HTML content of the HTTP response to *someData*.

See also: **content**

setContentEncoding

> public void **setContentEncoding**(int *anEncoding*)

Sets the encoding used for the content of the HTTP response. See "Content Encodings" in the class description for a mapped list of supported encodings and their Objective-C names. The default string encoding is ISO Latin1.

See also: contentEncoding

setHTTPVersion

> public void **setHTTPVersion**(java.lang.String *aVersion*)

Sets the version of HTTP used for the response (for example, "HTTP/1.0").

See also: httpVersion

setHeader

> public void **setHeader**(java.lang.String *aHeader*, java.lang.String *aKey*)

Sets the HTTP header *aHeader* in the receiver and associates, for retrieval, the HTTP key *aKey* with the header. This method is commonly used to set the type of content in a response, for example:

```
aResponse.setHeader("text/html", "content-type");
```

See also: headerForKey

setHeaders

> public void **setHeaders**(NSArray *headerList*, java.lang.String *aKey*)

Sets the list of HTTP headers *headerList* in the receiver and associates, for retrieval, the HTTP key *aKey* with the list of header elements.

See also: headerKeys, **headersForKey**

setStatus

> public void **setStatus**(int *anInt*)

Sets the HTTP status to *anInt*. Consult the HTTP specification or HTTP documentation for the significance of status integers.

See also: status

setUserInfo

> public void **setUserInfo**(NSDictionary *aDictionary*)

Sets a dictionary in the WOResponse object that, as a convenience, can contain any kind of information related to the current response. Objects further down the **appendToResponse** message "chain" can retrieve this information using **userInfo**.

status

> public int **status**()

Returns an integer code representing the HTTP status. Consult the HTTP specification or HTTP documentation for the significance of these status codes.

By default, the status is 200 ("OK" status).

See also: setStatus

userInfo

> public NSDictionary **userInfo**()

Returns a dictionary that, as a convenience, can contain any kind of information related to the current response. An object further "upstream" in the **appendToResponse** message "chain" can set this dictionary in the WOResponse object as a way to pass information to other objects.

See also: setUserInfo

WOSession

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOSession objects represent *sessions*, periods during which access to a WebObjects application and its resources is granted to a particular client (typically a browser). An application can have many concurrent sessions, each with its own special "view" of the application and its own set of data values. For instance, one client could be accessing a "catalog" application, where that client is going from page to page, filling a virtual shopping cart with items for purchase. Another client might be accessing the same application at the same time, but that person might have different items in his or her shopping cart.

Perhaps the most important thing a WOSession object does is encapsulate state for a session. After the application handles a request, it stores the WOSession until the next request of the session occurs. All the information that is important for maintaining continuity throughout the session is preserved. And the integrity of session data is maintained as well; the data of a session not only persists between requests but is kept separate from that of all other sessions.

When you develop an application, you identify data with session-wide scope by declaring instance variables in your subclass of WOSession (or, for scripted applications, in **Session.wos**). Then, before the end of a cycle of the request-response loop, ensure that the instance variables hold current session values.

The application uses a *session ID* to identify a session object. Upon receiving the first request of a session, the application assigns a session ID (a unique, randomly generated string) to the session. The session ID appears in the URL between the application name and the page name.

At the end of each cycle of the request-response loop, the application stores the WOSession object according to the storage strategy implemented by the chosen WOSessionStore. When the application receives the next request of the session, it restores the WOSession, using the session ID as key.

To be stored and restored according to any WOSessionStore strategy, a WOSession must be convertible to an object archive. WOSessions are therefore asked to serialize and deserialize themselves prior to being archived and unarchived (in either binary or ASCII format). To accomplish this, the WOSession should implement the **encodeWithCoder:** and **initWithCoder:** methods of the NSCoding protocol.

Because storage of sessions in application memory can consume large amounts of memory over time, WOSession includes methods for controlling the lifespan of session objects. The **setTimeOut** method sets a period of inactivity after which the session is terminated. The **terminate** method explicitly ends a session.

The WOSession class provides several other methods useful for tasks ranging from localization to database access:

- WOSession objects can interject custom session behavior into the request-response loop by implementing the request-handling methods (**takeValuesFromRequest**, **invokeAction**, and **appendToResponse**) as well as **awake** and **sleep**.

- For database access, the **defaultEditingContext** method gives each WOSession object in an application its own Enterprise Objects editing context.

- An application's WOSession objects also play a role in localization. Through the **setLanguages** method you can store a list of the languages supported by the application. The sequence of language strings in the list indicates the order of language preference for a particular session. Several resource-access methods in WOResourceManager, WOApplication, and WOComponent refer to the **languages** array when they locate such things as localized strings, images, and sounds.

- WOSession objects also allow you to affect load balancing with the **setDistributionEnabled** method; if the flag set by this method is **false** (the default), transactions of the session are restricted to a single application instance. If this the case, the application instance number as well as the application host name are appended to the URL.

Method Types

Constructor

     WOSession

Obtaining attributes

     isDistributionEnabled
     sessionID
     storesIDsInCookies
     storesIDsInURLs

Setting attributes

     setDistributionEnabled
     setStoresIDsInCookies
     setStoresIDsInURLs

Terminating

     terminate
     isTerminating
     timeOut
     setTimeOut

Localization

     languages
     setLanguages

Managing enterprise objects

        defaultEditingContext
        setDefaultEditingContext

Handling requests

        appendToResponse
        awake
        context
        invokeAction
        sleep
        takeValuesFromRequest

Statistics

        statistics

Page Management

        savePage
        restorePageForContextID

Constructors

WOSession

public **WOSession**()

Returns an initialized WOSession object. Session time-out is set by default to a very long period. This method throws exceptions if no session ID has been assigned or if it cannot initialize the object for any other reason. The **isDistributionEnabled** flag is set to **false**, meaning that each transaction will be assigned to an application instance specified in a configuration file for load balancing

Instance Methods

appendToResponse

public void **appendToResponse**(WOResponse *aResponse*, WOContext *aContext*)

This method is invoked during the phase of the request-response loop during which the objects associated with a response page append their HTML content to the response. WOSession's default implementation of this method forwards the message to the WOComponent that represents the response page. Then, it records information about the current transaction by sending **recordStatisticsForResponse** and then **descriptionForResponse** to the WOStatisticsStore object.

Compiled or scripted subclasses of WOSession can override this method to replace or supplement the default behavior with custom logic.

See also: **invokeAction**, **takeValuesFromRequest**

awake

   public void **awake**()

Invoked at the beginning of a WOSession's involvement in a cycle of the request-response loop, giving the WOSession an opportunity to initialize its instance variables or perform setup operations. The default implementation does nothing.

See also: **sleep**

context

   public WOContext **context**()

Returns the WOContext object for the current transaction.

See also: WOContext class

defaultEditingContext

   public com.apple.yellow.eocontrol.EOEditingContext **defaultEditingContext**()

Returns the default EOEditingContext object for the session. The method creates the editing context the first time that it is invoked and caches it for subsequent invocations. There is only one unique EOEditingContext instance per session. The instance is initialized with the default object store coordinator as the parent object store.

invokeAction

   public WOElement **invokeAction**(WORequest *aRequest*, WOContext *aContext*)

WOSession objects receive this message during the middle phase of the request-response loop. During this phase, the **invokeActionForRequest:inContext:** message is propagated through the objects of an application, most importantly, the WOElement objects of the request page. The dynamic element on which the user has acted (by, for example, clicking a button) responds by triggering the method in the request WOComponent that is bound to the action. The default behavior of WOSession is to send the message to

the WOComponent object that represents the request. Compiled or scripted subclasses of WOSession can override this method to replace or supplement the default behavior with custom logic.

See also: **appendToResponse**, **takeValuesFromRequest**

isDistributionEnabled

> public boolean **isDistributionEnabled**()

Returns whether state distribution among multiple application instances is enabled. Returns **false** by default since the default WOSessionStore (state in the server) does not allow distribution. If this flag is disabled, a specific application instance (whose identifying number is embedded in the URL) is assigned to the session.

See also: **setDistributionEnabled**

isTerminating

> public boolean **isTerminating**()

Returns whether the WOSession object will terminate at the end of the current request-response loop.

See also: **terminate**

languages

> public NSArray **languages**()

Returns the list of languages supported by the session. The order of language strings (for example, "French") indicates the preferred order of languages. This is initialized from the users's browser preferences unless explicitly set with **setLanguages**. For details, see "Localization" in the WebObjects programming topics.

See also: **setLanguages**

restorePageForContextID

> public WOComponent **restorePageForContextID**(java.lang.String *contextID*)

Returns a page instance stored in the session page cache. The key to the stored instance is its context ID, which derives from the transaction's WOContext or WORequest objects. This method returns **null** if restoration is impossible.

See also: **savePage**

savePage

public void **savePage**(WOComponent *aPage*)

Saves the page instance *aPage* in the session page cache. The context ID for the current transaction is made the key for obtaining this instance in the cache using **restorePageForContextID**.

savePageInPermanentCache

pubic void **savePageInPermanentCache**(WOComponent *aPage*)

Puts *aPage* into a separate page cache. This cache is searched first when attempting to restore the page the next time its requested. This effectively makes *aPage* live for the duration of the application regardless of the size of your page cache. This is useful whe you are using frames and its possible for a page of controls to be bumped from the page cache.

See also: **permanentPageCacheSize** (WOApplication), **setPermanentPageCacheSize** (WOApplication)

sessionID

public java.lang.String **sessionID**()

Returns the unique, randomly generated string that identifies the session object. The session ID occurs in the URL after the request handler key.

setDefaultEditingContext

public void **setDefaultEditingContext**(EOEditingContext *editingContext*)

Sets the editing context to be returned by **defaultEditingContext**. This can be used to set an editing context initialized with a different parent object store than the default. This is useful when, for instance, each session needs its own login to the database. Once a default editing context has been established, you may not call **setDefaultEditingContext:** again. Therefore, to provide your own default editing context, you must call **setDefaultEditingContext:** before ever calling **defaultEditingContext** since that will lazily establish an editing context.

See also: **defaultEditingContext**

setDistributionEnabled

public void **setDistributionEnabled**(boolean *aFlag*)

Enables or disables the distribution mechanism that effects load balancing among multiple application instances. When disabled (the default), generated URLs include the application instance number; the adaptor uses this number to route the request to the specific application instance based on information in

the configuration file. When this flag is enabled, generated URLs do not contain the application instance number, and thus transactions of a session are handled by whatever application instance is available.

See also: isDistributionEnabled

setLanguages

>   public void **setLanguages**(NSArray *languages*)

Sets the languages for which the session is localized. The ordering of language strings in the array determines the order in which the application will search *languages*.lproj directories for localized strings, images, and component definitions.

See also: languages

setStoresIDsInCookies

>   public void **setStoresIDsInCookies**(boolean *flag*)

Enables or disables the cookie mechanism. Two cookies are created for you when enabled: a session ID cookie with the name "wosid," and an instance ID cookie with the name "woinst." By default, the cookie mechanism is disabled.

setStoresIDsInURLs

>   public void **setStoresIDsInCookies**(boolean *flag*)

Enables or disables the storing of session and instance IDs in URLs. By default, IDs are stored in URLs.

setTimeOut

>   public void **setTimeOut**(double *seconds*)

Set the session timeout in seconds. When a session remains inactive—that is, the application receives no request for this session—for a period longer than the time-out setting, the session will terminate, resulting in the deallocation of the WOSession object. By default, the session time-out is set from the WOApplication method **sessionTimeout**.

See also: timeOut

sleep

> public void **sleep**()

Invoked at the conclusion of each request-response loop in which the session is involved, giving the WOSession the opportunity to deallocate objects initialized in the **awake** method. The default WOSession implementation does nothing.

statistics

> public NSArray **statistics**()

Returns a list of the pages accessed by this session, ordered from first accessed to last. For each page, the string stored is obtained by sending **descriptionForResponse** to the WOComponent object. By default, this returns the component's name. If the application keeps a CLFF log file, this list is recorded in the log file when the session terminates.

See also: appendToResponse

storesIDsInCookies

> public boolean **storesIDsInCookies**()

Returns whether the cookie mechanism for storing session and instance IDs is enabled. The cookie mechanism is disabled by default.

storesIDsInURLs

> public boolean **storesIDsInURLs**()

Returns whether the URL mechanism for storing session IDs and instance IDs is enabled. The URL mechanism is enabled by default.

takeValuesFromRequest

> public void **takeValuesFromRequest**(WORequest *aRequest*, WOContext *aContext*)

WOSession objects receive this message during the first phase of the request-response loop. During this phase, the dynamic elements associated with the request page extract any user input and assign the values to the appropriate component variables. The default behavior of WOSession is to send the message to the WOComponent object that represents the request. Compiled or scripted subclasses of WOSession can override this method to replace or supplement the default behavior with custom logic.

See also: appendToResponse, **invokeAction**

terminate

public void **terminate**()

Causes the session to terminate after the conclusion of the current request-response loop.

See also: isTerminating

timeOut

public double **timeOut**()

Returns the timeout interval in seconds.

See also: setTimeOut

Notifications

WOSessionDidCreateNotification

public static final java.lang.String **WOSessionDidCreateNotification**

Sent at the the end of the session initiation (including awake). The object of the notification is the session instance

WOSessionDidRestoreNotification

public static final java.lang.String **WOSessionDidCreateNotification**

Sent after the sesion is fully restored (including awake). The object of the notification is the session instance.

WOSessionWillTimeoutNotification

public static final java.lang.String **WOSessionDidCreateNotification**

Sent when a session times out but before it is released. The session ID is the object of the notification.

WOSessionStore

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

WOSessionStore, an abstract superclass, offers an object abstraction for storing client state per session. The application object (WOApplication) uses an instance of a concrete WOSessionStore subclass to implement a strategy for storing and retrieving session state. You typically set the WOSessionStore during application initialization through WOApplication's **setSessionStore** method.

An application first creates a session (WOSession) when it receives a request without a session ID. When this first request has been handled, the application stores the WOSession object under a randomly generated session ID by invoking its own **saveSessionForContext** method. This method by default forwards the message to the chosen WOSessionStore and that WOSessionStore takes care of the details of saving session state. When the next request comes in for that session, the application restores the session by sending itself **restoreSessionWithID**, which by default is forwarded to the application's WOSessionStore. The WOSessionStore then asks the WOContext of the transaction for the session ID of the session. Based on the implementation of the WOSessionStore, the session object is located and returned.

There is one subclass of WOSessionStore implemented for the developer's convenience. A *server* WOSessionStore (the default) stores session state in the server, in application memory. The **serverSessionStore** method returns this WOSessionStore.

See the chapter "Managing State" in the *WebObjects Developers Guide* for the purposes, mechanisms, and limitations of session store in the server, page, and cookies.

You can create a custom session store by making a subclass of WOSessionStore. The subclass should properly implement the **saveSessionForContext** and **restoreSessionWithID** methods (using the session ID as the key for storage) and should have a public method that the application object can use to obtain an instance. Some interesting session stores could be:

- A database session store that stores session data in a database as blobs, with the session ID as the primary key. This kind of WOSessionStore can be shared by many instances of the same WebObjects application, thus distributing the load (requests) among the instances.

- An adaptive session store that stores session state either in cookies or on the server, depending on what the client supports.

If you create your own WOSessionStore class that generates persistent objects, you should implement an algorithm that cleans up session state after the session is inactive for a long time. The server WOSessionStore provided by WebObjects performs this clean-up properly, but the API is not yet public.

Method Types

Obtaining a session store

serverSessionStore

Checking a session in and out

checkinSessionForContext
checkoutSessionWithID

Saving and restoring a context

restoreSessionWithID
saveSessionForContext

Static Methods

serverSessionStore

public static WOSessionStore **serverSessionStore**()

Returns a WOSessionStore object that stores session state in application memory. Since this is the default storage strategy, you do not need to explicitly set the session store during application initialization if this is the strategy you want.

State storage in the server is the most secure and is the easiest to implement. You can also easily manage the amount of storage consumed by setting session timeouts, limiting the size of the page-instance cache, and page uniquing. (See "Managing State" in the *WebObjects Developers Guide* for details on these techniques.)

You may use the coding constructor for the session (**WOSession**(NSCoder)) to restore session state from the archived data.

Instance Methods

checkinSessionForContext

public void **checkinSessionForContext**(WOContext *aContext*)

This method calls **saveSessionForContext** (implemented in the concrete subclass) to save the session referred to by *aContext* using whatever storage technique is supported by the receiver. This method also "checks in" the session so that pending (and future) requests for the same session may procede. This method is called by WOApplication to save the session even if the session was not previously checked out via **checkoutSessionWithID** (that is, the session is a new session which was just created and, therefore, not restored).

checkoutSessionWithID

public WOSession **checkoutSessionWithID**(java.lang.String *aSessionID,* WORequest *aRequest*)

This method returns a session for *aSessionID* if one is stored. This method calls **restoreSessionWithID** (implemented in the concrete subclass) to do the actual session restoration using whatever storage technique is supported by the receiver. If the session is located and restored, this method also "checks out" *aSessionID* so that simultaneous access to the same session is precluded. If the session is not restored, the *aSessionID* is not checked out.

restoreSessionWithID

public WOSession **restoreSessionWithID**(java.lang.String *aSessionID*, WORequest *aRequest*)

Implemented by a private concrete subclass to restore the current session object from a particular type of storage.

The default implementation of this method does nothing

saveSessionForContext

public void **saveSessionForContext**(WOContext *aContext*)

Implemented by a private concrete subclass to save the current session object using a particular strategy for state storage. The default implementation of this method does nothing.

You may use the NSCoding interface method **encodeWithCoder** to save session state to archived data.

WOStatisticsStore

Inherits From:	NSObject
Package:	com.apple.yellow.webobjects

Class Description

The WOStatisticsStore object records statistics about a WebObjects application while that application runs. All WebObjects applications have a WOStatisticsStore object, which you can access by sending **statisticsStore** to the WOApplication object.**Recording Information**

The WOStatisticsStore object records the bulk of its statistics at the end of each cycle of the request-response loop. Specifically, at the end of WOSession's **appendToResponse** method, the WOSession sends the **recordStatisticsForResponse** message to the WOStatisticsStore. This message tells the WOStatisticsStore to begin recording statistics. Then, WOSession sends it a **descriptionForResponse** message. This method sends the response component a **descriptionForResponse** message. The default implementation of **descriptionForResponse** in WOComponent returns the component's name.

You can override **descriptionForResponse** in each of your components if you want to record more information. For example, you might want to record the values of all of the component's variables or perhaps just one or two key variables.

If you want to record extra information about the session, you can override WOStatisticsStore's **recordStatisticsForResponse:inContext:** method.

Maintaining a Log File

You can maintain an application log file by sending the message **setLogFile** to the WOStatisticsStore object. When a log file has been specified, each session records information in the log file about the pages it accessed.

The log is maintained in Common Log File Format (CLFF) so that it can be analyzed by any standard CLFF-analysis tool. (For more information about the statistics recorded in the log file, see the **formatDescription** method description.) If a log file has been specified, the WOSession object keeps its own statistics about which pages it has accessed. When the session terminates, it writes this information to the log file.

Method Types

Constructor

> WOStatisticsStore

Recording information

> recordStatisticsForResponse
> descriptionForResponse
> setSessionMovingAverageSampleSize
> transactionMovingAverageSampleSize

Retrieving information

> statistics

Maintaining a CLFF log file

> setLogFile
> logFileRotationFrequencyInDays
> logFile

Recording information in the CLFF log file
> formatDescription
> logString

Securing access to the WOStats page
> setPassword
> validateLogin

Constructors

WOStatisticsStore

public **WOStatisticsStore**()

Returns an initialized WOStatisticsStore.

Instance Methods

descriptionForResponse

public java.lang.String **descriptionForResponse**(WOResponse *aResponse*, WOContext *aContext*)

Records information about the current response by sending the **descriptionForResponse** message to the response page and returning the result. This method is invoked at the end of the request-response loop in WOSession's **appendToResponse** method, after the **recordStatisticsForResponse** method.

formatDescription

> public java.lang.String **formatDescription**(java.lang.String *responseDescription*,
>   WOResponse *aResponse*,
>   WOContext *aContext*)

If log file recording is enabled, this method formats the string *responseDescription* in using Common Log File Format (CLFF). The resulting string contains:

- The host from which the HTTP request was received
- The name of the user that performed the request
- The current date
- The request's HTTP method (GET or PUT)
- The WebObjects application name
- The result of the **descriptionForResponse** method (by default, this method returns the response component's name)
- The request's HTTP version
- The HTTP status of the response
- The size of the response

You enable log file recording by setting a log file using the **setLogFile** method.

This method is used by WOSession to record information about the current transaction when log file recording is enabled.

See also: **logFile**, **logString**

logFile

> public java.lang.String **logFile**()

Returns the full path to the CLFF log file. This log file does not exist unless you send **setLogFile** to the WOStatisticsStore.

See also: **formatDescription**, **logFileRotationFrequencyInDays**, **logString**

logFileRotationFrequencyInDays

> public double **logFileRotationFrequencyInDays**()

The number of days a log file lasts. That is, a log file's contents are flushed after a certain time interval to ensure that it does not grow too large and a new log file is started. This method returns that time interval.

Before a new log file is started, the contents of the current log file are saved to a backup file. You can then inspect this log file and/or remove it when its data has grown stale.

See also: **setLogFile**

logString

public void **logString**(java.lang.String *aString*)

Writes the string *aString* to the CLFF log file specified by **logFile**. The method is used to record a session's statistics when that session ends. You can also use it to record any string to the log file that might be helpful to you.

See also: formatDescription

sessionMovingAverageSampleSize

public int **sessionMovingAverageSampleSiz**e()

Returns the sample size used to compute moving average statistics for each session. The WOStatisticsStore object uses this sample size to compute the response time for the last *n* transactions and the idle time between the last *n* transactions, where *n* is the number returned by this method. The default sample size is 10.

See also: setSessionMovingAverageSampleSize

recordStatisticsForResponse

public void **recordStatisticsForResponse**(WOResponse *aResponse*, WOContext *aContext*)

Records statistics for the current cycle of the request-response loop. This method is invoked at the end of WOSession's **appendToResponse** method, immediately before the **descriptionForResponse** method. By default, this method records the name of the response page for later use by **descriptionForResponse: inContext:**. You can override it if you want to record more information about the session before the current request and response are deallocated. You must begin your implementation by invoking the superclass method.

setLogFile

public void **setLogFile**(java.lang.String *filePath*, double *logRotation*)

Sets the full path of the log file to which CLFF statistics will be recorded to *filePath*. The *logRotation* argument specifies the number of days statistics will be recorded to this log file. Every *logRotation* days, the contents of the current log file are saved to a backup file and a new log file is started.

The default is not to record information to a log file.

See also: logFile, **logFileRotationFrequencyInDays**

setSessionMovingAverageSampleSize

public void **setSessionMovingAverageSampleSize**(int *aSize*)

Sets the moving average sample size for each session to *aSize*. The WOStatisticsStore object uses this sample size to compute the response time for the last *aSize* transactions and the idle time between the last *aSize* transactions.

The default moving average session sample size is 10 transactions.

See also: **sessionMovingAverageSampleSize**

setPassword

public void **setPassword**(java.lang.String *aPassword*)

Implements security for the WOStats page by setting its password to *aPassword*. By default, there is no password, so any user can access the WOStats page (provided they know the URL). If you implement this method, when you enter the WOStats URL, a login panel appears. You can leave the User name field blank; as long as you type the appropriate password in the password field, the WOStats page will appear.

See also: **validateLogin**

setTransactionMovingAverageSampleSize

public void **setTransactionMovingAverageSampleSize**(int *aSize*)

Sets the moving average sample size for each transaction to *aSize*. The WOStatisticsStore object uses this sample size to compute the response time for the last *aSize* transactions and the idle time between the last *aSize* transactions.

The default moving average transaction sample size is 100 transactions.

See also: **transactionMovingAverageSampleSize**

statistics

public NSDictionary **statistics**()

Returns a dictionary containing the statistics that the WOStatisticsStore records.

The averages that are displayed by this method are not computed until this method is invoked. Therefore, invoking this method is costly and should not be done at every request.

transactionMovingAverageSampleSize

    public int **transactionMovingAverageSampleSiz**e()

Returns the sample size used to compute moving average statistics for each transaction. The WOStatisticsStore object uses this sample size to compute the response time for the last *n* transactions and the idle time between the last *n* transactions, where *n* is the number returned by this method. The default sample size is 100.

See also: **setTransactionMovingAverageSampleSize**

validateLogin

    public boolean **validateLogin**(java.lang.String *string*, WOSession *aSession*)

Returns **true** if *string* is the password set by **setPassword**, and **false** otherwise. The password controls if the user can see the WOStats page.

WOActionResults

Implemented By:	WOComponent, WOResponse
Package:	com.apple.yellow.webobjects

Interface Description

The WOActionResults interface is the return type for direct actions. As a convenience, direct actions can return either WOComponent objects or WOResponse objects; both of which implement the WOActionResults protocol. This interface implements only one method **generateResponse**.

If you want to return any other class from a direct action, then that class must implement this protocol.

generateResponse

   public abstract WOResponse **generateResponse**()

Returns a response object. WOResponse's implementation of this method returns the receiver. WOComponent's implementation of this method calls **appendToResponse** on itself and all children components in its template and returns the result as a WOResponse object. If you want to return any other class from a direct action, then that class must implement this method.

WODisplayGroup.Delegate

Implemented By:	WODisplayGroup delegate objects
Package:	com.apple.yellow.webobjects

Interface Description

WODisplayGroup offers a number of methods for its delegate to implement; if the delegate does implement them, the WODisplayGroup instances invoke them as appropriate. There are methods that inform the delegate that the EODisplayGroup has fetched, created an object (or failed to create one), inserted or deleted an object, changed the selection, or set a value for a property. There are also methods that request permission from the delegate to perform most of these same actions. The delegate can return true to permit the action or false to deny it. See each method's description for more information.

Instance Methods

createObjectFailedForDataSource

public abstract void **createObjectFailedForDataSource**(
    WODisplayGroup *aDisplayGroup*,
    java.lang.Object *aDataSource*)

Invoked from **insertNewObjectAtIndex** to inform the delegate that *aDisplayGroup* has failed to create a new object for *aDataSource*. If the delegate doesn't implement this method, the WODisplayGroup fails silently.

didDeleteObject

public abstract void **didDeleteObject**(
    WODisplayGroup *aDisplayGroup*,
    java.lang.Object *anObject*)

Informs the delegate that *aDisplayGroup* has deleted *anObject*.

didFetchObjects

    public abstract void **didFetchObjects**(
        WODisplayGroup *aDisplayGroup*,
        NSArray *objects*)

Informs the delegate that *aDisplayGroup* has fetched *objects*.

didInsertObject

    public abstract void **didInsertObject**(
        WODisplayGroup *aDisplayGroup*,
        java.lang.Object *anObject*)

Informs the delegate that *aDisplayGroup* has inserted *anObject*.

didSetValueForObjectWithKey

    public abstract void **didSetValueForObjectWithKey**(
        WODisplayGroup *aDisplayGroup*,
        java.lang.Object *value*,
        java.lang.Object *anObject*,
        java.lang.String *key*)

Informs the delegate that *aDisplayGroup* has altered a property value of *anObject*. *key* identifies the property, and *value* is its new value.

displayArrayForObjects

    public abstract NSArray **displayArrayForObjects**(
        WODisplayGroup *aDisplayGroup*,
        NSArray *objects*)

Invoked from **updateDisplayedObjects**, this method allows the delegate to filter and sort *aDisplayGroup*'s array of objects to limit which ones get displayed. *objects* contains all of *aDisplayGroup*'s objects. The delegate should filter any objects that shouldn't be shown and sort the remainder, returning a new array containing this group of objects. You can use the NSArray methods **filteredArrayUsingQualifier** and **sortedArrayUsingKeyOrderingArray** to create the new array.

If the delegate doesn't implement this method, the WODisplayGroup uses its own qualifier and sort ordering to update the displayed objects array.

See also: **displayedObjects**, **qualifier**, **sortOrderings**

displayGroupDidChangeDataSource

> public abstract void **displayGroupDidChangeDataSource**(
> WODisplayGroup *aDisplayGroup*)

Informs the delegate that *aDisplayGroup*'s EODataSource (defined in the EOControl framework) has changed.

displayGroupDidChangeSelectedObjects

> public abstract void **displayGroupDidChangeSelectedObjects**(WODisplayGroup *aDisplayGroup*)

Informs the delegate that *aDisplayGroup*'s selected objects have changed, regardless of whether the selection indexes have changed.

displayGroupDidChangeSelection

> public abstract void **displayGroupDidChangeSelection**(WODisplayGroup *aDisplayGroup*)

Informs the delegate that *aDisplayGroup*'s selection has changed.

displayGroupShouldFetch

> public abstract boolean **displayGroupShouldFetch**(WODisplayGroup *aDisplayGroup*)

Allows the delegate to prevent *aDisplayGroup* from fetching. If the delegate returns true, *aDisplayGroup* performs the fetch; if the delegate returns false, *aDisplayGroup* abandons the fetch.

shouldChangeSelectionToIndexes

> public abstract boolean **shouldChangeSelectionToIndexes**(
> WODisplayGroup *aDisplayGroup*,
> NSArray *newIndexes*)

Allows the delegate to prevent a change in selection by *aDisplayGroup*. *newIndexes* is the proposed new selection. If the delegate returns true, the selection changes; if the delegate returns false, the selection remains as it is.

shouldDeleteObject

public abstract boolean **shouldDeleteObject**(
    WODisplayGroup *aDisplayGroup*,
    java.lang.Object *anObject*)

Allows the delegate to prevent *aDisplayGroup* from deleting *anObject*. If the delegate returns true, *anObject* is deleted; if the delegate returns false, the deletion is abandoned.

shouldInsertObject

public abstract boolean **shouldInsertObject**(
    WODisplayGroup *aDisplayGroup*,
    java.lang.Object *anObject*,
    int *anIndex*)

Allows the delegate to prevent **redisplay** from inserting *anObject* at *anIndex*. If the delegate returns true, *anObject* is inserted; if the delegate returns false, the insertion is abandoned.

shouldRedisplayForChangesInEditingContext

public abstract boolean **shouldRedisplayForChangesInEditingContext**(
    WODisplayGroup *aDisplayGroup*,
    NSNotification *aNotification*)

Invoked whenever *aDisplayGroup* receives an EOObjectsChangedInEditingContextNotification, this method allows the delegate to suppress redisplay based on the nature of the change that has occurred. If the delegate returns true, *aDisplayGroup* redisplays; if it returns false, *aDisplayGroup* doesn't.

See also: redisplay

shouldRefetchForInvalidatedAllObjectsNotification

public abstract boolean **shouldRefetchForInvalidatedAllObjects**(
    WODisplayGroup *aDisplayGroup*,
    NSNotification *aNotification*)

Invoked whenever *aDisplayGroup* receives an EOInvalidatedAllObjectsInStoreNotification, this method allows the delegate to suppress the refetching of the invalidated objects. If the delegate returns true, *aDisplayGroup* immediately fetches its objects. If the delegate returns false, *aDisplayGroup* doesn't immediately fetch, instead delaying until absolutely necessary.

See also: redisplay
